Pathologists assessment evidenced the presence of heterogeneous lesions among patients included within the same Mazzucco class. We thus proposed a novel classification of DKD, based both on renal pathology and according to the pathogenetic drivers. We identified 7 different histological classes of DKD: i) Class I: pure DN; ii) Class II: DN and nephroangiosclerosis; iii) Class III: DN and acute tubular necrosis; iv) Class IV: DN and Focal Segmental Glomerulosclerosis (FSGS); v) Class V: Nephroangiosclerosis; vi) Class VI: FSGS and other GN; vii) Class VII: FSGS and nephroangiosclerosis. According to the pathogenic drivers of DKD, we then grouped these classes in: pure metabolic damage (class II), metabolic damage and other drivers (including classes II, III, IV), pure vascular damage (class V) and immunological damage (classes VI, VII). Applying the newly proposed classification, we observed a significantly different distribution of key clinical parameters, uACR (p = 0.02), eGFR (p = 0.012), serum creatinine (p = 0.002) and proteinuria (p = 0.004). PAS glomerular staining positivity confirmed the more severe immunological damage of patients with vascular from those with immunological damage (p = 0.002). Finally, the renal resistive index measured through US significantly discriminated pure DN from mixed forms (p = 0.02).
Conclusion: The classification of renal damage in diabetes could represent a key strategy in the stratification of patients for precision medicine. The integration of renal pathology, US, ongoing MRI and omics data from the same patient has the potential to unlock new diagnostic tools and criteria to more accurately define the variety of renal phenotypes in diabetes.

IMPACT OF ADOPTING THE NEW CKD-EPI 2021 EQUATION ON eGFR AND CKD DETECTION IN A MULTI-ETHNIC DUTCH POPULATION: THE HELIUS STUDY
Brechje Huisman, Charles Agyemang, Bert-Jan van den Born, Irene van Valkengoed and Liefert Vogt
Amsterdam UMC, locatie AMC, Amsterdam, Netherlands
Background and Aims: The 2009 Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation is the current standard method for estimating GFR. There has been debate whether or not to exclude the race/ethnicity coefficient from this equation. Recently, the National Kidney Foundation and American Society of Nephrology Task Force on Reassessing Race in Diagnosing Kidney Disease recommended a new 2021 CKD-EPI race-free creatinine-based equation. The impact of this equation has not thoroughly been evaluated in the European population. We explored the impact of adopting this formula on both eGFR and estimates of CKD prevalence in a multi-ethnic Dutch population.
Method: We cross-sectionally analysed baseline data of 21,617 participants (mean age 44yr, 42% male) of the multi-ethnic HELIUS cohort study (Amsterdam, the Netherlands). Three groups were distinguished: participants of African Surinamese (4,151), Ghanaian (2,339) and other, non-African (15,127) background. eGFR was calculated using the 2009 and 2021 CKD-EPI equation. Multiple regression analyses were performed to determine differences in eGFR with additional adjustments for age, sex and traditional cardiovascular and renal risk factors. CKD prevalence (i.e., eGFR < 60ml/min/1.73m2) and/or ACR (≥ 3mg/mmol) was calculated. In each ethnic group three approaches to improve CKD case detection for both equations were compared by targeting participants with traditional renal risk factors (i.e., diabetes mellitus, hypertension or cardiovascular disease), by subsequently adding an age criterion (>40, > 50, or > 60 yrs), and low socio-economic status (none or elementary schooling). For each approach, c-statistics for CKD probability were compared.

KIDNEY ELASTOMETRY, KIDNEY MISMATCH INDEX AND CHRONICITY INDEX: NEW METHODS TO INTERROGATE THE DISEASED KIDNEY
Michele Della Corte1, Giannmarco Borriollo2, Ilenia Gravina2, Pietro Iulianello2, Andrea Camocardi2, Ciro Paglicioni2, Rossana Matrisicano1, Felice Napoli1, Pasquale Zamboli2 and Davide Viggiano2
1University of Campania, Nephrology Unit, Translational Medical Sciences, Naples, Italy, 2University of Campania, Nephrology Unit, Translational Medical Sciences, Naples, Italy, 3Ospedale del Mare, Department of Nephrology and Hemodialysis, Napoli, Italy, 4Hospital Santa Maria della Pietà Nephrology and Dialysis Unit, Nola, Italy and 5Nephrocare Italy, Department of Vascular Accesses for Hemodialysis, Naples, Italy
Background and Aims: Standard ultrasound mainly offers information about structural kidney alterations which may provide dates regarding the mass of the filtrating kidney (e.g. the nephron number), or obstructive alterations. Furthermore, the parenchymal Doppler ultrasound offers the resistance index, which is highly correlated to the plasma creatinine levels. However, in isolated proteinuria with normal kidney function these two classical methods do not reveal any alteration. We have hypothesized that kidney stiffness and a mismatch between creatinine levels and parenchymal resistance indices may offer additional features which may help the nephrologist in the classification of kidney diseases.
Method: In this respect, we have performed a transversal study on 468 patients with available resistance index of both the kidney and the spleen, clinical variables (including hemoglobin, creatinine, cholesterol, proteinuria, hypertension, diabetes) and shearwave elastometry, which gives an estimate of parenchymal stiffness. In order to identify patients with a mismatch between creatinine and renal resistance index we have introduced the kidney mismatch index (KMI) derived from the ratio between the renal resistance index and the creatinine levels. In order to identify chronic patients, we argued that in acute settings the creatinine levels (and hence the resistance index) are altered whereas the kidney size is normal: therefore the ratio of resistance index over the kidney size was tested as a quantitative marker of chronicity.
Results: Results confirm a strong correlation between kidney resistance index and creatinine (Pearson coeff. 0.318, p < 0.01). Interestingly, this index is also significantly dependent on age and cholesterol levels using a multiple regression model, after adjusting for creatinine levels. On the contrary, the resistance index of the spleen does not correlate neither with creatinine nor eGFR, whereas it correlated with cholesterol levels. Overall, creatinine levels could be predicted by the kidney size (longitudinal diameter, LD) and by the kidney resistance index (RI) using the following formula: creatinine = 1.8 - 0.175 LD + 2.601 RI Conversely, shearwave stiffness is only correlated to proteinuria (Pearson coeff. 0.497, p = 0.008) but not with creatinine. Finally, the kidney mismatch index (resistance index dissociated from creatinine levels) does not correlate with proteinuria and seems to identify particular subsets of patients with abnormal microcircular dynamics despite normal filtration rate, and should be tested in future studies as a prognostic factor.
Conclusion: In conclusion, kidney elastometry and kidney mismatch indices may prove additional sources of valuable informations that can be gathered from ultrasound methods which allow the identification of a diseased kidneys even in presence of normal architecture and normal resistance index.
Results: Differences between groups varied according to the equation used. Compared with non-African backgrounds (mean eGFR 102 mL/min/1.73m²), age- and sex-adjusted differences (p < 0.001) in the mean eGFR (SE) were 4.6 ± 0.2 and -8.9 ± 0.2 mL/min/1.73m² in participants with African Surinamese, and 3.2 ± 0.3 and -10.4 ± 0.3 mL/min/1.73m² in participants with Ghanaian background for the 2009 and 2021 CKD-EPI equations, respectively. Further adjustments did not change this. However, CKD prevalences were similar for both equations: 10.6% vs 10.8% (p = 0.30) in the whole cohort, 10.9 vs. 11.6% (p = 0.33) among African Surinamese and 12.0 vs 12.6% (p = 0.21) among Ghanaians. CKD case detection did not differ between the screening approaches nor between both equations. Also, c-statistics for CKD probabilities were not influenced by either equation.

Conclusion: In our cohort, adoption of the 2021 CKD-EPI equation leads to lower eGFR in participants of African Surinamese and Ghanaian background. However, only small not statistically significant differences in CKD prevalences, overall and in high-risk groups, were found. Our study indicates that discontinuation of the race-coefficient may have little impact on CKD detection in a multi-ethnic Dutch population.

#6881 ELEVATED LEVELS OF THE C5B9 TERMINAL COMPLEMENT COMPLEX IN PATIENTS RECEIVING RENAL REPLACEMENT THERAPY

Ole Petter Norødbo1, Ga Kei Tam2, Tarig Al-Hadi Osman3, Hans-Peter Marti1, Tom Erik Mollness4 and Sabine Leh2
1University of Bergen, Department of Clinical Medicine, Bergen, Norway, 2Haukeland University Hospital / Health Bergen, Department of Pathology, Norway, 3University of Bergen, Department of Clinical Dentistry, Bergen, Norway and 4Oslo universitetssykehus HF, Rikshospitalet, Department of Immunology, Norway.

Background and Aims: The complement cascade and its inhibitors play an important role in health and disease. Complement activation represents a key pathogenic mechanism underlying inflammatory diseases affecting the kidney. The study aimed to investigate the C5b9 system in renal biopsies, where we stained all obtained kidney biopsies from the year 2017 (n = 256).

Method: Antibody staining against terminal C5b9 was performed, and a C5b9 score for each glomerulus (n = 1942) was generated based on automated image analysis. Mean scores for the interstitium, tubules and blood vessels, and whole biopsy sections were also calculated.

Results: Globally and segmentally, sclerosed areas in glomeruli stained much stronger than their non-sclerosed glomerular counterparts. The results were linked with Renal Replacement Therapy (RRT) status and clinical data from the Norwegian Kidney Biopsy Registry. The study’s main findings were that elevated levels of C5b9 were present in patients on RRT in glomeruli, blood vessels and whole section staining. Fibrillar glomerulopathy and Membranous Glomerulonephritis had the highest C5b9 scores, while glomeruli from Hypertensive Nephrosclerosis were represented with a low score. C5b9 scores correlated weakly or non-significantly with clinical variables like age, blood pressure and eGFR. The degree of fibrosis showed an associated positive correlation to C5b-9 staining intensities. Additionally, patients with an elevated C5b9 score (from the 50th percentile and above) showed a significantly elevated risk of receiving RRT within 60 months of biopsy.

Conclusion: C5b9 levels were significantly elevated in sclerotic glomeruli as well as in patients receiving RRT. A weak correlation between C5b9 scores and clinical variables for renal function suggest that the C5b9 complement system may be an independent effect in CKD.

#2697 ASSOCIATION OF CARDIOMETABOLIC PROTEINS WITH EGFR DECLINE IN OLDER ADULTS WITH ADVANCED CHRONIC KIDNEY DISEASE

Ryan Aylward1,2, Samantha Hayward1,4, Nicholas Chesnaye5, Marie Evans6, Christiane Drehzler7, Christoph Wanner2, Friedo W. Dekker8, Claudia Torino9, Maciej Szynszczak10, Kitty J Jager8, Yoav Ben-Shlomo1, Nicki Tiffin11, Brian Rayner1, Kate Birnie1 and Fergus Caskey4

Background and Aims: Cardiovascular disease and advanced chronic kidney disease often coexist and share risk factors in older individuals. We investigated the association of cardiometabolic and cardiovascular proteins and pathways with decline in estimated glomerular filtration rate (eGFR).

Method: Two plasma protein panels (Olink®, cardiometabolic T96 and cardiovascular II T96, Uppsala, Sweden) were analysed at the baseline visit of individuals enrolled in the prospective observational European QUALity (EQUAL) study of older people > 65 years with advanced CKD (incident eGFR < 20 ml/min/1.73m²). Generalised linear mixed effects models with a log link and random intercept and slope were used to determine annualised eGFR slope (CKD-EPI 2009 equation) using a complete case model. The model was executed in a "discovery" sample (Germany, United Kingdom and Poland) and positive results (< false discovery rate [FDR] of 5%) were tested in a Swedish "validation" sample using the same FDR criterion. The primary analysis was adjusted for baseline age, sex, country, diabetes mellitus status, primary renal disease, systolic blood pressure, albumin to creatinine ratio (ACR), and the use of renin-angiotensin aldosterone inhibitors and β-blockers. A sensitivity analysis was conducted to determine the effect of informative censoring on eGFR slope using a joint model.

Results: The discovery and validation samples had 254 subjects (median age 67 years, 41% female, median baseline eGFR 18 ml/min/1.73m²) and 247 (median age 75 years, 28% female and median baseline eGFR 18 ml/min/1.73m²) respectively with longer follow-up time for the validation sample (median 3.6 versus 2.6 years) primarily due to less kidney replacement therapy initiation (33% versus 37%) and fewer losses to follow up (5% versus 12%). Two of the 175 proteins showed more rapid eGFR annual decline per doubling in protein levels (Figure 1): Receptor-type tyrosine-protein phosphatase S [PTPRS] (−15%; 95% confidence interval [CI] −24 to −7%, pFDR = 0.01) and Insulin-like growth factor-binding protein 6 [IGFBP6] (−8%; 95% CI −12 to −3%, pFDR = 0.03) (Figure 2). Predicted slopes were similar across both samples and for the sensitivity analyses.

Conclusion: Receptor-type tyrosine-protein phosphatase S and Insulin-like growth factor-binding protein 6 were associated with more rapid CKD progression. Further research is needed to determine if these proteins are pathophysiologically linked to accelerated progression of CKD in older people or a secondary consequence of disturbances in protein sequestration or excretion.
ASSOCIATION BETWEEN THE SERUM CREATININE-TO-CYSTATIN-C RATIO AND RAPID PROGRESSION OF CHRONIC KIDNEY DISEASE

Jiwon Lee, Saeyoung Jeong, Sang-Woong Han and MI-Yeon Yu
Hanyang University Guri Hospital, Rep. of South Korea

Background and Aims: Chronic Kidney Disease (CKD) is a common and progressive condition that affects a significant portion of the global population. It is a leading cause of death and requires timely evaluation and monitoring to ensure proper management. Cystatin C has been shown to be an effective marker of kidney function and a predictive marker of CKD progression. However, there is limited research evaluating the relationship between the serum creatinine-to-cystatin-C (Cr/cysC) ratio and the rapid progression of CKD. This study aims to investigate the effectiveness of the Cr/cysC ratio in predicting rapid progression of CKD.

Method: A retrospective study was conducted on 1,104 patients with CKD who were treated at the Nephrology Outpatient Clinic of Hanyang University Guri Hospital between December 2020 and November 2022. Eligible patients had at least two simultaneous measurements of serum creatinine and cystatin C, with a minimum interval of 6 months. The definition of rapid progression of CKD was a decrease in creatinine-based estimated glomerular filtration rate (eGFR) of more than 4 mL/min/1.73 m² over a 1-year period or initiation of renal replacement therapy (RRT). In addition, considering the short duration of the study, initiation of RRT was considered as a secondary outcome only in CKD stages 3b, 4, and 5.

Results: The study population consisted of patients with CKD stages 1 to 5, with a mean age of 69.7 years and 57.7% of the population being male. The mean baseline body mass index was 25.8 kg/m², and the mean initial eGFR was 46.7 mL/min/1.73 m². 38.4% of the total patients showed rapid progression of CKD. The analysis showed that a lower Cr/cysC ratio was significantly associated with an increased risk of rapid progression of CKD (OR: 0.812, 95% CI: 0.761-0.867, p < 0.001). After adjusting for age, sex, body mass index, and initial eGFR, a lower Cr/cysC ratio remained a significant risk factor for rapid progression of CKD (OR: 0.760, 95% CI: 0.685-0.844, p < 0.001). The initiation of RRT increased with the advancement of CKD stage, with 11 patients with CKD stage 3b, 30 patients with CKD stage 4, and 41 patients with CKD stage 5 initiating dialysis treatment. After adjusting for all variables, the OR was 0.774 (95% CI: 0.667-0.898, p = 0.001), indicating that as the Cr/cysC ratio increased, the progression of dialysis significantly decreased by 22.6%.

Conclusion: In this study, a lower Cr/cysC ratio was significantly associated with an increased risk of rapid progression of CKD and initiation of RRT. The results of this study suggest that monitoring the Cr/cysC ratio may provide valuable information for the management of CKD patients.
OMEGA-3 FATTY ACID ACTIVATES MITOCHONDRIAL BIOGENESIS AND PINK1 DEPENDENT MITOPHagy IN KIDNEY AND HEART OF ADENINE INDUCED UREMIC RATS

Dong Eun Yang1, Su HJ Lee1, Jun Chul Kim2 and Won Suk An3

1Dong-A University Hospital, Internal medicine, Busan, Korea, Rep. of South
2CHA Gumi Medical Center, CHA University, Internal medicine, Korea, Rep. of South and 3Dong-A University, College of Medicine, Internal medicine, Busan, Korea, Rep. of South

Background and Aims: Mitochondrial homeostasis is controlled by biogenesis, dynamics, and mitophagy. Mitochondrial dysfunction plays a central role in cardiovascular and renal disease and omega-3 fatty acids (FA) are beneficial for cardiovascular disease. We aimed to investigate whether omega-3 FA regulates the expression of mediators of mitochondrial biogenesis, dynamics, and mitophagy in kidney and heart of adenine-induced uremic rats.

Method: Sprague-Dawley rats were divided into three groups: normal control, adenine control, and omega-3 FA. Uremia was induced by feeding diets containing 0.75% adenine and 2.5% protein for the first 3 weeks. During next 4 weeks, they were received 2.5% protein with or without omega-3 FA (300 mg/kg/day). The renal and cardiac expression of PGC-1α, SIRT1/3, Nrf2, DRP-1, OPA1, Mfn1/2, PINK1, BNIP3 and NIX were examined by western blot analysis. The qPCR was used to determine mitochondrial DNA (mtDNA).

Results: Compared to normal, serum creatinine and heart weight/body weight in adenine control was increased and improved in omega-3 FA group. Compared with normal, PGC-1α, SIRT1/3 and Nrf2 were down-regulated in kidney and heart of adenine control. PGC-1α expression of kidney and heart was recovered in omega-3 FA group. DRP-1 of kidney was up-regulated but DRP-1 of heart was down-regulated in adenine control. DRP-1 of heart was recovered in omega-3 FA group. PINK1, BNIP3 and NIX were down-regulated in heart of adenine control and recovered in omega-3 FA group. PINK1 was down-regulated but BNIP3 and NIX were up-regulated in kidney of adenine control and those were mitigated in omega-3 FA group. mtDNA was decreased in kidney and heart of adenine control group but mtDNA of heart was recovered in omega-3 FA group.

Conclusion: DRP-1 related with mitochondrial fission may oppositely work in uremic kidney and heart. Omega-3 FA is beneficial for mitochondrial homeostasis by activating mitochondrial biogenesis and PINK1 dependent mitophagy in kidney and heart of uremic rats.

ALBUMINURIA IS ASSOCIATED WITH DECREASED SEVR AND ANKLE-BRACHIAL INDEX IN PATIENTS WITHOUT CKD

Nejc Piko1, Sebastian Bevc2,3, Radovan Hojs2,3, Franjo Naji4, Tadej Petreski2, Luka Varda1 and Robert Ekart1,3

1Clinic for Internal Medicine, Department of Dialysis, Maribor, Slovenia, 2Clinic for Internal Medicine, Department of Nephrology, Maribor, Slovenia, 3Faculty of Medicine, Maribor, Slovenia and 4Clinic for Internal Medicine, Department of Cardiology and Angiology, Maribor, Slovenia

Background and Aims: Albuminuria signifies subclinical vascular damage in the kidneys and other organs and is associated with systemic endothelial dysfunction and increased future cardiovascular risk. Subendocardial viability ratio (SEVR) is defined as diastolic to systolic pressure-time integral ratio and is a marker of subendocardial perfusion. Reduced SEVR has been uncovered in patients with chronic kidney disease (CKD) and simultaneous albuminuria. Albuminuria is also considered a risk factor for peripheral artery disease, especially in patients with additional atherosclerosis risk factors or diabetes mellitus. The aim of our study was to determine the impact of albuminuria on SEVR and ankle-brachial index (ABI) in patients without known CKD.

Method: We included 111 patients (73% male, mean age 64.2±9.3 years) that were hospitalized at our Cardiology department between 2016-2020 due to elective cardiac catheterization. Albuminuria was determined by urine albumin to creatinine ratio (UACR) from a random urine specimen. SEVR was determined by using application tonometry on radial artery (Sphygmocor, Atcor Medical, Australia). Ankle-brachial index (ABI) was measured by using an automated, non-invasive waveform analysis device (MESIÒ, Slovenia). Reduced SEVR has been uncovered in patients with chronic kidney disease (CKD) and simultaneous albuminuria. Albuminuria is also considered a risk factor for peripheral artery disease, especially in patients with additional atherosclerosis risk factors or diabetes mellitus. The aim of our study was to determine the impact of albuminuria on SEVR and ankle-brachial index (ABI) in patients without known CKD.

Results: Basic descriptive statistics, comorbidities, and medications are presented in Tables 1 and 2. Spearman’s correlation test showed significant correlation between UACR and SEVR (r = -0.238; p = 0.017) and UACR and ABI (r = -0.304; p = 0.003). Multiple regression analysis with SEVR as the dependent variable and waist-to-hip ratio, body mass index (BMI), arterial hypertension, diabetes, dyslipidemia, eGFR and UACR as independent variables, showed a significant association between UACR and SEVR (b = -0.232; p = 0.029). The same model was used for ABI as the dependent variable, and a significant association was found only between UACR and ABI (b = -0.232; p = 0.029).

Conclusion: Albuminuria is independently associated with decreased SEVR and ABI even in the absence of CKD.

Figure 1: Expression of mitochondrial dynamics and mitophagy related molecules in uremic kidney and heart.

Results: In both CSF and plasma, levels of all four uremic solutes were elevated in HD patients compared to healthy subjects (Table 1). The ratio of CSF-to-plasma levels was <100% for all solutes. Ratios for HD patients are altered compared to those reported in healthy subjects (Table 1). Longitudinal plasma and CSF solute levels are shown in Figure 1. Plasma RR for IS, pCS, TMAO and urea were 32%, 23%, 77%, and 67%, respectively. The respective CSF RR were 29%, 20%, 3%, and 25%.

**Conclusion:** To the best of our knowledge, this is the first report on CSF levels of IS, pCS, and TMAO in HD patients. Our results indicate that uremic solute levels are elevated in the CSF from HD patients compared to healthy subjects. Moreover, HD only moderately reduces uremic solute levels in CSF. Whether increased CNS levels of uremic solutes are related to cognitive impairment warrants further investigation.

