Background

Relapsed or refractory acute myeloid leukemia with fms-like tyrosine kinase 3 mutations (R/R FLT3^{mut}+AML) remains a major clinical challenge. Although gilteritinib monotherapy resulted in improved overall survival (OS) compared to salvage chemotherapy for R/R FLT3^{mut}+AML patients, the remission rates and survival with gilteritinib monotherapy are still unsatisfactory. Gilteritinib-based combination therapy demonstrated increased response rates, but the survival did not improve because of increased toxicities. Thus, the optimal regimen for R/R FLT3 mutated AML remained unclear.

Aims

To compare the efficacy and safety of gilteritinib-based combination therapy for R/R FLT3^{mut}+AML.

Methods

Patients with R/R FLT3^{mut}+AML in six hospitals of China were screened from July 2019 to July 2025. Eligible criteria include: (1) aged ≥18 years with confirmed FLT3^{mut}+AML; (2) relapse or refractory (R/R) to first or greater lines of AML treatment (3) received gilteritinib-based therapy: gilteritinib plus venetoclax (Gil+Ven), gilteritinib plus venetoclax and "X" (gilteritinib plus venetoclax and azacitidine, gilteritinib plus venetoclax, azacitidine and homoharringtonine), or gilteritinib combined with intensive chemotherapy (Gil+Chemo). The primary endpoint was the composite complete remission (CRc) rate after 1-2 cycle of treatment. The secondary endpoints were safety, OS, event-free survival (EFS) and relapse.

Results

54 patients were enrolled with a median age of 44.8 years old. 42 patients had FLT3-ITD mutation, 11 had FLT3-TKD mutation and 1 had both mutations. 14 received Gil+Ven, 29 received Gil+Ven+X and 11 received Gil+Chemo. There were no significant differences among the three groups in baseline patient characteristics. Gil+Ven group showed a trend toward higher CRc (85.7%) compared to Gil+Ven+X (65.6%) and Gil+Chemo (63.6%) groups ($p=0.341$). The CR rate of Gil+Ven group was 71.4%, numerically higher than Gil+Ven+X (41.4%) and Gil+Chemo (54.5%) groups ($p=0.127$). The MRD-negative rate in the Gil+Ven group (50%) was comparable with the Gil+Ven+X group (56%, $p=0.749$) and higher than the Gil+Chemo group (28.6%, $p=0.401$). The proportion of bridging to allogeneic hematopoietic stem cell transplantation were comparable across the Gil+Ven, Gil+Ven+X, and Gil+Chemo groups (57.1% vs. 55.2% vs. 63.6%, respectively, $p=0.894$). With a median follow-up of 18 months, the median OS was longer in Gil+Ven group (not reached) than that in Gil+Ven+X (7.0 months) or Gil+Chemo (19.0 months) group ($p=0.19$). Gil+Ven group had a higher 2-year OS (74.48%) than Gil+Ven+X group (31.78%, $p=0.009$) and Gil+Chemo group (38.35%, $p=0.083$), respectively. The 2-years EFS were also higher in Gil+Ven group (68.18%) than Gil+Ven+X (24.52%, $p=0.006$) and Gil+Chemo group (34.09%, $p=0.090$). Furthermore, the 2-year cumulative incidence of relapse (CIR) was lower in Gil+Ven group (12.5%) than Gil+Ven+X (36.91%, $p=0.147$) and Gil+Chemo group (46.43%, $p=0.144$). Gil+Ven group was associated with fewer grades 3 or higher hematologic and non-hematologic adverse events (AEs) compared to the other two groups. In Gil+Ven group, neutropenia ($p=0.023$), anemia ($p=0.048$) and BLOOD infection ($p=0.045$) were significantly less frequent than the other two groups.

Summary/Conclusion

Gilteritinib plus venetoclax demonstrated a trend toward better efficacy and fewer adverse events than other gilteritinib-based combination therapy, suggesting it might be the optimal salvage strategy for R/R FLT3^{mut}+AML.
