Background

Anti-CD20 antibodies remain central to the management of NHL, yet a substantial proportion of patients exhibit primary resistance or early relapse. FcγRIIb-mediated rituximab internalization is a known resistance-mechanism, and higher tumor FcγRIIb levels correlate with poor responses. BI-1206, an anti-FcγRIIb IgG1 antibody, blocks this internalization and restores rituximab activity. In relapsed/refractory FL patients, BI-1206 plus rituximab achieved a 59% ORR with good tolerability.

The ROSEWOOD trial showed that adding the BTKi zanubrutinib (Z) to the Fc-engineered anti-CD20 antibody obinutuzumab (O) increased ORR from 45% to 69%. In contrast, adding the BTKi acalabrutinib to rituximab resulted in only 31% ORR, despite similar kinase profiles for acalabrutinib and zanubrutinib. These findings suggest that the greater activity of the OZ regimen resulted from improved CD20-targeting, highlighting the need to overcome rituximab resistance. Tumor FcγRIIb-mediated internalization is a principal driver of rituximab resistance. Because BI-1206 directly targets this mechanism, and obinutuzumab shows reduced but not blunted FcγRIIb-mediated internalization, combining BI-1206 with rituximab plus acalabrutinib has the potential to further improve treatment responses.

Aims

Assess safety and efficacy of BI-1206 in combination with rituximab and acalabrutinib in R/R NHL.

Methods

This single-arm study evaluates BI-1206 with rituximab and acalabrutinib in up to 30 patients with relapsed or refractory NHL. The design compares two subcutaneous (SC) BI-1206 doses of 150 and 225 mg. BI-1206 plus rituximab is administered QW during a 4 week induction. Patients with disease control at week 6 may receive a 2nd induction, then maintenance every eight weeks for up to six cycles. Acalabrutinib is given at 100 mg twice daily for 1 year.

Results

As of Jan 26, 2026, 23 patients were treated with BI-1206 in combination with rituximab and acalabrutinib. Nineteen patients experienced treatment-related AEs, the majority of which were mild or moderate (86%). Nine patients had Gr 3 events considered related or possibly related to study treatment: three patients with neutropenia, two with lymphopenia, two patients with IRR related to rituximab. The following Gr 3 events were recorded once: thrombocytopenia, headache, increased transaminases, urticaria and maculo-papular rash.

No treatment-related serious AEs and no Gr 4/5 events were observed.

The overall response rate observed was 80%. Among 20 evaluable patients, 7 achieved complete responses, 9 partial responses, and the remaining patients all exhibited stable disease as best response. In the FL subset (n=13), ORR was 77%. At cut-off date, average treatment duration reached was 4 months. Five patients completed the study duration of one year. Study is still ongoing and data is expected to mature.

Summary/Conclusion

The combination treatment was well tolerated and demonstrates a highly promising therapeutic effect in R/R FL, achieving an ORR of 77%. Taken together with the approximately 80% ORR usually observed with SoC R2 therapy, these data suggest that the BI-1206 triplet may offer at least comparable efficacy with a highly manageable safety profile.

In this heavily pretreated R/R NHL population with limited therapeutic options, the BI-1206 triplet delivers robust, durable responses and a beneficial, manageable safety profile, making it a compelling future treatment option for patients with R/R FL.

We acknowledge AstraZeneca for providing acalabrutinib.