ELEVATED LEVELS OF UREMIC SOLUTES IN THE CEREBROSPINAL FLUID OF HEMODIALYSIS PATIENTS

Xin Wang¹, Zahiin Haq¹, Gabriela Ferreira Dias¹, Ludovic Debure³, Lin-Chun Wang⁴, Xia Tao⁴, Stephan Thijssen⁵, Thomas Wisniewski⁵, Peter Kotanko¹,³ and Nadja Grobe¹

¹Renal Research Institute, New York, United States of America, ²New York University Grossman School of Medicine, Center for Cognitive Neurology and Departments of Neurology, Pathology and Psychiatry, New York, United States of America and ³Icahn School of Medicine at Mount Sinai, New York, United States of America

**Background and Aims:** Uremic solutes are considered as contributing factors to impaired cognitive function in end stage kidney disease (ESKD) [1]. However, the distribution and accumulation of uremic solutes in the central nervous system (CNS) of ESKD patients are not well understood. We measured four uremic solutes in the cerebrospinal fluid (CSF) and plasma of two ESKD patients and investigated the role of routine hemodialysis (HD) in clearing these solutes from their CNS.

**Method:** We accessed CSF in HD patients with a ventriculo-peritoneal shunt. A review of about 160,000 electronic health records revealed 30 eligible patients, two of whom consented to participate in this IRB-approved one-week study (Western IRB #20172182). On dialysis days, CSF and plasma were collected 2 hours pre- and 2 hours post-HD. Non-dialysis day samples were collected 20 hours post-HD. Samples from healthy subjects were purchased from BioIVT (Westbury, NY). Urea was measured using Horiba C400 Chemical Analyzer. Indoxyl sulfate (IS), p-cresol sulfate (pCS) and trimethylamine N-oxide (TMAO) were analyzed using Agilent Ultivo triple quadrupole mass spectrometer. The dialytic reduction ratio (RR; in %) was calculated as 100 × (pre-HD level – post-HD level) / pre-HD level.

¹CSF (n = 9) and plasma (n = 9) samples in healthy subjects were not from the same subject. ²CSF-to-plasma ratios of IS, pCS and TMAO in healthy subjects (n = 9) were reported in Sankowski et al. 2020 [2] and the ratio of urea (n = 13) in Funder and Wieth 1967 [3]. In both references, CSF and plasma samples were from the same subject.
Background and Aims: Diabetic kidney disease (DKD) has an enormous disease burden globally. In the area of personalised medicine, biomarker is set to play an important role in the management of DKD. Prior studies have reported the possible association of Tumour Necrosis Factor Receptor 1 (TNFR1), Dickkopf-3 (DKK3) and B cell lymphoma 3 (BCL-3) with the pathogenesis of DKD. However, there had been no prior studies that investigate the association of these biomarkers as prognostic markers for DKD disease progression. Hence, we aim to investigate the correlation of these biomarkers with renal progression among the diabetic population with and without kidney disease.

Method: A total of 156 subjects were recruited, which consisted of 64 control vs 92 patients with DKD. The principal outcomes of this study were rapid renal decline (doubling of serum creatinine, renal decline > 5ml/min/year and > 10 ml/min/year) and their association with serum TNFR1, BCL-3 and urine DKK3. A bivariate analysis was used to test the association of rapid renal decline, and sensitivity and specificity were used to test the validity of the level of the biomarkers with outcomes.

Results: The baseline parameters for both case and control: age 50.19±9.22 vs 60.35±13.73, serum albumin 38.97±2.07 vs 33.01±8.98g/L (p< 0.001), eGFR 117.96±31.94 vs 38.00±22.04 ml/min/1.73 m² (p< 0.001), serum creatinine 77.34±14.15 vs 247.45±148.09 μmol/L (p < 0.00), uPCI g/day 0.001±0.0 vs 4.268±5.29 (p < 0.001), HbA1c 7.83±1.88 vs 7.86±1.78 mmol/L (p = 0.942), sTNFR1 11781.91±337.46 vs 4394.03±1960.06 pg/mL (p < 0.001), uDKK3/creatinine 132.84±37.61 and 1243.63±495.27 pg/mg (p < 0.001), and sBCL3 194.60±32.81 vs 490.17±259.02 pg/mL(p < 0.001). During the follow-up, there was a significant association of sTNFR1 with rapid renal decline > 5ml/min/year, > 10 ml/min/year and doubling of serum creatinine [p < 0.003 [IQR = 2891.50-4885.75], p < 0.009 [2891.50-4885.75], p < 0.001 [2891.50-4885.75]] but not with uDKK3 and sBCL-3 (Table 1). Specificity and sensitivity analyses on the performance of the biomarkers versus outcomes were highly significant (Figure 1).

Conclusion: Despite TNFR1, BCL-3 and urine DKK3 were all elevated in our DKD patients, there was a strong association between incident serum TNFR1 level and the subsequent deterioration of renal function which has not been reported in the literature before. In addition, TNFR1 level had consistently picked up cases of DKD that would experience rapid renal progression, be it > 5ml/min/year, > 10 ml/min/year or doubling of serum creatinine. The correlation studies have shown TNFR1 level high sensitivity, and specificity with renal progression among the diabetic population with and without kidney disease.

Table 1: The association of the renal outcome (doubling of serum creatinine, renal decline > 5ml/min/year and > 10 ml/min/year) with the level of biomarkers compared with the conventional markers. Results show there is a significant association of sTNFR1 with all renal outcomes but not with uDKK3 and sBCL3.

AMBIENT HEAT EXPOSURE AND ESTIMATED GLOMERULAR FILTRATION RATE Trajectory: A POST-HOC ANALYSIS OF THE DAPA-CKD TRIAL

Zhiyan Zhang1, Hiddo Lambers Heerspink2, Glenn Chertow3, Ricardo Correa-Rotter4, Antonio Gasparri1, Niels Jong3, Anna Maria Langkilde5, Malcolm Mistry1, John McMurray6, Peter Rossing7, Robert Toto8, Priya Vart2, Dorothea Nitsch1, David C. Wheeler9 and Ben Caplin9

1London School of Hygiene & Tropical Medicine, United Kingdom, 2University Medical Center Groningen, Groningen, Netherlands, 3Stanford University School Medicine, Stanford, United States of America, 4Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, México, D.F., Mexico, 5AstraZeneca R&D, Sweden, 6University Of Glasgow, United Kingdom, 7University of Copenhagen, København, Denmark, 8UT Southwestern Medical Center, Dallas, United States of America and 9University College London, United Kingdom

Background and Aims: Higher ambient temperatures have been associated with higher rates of admission for kidney stones and acute kidney injury. Occupational heat stress is also a risk factor for impaired kidney function in several rural resource-poor settings. It is unclear if higher ambient heat exposure is associated with a faster loss of kidney function in patients with established, all-cause, chronic kidney disease (CKD). We therefore undertook a post-hoc analysis of the DAPA-CKD trial linking participant data to publicly available climate measurements.

Method: The DAPA-CKD trial randomized 4304 patients with proteinuric CKD (estimated glomerular filtration rate, eGFR, 25-75 mL/min/1.73 m²; urinary albumin-to-creatinine ratio, ACR, 23-566 mg/mmol) to dapaglifozin or placebo in addition to standard of care. We examined the association between daily study centre-level ambient heat exposure (defined as a mean heat index, HI, >30; European Centre for Medium-Range Weather Forecasts ERA5 reanalysis dataset) and individual-level change in eGFR using both a linear-mixed effects model and a case-time series approach to address potential unmeasured individual- and centre-level confounding.

Results: Climate and eGFR data were available on 3915 (91%) participants across 361 centres in 21 countries. Over a median of 28 months, participants (mean age: 62 years; mean eGFR: 43mL/min/1.73 m²) were followed-up at centres where there was a median of 1 day (interquartile range: 0 to 64 days) with an HI>30. Each 30-day period of HI>30 over the study period was associated with a change in eGFR of ~0.7% (95% CI: -1.0% to -0.3%), equivalent to an additional eGFR loss of between 1.2 and 4.0mL/min/1.73 m² per year in a patient with an eGFR of 45mL/min/1.73 m² located in a very hot versus temperate environment. Similar estimates were obtained using the case time series approach. This association persisted after adjustment for potential haemoconcentration effects on the day of testing and further analyses provided no evidence that these findings varied with baseline eGFR, albuminuria or

Figure 1: Association between heat index and change in eGFR in subgroups. Linear mixed model of eGFR measures nested within individual-level random effects nested within centre-level random effects. Model adjusted for the following baseline variables: age; sex; ethnicity; smoking status; diagnosis of diabetes; history of cardiovascular disease; BMI; systolic blood pressure; urinary ACR; eGFR; ACE/ARB use; statin use; diuretic use; DAPA-CKD study arm; and time interactions (reflecting associations with eGFR slope) with age; BMI; systolic BP; eGFR; urinary ACR and DAPA-CKD study arm. Average marginal effects estimates presented for subgroups. Error bars show 95% confidence intervals. The DAPA-CKD trial was funded by AstraZeneca.

A HIGH PROTEIN DIET INDUCES DEPRESSION-LIKE BEHAVIOR IN CKD RODENT MODELS

Mara Lauriola1, Sander Dejongh1, Ricard Farré2 and Björn Meijers1

1KU Leuven, Department of Nephrology, University Hospitals Leuven, Leuven, Belgium and 2KU Leuven, Translational Research Center for Gastrointestinal Disorders (TARGID), KU Leuven, Leuven, Belgium

Background and Aims: The prevalence of depression among patients with Chronic Kidney Disease (CKD) is higher than the general population. Around 21-27% of CKD patients is estimated to be affected by depression. Several studies hypothesized that mood disorders may be due to reduced family support, older age, low educational status and low quality of life. However, adults with CKD are also known to exhibit altered tryptophan metabolism

Figure 1: A high specificity and sensitivity analyses of the biomarkers versus outcome sTNFR1 74% p < 0.001, 68.2% p = 0.009 and 73.8% p < 0.001, uDKK3 39.7% p = 0.102, 51.4% p = 0.839 and 42.8% p = 0.26 and sBCL-3 60.5% p = 0.096, 46.0% p = 0.561 and 52.1% p 0.744.
causing reduced plasma levels of tryptophan and elevated kynurenine and kynurenic acid. Moreover, CKD patients showed increased levels of indoxyl sulfate and indole-3-acetic acid, two protein-bound uremic toxins deriving from the gut microbiome metabolism of tryptophan. We postulate that depression is not just due to reduced quality of life but also to a biological reason. In addition, we hypothesize that a high protein diet may influence tryptophan metabolism and therefore affect depression symptoms.

Method: Eighteen Sprague-Dawley male rats (Janvier, Le Genest - St Isle, France), 7-8 weeks old, were induced with CKD utilizing 5/6 nephrectomy and were randomly assigned to a low protein (n = 10) or a high protein (n = 8) diet. A sham-operated control group for each diet was used (n = 7 respectively). The splash test was adopted to assess depressive symptoms in rats. In short, the splash test is a behavioral test consisting in sprinkling a 10% sucrose solution on the dorsal coat of a rat. Latency (time before the initiation of grooming) and duration of grooming were recorded for 5 min and used as an indication of self-care behavior. Delayed and reduced grooming is considered as a depression-like behavior of rats. Blood and urine creatinine were determined with standard laboratory techniques. Total plasmatic concentrations of tryptophan, kynurenine, kynurenic acid and indoxyl sulfate were measured using LC-MS/MS.

Results: The latency before the starting of the grooming behavior was significantly higher (p = 0.049) in CKD rats on a high protein diet compared to sham rats on the same diet while no difference was seen between the low protein groups. CKD rats reported significantly higher plasma levels of indoxyl sulfate and kynurenic acid and reduced tryptophan. Interestingly, kynurenic acid plasma levels were significantly reduced when administering a low protein diet to CKD rats (p = 0.025). Among CKD rats, the latency of the grooming behavior was correlated with plasmatic levels of creatinine clearance (Spearman r = -0.57, p value = 0.19), indoxyl sulfate (Spearman r = -0.64, p value = 0.007), and kynurenic acid (Spearman r = -0.63, p value = 0.009). The total grooming time was shorter in both CKD groups compared to the sham rats, but not significantly (p = 0.4881 and p = 0.4312, respectively).

Conclusion: These results suggest that biological factors contribute to depression onset and that the decline of kidney function and the accumulation of uremic toxins are potential risk factors for depression. Dietary interventions such as a low protein diet, are potential strategies to lower the plasmatic levels of uremic toxins which may alleviate depressive-like symptoms.

**DIFFERENCES IN CIRCULATING IMMUNE CELLS PROFILE BETWEEN MALES WITH CARDIORENAL SYNDROME TYPE II AND CKD PATIENTS WITHOUT CARDIOVASCULAR DISEASE**

Anila Duni1, Athanasios Kitsos1, Aris Bechlioulis2, Georgios Markopoulos3, Lampros Lakkas4, Gerasimos Baxevanos4, Ioanna Theodorou1, Katerina Naka5, George Vartholomatos1 and Evangelia Ntounou1

1University Hospital of Ioannina, Department of Nephrology, IOANNINA, Greece; 2University Hospital of Ioannina, Second Department of Cardiology, IOANNINA, Greece; 3University Hospital of Ioannina, Laboratory of Hematology - Unit of Molecular Biology, IOANNINA, Greece and 4Hatzikosta General Hospital of Ioannina, Internal Medicine Department, IOANNINA, Greece

**Background and Aims:** Maladaptive activation of the immune system plays an important role in the pathogenesis of cardiovascular disease (CVD) and chronic kidney disease (CKD). The immune system components can act as mediators of organ cross-talk and may be involved in the reciprocal dysfunction that occurs in cardiorenal syndromes (CRS). The aim of our study was to investigate potential differences in blood levels of specific immune cells subsets between a cohort of type II CRS patients and CKD patients without established CVD.

**Method:** 40 stable male patients with CRS type II and 30 male CKD patients with proteinuria were enrolled for eGFR (CKD-EPI) were enrolled in this cross-sectional study. Exclusion criteria were history of malignancy, autoimmune and active or chronic infections. The peripheral blood immune cell subsets CD14++CD16-, CD14++CD16+ and CD14+CD16+ absolute values and percentages out of total monocytes and NK cells (CD3+CD16+56+), CD3-CD19- B lymphocytes, CD3+ CD4+ T cells, CD3+CD8+ T cells and Tregs (CD4+CD25+FoxP3+) absolute values and percentages out of total lymphocytes were measured by flow cytometry. In a randomly selected subgroup of 40 patients, the correlation between the peripheral blood immune cell subsets and laboratory and echocardiographic data was assessed. Multiple regression analyses to assess independent relationships were performed by building separate models with each of the immune cells as the dependent variable and respective univariate correlates including patient group.

**Results:** Mean age of patients with CRS and CKD was 72±10 versus 66±10 years respectively (p = 0.01), mean eGFR was 37±14 and 33±16ml/min/1.73 m² respectively (p = 0.28) and median urinary protein to creatinine ratio (UPCR) was 0.19 (IQR: 0.10-0.52) versus 1.03 (IQR: 0.17-2.09) g protein/gr creatinine (p = 0.02) respectively. CRS patients displayed increased levels of pro-inflammatory, intermediary CD14++CD16+ monocyes [41 (IQR, 24-78)/μL compared to their CKD counterparts [35 (IQR, 18-43)]/μL (p = 0.04). A higher Tregs percentage was found in CRS patients [2.7% (IQR, 2.0%-3.9%)] compared to CKD patients [2.0% (IQR, 1.6%-2.6%)] (p = 0.03). Lower mean levels of lymphocytes were observed in CRS patients [153 (IQR, 80-245)]/μL compared to the CKD cohort [192 (IQR, 545-791)μL (p= 0.04). Finally, CRS patients displayed lower NK cell counts [148 (IQR, 103-258)]/μL compared to CKD patients [324 (IQR, 179-368)]/μL (p = 0.001). Age and UPCR did not correlate with immune cells subsets in the whole cohort, neither in the two groups separately. At multivariate regression analysis, the differences in immune cells between the two groups remained statistically significant. Specifically, in patients with CRS the intermediate CD14++ CD16+ monocyes counts correlated positively with CRP (p = 0.002) and ESR (p = 0.02). A positive correlation was found between eGFR and total lymphocytes (p = 0.009), T cells (p = 0.005) and CD4+ T cells (p = 0.005) counts. The number and percentage of nonclassical CD14+CD16+ macrophages were higher in CRS patients with left ventricular ejection fraction (LVEF) less than 30% compared to patients with LVEF above 30% [33 (IQR, 18-37)]/μL versus 13 (IQR, 10-29)/μL (p = 0.02) and 4.5% (IQR, 3.4%-7.2%) versus 2.7% (IQR, 1.9%-5.4%) (p = 0.03) respectively. With regard to etiology, patients with dilated cardiomyopathy compared to patients with ischemic CVD displayed increased counts of intermediate CD14++CD16+ monocytes [75 (IQR, 41-104)]/μL versus 36 (IQR, 22-61)]/μL (p = 0.01) and non-classical CD14+CD16+ macrophages [35 (IQR, 19-51)]/μL versus 21 (IQR, 12-32)]/μL (p = 0.02). Finally, NK cells and Tregs levels were lower in patients with atrial fibrillation compared to those without [133 (IQR, 79-173)]/μL versus 260 (IQR, 151-314)]/μL (p = 0.01) and [32 (IQR, 21-43)]/μL vs 47 (IQR, 34-85)]/μL (p = 0.006) respectively.

**Conclusion:** Patients with CRS type II exhibit alterations of the immune cells subsets profile in the peripheral blood compared to CKD patients of similar kidney function but without CVD. Our findings suggest that distinct immune mechanisms might be involved in the pathogenesis or the chronic course of CRS type II as compared to CKD. Future research is required to test their pathophysiological or prognostic significance.

**ADPKD PREDICTOR: A CLOUD-BASED PROGNOSTIC TOOL FOR AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE**

Vincenzo Carbone1, Matteo Gazzin1, Roberta Bursi1, Riccardo Magistrioni2 and Cristiana Corsi3

1InSilicoTrials Technologies SpA, Trieste, Italy, 2InSilicoTrials Technologies BV, s-Hertogenbosch, Netherlands, 3Università di Modena e Reggio Emilia, Nefrologia, Dialisi e Trapianto Renale, Modena, Italy and 4Università di Bologna, Biomedical Imaging Group, Bologna, Italy

**Background and Aims:** ADPKD is a progressively debilitating genetic disease characterized by the growth of numerous cysts in the kidneys, leading eventually to end-stage renal disease. Total Kidney Volume (TKV) is accepted by FDA and EMA as a prognostic biomarker and quantitative predictor of kidney function decline, and is currently used to select patients to receive Tolvaptan treatment. However, TKV calculation from manual tracing of medical images is labor-intensive; for better accuracy, current available methods involve the injection of an iodinated contrast medium for CT scan, with important limitations in patients with impaired renal function. We developed ADPKD Predictor, a user-friendly cloud-based tool for fast and accurate estimation of disease classification and progression, based on automated kidney and cysts segmentation from MRI data.

**Method:** An online tool was designed on Microsoft Azure Cloud to automate the set-up and running of a previously developed algorithm implemented in MATLAB to automatically detect kidneys and cysts contours from MRI data (T2-weighted turbo-spin-echo SPIR), based on advanced image processing techniques [1]. Through the web interface, the user is requested to upload the MRI data and select one point inside kidney’s parenchyma in the central slice (Figure 1). Then, TKV is automatically calculated and eGFR based on CKD-EPI equation, ADPKD Imaging Classification and future eGFR [2], estimated Tolvaptan treatment effect [3], and GFR Category based on KDIGO CKD staging system are also obtained (Figure 2). The MRI dataset is anonymized before upload to the cloud; data and results are stored in a secure and reliable environment controlled by the user.

**Results:** The proposed solution is very fast and precise compared to manual segmentation of medical images (absolute mean error 2.4% ± 2.7%) [1]. Moreover, it is faster and more accurate than the commonly used ellipsoid-based method, resulting in a manifold reduction of misclassification.
error (2.5%) [1] and therefore potential therapeutic consequences. Another advantage is its usability, with no specific computational expertise, numerical software or dedicated hardware required, since all computations are run remotely in the cloud.

**Conclusion:** ADPKD Predictor provides a fast and reproducible assessment of risk classification and disease progression, based on precise morphologic classification of the renal and cysts volume of patient. The proposed solution represents an extremely useful tool for researchers and clinicians to easily obtain an accurate estimation of risk classification potentially helping in a correct and effective stratification of patients, and monitor patient’s disease progression, hence supporting a correct and effective therapy administration. Also, it would represent a great benefit for the patient, since the tool analyzes medical images obtained without the use of contrast medium.

Figure 1: ADPKD Predictor web interface – Input page - User uploads MRI data, scrolls through images and selects one point inside kidney’s parenchyma in the central slice.
ADPKD Predictor web interface – Output page showing TKV and ADPKD Imaging Classification, eGFR history, future eGFR and estimated effect of Tolvaptan treatment, GFR Category.

ROLE OF KIDNEY FUNCTION ON NRF2 MRNA LEVELS IN TYPE-2 DIABETES

Cristina Politi1, Belinda Spoto1, Maurizio Postorino2, Rosa Parlongo1, Domenico Mannino3, Alessandra Testa1, Eugenio Alessi4, Giovanni Luigi Tripepi1, Francesca Mallamaci1,2 and Carmine Zoccali1,6,7

1CNR-Institute of Clinical Physiology, Italy, 2Nephrology, Dialysis, and Transplantation Unit (GOM-BMM), Italy, 3AMD-Associazione Medici Diabetologi, Italy, 4Endocrinology and Diabetes Unit (GOM-BMM), Italy, 5Renal Research Institute, United States of America, 6BIOGEM, Italy and 7IPNET, Italy

**Background and Aims:** Nuclear factor erythroid 2-related factor 2 (Nrf2) is a transcription factor that induces the expression of genes coding for antioxidant proteins and phase II detoxifying enzymes. Repressor molecule Kelch-like ECH-associated protein 1 (Keap1) and several microRNAs (miRNA) negatively regulate Nrf2 gene expression at post-transcriptional level. Oxidative stress is a major factor for kidney damage in diabetes but the role of Nrf2 in kidney dysfunction in diabetes is still unclear.

**Method:** To test whether the gene expression of Nrf-2 is downregulated in type-2 diabetes and whether kidney dysfunction per se further reduces Nrf2 in diabetic patients with diabetic nephropathy, we carried out a case-control study including 99 participants divided into three independent groups: 33 patients with diabetic nephropathy (DN), 33 patients with type 2 diabetes without nephropathy (D) and 33 control subjects (C), all accurately matched for age and sex. Standard ANOVA compared outcome measures in the three groups. Multiple linear regression analysis was used to test the expression levels of Keap1, miR-28-5p, miR-93-5p, miR-30e-5p, miR-125b-5p and miR-150-5p as potential mediators in the observed reduction of Nrf2 mRNA levels in patients with diabetic nephropathy.

**Results:** In patients with diabetic nephropathy, Nrf2 gene expression levels (0.82 arbitrary units, AU, IQR: 0.60-1.22 AU) were significantly lower than in diabetic patients without nephropathy (1.19 AU, 0.90-1.38 AU, *P* = 0.01) and control subjects (0.82 AU, 0.60-1.22 AU vs 1.04 AU, 0.87-1.66, *P* = 0.02) while there was no difference between diabetic patients without nephropathy and control subjects (*P* = 0.69). Keap1 gene expression levels were almost identical in patients with and without diabetic nephropathy (1.15 AU, 0.63-2.14 AU vs 1.13 AU, 0.79-1.73 AU, *P* = 0.91) and higher than in control subjects (1.15 AU, 0.63-2.14 AU vs 0.79 AU, 0.49-1.08 AU, *P* = 0.046). MiRNA expression levels were comparable in diabetic patients with and without nephropathy, but miRNA 30e-5p was lower in patients with diabetic nephropathy than in diabetic patients without nephropathy (0.91 AU, 0.76-1.10 AU vs 1.06 AU, 0.89-1.23 AU, *P* = 0.016). The expression levels of Nrf2 and miRNA 30e-5p were unrelated in patients with (*r* = 0.15, *P* = 0.44) and without (*r* = -0.02, *P* = 0.90)
diabetic nephropathy. In linear regression analyses, eGFR emerged as the first factor in rank for explaining the difference in Nrf2 mRNA levels (adjusted variance 76%) among patients with and without diabetic nephropathy.

**Conclusion:** This case-control study comparing the gene expression level of Nrf2 in diabetic patients with and without nephropathy shows that kidney dysfunction is the key factor that explains the variability in Nrf2 mRNA levels in diabetes. These data suggest a primary role of Nrf2 in redox homeostasis and kidney damage in diabetic nephropathy.

**ESTIMATED GLOMERULAR FILTRATION RATE USING CYSTATIN C AND CREATININE IN CHILDREN WITH NEUROGENIC BLADDER – IMPACT OF DEMOGRAPHICS AND PROTEINURIA**

Bebiana Sousa 1, Luis Salazar 1, Sofia Poço Miranda 1, Sofia Ventura 1, Rosa Amorim 1, Maria Do Sameiro Faria 2, Teresa Costa 3 and Maria Conceição Mota 5

1 Centro Materno Infantil do Norte, Pediatrics, Portugal, 2 Unidade Local de Saúde do Alto Minho, Pediatrics, Portugal, 3 Hospital do Divino Espírito Santo, Nephrology, Portugal, 4 Centro Hospitalar e Universitário de Santo António, Physiatrics, Portugal and 5 Centro Materno Infantil do Norte, Pediatric Nephrology Unit, Portugal

**Background and Aims:** There is a high-risk of progressive chronic kidney disease (CKD) in patients with neurogenic bladder (NB) and early detection of estimated glomerular filtration rate (eGFR) reduction is essential, preventing delayed diagnosis. Creatinine-based formulas can overestimate eGFR in these patients due to decreased muscle mass. This study aims to compare eGFR calculated by different equations using serum creatinine (Cr) and/or cystatin C (CysC), in children with NB, and analyse the influence of demographic variables and proteinuria.

**Methods:** Data on pediatric patients with NB and CKD stage 1 and 2, based on eGFR calculated by the CKiD-Cr formula, were collected from January 2009 to December 2022, in a Pediatric Nephrology Unit from a tertiary hospital. The eGFR was calculated using CKiD CysC, Schwartz combined Cr/CysC, Zapitelli-CysC and Zapitelli combined Cr/CysC formulas. Proteinuria was defined by urine protein-to-creatinine ratio greater than 0.2 (mg/mg).

**Results:** Fifty patients were evaluated, with a median (25th-75th percentile) age of 14.2 (9.0-16.7) years, 48% (n = 24) female, with a median height of 142 (119.8-154.3) cm, mostly below 5th percentile (64%, n = 32) and a median body mass index of 20.5 (15.5-26.7) kg/m2, 58% (n = 29) of patients had lipo/myelomeningocele and 76% (n = 38) were classified as stage 1 CKD. The median eGFR (ml/min/1.73m2) calculated by different formulas was: CKiD-Cr 108.1 (89.2-129.6); CKiD-CysC 77.1 (59.7-87.7); CKID-Cr/CysC 86.6 (67.4-98.1); Zapitelli-CysC 83.3 (63.3-95.7) and Zapitelli combined- Cr/CysC 101.4 (75.5-121.2). When compared to CKiD-Cr, all the CysC-based formulas showed significantly lower values of eGFR (p < 0.01). No statistical differences were obtained in eGFR calculated by CKiD-Cr and CKID-CysC equations regarding age, sex, percentile of height or body mass index. In patients without independent gait (wheelchair or orthosis), with more muscle atrophy and underdeveloped lower limbs (54%, n = 27), the eGFR calculated by CKID-Cr was higher than in the patients who are ambulatory (119.0 (102.8-150.0) vs 91.6 (64.5-111.8); p = 0.01). On the other hand, there were no differences regarding eGFR obtained by CKiD-Cr and CKID-CysC equations in all those two groups of patients (p = 0.64). Proteinuria was detected in 39% (n = 15) of the patients with stage 1 CKD and of these 87% (n = 13) had CKD upstaging using CKID-CysC equation. In addition, the difference between the median Cr-eGFR and CysC-eGFR was significantly higher in the group of patients with proteinuria (53.1 (36.2-59.7) vs 32.6 (13.4-45.9); p = 0.007). Proteinuria was significantly higher in the group of children with more muscle atrophy, without independent gait (wheelchair or orthosis) compared to ambulatory (0.30 (0.12-0.43) vs 0.12 (0.06-0.20); p = 0.021).

**Conclusions:** In pediatric patients with NB and poor muscle mass Cr-based formulas can overestimate eGFR and delay the diagnosis and correct staging of CKD. In these patients CysC-based equations seem to be more reliable in assessing kidney function. In children with NB proteinuria appears to be a possible early and sensitive marker of CKD progression, mostly in those with more muscle depletion.

**PREDICTORS OF KIDNEY DISEASE PROGRESSION IN MALES WITH X-LINKED ALPORT SYNDROME**

Marina Aksenova, Natalia Zaikova, Oxana Piruzeeva, Tatjana Lepaeva, Varvara Obuhova, Tatjana Nikishina and Natalia Konkova

Y.Velitschev Research and Clinical Institute for Pediatrics and Pediatric Surgery at N.Pirogov Russian National Research Medical University, Nephrology Department, Moscow, Russia

**Background and Aims:** Alport’s syndrome is the second most common monogenic cause of end-stage renal disease (ESRD). Males with X-linked Alport’s syndrome (XLAS) have a high risk of early ESRD development. The aim of study was to determine the predictors of unfavorable renal prognosis in boys with XLAS.

**Method:** The children with genetically confirmed XLAS (n = 84, age 8.7±4.3 yrs, eGFR 102±16.2 ml/min/1.73 m2, 59 pts with missense COL4A5 mutations) were included in observation single center study (FU 6.8±2.4 yrs). Seventy three pts (q = 0.87) were treated with ACEi (age of start 7.6±3.3 yrs, dose for Ramipril 2.7±0.8 mg/m2/day). Arterial blood pressure (BP), proteinuria (Pt, mg/m2/day), eGFR (Schwartz equation, ml/min/1.73 m2), gene mutation type and ACEi-treatment data (age of pts and disease stage at the therapy start, ACEi dosage, dynamics of Pr and eGFR) were obtained and updated for each patient. BP >90 perc for gender, age and height was defined as uncontrolled (uBP); Pr was categorised according to its level as a low (100<250 mg/m2/day), moderate (250-500 mg/m2/day), high (>500-1000 mg/m2/day) and nephrotic (>1000 mg/m2/day). Gene mutations were divided into severe (nonsense, deletion, splicing) and less severe (missense) mutations. The eGFR<60 ml/min/1.73 m2 was defined as primary outcome.

**Results:** Twenty seven pts (q = 0.24, age 13.5±2.96 yrs) reached the end point during observation period. Non-missense COL4A5 mutations (HR = 4.28, 95% CI 1.47-12.4, p = 0.007), uBP (HR = 20, 95% CI 4.68-29.6, p < 0.001), persistent Pr >250 mg/m2/day (HR = 20, 95% CI 3.36-21, p < 0.001), absence of ACEi treatment (HR = 10.7, 95% CI 2.45-147, p = 0.02) or start therapy at proteinuric stage of disease (HR = 20, 95% CI 2.2-138, p < 0.001) were the risk factors of disease progression. Multiple regression analysis adjusted for age, initial eGFR revealed that late start of ACEi treatment (β = 0.23, p = 0.036), persistence of uBP (β = 0.26, p = 0.008) and Pr > 250 mg/m2/day (β = 0.17, p = 0.04) had independent significance and predict unfavorable renal prognosis (R = 0.76, R2 = 0.57, p < 0.000).

**Conclusion:** Persistent proteinuria and uncontrolled blood pressure, initiation of ACEi treatment at the proteinuric stage of glomerulopathy are the factors of unfavorable prognosis in male with XLAS.
Conclusion: Our data indicate that PPARγ agonist pioglitazone not only attenuates the TGF-β induced miR-21 overexpression, but also the renal dysregulation of miR-130a and miR-199, supporting its anti-fibrotic effects.

CIRCULATING ACTIVIN A REFLECTS THE SEVERITY OF RENAL FIBROSIS IN BIOPSY-PROVEN KIDNEY DISEASES—THE TAIPEI RENAL BIOPSY COHORT STUDY
Ming-Tsun Tsai, Shuo-Ming Ou and Szu-Yuan Li
Taipei Veterans General Hospital, Division of Nephrology, Department of Medicine, Taipei, Taiwan, Rep. of China

Background and Aims: Despite considerable evidence indicating circulating activin A as a novel renal biomarker, its performance for predicting the severity of renal fibrosis and major adverse renal events (MARE) has not yet been extensively studied.

Method: We sought to assess the relationship between plasma activin A, renal fibrosis severity, and incidence of MARE in 339 patients undergoing clinically indicated native renal biopsies. To determine the primary source of circulating activin A, RNA-sequencing and histological analyses were performed on kidney biopsy specimens from patients with chronic kidney disease (CKD). We also conducted in vitro experiments to investigate whether inhibiting endogenous activin A could attenuate TGF-β-mediated activation of cultured fibroblasts.

Results: The median baseline eGFR and proteinuria were 36 mL/min/1.73 m² and 2.9 mg/mg creatinine, respectively. After multivariable adjustment, elevated plasma activin A was associated with the extent of renal fibrosis. Histological analysis showed increased activin A expression in kidney tissues from patients with CKD, mainly in interstitial myofibroblasts. RNA-sequencing of tubulointerstitial tissue from human biopsy samples also revealed a direct correlation between tissue activin A mRNA expression and plasma activin A levels. During a median follow-up of 22 months, 113 participants suffered MARE. Cox proportional hazards analysis revealed that plasma activin A was associated with higher risk of renal events; however, the association became insignificant after correcting for confounders. Results from in vitro studies demonstrated that knocking down activin A expression could prevent TGF-β-induced activation of NRK49F fibroblasts.

Conclusion: The findings of this study support activin A as a potential diagnostic and therapeutic target in fibrotic kidney disease.

Figure 1: Cumulative incidence of MARE associated with low vs high plasma activin A (ActA) group in patients undergoing clinically indicated kidney biopsies. The median follow-up time for each group was as follows: for the high ActA group 19.4 months (interquartile range 10.5–28.7) and the low ActA group 23.6 months (interquartile range 16.7–32.6).
Figure 2: Reduction of TGF-β-induced pro-fibrotic effects by interrupting activin A signaling in renal fibroblasts. (A and B) The qPCR-based analysis of mRNA levels of *Inhba* (A), *Acta2*, *Ccn2*, and *Col3a1* (B) in NRK49F cells transfected with negative control or si-*Inhba* following treatment with vehicle or 10 ng/ml TGF-β for 24 h. (C) Representative images of Western blotting showing the protein expression levels of activin A, collagen 3a1, and α-SMA in different groups of NRK49F cells. (D) Densitometric analysis of the western blot results presented in C.

PILOT MONITORING STUDY IN PATIENTS WITH DIABETIC KIDNEY DISEASE USING NORA APPLICATION

Néstor Toapanta Gaibor¹, Ester Sánchez¹, Cristina Guirao¹, Juan Carlos León Román¹, Natalia Ramos Terrada¹, Ander Vergara¹, María A. Azancot¹, Irene Agraz¹, Sheila Bermejo¹, Estefanía Montiel², Carlos Molina², Marc Ribó² and María Jose Soler Romeo³

¹Vall d’Hebron, Hospital, Nephrology, Spain and ²Vall d’Hebron, Hospital, Neurology, Spain

**Background and Aims:** Diabetic Kidney Disease (DKD) is the most common cause of end-stage chronic kidney disease (CKD), conditioning these patients to a worse renal prognosis and higher cardiovascular mortality and/or requirement for renal replacement therapy. The use of novel information and communication technologies (ICTs) focused on the field of health, may facilitates a better quality of life and disease control in these patients. Our objective is to evaluate the effect of monitoring DKD patients using NORA-app.

**Method:** Prospective feasibility/validation study of NORA-app in patients with DKD stage G3bA3 or higher, followed in outpatient clinics of a tertiary care hospital. NORA-app is an application for smartphones designed to control risk factors, share educational medical information, communicate via chat with health professionals, increase treatment compliance (Morisky-Green), and collect patient reported outcomes such as anxiety and depression using HADs scale. Clinical-laboratory variables were collected at 3 months and compared to control patients who declined using NORA-app.

**Results:** From 01/01/2021 to 03/03/2022 the use of NORA-app was offered to 118 patients, 82 accepted and 36 declined (controls). After a mean follow-up period of 6.04 months and at the time of data extraction 71 (86.6%) NORA-app patients remain active users, 2 have completed the follow-up at one year and 9 are inactive (3 due to death and 6 due to non-locatable). There were no differences in baseline characteristics including Creatinine [2.1 (1.6-2.4) vs. 1.9 (1.5-2.5)] mg/dL and alb/creat [962 (475-1784) vs. 1036 (560-2183)] mg/gr between Nora and control patients respectively. The therapeutic compliance rate in the NORA-app group was 77%, improving at 90 days to 91%. Patients in the NORA-group showed significantly lower levels of alb/creat than controls (768 (411-1971) mg/g Vs 2039 (974-3214) p = 0.047) at 90-day follow-up.

**Conclusions:** In patients with DKD the use of NORA-app was maintained in the long-term, leading to high levels of treatment compliance, and achieving a better disease control. Our study suggests that the generalized use of ICTs may help in the personalized monitoring of these patients to delay the progression of kidney disease.

RISK FACTORS AND TRANSITIONAL PROBABILITY OF CLINICAL EVENTS IN KOREAN CKD PATIENTS USING THE MULTI-STATE MODEL: RESULTS FROM THE KNOW-CKD STUDY

Ji Hye Kim¹, Jayoun Kim², Jinheum Kim³ and Kook-Hwan Oh⁴

¹Chungbuk National University Hospital, Internal Medicine, Cheongju, Rep. of South Korea, ²Seoul National University Hospital, Medical Research Collaborating Center, Rep. of South Korea, ³Suwon University, Applied Statistics, Hwaseong-si, Rep. of South Korea and ⁴Seoul National University Hospital, Internal Medicine, Rep. of South Korea

Background and Aims: Compared to western countries, Korean CKD patients show distinctive differences in clinical outcomes including lower cardiovascular disease (CVD) and higher end-stage kidney disease (ESKD) events. This study analysed the risk factors, transition probability and cumulative hazards associated with clinical events using the multi-state model.

Method: This study included 1423 patients at CKD stages 1-4 from Korea NCohort Study for Outcome in Patients With Chronic Kidney Disease. Multivariate multi-state model analysis was performed to investigate the risk factors, 10-year transition rate and cumulative hazard estimates for five clinical event status including ESKD, CVD, death, death after ESKD and death after CVD events.

Results: Among 1423 patients (age 54 [44-63] years), the overall prevalence of clinical events were the following: ESKD (22.6%), CVD (7.5%), death (3.3%), death after ESKD (3.6%) and death after CVD (1.2%). Different risk factors were associated with different clinical outcomes and in particular the risk factors associated with higher ESKD event were underlying CVD, diabetes, polycystic kidney disease, fibroblast growth factor-23 while hypertension, increased age and estimated glomerular filtration rates were associated with lower risks. The 10-year progression probability for each event status include the following: 0.23 for ESKD, 0.08 for CVD, 0.04 for death, 0.09 for death after ESKD and 0.01 for death after CVD (Figure 1). The 10-year cumulative hazard estimates for each event status were the following: ESKD [0.43, 95% CI (0.37-0.49)], CVD [0.12, (0.10-0.15)], death [0.05, (0.03-0.06)], death after ESKD [0.52, (0.20-0.84)] and death after CVD [0.27, (0.15-0.40)] (Figure 2).

Conclusion: Different risk factors were associated with varying clinical outcomes in Korean CKD patients. The 10-year progression probability was the highest in ESKD followed by death after ESKD events. Also, the 10-year cumulative hazard estimate was the highest for death after ESKD followed by ESKD events. These findings correlate with the distinctive clinical outcome features of Korean CKD patients.

Figure 1: 10-year progression probability for each clinical event status.
INTERACTIONS BETWEEN FIBROBLAST GROWTH FACTOR 23 AND SYSTEMIC INFLAMMATION IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Matteo Abinti,1 Simone Vettoretti,2 Deborah Mattinzoli,2 Lara Caldirola,1 Paolo Molinari,1 Masami Ikehata3, Carlo Maria Alfieri1,3, Giuseppe Castellano1,3 and Piergiorgio Messa1

1Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Department of Nephrology, Dialysis and Renal Transplantation, Milan, Italy, 2Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Renal Research Laboratory, Milan, Italy and 3University of Milan, Department of Clinical Sciences and Community Health, Milan, Italy

Background and Aims: In patients with Chronic Kidney Disease (CKD), serum concentration of Fibroblast Growth Factor 23 (FGF23) is inversely correlated with Glomerular Filtration Rate (eGFR), as an adaptive mechanism to counterbalance the alterations of mineral metabolism. Transcription, secretion and cleavage from the intact form (iFGF23) to the c-terminal fraction (cFGF23) are regulated by several mechanisms among which inflammatory mediators seem to play a significant role. We investigated whether there was any correlation between FGF23 and several inflammatory mediators.

Method: In the present study we evaluated cross sectionally the correlation between FGF23 (iFGF23 and c-FGF23) and some pro-inflammatory (IL-6, TNFα) and anti-inflammatory (IL-10) cytokines in a cohort of 111 prevalent CKD patients stages III-V not yet on dialysis. We excluded patients with infections or chronic inflammatory diseases in the last 3 months, neoplasia or under immunosuppressive therapy. FGF23 and cytokines were dosed by ELISA.

Results: Descriptive characteristics of the cohort are reported in Table 1. We found an increase in inflammation as eGFR declines: IL6 (r = -0.315, p < 0.001), TNFα (r = -0.202, p = 0.033) and MCP1 (r = -0.278, p = 0.003). Furthermore, the ratio between C-terminal FGF23 to intact FGF23 (c/iFGF23) was directly correlated to eGFR, even if it did not reach statistical significance (r = 0.127, p = 0.113). The correlations between FGF23 and markers of osteo-mineral metabolism and inflammation are reported in Table 2. We found positive correlations of iFGF23 with: IL-6 (r = 0.465, p < 0.001), TNFα (r = 0.241, p = 0.009) and IL-10 (r = 0.197, p = 0.061). After the adjustment for eGFR, iFGF23 maintained its correlations only with IL-6 (r = 0.370, p < 0.001) and TNFα (r = 0.163, p = 0.044) while c/iFGF23 was negatively correlated with IL-6 (r = -0.251, p = 0.008) and positively with MCP-1 (r = 0.204, p = 0.032).

Conclusion: Our data confirm that in CKD patients, as the renal function declines, there is an important increase of inflammatory cytokines and a tendency to an impaired cleavage of FGF23 from the intact to the C-terminal form. Furthermore, we observed strong correlations of iFGF23 with several inflammatory cytokines (IL-6, TNFα, IL-10) that seem to be independent of the adjustment for eGFR, even if it did not reach statistical significance (r = 0.264, p = 0.061).
of eGFR. On the contrary we did not find any correlation of cFGF23 with inflammatory mediators, except for MCP-1. Therefore, we believe that overall our results suggest that inflammatory markers are differently associated with cFGF23 and iFGF23, as if inflammation may independently influence FGF23 turnover (i.e., c/iFGF23 ratio).

#4204
MULTIPARAMETRIC MAGNETIC RESONANCE IMAGING BIOMARKERS OUTPERFORM LAB BIOMARKERS FOR PREDICTING PROGRESSION OF DIABETIC KIDNEY DISEASE
Paul Hockings1, Kianoush Makvandi2, Johannes Hulthe1 and Seema Baid-Agrawal2
1Antaros Medical, Molndal, Sweden and 2Sahlgrenska University Hospital, Gothenburg, Sweden

Background and Aims: We recently showed that comprehensive non-contrast multiparametric Magnetic Resonance Imaging (mpMRI) allowed functional and structural assessment of diabetic kidney disease (DKD) and that an imaging endpoint, R1 cortex, showed significant predictive property for progression of DKD. We further investigated the performance of other MRI and lab biomarkers for predicting disease progression.

Method: In this prospective study, 38 DKD subjects aged 18–79 years and 20 age- and gender-matched healthy volunteers (HV) were included at baseline. 31 DKD subjects (2 stage 2, 13 stage 3, 14 stage 4, and 2 stage 5) and 17 HV were re-examined at 2 years ± 6 months. Clinical and lab examination, iohexol clearance for measured glomerular filtration rate (mGFR), urine albumin:creatinine ratio (UACR) and mpMRI were performed at both visits. A wide range of MRI biomarkers associated with kidney hemodynamics, oxygenation and macro/microstructure were included for evaluation. Disease progression was defined by at least one of the following at 2 years: decrease in mGFR slope of >5 mL/year/1.73 m²; worsening UACR category; or any major adverse kidney event defined as sustained decrease in eGFR of >40%; doubling of serum creatinine from baseline; development of kidney failure with mGFR <15 ml/min/1.73 m²; or death from renal cause. Univariable logistic regression analyses were performed to discriminate between progressors and non-progressors using each relevant lab and imaging endpoint as a predictor variable.

Results: Mean 2-year mGFR decline (ml/min/1.73 m²) in DKD patients was -2.7± 5.4 and in HV -1.9 ± 10.7. 13/31 (42%) DKD subjects and 4/17 (24%) HV progressed. Key lab biomarkers are shown in Table 1 and MRI biomarkers in Table 2.

Conclusion: Of all analyzed biomarkers, only the imaging biomarker R1 cortex, which reflects molecular environment viscosity, fibrosis, and inflammation (interstitial oedema, cellular swelling) showed significant predictive property for progression of DKD. UACR trended towards significance but was not statistically significant. R1 cortex outperformed all other imaging and lab biomarkers, but further studies with R1 cortex as a pre-specified endpoint are required to confirm these results.

Table 1: Logistic regression to predict 2-year progression using lab biomarkers.

**Background and Aims:** Progression of chronic kidney disease (CKD) is a compound process, where activation of immunocompetent cells and subclinical inflammation play a pivotal role. Enhanced atrophy of the tubular cells, and finally, gradual fibrosis of tubulointerstitial tissue, are responsible for irreversible character of the disease. Multiple molecules influence above-mentioned processes. Growth differentiation factor (GDF)15, a member of TGF-β cytokine superfamily, is a marker of inflammation and an integrative signal in both acute and chronic stress conditions. Elevated serum concentrations of GDF15 were associated with increased risk of development and progression of CKD in adults, as well as with mortality in this group of patients. Our previous investigation revealed increased serum GDF15 concentrations in children on chronic dialysis. Epidermal growth factor (EGF), a tubule-specific protein, promotes proliferation, differentiation and migration of epithelial cells, and therefore, modulates regeneration of injured renal tubules. Decreased concentrations of EGF in urine were observed in variety of kidney diseases, including diabetic nephropathy, lupus nephritis or CKD. Our previous analysis of EGF serum concentrations in CKD children confirmed their decreased values on chronic dialysis. Neopterin is a product of activated monocytes and macrophages and serves as a marker of cell-mediated immunity. Elevated serum concentrations of neopterin were observed in CKD adult patients, our previous investigation revealed increased serum GDF15 concentrations in children on chronic dialysis. Epidermal growth factor (EGF), a tubule-specific protein, promotes proliferation, differentiation and migration of epithelial cells, and therefore, modulates regeneration of injured renal tubules. Decreased concentrations of EGF in urine were observed in variety of kidney diseases, including diabetic nephropathy, lupus nephritis or CKD. Our previous analysis of EGF serum concentrations in CKD children confirmed their decreased values on chronic dialysis. Neopterin is a product of activated monocytes and macrophages and serves as a marker of cell-mediated immunity. Elevated serum concentrations of neopterin were observed in CKD adult patients, our previous investigation revealed increased serum GDF15 concentrations in children on chronic dialysis.

**Method:** The study group consisted of 153 children with pre-dialysis CKD stages 1-5 (stage 1 – 27 patients, stage 2 – 26 patients, stage 3 – 51 patients, stage 4 – 28 patients, stage 5 – 21 patients). EGF, GDF-15 and neopterin serum concentrations were assessed by ELISA. The patient database was implemented into the artificial neural network. In detail, the recursively selected subsets of input variables constituted the input layer of an artificial neural network built of perceptrons (multi-layer perceptron). Anthropometric data, biochemical parameters, EGF, GDF15 and neopterin were included into the model, serum creatinine and eGFR, as direct classifiers of CKD stage, were excluded. Various models were tested, regarding their accuracy, AUROC and Matthews correlation coefficient (MCC) values.

**Results:** EGF serum concentrations decreased gradually, whereas GDF15 and neopterin values rose systematically with CKD progression, keeping statistically significant inter-stage differences. Moreover, the most precise ANN model, among the tested artificial neural networks, contained EGF, GDF15 and neopterin as input parameters and classified patients into either CKD 1-3 or CKD 4-5 groups. This model has put new patients into appropriate classes with excellent Accuracy of 96.77%, AUROC 0.9169 and Matthews correlation coefficient (MCC) of 0.9157.

**Conclusion:** The presented model of an artificial neural network, with serum concentrations of EGF, GDF15 and neopterin as input parameters, may serve as a useful predictor of CKD progression in the pediatric population. It suggests the essential role of inflammatory processes, defined by newly discovered markers, in the renal function decline towards advanced stages of CKD in children.

**Background and Aims:** Chronic Kidney Disease (CKD) is a common and debilitating condition that affects over 850 million people worldwide. The disease is associated with high mortality rates that can reach up to 10-15%...
per year, multiple complications, among which cardiovascular ones stand out. These complications can contribute to the progression of CKD, and this in turn to the appearance of complications, feeding each other. Despite the availability of clinical guidelines and predictive models, accurately predicting disease progression and identifying risk factors for progression in CKD patients remains a challenge. The limitations of current methodologies, including simplifying complex relationships and relying on linear assumptions, have hindered progress in this area. The advancement of Artificial Intelligence and Machine Learning has provided a new opportunity to address these challenges. The goal of this study was to evaluate the performance of gradient boosting algorithms in predicting the progression of renal disease in a large dataset of 1327 patients with a follow up of 10 years.

**Method:** Design: Retrospective analysis of a historical cohort from the Register of Renal Patients of Catalonia (RMRC) and the Data analytics program for health research and innovation (PADRIS) from Health Quality and Assessment Agency of Catalonia (AQuAS). Inclusion Criteria: > 18 y.o. CKD stages from 2 to Renal Replacement Therapy (RRT) and adequate data after pre-processing the sample, N = 1,327 patients with 27,572 records. Follow up of 10 years (January 2010 - December 2020). Variables: Age, gender, BMI, Diagnoses

**Method:** By using Light Gradient-Boosting Machine (LGBM) testing CKD progression prediction horizon in quarterly windows for multiple periods. Methodology: 1. Pre-processing of the sample and data. 2. Training and testing for variables exploration. 3. Dataset structuring in quarterly windows. 4. Samples randomization and data separation for a 5-fold cross-validation (20% test - 80% training). 5. Training and tuning of LGBM model for different prediction horizons.

**Results:** Age: 62 ± 13 years; Gender: 34% female, 66% male. Best prediction horizon was for 8 quarters (2 years), with a ROC curve of 0.967 and accuracy of 0.960. The 10 variables with major relevance in the model in order were estimated Glomerular Filtration Rate, Age, Microalbuminuria, BMI, HDL, Glucose, Urea, Platelets, Triglycerides and Sodium.

**Conclusion:** 1. The prediction of CKD progression can benefit from the use of Machine Learning with results that outperform methods based on classical statistics. 2. It can allow the individualization of the prognosis and thus be able to carry out early interventions to improve the prognosis.

**Figure 1:** ROC Curve for stages 2, 3, 4, and 5 of CKD.

---

**Background and Aims:** Chronic kidney disease (CKD) is widely linked to chronic inflammation, with a higher incidence in the advanced stages of the disease. Recognition of systemic inflammation may be useful for prompt diagnosis and management of various CKD related disorders and may open the door towards the development and application of anti-inflammatory strategy treatments. This case-control and cross-sectional study investigates the association of neutrophil to lymphocyte ratio (NLR), platelet-to-lymphocyte ratio (PLR), total iron binding capacity (TIBC) and serum albumin with high serum interleukin-6 (IL-6) in children with chronic kidney disease (CKD).

**Method:** NLR and PLR were measured in 53 patients (median age: 12.9 years) and 25 healthy controls, stratified by age and sex. Lipid and iron profile, glucose tolerance parameters, serum albumin, uric acid and IL-6 were measured in the patient group.

**Results:** Compared to controls, NLR and PLR were higher in patients (p = 0.004 and p = 0.032 respectively), and particularly in those with CKD on dialysis (CKD 5D) (17 patients) (p < 0.001 and p = 0.001). LnIL-6 was correlated to NLR (rs = 0.344, p = 0.014), albumin (rs = -0.350, p = 0.011) and TIBC (rs = -0.345, p = 0.012) after adjustment for CKD stage, while the correlation between lnIL-6 and PLR was not significant (rs = 0.206, p = 0.151). Patients with NLR ≥1.7, TIBC ≤300 μg/dl and albumin ≤3.8 g/dl presented a higher risk for increased IL-6 (15 patients) regardless CKD stage (OR 5.499, 95% CI 1.272-22.017, p = 0.016, OR 9.818, 95% CI 2.311-41.766, p = 0.002 and OR 7.543, 95% CI 1.891-30.083, p = 0.004). NLR ≥1.7 and TIBC ≤ 300 μg/dl and serum albumin ≤ 3.8 g/dl with the highest sensitivity (73.3%), while NLR ≥ 1.7, TIBC ≤ 300 μg/dl and serum albumin ≥ 3.8 g/dl with the highest specificity (97.4%).
Conclusion: Both NLR and PLR increase in pediatric CKD, especially in CKD 3D. NLR rather than PLR may serve as a diagnostic marker of systemic inflammation in pediatric CKD, along with TIBC and serum albumin.

CORTICAL IRON DEPOSITION ASSESSED BY MAGNETIC RESONANCE IMAGE IS ASSOCIATED WITH KIDNEY FIBROSIS

Carlos Couceiro1, Sergi Codina1, Diego Sandova1, Laia Oliveras1, Isabel Puig1, Eugenia De Lama1, Anna Sola2, Anna Manonelles1, Edoardo Melilli1, Nuria Montero3, Ana Coloma1, Alexandre Fava1, Mate Maus3, Manuel Serrano1 and Josep Cruzado2

1Bellvitge University Hospital, L’Hospitalet de Llobregat, Spain, 2IDIBELL Institut d’Investigació Biomèdica de Bellvitge, L’Hospitalet de Llobregat, Spain and 3IRB Barcelona - Institute for Research in Biomedicine, Barcelona, Spain

Background and Aims: Fibrosis is responsible for the loss of kidney function as a result of several insults, such as ischemia-reperfusion injury or hyperfiltration. This process can continue even after cessation of the primary insult, as documented in acute kidney injury to chronic kidney disease. Recently, we discovered that iron accumulation is a hallmark of fibrotic diseases [1]. We found that in mouse models, iron deposition in the kidney accompanies the progression of the disease. Based on these results, we propose that chronic-low grade hemolysis produced in situation like ischemia-reperfusion injury may be one of the drivers of fibrosis through the damage in the filtrated hemolytic iron cause to the kidneys. Early detection of this iron could help the detection of ongoing fibrogenesis and improve the outcomes by prompt intervention. The challenge of this approach is the lack of non-invasive markers of fibrosis. We evaluated if magnetic resonance image (MRI)-based detection of iron levels in the kidney are correlated to fibrosis in biopsies from kidney transplant recipients.

Method: After approval from the Institutional Revision Board, we carried out a transversal study in our center between 2020 and 2021. We evaluated iron deposits through MRI in patients who underwent a kidney biopsy (per protocol or by clinical indication) and its association with histological parameters. MRI was performed at the same period the biopsy was done. Iron deposits were assessed by using the R2* sequence considering the Grasedonio protocol [2].

Results: We collected data from 15 kidney transplant recipients. Mean age was 58.3 years old. Mean time from kidney transplant to the biopsy was 4.3 years and mean eGFR was 44.4 ml/min/1.73 m². We analyzed by MRI the R2* signal in the kidney cortex, and their level of fibrosis measured on the biopsies (IFTA score, interstitial fibrosis and tubular atrophy). We found that patients with high IFTA score (2 and 3) presented with significantly higher R2* signal (p = 0.005), than patients with low IFTA score (0 and 1). We also found positive and significant correlation between IFTA (0-3) and iron deposits (Spearman correlation index: r = 0.7537, p = 0.0012).

Conclusion: Iron deposits in the kidney are higher in patients with more fibrosis, and its detection through MRI could be considered a non-invasive marker.
THE ERROR OF ESTIMATED GFR IN PREDIALYSIS CARE: IMPACT ON CLINICAL DECISION MAKING
Beatriz Escamilla Cabrera¹, Sergio Luis Lima⁴, Eduardo Gallego Valcarce², Federico González Rinne⁴, Nuria Victoria Sánchez Dorta⁴, Natalia Negrá-n Mena³, Coriolano Cruz Perera⁶, Laura Diaz Martin⁶, Armando Torres Ramírez⁶ and Esteban Porrini⁴

¹Hospital Universitario de Canarias, Nephrology Department, San Cristóbal de La Laguna, Spain, ²Hospital Universitario de Canarias, Laboratory Department, San Cristóbal de La Laguna, Spain, ³Hospital Universitario Fundación Alcorcón, Nephrology Department, Madrid, Spain, ⁴Hospital Universitario de Canarias, Laboratory of Renal Function, San Cristóbal de La Laguna, Spain, ⁵Hospital Universitario de Canarias, Nephrology Department, Spain and ⁶Hospital Universitario de Canarias, Laboratory of Renal Function, Spain

Background and Aims: The error of estimated glomerular filtration rate (eGFR) and its consequences in predialysis are unknown.

Method: We analysed 315 predialysis patients who underwent measured GFR (mGFR) by the clearance of iohexol and eGFR by 52 formulas. We evaluated the agreement between eGFR and mGFR by the concordance correlation coefficient (CCC), total deviation index (TDI) and coverage probability (CP). In a sub-analysis we investigated the impact of the error of eGFR in decisions like (i) starting dialysis, (ii) preparation for renal replacement therapy (RRT) and (iii) continuing with clinical follow-up. For this sub-analysis patients who started dialysis due to uremia or fluid overload were excluded (n = 18).

Results: Patients: 315 patients were included, 70% male and mean age was 66 ± 13 years. 38% had diabetic nephropathy. Mean mGFR was 22 ± 8 ml/min. Mean eGFR was 22 ± 8 ml/min (CKD-EPI), 22 ± 8 ml/min (MDRD) or 26 ± 10 ml/min (24-h creatinine clearance). Cystatin C measurement was available in 266 patients (84%) and averaged 2.8 ± 1.08 mg/L. Over 70% of the patients had proteinuria 1588 ± 2204 mg/24 h. Agreement between eGFR and mGFR had very low precision and accuracy in reflecting mGFR as reflected by average CCC, TDI and cp of 0.60, 70% and 22%, respectively. The error was comparable between creatinine- and cystatin-based formulas. Extreme variations -larger than 10 ml/min- between mGFR and eGFR were frequent. Differences in clinical decision making: Concerning clinical decisions, the error of formulas (mainly GFR overestimation) would have suggested (a) early unnecessary preparation for RRT in 14% of clinically stable patients evaluated by mGFR; (b) to continue with clinical follow-up in 59% of the subjects in whom RRT was indicated by low mGFR and (c) to delay the starting of dialysis in all patients (n = 6) in whom RRT was indicated based on very low mGFR without uremic symptoms or fluid overload.

Conclusion: The error of formulas in predialysis care was frequent and large and may have consequences in clinical care.
Background and Aims: Low sodium intake is associated with a lower blood pressure and less proteinuria, which are important therapeutic targets in chronic kidney disease. In contrast, a low potassium intake has been associated with higher blood pressure and a higher incidence of chronic kidney disease and cardiovascular events. Counselling of patients regarding their sodium and potassium intake requires accurate estimation of their intake, but 24-hour urinary sodium and potassium excretion can deviate substantially from actual intake. Urinary sodium-to-potassium (Na/K) ratio is a promising alternative as it is less affected by incomplete urine collections and additionally captures both the effect of sodium and potassium. Our study aimed to assess whether the Na/K ratio in 24-hour urine reflects dietary intake more accurately than separate measurement of sodium or potassium in 24-hour urine.

Method: We performed a post-hoc analysis on data from the long-term sodium balance studies Mars105 and Mars520. Ten healthy participants consumed a diet with a known sodium and potassium content and collected 24-hour urine samples for 105 or 205 days. We calculated the log fold difference between dietary intake and urinary excretion of sodium, potassium and Na/K ratio. A mixed-effects model with a random intercept per subject was used to compare these estimates of accuracy. Subsequently, we performed a subgroup analysis per salt intake level (i.e. 6, 9 or 12 grams per day) and assessed the effect of increasing the number of 24-hour urine collections.

Results: Overall, the urinary Na/K ratio underestimated dietary Na/K ratio with a median difference of -0.21 (IQR -0.47 to 0.09). Estimation of dietary Na/K ratio intake using the urinary Na/K ratio was significantly less accurate compared to using urinary sodium or potassium measurement for estimation of sodium or potassium intake (Figure 1A). Only during a salt intake of 6 grams per day, the urinary Na/K ratio did not perform significantly worse than sodium measurements. Although increasing the number of 24-hour urine measurements to three or seven improved the accuracy of the urinary Na/K ratio, it remained inferior to separate assessment of urinary sodium and potassium excretion (Figure 1B).

Conclusion: The 24-hour urinary Na/K ratio is less accurate than 24-hour urinary sodium or potassium excretion for estimation of dietary intake in a controlled setting in healthy volunteers.

CROSS-TALK BETWEEN FRAILTY AND IMMUNOSENSCENCE IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Noemi Ceprian1, Paula Jara Caro Espada2, Gemma Valera Arévalo1, Claudia Yuste Lozano2, Ignacio González de Pablo2, Andrea Figuer Rubio4, Matilde Alique4, Manuel Ramírez Chamond4, Enrique Morales2 and Julia Carracedo1

1Departamento de Genética, Fisiología y Microbiología, Universidad Complutense de Madrid, Instituto de Investigación Sanitaria Hospital 12 de Octubre (imas12), Madrid, Spain, 2Departamento de Nefrología, Hospital Universitario 12 de Octubre, Instituto de Investigación Sanitaria 12 de Octubre, Madrid, Spain, 3Departamento de Nefrología, Hospital Universitario 12 de Octubre, Madrid, Spain and 4Departamento Biología de Sistemas (Unidad Fisiología), Facultad de Medicina, Instituto Ramón y Cajal de Investigación Sanitaria (IRYCIS), Alcalá de Henares, Spain

Background and Aims: Chronic kidney disease (CKD) has been proposed as a model of premature ageing. The immune system is an important factor in the ageing process and can modulate the rate of ageing. The uremic environment highly affects this system, deteriorating its functionality and increasing susceptibility to infections, cancer, and pathologies like cardiovascular disease. Also, CKD patients are highly predisposed to frailty, which increases the organism’s vulnerability to disease. This premature ageing, partially caused by the immune disorder and increased frailty, is responsible for these patients’ high morbidity and mortality. Understanding these processes and how they are affected by different treatments will help generate better nutritional, pharmacological and lifestyle strategies. For this, the aim of this study was to determine the immune and frailty status of patients with CKD and their therapies.

Method: We performed a cross-sectional study involving 18 healthy subjects (HS) and 156 patients from the Nephrology Department of the Hospital Universitario “12 de Octubre” (Madrid, Spain). The distribution of patients was as follows: 40 with end-stage renal disease (ESRD), 40 on haemodialysis (HD), 36 on peritoneal dialysis (PD) and 40 patients who had received initial kidney transplantation (KT). The frailty status of the patients was assessed by the Edmonton Frail Scale test. Lymphocyte populations (T lymphocytes, T-helper lymphocytes, T-cytotoxic lymphocytes, and B lymphocytes) and monocytes (classical, intermediate, non-classical, and the expression of the adhesion molecule ICAM-1 and co-stimulatory B7.2) were determined in peripheral blood samples.

Results: The patients were similar in age and sex. The number of frail individuals was higher in patients (ESRD p < 0.001, PD p < 0.001, KT p = 0.004) than in HS, particularly in HD (p < 0.001) (Figure 1). Regarding immune phenotype (Figure 2), HD patients showed a lower number of T-cells (p < 0.001), particularly T-helper cells (p < 0.001), than the other groups. Also, DP patients presented fewer T and T-cytotoxic cells than HS (p = 0.029, p = 0.05). Also, HD showed lower T-cytotoxic and helper/cytotoxic ratios than HS (p = 0.022; p = 0.011) and ESRD (p = 0.017; p = 0.008). The proportion of classical monocytes decreased, and the proportion of intermediate and non-classical monocytes increased in HD with respect to the other groups (p < 0.001). The expression of the costimulatory molecule B7.2 was increased in the patients with respect to HS in all monocyte subsets (Classical: ESRD p = 0.002, HD p < 0.001, PD p < 0.001, KT p < 0.001; Intermediate: ESRD p = 0.014, HD p < 0.001, PD p < 0.001, KT p = 0.002; Non-classical: ESRD p = 0.006, HD p < 0.001, PD p < 0.001, KT p = 0.013), while adhesion molecules were only elevated in HD with respect to HS in all subsets (classical p < 0.001, intermediate p < 0.001, non-classical p = 0.023).

Conclusion: The CKD patients, regardless of the treatment, showed, in general, an alteration in the lymphocyte subsets. These alterations were more significant in dialysis patients, particularly in HD patients. This group also presented the most significant alterations in monocyte subsets and higher frailty. This may explain why haemodialysis patients show major adverse outcomes compared to other treatments. Determining immune profiles can help us to relate these alterations to adverse events to carry out preventive and personalised medicine.
**Figure 2**: Description of leukocyte subpopulations. Count of T-helper cells (A), helper/cytotoxic (CD4/CD8) ratio (B), B cells (C), monocytes subsets distribution (D), and the amount of the co-stimulatory molecule B7.2 (E) and adhesion molecule ICAM-1 (F) in healthy subjects, patients with end-stage renal disease (ESRD), haemodialysis (HD), peritoneal dialysis (PD), and kidney transplantation (KT). Statistical significance was denoted by *p \leq 0.05, **p \leq 0.01, ***p \leq 0.001 vs HS; #p \leq 0.05, ##p \leq 0.01, ###p \leq 0.001 vs ESRD; $$p \leq 0.01,$$$p \leq 0.001 vs HD; &&p \leq 0.01 vs DP.

#6600
ASSOCIATION BETWEEN ADVANCED GLYCATION END-PRODUCTS AND SARCOPENIA IN PATIENTS WITH CHRONIC KIDNEY DISEASE
Paolo Molinari, Lara Caldironi and Simone Vettoretti
Milan, Italy

**Background and Aims**: In patients with chronic kidney disease (CKD), there is an overproduction and accumulation of advanced glycation end-products (AGEs). Since AGEs may have detrimental effects on muscular trophism and performance, we evaluated whether they may contribute to the onset of sarcopenia in CKD patients.

**Method**: We enrolled 117 patients. The AGEs were quantified by fluorescence intensity using a fluorescence spectrophotometer and soluble receptor for AGE (sRAGE) isoforms by ELISA. As for the sarcopenia definition, we used the European Working Group on Sarcopenia in Older People (EWGSOP2) criteria.

**Results**: The average age was 80 ± 11 years, 70% were males, and the mean eGFR was 25 ± 11 mL/min/1.73 m². Sarcopenia was diagnosed in 26 patients (with a prevalence of 22%). The sarcopenic patients had higher levels of circulating AGEs (3405 ± 951 vs. 2912 ± 722 A.U., p = 0.005). AGEs were higher in subjects with a lower midarm muscle circumference (MAMC) (3322 ± 919 vs. 2883 ± 700 A.U., respectively; p = 0.005) and were directly correlated with the gait test time (r = 0.180, p = 0.049). The total sRAGE and its different isoforms (esRAGE and cRAGE) did not differ in patients with or without sarcopenia.

**Conclusion**: In older CKD patients, AGEs, but not sRAGE, are associated with the presence of sarcopenia. Therefore, AGEs may contribute to the complex pathophysiology leading to the development of sarcopenia in CKD patients.

**Table 1**: Concentration of AGEs and sRAGE isoforms in sarcopenic and non-sarcopenic CKD patients.

**EVALUATION OF PROTEIN MALNUTRITION IN CKD PATIENTS ON LOW-PROTEIN DIET**

Arianna Bologna1,2, Matteo Brambilla Pisoni1,2, Monica Avino1,2, Federica Giambò1,2, Teresa Arcidiacono1,3, and Giuseppe Vezzoli1,2

1IRCCS San Raffaele Scientific Institute, Division of Nephrology and Dialysis, Milan, Italy and 2Università Vita Salute San Raffaele, Milan, Italy

**Background and Aims:** Low-protein diet is considered crucial in patients with chronic kidney disease to slow down kidney function deterioration and control metabolic variables such as serum phosphate, urea and bicarbonate. However, low-protein diet may result in malnutrition if patients do not respect nutritional prescription. Thus, the present study examined the risk of protein malnutrition in CKD patients who started a low-protein diet.

**Method:** We analysed anthropometric variables, nutrient intake and body composition in 27 patients with CKD stage 4-5 (M/F 15/12; 69±15 years; 72±18 kg; BMI 27.3±7 kg/m²; serum creatinine 4.9±1.9 mg/dl; GFR 11±4 ml/min; 10 diabetic patients) before and after 3-months of low-protein diet (0.6 g/kg). We estimated nutrient intake with a food frequency questionnaire composed of 37 items and administered by a nutritionist who also prescribed the low-protein diet. We also measured body fat mass (FM) and free-fat mass (FFM) and appendicular skeletal muscle mass using bioimpedimetry analysis (Akern, Florence). Patients having a protein intake lower than 0.6 g/kg at the nutritional survey was defined as malnourished.

**Results:** In the whole sample, after a 3-month diet protein intake decreased from 0.87±0.23 to 0.69±0.18 g/kg (p<0.001; Wilcoxon test). Protein intake was positively correlated with 24-h urine excretion of phosphate at baseline (r = 0.69, p = 0.012) and after 3-months of diet (r = 0.62, p = 0.02). The diet induced a decrease in body weight (72±18 to 70±17 kg; p = 0.001), BMI (27.3±7 to 26.7±6.8 kg/m²; p = 0.001), FM (24±11 to 21±11 kg; p = 0.006), serum phosphate (1.68±0.33 to 1.52±0.32 mmol/l; p = 0.033) and urea (166±53 to 133±42 mg/dl; p<0.001), whereas FFM, expressed as percentage of body weight, significantly increased (69±9 to 73±8%; p = 0.011). Six patients (22%; 3 diabetic patients) had a protein intake lower than 0.6 g/kg after 3-months of diet. Their protein intake was significantly lower than that in the other 21 patients with protein intake above 0.6 g/kg (0.43±0.1 vs 0.77±0.12 g/kg; p<0.001). These patients had lower FM (4±2 vs 4±1 kg; p = 0.03) and protein intake before starting the low-protein diet than the other 21 patients (0.64±0.06 vs 0.94±0.21 g/kg; p = 0.003). Patients with protein intake lower than 0.6 g/kg slightly decreased FFM after 3 months of diet compared to the value at baseline (52±7 to 50±7 kg; p = 0.07); conversely the other 21 patients did not change FFM (51±10 to 53±11 kg; p = 0.17), but significantly decreased FM (26±11 to 23±12 kg; p<0.001).

**Conclusion:** In conclusion, protein malnutrition may occur during a low-protein diet in CKD patients with a low consumption of proteins before starting this diet. Nutritional analysis is necessary to identify CKD patients at risk of

---
protein malnutrition and to adequately follow up CKD patients on low protein diet.

#3103
OMENTIN-1 AND SUBCLINICAL ATHEROSCLEROSIS IN ESKD PATIENTS UNDERGOING HEMODIALYSIS AND IN KIDNEY TRANSPLANT RECIPIENTS

Marie Teresa Zicarelli, Manco Greco, Valentina Arcidiacono, Pierangelo Presta, Alfredo Caglioni, Michele Andreucci, Francesco Dragone, Daniela Foti, Giuseppe Coppolino and Davide Bolignano

Magna Graecia University, Catanzaro-Italy, Italy

Background and Aims: In end-stage kidney disease (ESKD) patients, atherosclerosis is a key-player for cardiovascular risk, being influenced by endothelial dysfunction, inflammation and mineral dysmetabolism. Omentin-1 is an adipokine involved in various pathological conditions (diabetes, metabolic syndrome, obesity), and has recently been studied as a prognostic factor for atherosclerosis progression and mortality in the general population. In this study, we evaluated the possible relationships between Omentin-1 and incident carotid atherosclerosis in the clinical setting of ESKD.

Method: Circulating blood Omentin-1 levels were measured in a cohort of 77 asymptomatic ESKD patients (40 kidney transplant recipients, Ktx and 37 chronic hemodialysis patients, HD) and in 30 healthy controls. Carotid intima-media thickness (cIMT) was measured before a single HD session or before a Ktx outpatient visit.

Results: Omentin-1 levels were higher in the entire ESKD cohort than in healthy controls (324 [90.3-770] vs. 110 [35.4-240.9] pg/ml; p = 0.03). Ktx patients had lower levels than HD patients (p = 0.01) while higher Omentin-1 levels were found in HD patients (474.9 [197.2-1432.1] ng/ml) compared to both healthy subjects (p = 0.009) and Ktx (p = 0.01). Mean cIMT in all ESKD was 0.78 ± 0.32 mm. 36 patients (46.7%) with pathological cIMT values displayed lower Omentin-1 levels as compared with others (168.7 [51.1-457.8] vs 474.9 [197.2-1432.1] and p = 0.004). Multivariate correlations analyses indicated Omentin-1 as the stronger independent predictor of carotid atherosclerosis (β = -0.687; p = 0.03) in the whole cohort, even more than age, total cholesterol and diastolic BP.

Conclusion: In ESKD patients, Omentin-1 reflects the severity of carotid atherosclerosis independently from traditional confounders and may serve as an additive biomarker for risk prediction and risk stratification. Further studies are awaited to confirm these preliminary findings in larger cohorts.

NPY GENE POLYMORPHISMS ARE STRONGLY LINKED TO CKD PROGRESSION: A MENDELIAN RANDOMIZATION STUDY

Belinda Spoto1, Francesca Mallamaci2,3, Cristina Politi2, Rosa Parlongo4, Giovanni Luigi Tripepi1, Daniela Leonardi4, Giovambattista Capasso5 and Carmine Zoccali6,7

1CNR-Institute of Clinical Physiology, Italy, 2Nephrology, Dialysis, and Transplantation Unit (GOM-BMM), Italy, 3CNR-Institute of Clinical Physiology, Reggio Calabria, Italy, 4CNR-Institute of Clinical Physiology, Italy, 5BIOGEM, Italy, 6Renal Research Institute, United States of America and 7IPNET, Italy

Background and Aims: Neuropeptide Y (NPY) is a 36 amino-acid neuropeptide that regulates various physiological processes in both the central and peripheral nervous systems, including cardiovascular and metabolic control. We showed that high plasma NPY predicts CKD progression (NDT 2018;33:1805-1812) in a cohort of 735 patients with stage G2-5 CKD. Whether this association is causal is nature is undetermined.

Method: In the same cohort of the case study, we tested the relationship between NPY gene variability, as assessed by six single nucleotide polymorphisms (SNPs) representative of the gene haplomblock structure which explained about 80% of gene variability, and the incidence rate of renal events (diabetes/transplantation/eGFR reduction >30%) over a median follow up of 36 months (inter-quartile range 33-37 months).

Results: Three variants (rs161316 [TT, n = 563; CT+CC, n = 172], rs16140 (CC+GG, n = 413; CC, n = 322), rs16148 (CT+CC, n = 456; TT, n = 279) coherently associated to the incidence rate of renal events (HR ranging from 1.36 to 1.57, P < 0.029). A dose response relationship was found between the number of risk variants and renal events, the HR for this outcome being highest in patients with three risk genotypes (HR: 1.66, 95% CI 1.05-2.61). In a multivariate model adjusting for traditional risk factors (age, gender, smoking, diabetes, cholesterol, systolic BP and background cardiovascular comorbidities) and factors peculiar to CKD (haemoglobin, eGFR, albumin, phosphate, C-reactive protein), the association remained highly significant (P for trend = 0.001). In a separate analysis including the three variants simultaneously, only the rs161316 variant maintained an independent association with the risk for renal events (HR: 1.58, 95% CI 1.11-2.24, P = 0.01).

Conclusion: This Mendelian randomization study based on three gene variants is fully in line with findings indicating that high plasma NPY predicts a high risk for renal events and lends support to the hypothesis that NPY is causally involved in CKD progression. Establishing the functional significance of the rs161316 variant is a clinical research priority. Drugs antagonizing circulating NPY or its receptors, indeed, might favourably impact on CKD progression.

#6157
PREDICTORS OF 24 PULSE WAVE VELOCITY IN HYPERTENSIVE CHRONIC KIDNEY DISEASE PATIENTS: A CASE CONTROL STUDY

Josipa Radic1, Marijana Vučković1, Hana Dogaš1, Andrea Gelemanović1, Ela Kolak1, Dora Bučan Nenadice2 and Mislav Radic3

1University Hospital of Split, Internal Medicine Department, Nephrology and Hemodialysis Division, Split, Croatia, 2University Hospital of Split, Internal Medicine Department, Nephrology and Hemodialysis Division, Split, Croatia, 3Mediterranean Institute for Life Sciences, Croatia, 4University Hospital of Split, Nutrition and Dietetics Department, Croatia and 5University Hospital of Split, Internal Medicine Department, Rheumatology, Allergy and Clinical Immunology Division, Croatia

Background and Aims: Pulse wave velocity (PWV) is a significant predictor of chronic kidney disease (CKD) progression and death in people with impaired kidney function. It is known that patients with type 2 diabetes mellitus have higher values of PWV. Our study assessed the difference in arterial stiffness parameters (value of peripheral and central blood pressure parameters and PWV) according diabetic status and to evaluate predictors of PWV in hypertensive CKD patients.

Method: This case control, cross-sectional study included 252 hypertensive CKD patients 143 (56.7%) men and 109 (43.3%) women, aged 67 years (IQR = 15). For each participant data about sex, age, height, presence of CKD, AH and other comorbidities were collected. Laboratory parameters (urea, creatinine, estimated glomerular filtration rate (eGFR), glycated hemoglobin (HbA1c)) were obtained from peripheral blood and 24-hour urine samples were collected to analyze albuminuria. Each participant underwent 24-hour ambulatory blood pressure measurement using the IEM Mobil-O-Graph based on the oscillometry. Tanita MC780 Multi Frequency segmental body composition analyzer was used to measure body weight and level of visceral fat. Body mass index (BMI) was calculated.

Results: Out of 252 participants with AH and CKD, 107 (42.5%) also had DM. Participants with DM were older (p < 0.001), had higher pulse pressure (p < 0.001) and PWV (p < 0.001) while the levels of peripheral and central diastolic pressure (p < 0.001) were lower. Regarding body composition parameters, DM participants had higher BMI (p = 0.001) and visceral fat level (p < 0.001). Positive predictors of PWV adjusted for age, sex, presence of DM and eGFR were HbA1c (β = 0.216, p = 0.007), albuminuria (β = 0.000, p = 0.002), central and peripheral systolic and diastolic blood pressure (β = 0.035, p < 0.001; β = 0.035, p < 0.001; β = 0.033, p < 0.001; β = 0.035, p < 0.001), pulse pressure (β = 0.047, p < 0.001) and mean arterial pressure (β = 0.042, p < 0.001). Body composition parameters were not found to be significant predictors of PWV.

Conclusion: We found significant differences in 24-hour blood pressure parameters and body composition in relation to the presence of DM. One possible explanation for the lower peripheral and central diastolic blood pressure in diabetic patients is the older age of these participants. Accordingly, PWV as a parameter of arterial stiffness, which is higher in DM participants, could also be due to age difference. As for the predictors of PWV, the expected predictors were blood pressure level. HbA1c and albuminuria were also associated with PWV as parameter of arterial stiffness in CKD patients with AH.

#3383
ASSOCIATION BETWEEN MELAMINE AND PHTHALATES AND URINARY RENAL INJURY MARKERS AMONG CHILDREN AGED 4 YEARS

Hui-Ju Tsai1, Ming-Tsang Wu2 and Yi-Chun Tsai3

1Kaohsiung Municipal Ta-Tung Hospital, Family Medicine, Kaohsiung, Taiwan, Rep. of China, 2Kaohsiung Medical University, Research Center for
Background and Aims: Chronic kidney disease (CKD) is a global public health issue and the prevalence and incidence of CKD and end-stage renal disease (ESRD) in Taiwan are among the highest in the world. The pathophysiology of renal function downhill is complex and multifactorial, and previous studies suggest that we should be concerned about the effects of low-dose environmental exposure to melamine and phthalate in increasing the risk of renal injury in susceptible populations such as children. However, the sex difference in renal injury related to environmental exposure among children is unknown. The aim of this study is to investigate the relationship between early renal injury biomarkers and melamine and phthalate exposure among boys and girls aged 4 years in Taiwan.

Method: In total, 1,676 pregnant women were enrolled in the original Taiwan Maternal and Infant Cohort Study (TMICS), a multicenter birth cohort study of 9 hospitals in northern, central, southern, and eastern Taiwan from October 2012 to May 2015. Of those, 694 children aged 4 years participated in follow-up questionnaire interviews, received physical examinations and blood and urine tests from August 2016 to February 2020. After excluding 142 participants with missing data, the final statistical analysis of follow-up data included 552 children. One-spot overnight urine specimens were used to simultaneously measure melamine, 11 phthalate metabolites, and two markers of renal injury, microalbumin and N-acetyl-beta-D-glucosaminidase (NAG). Average daily intake (ADI) levels of melamine and six parental phthalates, including DEHP (di-2-ethylhexylphthalate), DiBP (Dibutyl phthalate), DnBP (Di-n-butyl phthalate), BBzP (Butyl benzyl phthalate), and DEP (Diethyl phthalate), were estimated using a creatinine excretion-based model from urine melamine and phthalate metabolites. We used a weighted quartile sum (WQS) regression model to select the most important exposure variables of ADI levels of phthalates and melamine associated with urine microalbumin to creatinine ratio (ACR) and NAG; Furthermore, to examine effects of those most important exposure variables on ACR and NAG in multivariable linear regression models. The significance was set as two-sided p < 0.05.

Results: Of them, 319 (57.8%) and 223 (42.2%) were boys and girls, respectively, with a median age of 4.0±0.8 years old. Median ADI levels (μg/kg bw/day) were 5.73 for DEHP, 1.75 for DEP, 3.23 for DnBP, 0.07 for BBzP, 1.37 for DiBP, and 1.18 for melamine and there is not significantly different between boys and girls. Using the WQS regression model to examine the association between ADI levels of melamine and phthalates and urine ACR and NAG, we found that a significant and positive association between the WQS score and ACR (β1 = 0.083, p = 0.023). ADI levels of melamine had the highest weight (0.650). Furthermore, we found that the highest (quartile 4) of ADI levels of melamine had the significantly higher ACR in all children (adjusted β = 0.131, p = 0.036), compared to other quartiles (quartile 1, 2 and 3). In subgroup analysis, the significant association between melamine intake and urine ACR was found in boys (adjusted β = 0.249, p = 0.003), not in girls.

Conclusion: Environmental exposure to melamine may be associated with urine ACR among children aged 4 years in Taiwan, and boys may be easily affected by melamine exposure.
regulate post-transcriptional gene expression) has previously been implied in pathological cardiac remodelling. Nevertheless, scarce evidence has accrued so far on a possible significance in CV morbidity and mortality in HD patients, in relationship with the presence of uremic cardiomyopathy.

**Method:** We run a pilot, prospective, multicentre cohort study involving 74 ESKD patients undergoing chronic HD from 3 different hospitals in Italy and Greece. HD patients underwent a thorough clinical, laboratory and echocardiography assessment and were then prospectively followed for 24 months or until the occurrence of a composite endpoint of (CV and all-cause) mortality or non-fatal CV events. Through a systematic review of the literature, we identified a small panel of miRNAs (30a-5p, 23a-3p, 451a and let7d-5p), which levels are known to be altered in either major CV disorders and kidney failure. miRNAs were then measured in the blood of HD patients and in a small group of matched healthy controls.

**Results:** miRNAs 23a-3p (p < 0.0001), 451a (p = 0.001), 30a-5p (p = 0.003) and let7d-5p (p < 0.0001) were all reduced in HD patients as compared with controls. Significant correlations were found between miRNAs and indexes of cardiac dysfunction such as Vmax, TAPSE and E/E', as well as with some other laboratory parameters such as uric acid, sodium, potassium, HDL and CRP. During follow-up, 30/74 patients (40.5%) reached the composite endpoint. In these individuals, all miRNAs but let7d-5p were significantly reduced at baseline (p < 0.0001). As showed by multivariate Cox-regression analyses, miRNAs 23a-3p, 451a, 30a-5p were all predictors of the composite endpoint and Kaplan-Meier analyses confirmed a faster progression to the endpoint in subjects with miRNAs levels below an optimal ROC-derived cut-off value (p ranging from 0.001 to < 0.0001; crude HRs 7.95 to 8.61; Figure 1).

**Conclusion:** Our study demonstrated that the evaluation of a very small panel of circulating miRNAs (30-5p, 23a-3p and 451a) may impart important prognostic information in chronic HD patients with respect to mortality and CV risk. Although the biological meaning of their deregulation remains unanswered, these preliminary findings may set the stage for larger investigation to generalize their usefulness as biomarkers, as well as possible therapeutic targets.

---

**SECOND, THIRD, AND MORE HITS: IMPACT OF SUCCESSIVE AKI EPISODES ON CKD PROGRESSION AND AKI TO CKD TRANSITION**

Isabel Acosta-Ochoa, Armando Coca, Paula Ardura, María Martínez Manrique, Carlos Merizalde, Kenia Cobo and Alicia Mendiluce

University Clinical Hospital of Valladolid, Nephrology, Valladolid, Spain

**Background and Aims:** The second hit theory refers to the link between two or more deleterious events that cause AKI simultaneously (e.g., triple whammy) or successively (e.g., cardiac surgery after coronary angiography). We investigated the effect of 3 or more consecutive AKI episodes on baseline serum creatinine (SCr) and if these changes led to AKI to CKD transition (Transition), CKD progression (Progression) or stable SCr.

**Method:** Retrospective study of patients with AKI attended by nephrology during a 3-year period. AKI severity was categorized by KDIGO criteria. We searched for patient’s successive admissions and if suffered a new AKI episode and included all patients with ≥3 AKI episodes during the study period. We analyzed the baseline SCr for every episode and investigated if serial AKI episodes leaded to incident CKD, Progression, or no changes in SCr.

**Results:** 144 individuals that suffered 525 AKI episodes were included. We observed 36 patients in the Transition, 70 in the Progression group, and 38 didn’t vary their SCr. We found no statistically significant differences in hypertension, DM, Charlson’s Index, admission to ICU, severity of AKI or length of stay between groups. See Table 1A. We found that progressors had shorter time to nephrology consultation, they were more prone to receive acute HD and to be dialysis dependent at discharge. With no differences in the mortality rate between groups. See Table 1B. Figure 1 plots baseline SCr of every episode that shows a trend to incremental cyphers.

**Conclusion:** In our study the clinical characteristics between Transition and Progression groups were similar. We observed more individuals in the Progression group and their time to nephrology consultation was significantly shorter, maybe because no nephrology specialists are afraid of managing CKD patients. Patients that progressed needed acute HD more frequently and were more dialysis dependent at discharge, this finding could be explained by their diminished renal reserve, with no differences in the rate of in-hospital mortality. Successive AKI episodes portend a higher risk of adverse clinical outcomes, with excessive burden for patients with previous CKD. New AKI therapies could change the course of these ominous outcomes? This issue is under intense investigation, but it is very difficult to translate bench to bedside. Therefore, now we can only count on prevention and timely nephrological attention.
Figure 1: Plot of Baseline Serum Creatinine in Successive AKI Episodes, Showing a Slight Trend to Increments.

Background and Aims: Kidneys have an intrinsic reserve capacity to respond to a higher workload by increasing filtration in their nephrons, called renal functional reserve (RFR). Despite the high clinical relevance of RFR, the necessary dynamic measurements are rarely done in the clinical routine, due to time- and workload as well as lack of standardized protocols.

Method: We developed a novel RFR protocol using 99mTc-DTPA (DTPA-Cl) before and after an oral protein load performed in an outpatient clinical setting within one day. Following a weak of low protein diet and using standardized hydration baseline and post-stimulation GFR were measured. 50 MBq activity were given i.v. at 0 and 240 mins, the plasma clearance was calculated based on the activity course at 13 time-points over 480 mins. RFR was expressed as the difference of post-protein stimulation peak mGFR to baseline mGFR in fasting state.

Results: In the pilot study we measured RFR in 7 healthy participants. The results showed a high heterogeneity. Therefore, we modified the study protocol for the next 16 patients by (a) extending the time of measurements to 330 min post-stimulation and (b) increasing the frequency of activity measurements to every 30 mins. In addition, we used a protein load of 1.5 g/kg bw of beef protein. These standardized measurements showed inter-individual time differences in reaching the peak GFR values post-protein load, the peaks detectable between 150 to 270 mins after the protein meal. The mean RFR (+SD) was 14 (+13) ml/min/1.73 m² corresponding to 16 (+15)% [Fig. 1]. All participants demonstrated a significant fall in DTPA-Cl 60 mins post-stimulation.

Conclusion: RFR can be measured with a same day pre- and post-stimulation DTPA-clearance protocol. Using a high oral load of beef protein and a long, post-stimulation period of measurements demonstrates inter-individual differences in reaching the hyperfiltration peak and a significant, previously not appreciated, post-prandial drop in GFR.
Results: hyperoxaluria following small bowel resections. Other medications include: on Azathioprine for his Crohn’s and his initial decline in renal function (subsequent reversal), inguinal herniorrhaphy, hypertension and BPH. He was right hemicolectomy 26 years ago with revision 4 years ago, ileostomy (with obstruction). His AKI was initially thought to be pre-renal and there was some improvement in renal function with fluids during his first admission although renal function didn’t return to baseline. His renal function progressively worsened in a spate of a few months. He had a baseline creatinine of 130 prior to his laparotomy which worsened to 184 post surgery but the improved to 9 months postop. He eventually had a renal biopsy that showed chronic damage and glomerular sclerosis. Ultrasound ruled out any obstruction. Despite pausing Azathioprine, renal function continued to deteriorate with creatinine peaking at 561 over the next 2 months. He subsequently had a renal biopsy that showed chronic damage with oxalate casts. He was subsequently commenced on haemodialysis.

Conclusion: These two cases highlight the need to consider enteric hyperoxaluria in patients presenting with unexplained decline in renal function who have had bowel surgery or have risk factors for fat malabsorption. This is important due to the usual poor prognosis in this group of patients [1].

OXALATE NEPHROPATHY SECONDARY TO ENTERIC HYPEROXALURIA: A RARE CAUSE OF END STAGE RENAL FAILURE – A REPORT OF 2 CASES
Babaniji Omosule, Thelma Mushambi and Asif Mahmud

Worcester Acute Hospital Trust, Renal, Worcester, United Kingdom

Background and Aims: Oxalate nephropathy is a rare cause of renal failure which is usually due to primary or secondary hyperoxaluria. Secondary hyperoxaluria results from increased intake or increased intestinal oxalate availability (enteric hyperoxaluria), increased intestinal oxalate degradation, or increased colonic permeability to oxalate [1]. Little is known about the burden of end stage kidney disease in this group of patients as most of the initial literature was from case reports and case series. More recently, prevalence of 1-4.01% was reported from biopsy studies suggesting that this entity is indeed a cause of kidney failure that needs to be considered [2,3].

Method: We present two cases of oxalate nephropathy secondary to enteric hyperoxaluria following small bowel resections.

Results: CASE ONE 82 year old man with a solitary kidney who was admitted in the ED on account of a decline in renal function on a background of episodes of loose stools. This was his second admission in two months on account of decline in renal function. He had emergency laparotomy and adhesiolysis as a result small bowel obstruction from volvulus 12 months earlier. Other past medical history include left nephroureterectomy for renal cancer, transurethral resection of bladder tumour, hypertension, Barretts and appendectomy. His medications were Omeprazole (which was switched to Famotidine due to hypomagnesaemia 7 months postop), Atenolol and Adcal D3. Renal immunology and myeloma screen were negative. Urine was bland and ultrasound did not show any obstruction. His AKI was initially thought to be pre-renal and there was some improvement in renal function with fluids during his first admission although renal function didn’t return to baseline. His renal function progressively worsened in a spate of a few months. He had a baseline creatinine of 130 prior to his laparotomy which worsened to 184 post surgery but the improved to about 109 few days post op. However, his renal function was noticed to decline 9 months post op and eventually his creatinine peaked at 751, fourteen months post op. He eventually had a renal biopsy 13 months post op that showed oxalosis, acute tubular injury and patchy interstitial fibrosis. His renal function continued to deteriorate and he was eventually commenced on haemodialysis.

CASE TWO
A 75 year-old man who was referred to the renal clinic on account of a decline in renal function. He had a past medical history of Crohn’s disease, previous right hemicolectomy 26 years ago with revision 4 years ago, ileostomy(with subsequent reversal), inguinal herniorrhaphy, hypertension and BPH. He was on Azathioprine for his Crohn’s and his initial decline in renal function was thought to be attributable to Azathioprine. Other medications include:

Amlodipine 5 mg, Finasteride 5 mg, Loperamide 2 mg bd, Tamsulosin 400mcg od. At referral, his renal function had progressively deteriorated over the previous few months from a baseline creatinine of 145 to 303, 44 months after his last surgery. Urinalysis showed trace of protein and + of blood however, urine ACR was normal. Vasculitis and myeloma screen were also normal. Ultrasound ruled out any obstruction. Despite pausing Azathioprine, renal function continued to deteriorate with creatinine peaking at 561 over the next 2 months. He subsequently had a renal biopsy that showed chronic damage with oxalate casts. He was subsequently commenced on haemodialysis.
filtration rate from baseline measurement or initiation of kidney replacement therapy.

**Results:** During 10,550 person-years of follow-up (median, 5.2 years), the composite outcome occurred in 800 (38.5%) participants. In the multivariable cause-specific hazard model, higher SBP was associated with an increased risk of CKD progression. There was a significant interaction between SBP and u-AGT/Cr ratio on the risk of the primary outcome (P-for-interaction = 0.019). In patients with u-AGT/Cr < 3.65 μg/gCr, the hazard ratios (HRs) (95% confidence intervals [CIs]) for SBP 120–129, 130–139, and ≥ 140 mmHg were 1.47 (1.08-2.01), 1.74 (1.26-2.39), and 2.43 (1.76-3.37), respectively, compared with SBP < 120 mmHg. In addition, each 10 mmHg increase in SBP was associated with an 18% higher risk of CKD progression. Moreover, there was a greater decline in the estimated glomerular filtration rate among the higher SBP categories. However, these associations were not observed in patients with u-AGT/Cr ≥ 3.65 μg/gCr.

**Conclusion:** Urinary angiotensinogen levels may modify the association between SBP and adverse kidney outcomes.

**PRESEPSIN AS A POTENTIAL BIOMARKER FOR RENAL INVOLVEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

Oleg Iaremenko¹, Daria Koliaidenko¹, Natalia Stepanova² and Kateryna Iaremenko³

¹Bogomolets National Medical University, Internal Medicine #3, Kyiv, Ukraine. ²State Institution “Institute of Nephrology of the National Academy of Medical Science of Ukraine”, Nephrology & Dialysis, Kyiv, Ukraine and ³Alexander Clinical Hospital, Kyiv, Ukraine

**Background and Aims:** Presepsin is a soluble CD14 subtype known as a sepsis biomarker. Recently, it has been reported to correlate with kidney function decline in elderly patients with chronic kidney disease and to predict acute kidney injury in patients with sepsis. However, the potential role of presepsin in systemic lupus erythematosus (SLE) with kidney involvement is still unclear. This study aimed to evaluate the relationship between serum presepsin level and SLE disease activity and laboratory parameters and to validate presepsin as a biomarker for lupus nephritis (LN).

**Method:** This cross-sectional study included 78 SLE patients aged 38.9±12.8 years. Among them, there were 68 (87.2%) women, 36 (46.2%) patients with LN, and 42 (53.8%) patients without LN. LN was diagnosed by renal biopsy and/or according to the renal SLE disease activity index (SLEDAI) criteria. Patients with infections were not included in the study. Serum presepsin level was determined by ELISA. The diagnostic value of presepsin level for the detection of LN was assessed by receiver-operating characteristic curves (ROC), the area under the curve (AUC), and 95% confidence intervals (CI). Spearman and Pearson correlation tests were performed to evaluate the relationships between presepsin level and SLEDAI score, serum complement concentrations, anti-double-stranded DNA antibodies (anti-dsDNA), inflammatory markers, urinary protein, and estimated glomerular filtration rate (eGFR) with CKD-EPI.

**Results:** The median serum presepsin level was significantly higher in patients with LN than in those without kidney damage [145 (110-197) pg/ml vs 102 (82-146) pg/ml, p = 0.011]. The ROC analysis found that the most appropriate cut-off point for presepsin concentration as a biomarker for LN in LSE patients was 106 pg/ml with a sensitivity of 81.8% (95% CI 64.5-93.0), and specificity of 54.3% (95% CI 36.6-71.2). The AUC was 0.714 (95% CI 0.592-0.837) with a positive predictive value of 62.8% (95% CI 46.7-77.0), and a negative predictive value of 76.0% (95% CI 54.9-90.6) (Fig. 1). The mean value of eGFR was 83.8±27.0 ml/min/1.73 m² in the LN group and 94.1±18.0 ml/min/1.73 m² in the non-LN group (p = 0.112). A significant negative correlation was observed between presepsin levels and eGFR in LN patients (Fig. 2). Moreover, presepsin levels in the LN group significantly correlated with SLEDAI score (r = 0.372, p = 0.036), anti-dsDNA titer (r = 0.363, p = 0.04) and severity of proteinuria (r = 0.630, p<0.01). No such associations were found in SLE patients without kidney involvement. Presepsin concentration did not correlate with C3, C4, C-reactive protein, erythrocyte sedimentation rate, and procalcitonin levels in both groups.

**Conclusion:** Serum presepsin may be considered a potential biomarker for the detection of kidney damage in patients with SLE. Further studies focusing on the clinical and pathological associations of presepsin in LN would be of interest.

**Figure 1:** ROC-curve for the cut-off value of serum presepsin concentration to predict renal involvement in patients with SLE.

**TYG INDEX CORRELATED WITH PROGRESSION OF CHRONIC KIDNEY DISEASE IN METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE**

Hoon Young Choi, Jung Eun Lee, Jong Hyun Jhee and Hyeong Cheon Park

Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Rep. of South Korea

**Background and Aims:** Chronic kidney disease (CKD) is an established major risk factor for cardiovascular disease. Moreover, progression of CKD results in end-stage kidney disease, and an increased risk of death. The recently proposed metabolic dysfunction-associated fatty liver disease (MAFLD) has been suggested to better reflect risk of developing CKD. This study aimed to evaluate the association between the triglyceride-glucose (TyG) index and CKD progression in patients with MAFLD.

**Method:** In the data from the medical records database in Gangnam Severance Hospital from 2006 through 2020, a longitudinal analysis included participants with CKD. MAFLD was diagnosed in patients with was diagnosed in individuals with hepatic steatosis and at least one of the conditions as follows: 1) overweight or obese (defined as body mass index [BMI] ≥ 23 kg/m²), 2) type 2 diabetes mellitus, or 3) two or more metabolic abnormalities. Progression of CKD was defined by a reduction in the GFR ≥30% of baseline. Logistic regression analysis was used to obtain the association between TyG index and progression of CKD by adjusting for the influence of confounders.

**Results:** The study included 4,286 patients, of whom 582 had MAFLD. Mean age was 51.49 ± 11.451 years. After adjusting for age, sex, systolic blood pressure, fasting plasma glucose, CRP, LDL-cholesterol and smoking status, TyG index was associated with progression of CKD (OR 1.760 [1.089-2.844], P = 0.021).

**Conclusion:** This study demonstrated that TyG index was significantly associated with progression of CKD in patients with MAFLD.

**MUSCLE OXYGENATION AND MICROVASCULAR REACTIVITY ACROSS DIFFERENT STAGES OF CHRONIC KIDNEY DISEASE: A NEAR-INFRARED SPECTROSCOPY STUDY**

Marieta Theodorakopoulou1, Andreas Zafeiridis2, Konstantina Dima2, Danai Faitatzidou1, Ággelo Koutras2, Michael Doumas3, Aikaterini Papagianni4 and Panetelis Sarafidis1

1 Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece, 2 Aristotle University of Thessaloniki, Exercise Physiology & Biochemistry Laboratory, Department of Sport Sciences at Serres, Serres, Greece and 3 Aristotle University of Thessaloniki, Second Propedeutic Department of Internal Medicine, Hippokration Hospital, Thessaloniki, Greece.

**Background and Aims:** Previous studies in chronic kidney disease (CKD) showed that vascular dysfunction in different circulatory beds is progressively deteriorating with CKD severity. This study evaluated muscle oxygenation and microvascular reactivity at rest, during an occlusion-reperfusion maneuver, and during exercise in patients with pre-dialysis CKD versus controls, as well as between different CKD stages.

**Method:** Continuous measurement of muscle oxygenation (tissue saturation index (TSI%) via near-infrared-spectroscopy at rest, during occlusion-reperfusion, and during a 3-min handgrip exercise(at 35% of maximal voluntary contraction). Aortic pulse wave velocity (PWV) and carotid intima-media thickness (cIMT) were also recorded.

**Results:** Resting muscle oxygenation did not differ among the study groups (control: 64.3 ± 2.9 stage-2: 63.8 ± 4.2 stage-3a: 64.1 ± 4.1 stage-3b: 62.3 ± 3.3 stage-4: 62.7 ± 4.3%; p = 0.6). During occlusion, no significant differences among groups were detected in TSIocl magnitude- and occlusion-slope. However, during reperfusion, the TSImax and the hyperemic response were significantly lower in groups of patients with more advanced CKD stages (controls: 11.2 ± 3.7 stage-2: 8.3 ± 4.6 stage-3: 7.8 ± 5.5 stage-3b: 7.3 ± 4.4 stage-4: 7.2 ± 3.3; p = 0.04). During handgrip exercise, muscle oxygenation (TSIaverage-decline) was marginally lower in CKD patients than controls, but no significant differences were detected between CKD stages.

**Conclusion:** Although no differences were observed in muscle oxygenation at rest and during occlusion, the microvascular hyperemic response during reperfusion was significantly impaired in CKD and deteriorated in more advanced CKD stages. This impaired ability of microvasculature to respond to stimuli may be a crucial component of the adverse vascular profile of CKD patients and may contribute to exercise intolerance.

**URINARY FETUIN-A FRAGMENT EXCRETION IN PATIENTS WITH TYPE 2 DIABETES AND ITS CORRELATION WITH RENAL FUNCTION**

Varun Kumar Bandi1, Naga Sai Sri Harsha Narilla1, Sindhu Chaganti1, Sirisha Yarlagadda1 and Suresh Eadala2

1 Dr. Pinnamneni Siddhartha Institute of Medical Sciences & RF, Nephrology, Gannavaram, India, 2 Dr. Pinnamneni Siddhartha Institute of Medical Sciences & RF, General Medicine, Gannavaram, India and 3 Dr. Pinnamneni Siddhartha Institute of Medical Sciences & RF, Biochemistry, Gannavaram, India.

**Background and Aims:** Fetuin-A is associated with production of pro-inflammatory cytokines, which can lead to progression of vascular complications in patients with diabetes. We planned a study to evaluate the correlation of urinary excretion of post translationally modified fetuin-A fragment (PTM Fetuin A) with albuminuria and chronic kidney disease.

**Method:** We conducted a cross-sectional study between July to August 2022 in patients with type 2 diabetes. The baseline characteristics such as Age, Gender, history of Diabetes Mellitus, Hypertension, Cardiac disease, and CKD were obtained. The subject's blood pressure, Haemoglobin, Random blood sugar, Creatinine, was obtained, and eGFR (Glomerular Filtration Rate) was calculated using the CKD-EPI equation. The spot urine was tested for urine inflammatory cytokines, which can lead to progression of vascular complications in patients with diabetes.
albumin to creatinine ratio (UACR) and PTM-Fetuin-A: Creatinine ratio (FCR). PTM-Fetuin A was measured by an ELISA using DNLite-IVD103 ELISA test kit, Bio Preventive Medicine Corp, Taiwan.

Results: A total of 68 subjects were included, with 37 being men (54.4%). The mean age, eGFR, UACR, and FCR were 55 ± 11.4 years, 61.9 ± 37.5 ml/min/1.73 m², 1060.7 ± 1550 mg/g, and 522.2 ± 915.1 ng/g respectively. There was significant positive correlation between FCR and UACR (p<0.005), serum creatinine (p<0.005), and eGFR (p<0.001). There was a trend noted of increasing PTM-Fetuin A levels and UACR with worsening eGFR. The AUROC for UACR and FCR for predicting patients with CKD stage 3 onwards were 0.703 and 0.789 respectively (Figure 1). In our study, the significance of predicting CKD stage 3 onwards with a UACR cut-off of 300 mg/g, UACR cut-off of 1150 mg/g and a FCR cut-off of 123 ng/g were p = 0.008, p = 0.003, and p<0.0001 respectively.

Conclusion: PTM-Fetuin A is significantly associated with worsening renal function. It has very significant correlation with the albuminuria, and at a FCR cut-off of 123 ng/g, it could significantly differentiate CKD stages, compared to UACR. Further prospective studies are needed to evaluate the correlation between PTM-Fetuin A levels and rate of progression of nephropathy.

Figure 1: ROC curve for UACR and FCR for predicting CKD stage 3-5.
ASSESSING THE 3-YEAR RISK OF 40% EGFR DECLINE OR KIDNEY FAILURE IN THE US POPULATION

Maria Clarissa Tio1, Xiaqian Zhu1,2, Yoshitsugu Obi1, Timothy Edmund Yen1, Michael Hall1, Neville Dossabhoy1 and Tariq Shafi4

1University of Mississippi Medical Center, Department of Medicine, Division of Nephrology and Hypertension, Jackson, United States of America, 2University of Mississippi Medical Center, The Memory Impairment and Neurodegenerative Dementia (MIND) Center, Jackson, United States of America, 3University of Mississippi Medical Center, Department of Medicine, Division of Cardiology, Jackson, United States of America and 4Houston Methodist Hospital, Department of Medicine, Division of Kidney Diseases, Hypertension, and Transplantation, Houston, United States of America

Background and Aims: Prognostication of CKD progression currently relies exclusively on eGFR and albuminuria and do not consider comorbid conditions. Recently, the Chronic Kidney Disease Prognosis Consortium (CKD-PC) equation was developed to predict the 3-year risk of 40% eGFR decline or kidney failure in the general population [1]. The goal of our study was to assess the distribution of this risk in the US population.

Method: We included US adults from the 1999-2020 United States National Health and Nutrition Examination Survey (NHANES; N = 51,699). We calculated eGFR using the CKD-EPI 2021 equation and the 3-year risk of 40% eGFR decline or kidney failure using the CKD-PC equation (3-year risk). We categorized the 3-year risk as <1%, 1% to <5%, 5% to <10%, ≥10% and compared this with the current KDIGO 2012 CKD staging (eGFR<60 mL/min/1.73 m² or albuminuria≥30 mg/g).

Results: Among 199.8 million US adults, mean age was 46±15 years, 51% were female, 11% were non-Hispanic Black persons, and mean BMI was 29±6 kg/m². 71 million (36%) had hypertension and 26 million (13%) had diabetes. Table 1 shows the distribution of 3-year risk across stages of eGFR and albuminuria. Among 26 million US adults with CKD, the 3-year risks were <1% in 4 million (15%), 1% to <5% in 15 million (56%), 5 to <10% in 4 million (17%), and ≥10% in 3 million (11%). Importantly, among persons without CKD by current criteria, 1 million persons (0.58%) had a ≥5% 3-year risk, whereas only 331,840 (6%) persons with CKD 3a A1 had a ≥5% 3-year risk of CKD progression or kidney failure.

Conclusion: Calculating the 3-year risk of a 40% decline in eGFR or kidney failure can identify at-risk persons beyond the current eGFR and albuminuria staging. Our findings highlight the importance of factors besides eGFR and albuminuria in considering the risk for CKD progression.

KIDNEY FUNCTION-SPECIFIC CUT-OFF VALUES OF HIGH-SENSITIVITY CARDIAC TROPONIN T FOR THE DIAGNOSIS OF ACUTE MYOCARDIAL INFARCTION
Ruixuan Chen¹, Fan Fan Hou² and Sheng Nie³

¹National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Division of Nephrology, Guangzhou, P.R. China, ²National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Division of Nephrology, Guangzhou, P.R. China and ³National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Division of Nephrology, Guangzhou, P.R. China

Background and Aims: Acute myocardial infarction (AMI) is the leading cause of death worldwide. Patients with kidney dysfunction have high prevalence of AMI, thus early detection of AMI is necessary. However, in patients with decreased estimated glomerular filtration rate (eGFR), using the traditional cut-off value (14 ng/L) of high-sensitivity cardiac troponin T (hs-cTnT) resulted in lower specificity for diagnosing AMI. Our study aims to determine and validate kidney function-specific cut-off values of hs-cTnT for diagnosing AMI in patients with different degrees of kidney dysfunction.

Method: This large, multicenter, observational cohort study included 21,912 hospitalized patients who had undergone coronary angiography in 6 clinical centers from 2013 to 2021. The study outcome was the diagnosis of AMI. In the derivation cohort, kidney function-specific cut-off values of hs-cTnT for diagnosing AMI were determined to improve the specificity without the cost of sensitivity, as compared to that using 14 ng/L as the cut-off value in the normal kidney function group. The efficacy of the novel cut-off values was validated in an independent validation cohort enrolled from another clinical center.

Results: In the derivation cohort (n = 12,900), 3,247 patients (25.2%) had an eGFR <60 mL/min/1.73m². Even in the absence of AMI, 1,485 (50.2%) participants with eGFR <60 mL/min/1.73m² had a hs-cTnT concentration ≥14 ng/L. Using 14 ng/L as the threshold of hs-cTnT for diagnosing AMI led to a significantly reduced specificity (9.1–52.7% vs. 75.0%) and positive predictive value (15.5–21.1% vs. 28.7%) in patients with kidney dysfunction, as compared with patients with normal kidney function. The kidney function-specific cut-off values (eGFR ≥60 mL/min/1.73m²: 14 ng/L, 60>eGFR≥30 mL/min/1.73m²: 18 ng/L, and eGFR <30 mL/min/1.73m²: 48 ng/L) were determined and remarkably improved the diagnostic accuracy for AMI in participants with different levels of kidney dysfunction (specificity: reach to 52.8–63.0%; positive predictive value: 18.7–33.6%), without compromising sensitivity (96.6–97.9%). The kidney function-specific cut-off values increased the diagnostic accuracy of hs-cTnT for diagnosing AMI in every eGFR subgroup in the independent validation cohort (n = 8,012).

Conclusion: The kidney function-specific cut-off values of hs-cTnT significantly improved the diagnostic accuracy of AMI in patients with kidney dysfunction, and might be generally useful in clinical practice.

Table 1: The performance of hs-cTnT for diagnosing AMI using the traditional (14 ng/L) or kidney function-specific cut-off values in the validation cohort stratified by eGFR.

INCIDENT CHRONIC KIDNEY DISEASE IN NEWLY DIAGNOSED DIABETES MELLITUS

Jie Ming Nigel Fong1, Zheng Xi Kog1, Xu Yang1, Pek Siang Edmund Teo2, Cheng Boon Poh1, Hui Boon Tay4, Jason Choo1, Ngiap Chuan Tan5, Yong Mong Bee4 and Jia Liang Kwek1

1Singapore General Hospital, Renal Medicine, Singapore, 2Singapore General Hospital, Health Services Research Unit, Singapore, 3Changi General Hospital, Department of Medicine, Singapore, 4Sengkang General Hospital, Department of Renal Medicine, Singapore, 5Singhealth Polyclinics, Singapore and 6Singapore General Hospital, Department of Endocrinology, Singapore

Background and Aims: Singapore has the world's 3rd highest rate of incident end-stage kidney disease (ESKD) on dialysis. Diabetes mellitus (DM) was the cause of ESKD in 68% of patients initiating dialysis in 2020. We explored the rate of incident CKD in newly diagnosed DM, and risk factors associated with the development of incident CKD.

Method: This is a retrospective cohort of patients newly diagnosed with DM in 2014-2020, in primary care and specialist clinics across Singapore's largest health system. Patients were excluded if they had known CKD, were not screened for CKD, or were diagnosed with CKD at the first screening (which may reflect pre-existing CKD). CKD was defined as a CKD-EPI glomerular filtration rate (GFR) <60 ml/min/1.73 m², and/or urine albumin-creatinine ratio (UACR) >3 mg/mmol. Two readings ≥3 months apart were required for diagnosis. Demographic and laboratory data was retrieved from electronic records, and analysed using Pearson's Chi-square, Wilcoxon rank-sum test, and Cox regression evaluating time to onset of incident CKD.

Results: Of 25714 patients with newly-diagnosed DM and no known CKD, 3963 (15.4%) were not screened for CKD, and 2019 (7.9%) were diagnosed with CKD at the first screening; both groups were excluded. The remainder 19732 patients (76.7%) formed the study cohort. This included 14175 Chinese (71.8%), 3085 Malay (15.6%), 1658 Indian (8.4%), and 814 patients of other ethnicities (4.1%). Baseline mean (SD) GFR was 90.7 (17.6) ml/min/1.73 m². Over a mean follow up of 2.28 (1.98) years, 5929 patients (30.0%) developed incident CKD after a mean of 1.35 (1.09) years. Of patients who developed CKD, 869 (14.7%) met the GFR criteria, 4847 (81.8%) developed albuminuria, and 213 (3.6%) met both criteria. GFR decline began in the first year. Baseline characteristics associated with incident CKD on bivariate analysis (Table 1) included older age (61(11) vs 59(12) years, p<0.001), female gender (p<0.001), lower GFR (89 (19) vs 91 (17) ml/min/1.73 m², p<0.001), higher systolic blood pressure (136 (17) vs 135 (17) mmHg, p<0.001), and ischemic heart disease (p<0.001). On multivariate Cox regression exploring characteristics associated with time to incident CKD, independent risk factors include female gender (HR 1.30, 95%CI 1.23-1.39), lower GFR (per 10ml/min/1.73 m² lower GFR, HR 1.10, 95%CI 1.08-1.11), higher systolic blood pressure (per 10mmHg rise, HR 1.06, 95%CI 1.04-1.08), higher HbA1c (per 1% rise, HR 1.06, 95%CI 1.05-1.08), cerebrovascular accident (HR 1.16, 95%CI 1.02-1.31) and gout (HR 1.16, 95%CI 1.01-1.32). Despite a prevalence of hypertension of 85%, only 5440 (28%) of the cohort with incident CKD received an angiotensin converting enzyme inhibitor (ACE) or angiotensin receptor blocker (ARB) (as at 6 months after diagnosis of DM). 498 patients (2.5%) received a sodium-glucose cotransporter-2 inhibitor, which was not widely available during the period of this study.

Conclusion: Incident CKD was frequent in early DM; the risk factors above may identify higher-risk patients who benefit from enhanced screening. The relatively low rate of ACE/ARB prescription may require further review.
#5476

SEX DIFFERENCES IN INCIDENT KIDNEY FAILURE AND THE IMPACT OF RISK FACTORS IN A POPULATION STUDY

Michael Sullivan¹, Nicole De La Mata², Brenda Rosales², Melanie Wyld³, Patrick Mark¹, Angela Webster² and Jennifer Lees¹

¹University of Glasgow, School of Cardiovascular and Metabolic Health, Glasgow, United Kingdom, ²University of Sydney, Sydney School of Public Health, Sydney, Australia and ³University of Sydney, Sydney Medical School, Sydney, Australia

Background and Aims: Chronic kidney disease (CKD) has different effects on women and men. Women are more likely to have CKD, but men are more likely to develop kidney failure requiring treatment (KFRT: dialysis or transplantation). Recent studies have highlighted sex differences in CKD progression and there is a need to determine if this relates to differential effects of risk factors.

Method: We used primary care data stored within the electronic health records repository Secure Anonymised Information Linkage Databank (SAIL) for adults with CKD stages G3/4 (estimated glomerular filtration rate (eGFR) 15-59 mL/min/1.73 m²) living in Wales, UK. We studied the relationship between sex and the development of kidney failure (KFRT or incident eGFR<15 mL/min/1.73 m² for ≥3 months). Sex-specific rates of kidney failure were compared using an event plot with patients censored on the date of death. Cox proportional hazards models tested associations between sex and kidney failure, before and after adjustment for other known risk factors (age, baseline eGFR, smoking, social deprivation, diabetes mellitus and hypertension). Interactions between sex and risk factors were sought and interaction terms were retained if these were statistically significant (p-value<0.05). Models were then stratified by sex to compare the impact of risk factors in men and women.

Results: 135,635 patients (median age 78 years, 57% female, median baseline eGFR 50 mL/min/1.73 m²) were followed up for a median of 6.8 years, representing a total of 782,237 patient years. 1.1% of women and 2.3% of men developed kidney failure. An unadjusted Cox model including both sexes showed a hazard ratio of 2.06 (95% confidence interval 1.89-2.24) for men. After adjustment for all risk factors and inclusion of interaction terms (between sex and baseline eGFR and sex and age), men were not more likely to develop kidney failure (aHR 0.91, 0.60-1.38) (Figure 1A). In sex-stratified models, kidney failure was most likely to develop in those with low baseline eGFR, younger age, current and ex-smokers, patients with diabetes mellitus and patients with hypertension (Figure 1B). Diabetes was a more important risk factor for kidney failure in women (aHR in women 1.73 (1.51-1.98) compared with men (aHR 1.56, 1.39-1.74). Hazard ratios for other risk factors were similar in men and women.

Conclusion: We found that sex differences in rates of kidney failure are related to a differential impact of risk factors – in particular diabetes – on CKD progression. These results warrant further investigation with a need to determine whether risk reduction strategies should be different in men and women with CKD, or whether current diagnosis, monitoring and treatment strategies are either applied differentially or have different benefit and harms by sex.

BURDEN OF NONCOMMUNICABLE DISEASES ATTRIBUTABLE TO KIDNEY DYSFUNCTION: RESULTS FROM THE GLOBAL BURDEN OF DISEASE STUDY 2019

Chen Jing
West China Hospital, Sichuan University, Division of Nephrology, Sichuan Province, P.R. China

Background and Aims: Non-communicable diseases (NCD) represent a major public health and disability burden worldwide. The UN Sustainable Development Goal (SDG) target 3.4 called for reducing premature mortality from NCD by one third through prevention and treatment by 2030. To lessen the impact of the burden of NCD, evidence-based and precise data are needed for making policy and allocating resources. However, the burden of NCD attributable to kidney dysfunction has not been systematically estimated. We aimed to estimate the global latest trend of kidney dysfunction-related NCD quantified by death and disability-adjusted life-years (DALY) at global, regional, and national levels using data extracted from the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) 2019.

Method: In GBD study 2019, kidney dysfunction is classified as level 2 risk factor for disease in metabolic risk factors hierarchy, which refers to glomerular filtration rate (GFR) < 60 mL/min/1.73 m² or albumin-to-creatinine ratio (ACR) > 30 mg/g. The GBD study 2019 provides a systematic assessment of published, publicly available, and contributed data on mortality and disability-adjusted life-years (DALY), which were estimated with Bayesian geospatial regression using data at global, regional and country level. Further analyses were performed by year, age, sex, and regions in 204 countries. To assess the change trend, we calculated the estimated annual percentage change (EAPC) of age-standardized rate with the linear regression model. The Socio-demographic Index (SDI) was used as an comprehensive indicator of national socioeconomic status. we explored the relationship between age-standardized mortality or DALY rate and SDI using Pearson’s correlation analysis. Additionally, burdens in main types of NCD (including cardiovascular disease and chronic kidney disease) attributable to impaired kidney function were analyzed.

Results: From 1990 to 2019, the absolute numbers of death and DALYs increased, while the age-standardized rates of deaths and DALYs of NCD attributable to kidney dysfunction deceased worldwide. The age-standardized mortality decreased by an average of −0.35% (95% UI −0.41 to −0.29) per year, from 45.17 (95% UI 37.62 to 52.33) per 100,000 population in 1990 to 40.64 (95% UI 34.81 to 46.71) per 100,000 population in 2019. Over the same interval, the age-standardized DALYs rate declined from 1024.13 (95% UI 898.38 to 1154.8) per 100,000 population to 945.31 (95% UI 836.33 to 1066.77) per 100,000 population, with an EAPC of −0.25% (95% UI −0.31 to −0.19). Globally, gender imbalance existed over the past 29 years, the burden in males were higher than those in females. Besides, the burden of NCDs as a result of kidney dysfunction increased with age growth, and the elder had higher rate of death and DALYs. Geographically, the age-standardized DALYs rate attributed to kidney dysfunction increased in Central Latin America, Southern Sub-Saharan Africa, Caribbean, Central Asia, Andean Latin America, Oceania, Southeast Asia. Age-standardized death and DALY rates demonstrated a higher burden in low, low-middle and middle SDI countries than those in high-middle and high SDI countries.

Conclusion: The result of the present work implied that the NCD as a result of kidney dysfunction has been an important contribution to the increasing burden of NCD over the past several decades, particularly in developing countries. Therefore, greater efforts are needed to carry out early screening and detection, primary care, and reasonable resource allocation to reduce mortality and the long-term burden, especially in low-to-middle Socio-demographic Index regions. Our data would provide the necessary information for priority setting and precision planning of health services to prevent and control NCD.

HIGHER MORTALITY RISK WITH CHRONIC KIDNEY DISEASE IN TYPE 2 DIABETES IN YOUNGER AGES: A DANISH NATIONWIDE COHORT STUDY 2014-2018

Martin Nyeland1, Rasmus Rørth 1, Bendix Carstensen 1, Frederik Persson1, Peter Rossing1,2, and Dorte Vistisen 1,3

1Copenhagen University Hospital – Steno Diabetes Center Copenhagen, Clinical Research Unit, Herlev, Denmark, 2University of Copenhagen, Department of Clinical Medicine, Copenhagen N, Denmark and 3University of Copenhagen, Department of Public Health, Copenhagen K, Denmark

Background and Aims: Chronic kidney disease (CKD) is a frequent complication to diabetes. CKD is associated with significantly increased risk of morbidity and mortality among people with diabetes. It is well known that the incidence and progression of CKD differ between men and women. Women
are more likely to get CKD, while men have a more rapid progression of the disease. However, previous studies were based on small populations. We aimed to investigate the mortality with and without CKD in men and women with type 2 diabetes (T2D).

**Method:** Secular and age trends in mortality rates and sex differences were investigated in a dynamic, nationwide cohort of people with T2D. CKD was defined based on hospital diagnosis, procedure codes and laboratory measurements. Mortality rates were modelled as an age-period-cohort model using Poisson models with log person time, smooth effects of current age, and calendar time (date of follow-up), separate for each sex and CKD status.

**Results:** The study included 304,956 persons (55.9% men) and 1.2 million person-years. 87,696 persons were recorded with CKD, of which 34,967 people with and without CKD. The overall mortality rate was 37.8 [37.4; 38.2] versus 31.1 [30.4; 31.7] per 1000 person-years for people with T2D, without and with CKD, respectively. The mortality rate for people with T2D and CKD is larger and more pronounced in the younger ages. For elderly people the mortality rate is larger for people with T2D and without CKD. In general, mortality for men is higher than mortality for women at all ages, observed for both people with and without CKD. The overall secular trend per year was increasing for persons without CKD 2.0 [1.8; 2.2] %/year. For those with CKD, a decrease −2.4 [−2.1; −2.6] %/year was observed, decreasing until start 2017 followed by an increase. The overall M/F mortality ratios were 1.23 [1.20; 1.25] and 1.91 [1.83; 2.00], respectively.

**Conclusion:** The observed larger and more pronounced mortality rate for people with T2D and CKD in the younger ages, suggests a potential for early preventive intervention among young adults. Supported by an unrestricted grant from Bayer.

---

**Background and Aims:** Incidence of cancer is increased in patients with chronic kidney disease (CKD), with a number of large population cohorts suggesting that lower estimated glomerular filtration rate (eGFR) increases overall risk of cancer death after adjustment for overlapping risk factors. In the general population, advanced cancer stage at presentation is associated with poorer outcomes. We sought to determine whether patients with CKD were more likely to present with advanced stage cancer, whether this impacted on their survival, and whether these factors varied by sex.

**Method:** Data were from Secure Anonymised Information Linkage Databank (SAIL), a Welsh primary care cohort with linkage to cancer and death registries. We included patients with a new cancer diagnosis between 2009 and 2020, and at least two kidney function tests before and within two years of diagnosis. eGFR based on serum creatinine (eGFRcr) was calculated using the CKD-EPI 2009 equation and measured in mL/min/1.73 m². Albuminuria was not routinely available. Logistic regression models determined odds of presenting with advanced cancer (stage 3 or 4 at diagnosis). Cox proportional hazards models tested associations between eGFRcr and all-cause mortality (reference group: eGFR 75 to <90). Comparisons were made both between- and within-sex.

**Results:** There were 95,689 patients: 43,720 (45.7%) were female, mean age was 70.3 (SD 13.8) years in women and 71.4 (SD 11.4) years in men; median eGFR at baseline was 77 (IQR 63 – 89) mL/min/1.73 m² in both women and men. Over a median follow-up time of 3.4 (IQR 0.9 – 5.7) years in women and 3.4 (IQR 0.9-5.5 years in men), there were 22,355 deaths in women and 27,681 in men. Adjusted for age, baseline eGFR, smoking status, number of comorbidities, deprivation and cancer site, men were slightly more likely to present with advanced cancer (aOR 1.02, 95% CI 1.01-1.04) and had higher hazards of death after cancer diagnosis than women (aHR 1.10 95% CI 1.08-1.13). In sex-stratified analyses, lower eGFRcr was weakly associated with higher odds of presenting with advanced cancer in men (eGFRcr 45–<60: OR 1.02, 95% CI 1.01-1.04; 30–<45: OR 1.02 95% CI 1.00-1.05; <30 OR 1.07 95% CI 1.03-1.11), but only in women with eGFRcr 45–<60 (OR 1.04 95% CI 1.02-1.06); Figure 1). Lower (and higher) eGFRcr was associated with higher hazards of death after cancer diagnosis in both men and women; however, the relative increase in hazards of death with eGFRcr <75 was stronger in women than in men, with a widening discrepancy as baseline eGFR decreased (Figure 1).

**Conclusion:** Men were more likely than women to be diagnosed with advanced cancer and more likely to die after cancer diagnosis than women. Lower eGFR was associated with higher hazards of death after cancer diagnosis in both men and women. Despite an initial survival advantage compared to men, women with lower eGFR had disproportionately higher hazards of death. Though potential explanations are manifold, scrutiny of efficacy and safety of cancer treatments in people with CKD – particularly women with CKD – are warranted.

ACCURACY OF NOVEL GFR ESTIMATING EQUATIONS BASED ON CREATININE, CYSTATIN C OR BOTH IN ROUTINE CARE
Edouard Fu1,2,3, Andrew Levey4, Anne-Laure Faucon5, Pierre Delanaye5, Lesley Inker4 and Juan Jesus Carrero2
1Brigham and Women’s Hospital, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, United States of America, 2Karolinska Institutet Campus Solna, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, 3Leiden University Medical Center (LUMC), Department of Clinical Epidemiology, Leiden, Netherlands, 4Tufts Medical Center, Division of Nephrology, Department of Internal Medicine, Boston, United States of America and 5Chu De Liège, Department of Nephrology-Dialysis-Transplantation, Luik, Belgium

Background and Aims: New equations to estimate GFR (eGFR) based on creatinine, cystatin C or both have been developed in the last two years. A comprehensive comparison of their accuracy is currently lacking, particularly in cohorts not involved in their development or validation and among people with comorbid conditions.

Method: We included 6174 adults from the Stockholm Creatinine Measurements (SCREAM) project referred for plasma clearance of iohexol during 2011-2021, in whom we observed 9579 concurrent measurements of creatinine, cystatin C and iohexol clearance. We assessed the performance against measured GFR (mGFR) of eGFR equations proposed by the CKD-EPI collaboration (CKD-EPI 2009, 2012 and 2021), European Kidney Function Consortium (EKFC 2021 and 2023), and the revised Lund-Malmö (2011) and CAPA (2014) equations, which are used in Sweden. Bias was expressed as the median difference in eGFR minus mGFR, with negative biases indicating underestimation of mGFR. P30 described the percentage of individuals with eGFR within 30% of mGFR. Correct classification was defined as agreement of eGFR and mGFR categories using the KDIGO GFR categories. Subgroup analyses were conducted according to age, sex, BMI, eGFR, cancer, cardiovascular disease, diabetes, heart failure and liver disease.

Results: Mean age was 57 years, 46% of participants were female, mean mGFR was 62 mL/min/1.73 m² and mean BMI was 26 kg/m². Cardiovascular disease was the most common comorbid condition (30%), followed by liver disease (28%), diabetes (26%) and cancer (26%). Equations that used both creatinine and cystatin C had better performance than eGFR using each marker alone, regardless of the equation used; all such equations had small bias and P30 close to 90%. Among creatinine-based equations, CKD-EPI 2009 and CKD-EPI 2021 showed larger overestimates of mGFR than EKFC 2021 and revised Lund-Malmö, with median biases of 5.6, 9.1, 2.7 and 0.2 mL/min/1.73 m², respectively (Table 1). There were no meaningful differences in performance across eGFR equations based on cystatin C. Findings were consistent across subgroup analyses stratifying for comorbid conditions (Figure 1).

Conclusion: eGFR equations that combined information on creatinine and cystatin C performed better than equations based on creatinine or cystatin C alone in this Swedish cohort of routine referrals for plasma clearance of iohexol. There was larger variation in the performance of equations based on creatinine than cystatin C.

DRUG UTILIZATION FOLLOWING INCIDENT CHRONIC KIDNEY DISEASE: AN OBSERVATIONAL STUDY IN THE UNITED STATES AND JAPAN

Navdeep Tangri1, Johan Bodegard2, Lai San (Corinna) Hong3, Cassandra Nan2 and Tadashi Sofue4

1University of Manitoba Max Rady College of Medicine, Winnipeg, Canada, 2AstraZeneca, BioPharmaceuticals Medical, Gothenburg, Sweden, 3Redsen Limited, Bournemouth, United Kingdom and 4Kagawa University, Department of Cardiorenal and Cerebrovascular Medicine, Kagawa, Japan

Background and Aims: Chronic kidney disease (CKD) affects >840 million individuals worldwide and is a leading cause of morbidity and mortality. Complications include cardiorenal outcomes (e.g. end stage kidney disease and heart failure (HF)) and premature death, which may be preventable with early identification and appropriate treatment of CKD. Treatment of CKD with renin-angiotensin-system inhibitors (RASI) has been the main recommendation of guidelines in the past 20 years, but prescribing rates remain low and discontinuation rates remain high, particularly after adverse events like
hyperkalaemia episodes. This study aims to describe RASi utilization following incident CKD.

**Method:** Adult patients with incident CKD in the United States (US; OPTUM Market Clarity until 31 March 2022) and Japan (Medical Data Vision until 28 February 2022) from 1 January 2016 onwards were included. CKD was defined as any of the following: a UACR measure of $\geq 30$ mg/g, two estimated glomerular filtration rate (eGFR) $\geq 90$ days apart of which the second was $\leq 75$ ml/min/1.73 m$^2$, or a CKD diagnosis code. Patients were included if they had an eGFR $\leq 60$ ml/min/1.73 m$^2$. Patients with ongoing RASi treatment at index, a history of diabetes, heart failure or dialysis were excluded.

**Results:** A total of 66,375 incident CKD patients were identified in the US ($n = 32,158$) and Japan ($n = 34,217$). Mean age was 66 and 78 years in the US and Japan, respectively, and about half of the patients were female. Mean eGFR was 48 and 40 ml/min/1.73 m$^2$ in the US and Japan, respectively. Approximately 30% of patients had cardiovascular disease, but only 13% (US) and less than 5% (Japan) were prescribed cardiovascular preventive drugs (e.g. statins and low dose aspirin). During a 1-year follow-up after the incident CKD index date, only 15% and 5% had been initiated on RASi in the US and Japan, respectively (Figure 1). Time to RASi initiation was shorter among those with a CKD diagnosis vs those without a diagnosis (US: 15 vs 19 months, Japan: 6 vs 11 months). Of those who initiated treatment, approximately 50% discontinued within one year (Figure 1). Results for initiation and discontinuation were similar across CKD stages in both countries.

**Conclusion:** In the US and Japan, initiation of RASi was remarkably low among newly identified CKD patients, and discontinuation of initiated treatment was substantial. Given that most patients with CKD benefit from multi-drug therapy (RASi + SGLT2i) for slowing CKD progression and reduction of adverse events, efforts to increase prescribing and adherence are needed.

---

**EXTERNAL VALIDATION OF A NOVEL MULTIMARKER GFR ESTIMATING EQUATION**

Maria Clarissa Tio 1, Xiaojian Zhu 1,2, Seth Lirette 3, Andrew Rule 4, Kenneth Butler 2, Michael Hall 3, Neville Dossabhoy 1, Thomas Moseley 2 and Tariq Shafi 6

1 University of Mississippi Medical Center, Department of Medicine, Division of Nephrology and Hypertension, Jackson, United States of America, 2 University of Mississippi Medical Center, The Memory Impairment and Neurodegenerative Dementia (MIND) Center, Jackson, United States of America, 3 University of Mississippi Medical Center, Department of Data Science, Bower School of Population Health, Jackson, United States of America, 4 Mayo Clinic, Division of Nephrology and Hypertension, Department of Internal Medicine, Rochester, United States of America, 5 University of Mississippi Medical Center, Division of Cardiology, Department of Medicine, Jackson, United States of America and 6 Houston Methodist Hospital, Department of Medicine, Division of Kidney Diseases, Hypertension, and Transplantation, Houston, United States of America

**Background and Aims:** The use of multiple markers may improve the accuracy in glomerular filtration rate (GFR) estimation especially when the interpretation of creatinine and cystatin C is limited. We sought to externally validate a recently developed multi-marker nuclear magnetic resonance (NMR)-based estimated GFR equation (eGFR-NMR) using the biracial Genetic Epidemiology Network of Arteriopathy cohort.

**Method:** We included 224 sex, race/ethnicity, and mGFR-category-matched participants. GFR was measured using urinary clearance of iothalamate (mGFR). We calculated eGFR-NMR using serum creatinine, valine, myo-inositol, and cystatin C, age, and sex. We compared the reliability of eGFR-NMR with current eGFR equations (2021 Chronic Kidney Disease Epidemiology Collaboration equations for creatinine [eGFR-Cr] and creatinine with cystatin C [eGFR-Cr-CysC]) using median bias, precision, and accuracy metrics. In particular, we evaluated its performance in age, sex, and race subgroups.

**Results:** In the overall cohort, mean age was 63 (±8) years, 54% were females, 49% were Black individuals, and mean mGFR was 78.7 (±24.3) ml/min/1.73 m$^2$. eGFR-NMR overestimated mGFR by 2 mL/min/1.73 m$^2$ (95% CI, 4 to 0.7) while eGFR-Cr-CysC underestimated mGFR by $-5$ ml/min/1.73 m$^2$ (95% CI, $-2$ to $-7$). All equations had acceptable accuracy metrics. When stratified by age, sex, and race, eGFR-NMR performed the best among Black males age <65 years compared to current equations (Figure 1). In this subgroup, eGFR-NMR was unbiased (bias, $2$ ml/min/1.73 m$^2$ [95% CI, $-3$ to $10$]) compared to substantial biases of eGFR-Cr (bias, 17 ml/min/1.73 m$^2$ [95% CI, 9 to 24]) and eGFR-Cr-CysC (bias, $15$ ml/min/1.73 m$^2$ [95% CI, 6 to 20]). In other subgroups, measures of accuracy for eGFR-NMR, eGFR-Cr, eGFR-Cr-CysC were generally similar.

**Conclusion:** eGFR-NMR can be used to estimate mGFR and was more accurate than CKD-EPI equations among Black males age <65 years.
Figure 1: Performance of eGFR-NMR compared to eGFR-Cr and eGFR-Cr-Cys in the GENOA cohort stratified by age, sex, and race. (1-A) Median bias is defined as the median of the differences between mGFR and eGFR, units in mL/min/1.73 m². A positive bias denotes that eGFR underestimates mGFR while a negative bias denotes that eGFR overestimates mGFR; (1-B) MAE is defined as the average of the absolute differences between each eGFR and corresponding mGFR, units in mL/min/1.73 m². GENOA = Genetic Epidemiology Network of Arteriopathy cohort; eGFR-NMR = estimated glomerular filtration rate calculated from the multi-metabolite nuclear magnetic resonance multiplex assay measuring serum creatinine, valine, and myo-inositol, with the addition of age, sex, and serum cystatin C; eGFR-Cr = GFR estimated using the race-free CKD-EPI 2021 creatinine equation; eGFR-Cr-CysC = GFR estimated using the race-free CKD-EPI 2021 creatinine and cystatin-C equation; mGFR = measured glomerular filtration rate; MAE = mean absolute error.
CANCER RELATIVE SURVIVAL IN DIALYSIS AND KIDNEY TRANSPLANT RECIPIENTS: A POPULATION-BASED STUDY IN AUSTRALIA AND NEW ZEALAND 1980-2019
Laia Oliveras1, Brenda Rosales2, Nuria Montero1, Edoardo Melilli1, Josep Cruzado1, Angela Webster2 and Nicole De La Mata2

1Hospital Universitari de Bellvitge, Nephrology Department. L’Hospitalet de Llobregat, Spain and 2Sydney School of Public Health, Sydney Medical School, University of Sydney, Camperdown, Australia

Background and Aims: Cancer survival in the general population has improved over time. Kidney failure population have a higher incidence of cancer with increased mortality. Relative survival following cancer diagnosis can provide more insight into the excess mortality directly or indirectly attributed to cancer in the kidney failure population.

Method: We estimated and compared the relative survival for dialysis patients, kidney transplant recipients and general population with cancer in Australia and New Zealand from 1980 to 2019. The general population was reference group for background mortality, matching on sex, age, calendar year and country. We used Poisson regression to quantify the excess mortality between these three groups with cancer.

Results: We included 4,089 dialysis patients and 3,253 kidney transplant recipients with an incident cancer. Dialysis patients were older, had a higher proportion of indigenous people and had more comorbidities than kidney transplant recipients. The kidney failure population had lower 5-year relative survival: 0.25 (95%CI: 0.23-0.26) for dialysis, 0.55 (95%CI: 0.53-0.57) for kidney transplant and 0.670 (95%CI: 0.669-0.670) in the general population with cancer (Figure 1). At any given time, dialysis patients had a 2.10 times higher adjusted excess mortality compared to the general population with cancer (2.10, 95%CI: 2.02-2.18), whereas kidney transplant recipients had no excess mortality (1.02, 95%CI: 0.97-1.08). Relative survival and excess mortality varied by cancer site: lung had the lowest relative survival rates, while kidney failure population with melanoma, breast and prostate cancers had the highest excess mortality. There were also sex differences: women had greater relative survival.

Conclusion: Relative survival was lower among the kidney failure population with incident cancer compared to the general population with cancer, for all-site and particularly for melanoma, breast and prostate cancer. Decreased survival may be due to poorer access to, more harm or less efficacy of treatments.

Figure 1: All-site cancer and cancer-type relative survival ratios.
THE ENVIRONMENTAL IMPACT OF CHRONIC KIDNEY DISEASE INTERNATIONALLY: RESULTS OF A LIFE CYCLE ASSESSMENT

Carmine Zoccali1, Katherine Barraclough1, Matthew Eckelman1, Aleix Cases Amenos4, Celine Germond-Duret5, Roberto Pecoits-Filho6, Juan Jose Garcia Sanchez7, Viknesh Selvarajah8, Luke Hubbert9 and Lindsay Nicholson9

1Università degli Studi di Palermo - Facoltà Medicina e Chirurgia, Caltanissetta, Italy, 2School of Medicine, University of Melbourne, Parkville, Australia, 3Department of Civil & Environmental Engineering, Northeastern University, Boston, MA, United States of America, 4Hospital Clinic de Barcelona, Barcelona, Spain, 5Lancaster University, Politics, Philosophy and Religion, United Kingdom, 6Arbor Research Collaborative for Health, United States of America, 7AstraZeneca, Cambridge, United Kingdom, 8AstraZeneca, Cambridge, United Kingdom and 9Maverex Ltd, Newcastle upon Tyne, United Kingdom

Background and Aims: The environmental impact of healthcare is high, and kidney care for chronic kidney disease (CKD) contributes significantly to this. Haemodialysis represents the only viable kidney replacement option for certain patients with CKD, in whom the clinical benefits are lifesaving. Haemodialysis is also resource-intensive, requiring frequent sessions, and energy- and water-intensive equipment. In recognition of this, the ERA has implemented a green nephrology initiative aiming to minimize the environmental impact of kidney care. However, there is a paucity of up-to-date analysis on the environmental impact of different dialysis techniques and CKD overall. This study presents an international, holistic life cycle assessment (LCA) of the environmental impact of CKD in adults at all CKD stages.

Method: LCA methodology was used, conducted according to ISO 14040/14044 international standards, to estimate the annual environmental impacts of each stage (1–5) of CKD per patient. At CKD Stage 5, supportive care, haemodialysis, peritoneal dialysis, and transplantation pathways were considered. A literature review was performed to identify all studies reporting healthcare resource use in CKD, stratified by CKD stage. The study boundary is summarised in Figure 1. GaBi software was used to model the pathway based on ecoinvent Life Cycle Inventory database version 3.8. Environmental impact categories were reported according to the impact assessment methods, ReCiPE 2016 v1.1 and TRACI 2.1 (US only). Here, we describe the preliminary analysis of the international study, presenting results on the annual environmental impact of in-centre haemodialysis in the UK, based on one patient receiving haemodialysis three times weekly for four hours per session. The inputs for in-centre haemodialysis comprised dialysis consumables and their transport, energy/water used by the haemodialysis machine (including reverse osmosis), heating/cooling/lighting of the healthcare area, waste disposal, and patient transport.

Results: A total of 93,600 litres of water and 3,058 kWh electricity was estimated per patient for in-centre haemodialysis annually in the UK. The carbon footprint of in-centre haemodialysis in the UK per patient was estimated to be 3,900 kg CO2 equivalents, comparable to the average UK persons annual greenhouse gas footprint, effectively doubling their yearly greenhouse gas impact. Several other environmental impact categories were measured beyond the carbon footprint, including photochemical oxidation potential (ground-level ozone formation) and fine particulate matter, measured as PM2.5. Across each impact category, the parameters that drove each environmental impact differed (Figure 2). For example, dialysis consumables, haemodialysis machine, and patient transport were the main environmental contributors of fine particulate matter, while patient transport was the main driver of terrestrial ecotoxicity.

Conclusion: The results of this LCA build upon previous published research and demonstrate a high carbon footprint for in-centre haemodialysis, in line with other studies. The results also show that the environmental impact of in-centre haemodialysis goes beyond that of its carbon footprint, to other important environmental aspects such as PM2.5 emissions, in which long-term exposure is associated with health problems, such as cardiovascular...
and respiratory diseases, and an increased risk of CKD. This study hopes to highlight the need for evidence-based policy interventions around the implementation of green nephrology initiatives such as use of renewable energy to power haemodialysis, utilisation of water conserving reverse osmosis systems, and reduction in waste. Furthermore, healthcare policy initiatives that could help detect patients in the early stages of CKD and thereby enable them to be managed proactively could eventually reduce the need for resource-intensive dialysis therapy.

**CHRONIC KIDNEY DISEASE IN NON-RENAL SOLID ORGAN TRANSPLANTATION: WHAT IS THE ROLE OF THE NEPHROLOGIST?**

Iris Viejo Boyano¹, Luis Carlos López Romero², Maria Peris-Fernandez³, Luis D’marco⁴, Enrique Garrigos Almerich¹, Carmela Ramos⁴, Ana Peris¹ and Julio Hernandez Jaras¹

¹University and Polytechnic La Fe Hospital, Nephrology, Valencia, Spain,
²University General Hospital of Valencia, Nephrology, Valencia, Spain and
³Cardenal Herrera-CEU University, Alfara del Patriarca, Valencia, Spain

**Background and Aims:** Chronic kidney disease (CKD) is a frequent complication of non-kidney solid organ transplant (NKSOT) and is related to increased morbidity and mortality. Identifying predisposing factors is crucial for an early approach and correct referral to Nephrology, a specialty with an important role in managing these patients.

**Method:** This is a single-center retrospective observational study of a cohort of CKD patients under follow-up in the department of nephrology during the period between January 2010 to December 2020. A total of 212 patients were analyzed. Patients transplanted before 2010 (101 patients), with combined transplantation with renal transplantation (9 patients), and those with no follow-up in external consultations (28 patients) were removed from the sample. A final population sample was obtained with 74 patients. Statistical analysis was performed between all the risk above factors (Figure 1) and the four dependent variables: advanced chronic kidney disease (ACKD), increased serum creatinine ≥50%, renal replacement therapy (RRT), and death in three different periods: pre-transplant period, peri-transplant period and post-transplant period.

**Results:** 74 patients were analyzed (7 heart transplant recipients, 34 liver transplant recipients, and 33 lung transplant recipients).

- 45 patients presented an increase in Creatinine ≥50%. Receiving a lung transplant confers more risk versus a liver (HR 0.048 [95% CI 0.012 to 0.192) or heart (HR 0.075 [95% CI] 0.01 to 0.5) transplant. It was significantly associated with pre-transplant obesity (p 0.003), peri-transplant mechanical ventilation (p < 0.001), peri-transplant (p 0.009) and post-transplant (p 0.005) anticalcineurin overdose, peri-transplant (p 0.046) and post-transplant nephrotoxics (0.03) and the number of hospital admissions (p. 0.002). Not having follow-up by Nephrology in the pre-transplant (p 0.027), peri-transplant (p 0.045), and the longest time until external consultations (HR 1.032 [95% CI] 1.011 to 1.054) conferred more risk.

- 24 patients developed ACKD. Receiving a lung transplant confers more risk versus a liver (HR 0.14 [95% CI] 0.045 to 0.463) or heart (HR 0.13 [95% CI] 0.015 to 1.28) transplant. Per-transplant mechanical ventilation (p 0.03), peri-transplant (p 0.024) and post-transplant (p 0.038) anticalcineurin overdose, peri-transplant (p 0.045) and post-transplant nephrotoxic antimicrobials (p. 0.04) and the number of hospital admissions (p 0.015) were significantly associated. The time to nephrology consultations after the transplant (p 0.035) conferred more risk. Mean ACKD-free survival was 93.29 months (95% CI of 79.04-107.5), 121.5 months in heart transplantation recipients (95% CI of 86.70-155.29), 104 months in liver transplantation recipients (95% CI of 86.67-122.134) and 66.86 months in lung transplantation recipients (CI at 95% of 55.93 – 80.79) (Figure 2).

- 8 patients required RRT. It was significantly associated with the active smoking habit in the pre-transplant period (p 0.02) and the overdose of calcineurin inhibitors in the peri-transplant period (p 0.045).

- 21 patients died. It was significantly associated with the active smoking habit in the pre-transplant (p 0.03) and the number of hospital admissions in the post-transplant (p 0.006).

**Conclusion:** Early follow-up by Nephrology is associated with a decrease in the deterioration of renal function and the development of advanced chronic kidney disease, by being able to act on the risk factors for each transplant recipient, such as an overdose of calcineurin inhibitors and nephrotoxicity, and allowing the identification of patients at higher risk, such as those requiring mechanical ventilation during peri-transplantation, patients with the highest number of hospital admissions, and lung transplant patients.
Background and Aims: The tissue pathology of both aging and chronic kidney disease (CKD) is nephrosclerosis defined by globally sclerotic glomeruli (GSG) and interstitial fibrosis and tubular atrophy (IFTA). We sought to determine if risk of CKD outcomes is better predicted by age-based or young adult-based thresholds for nephrosclerosis.

Method: Using the Aging Kidney Anatomy study, living kidney donors, kidney tumor patients, and native kidney disease patients had kidney biopsy images analyzed morphometric to quantify %GSG, %IFTA, and IFTA foci density (Figure 1). Using normotensive donors, young (18-29 y) thresholds and age-based (18-29 y, 30-39 y, 30-39 y, 50-59 y, 60-69 y, 70+ y) 95th percentile thresholds were defined. Progressive CKD was defined as a 40% decline in serum creatinine based estimated GFR or kidney failure (dialysis or transplantation) from a 4-month post-biopsy baseline (due to the nephrectomy event in tumor patients and due to the common occurrence of acute kidney injury in the native kidney disease patients at the time of biopsy). The age-adjusted risk of progressive CKD in tumor patients and native kidney disease patients was compared between those with nephrosclerosis that was "normal compared to young", "normal for age but abnormal compared to young", and "abnormal for age" (Figure 2).
Figure 1: An example of the TRI-stained biopsy image for kidney donors (A) were used to trace cortex (traced in green), non-sclerosed glomerulus (NSG) (traced in blue), each globally sclerosed glomerulus (GSG) (traced in red), and each distinct IFTA focus (traced in black). Example of PAS-stained biopsy section (B) for tumor patients. Example of TRI-stained section (C) for native kidney disease patients.

Figure 2: Conceptual model of young-threshold and age-based thresholds for nephrosclerosis measures defined using 2583 normotensive kidney donors. The 95th percentile for 18-29 years defined the abnormal compared to young threshold. The 95th percentile for 70-77 years defined the abnormal for age threshold for all persons 70 years and older.
Results: There were 2583 normotensive living kidney donors, 1363 tumor patients, and 314 native kidney disease patients studied. The 95th percentiles for 18-29y to 70 +y age groups among normotensive donors were 1.7% to 16% for %GSG, 0.18% to 6.5% for %IFTA, and 8.2 to 59.3 per cm2 for IFTA foci density. The risk of CKD outcomes did not differ between tumor patients and native kidney disease patients with nephrosclerosis “normal compared to young” versus “abnormal compared to young but normal for age” in both cohorts. Thus, these two categories were combined into “normal for age”. The risk of progressive CKD over a median 5.5 years follow-up for tumor patients was higher with %GSG, %IFTA, and IFTA foci density that was abnormal for age vs normal for age (HRs 2.28, 2.41, and 3.11, respectively, p<.0001 for all). The risk of progressive CKD over a median 7.2 years follow-up for native kidney disease patients was higher with %GSG, %IFTA, and IFTA density that was abnormal for age vs normal for age (HRs 1.87, 2.65, and 3.11, respectively, p<.0001 for all).

Conclusion: There is a substantial increase in nephrosclerosis from aging alone in healthy adults that is not prognostic for CKD outcomes. Age-based thresholds better identify clinically relevant CKD.

PROGRESSION OF INCIDENT CHRONIC KIDNEY DISEASE: A DANISH NATIONWIDE POPULATION-BASED COHORT STUDY
Anne Høy Seemann Vestergaard1, Simon Kok Jensen1, Uffe Heide-Jørgensen1, Line Elmerdahl Frederiksen1, Henrik Birn1,2, Frederik Persson3, Reimar Thomsen1 and Christian Fynbo Christiansen1
1Department of Clinical Epidemiology, Department of Clinical Medicine, Aarhus University and Aarhus University Hospital, Aarhus C, Denmark, 2AstraZeneca Nordics, Ballerup, Denmark, 3Departments of Clinical Medicine and Biomedicine, Aarhus University, Aarhus N, Denmark, 4Department of Renal Medicine, Aarhus University Hospital, Aarhus N, Denmark, 5Research Unit of General Practice, Department of Public Health, University of Southern Denmark, Odense C, Denmark and 6Steno Diabetes Center Copenhagen, Herlev, Denmark

Background and Aims: The increasing global burden of kidney failure calls for targeted interventions to slow progression of chronic kidney disease (CKD). However, the understanding of progression from CKD stage G3 is limited. We aimed to characterise individuals with incident CKD stage G3 in Denmark and to examine CKD progression defined by three different measures.

Method: We conducted a nationwide, population-based cohort study using routinely collected individual-level data from national health and administrative databases in Denmark (population ~5-9 million). Using creatinine tests performed in general practice and the outpatient hospital setting from 1 January 2017 to 31 December 2020, we included all adults in Denmark with incident CKD stage G3, based on the Kidney Disease: Improving Global Outcomes (KDIGO) criteria (≥2 creatinine measurements corresponding to an estimated glomerular filtration rate (eGFR) between 30-59 ml/min/1.73 m² separated by ≥90 days). We used the 2009 CKD Epidemiology Collaboration Creatinine Equation for calculating eGFR. The three years leading up to the study period constituted a washout period to minimize inclusion of patients with prevalent CKD. We explored CKD progression based on three outcome measures of different sensitivity, including 1) rapid CKD progression (decline in eGFR of ≥5 ml/min/1.73 m²/year, that is, for each eGFR measurement taken during follow-up, we considered this and the measurements taken in the prior year (requiring ≥2 eGFR measurements separated by ≥90 days)); 2) drop in GFR category (drop between GFR categories, 45–59 [G3a], 30–44 [G3b], 15–29 [G4], <15 [G5] ml/min/1.73 m², accompanied by ≥25% drop in eGFR from baseline); and 3) kidney failure (≥2 eGFR measurements <15 ml/min/1.73 m² separated by 90 days and/or kidney replacement therapy). The 1- and 3-year risks of CKD progression according to the three definitions and all-cause mortality were examined as cumulative incidences using the Aalen-Johansen method.

Results: We included 133,443 individuals with incident CKD stage G3. The median age at inclusion was 75 years (interquartile range (IQR): 69-82) and 55% were females with 59% having hypertension, 18% having diabetes and 10% having heart failure. The median eGFR at inclusion was 56 ml/min/1.73 m² (IQR: 51-58) and the median number of eGFR measurements was 3 (IQR: 2-5) in the prior year. Among the 133,443 individuals with incident CKD stage G3, 48,997 (37%) fulfilled the criteria for rapid CKD progression at inclusion. Among the 84,446 individuals without rapid progression on the day of inclusion, the 1- and 3-year risks of rapid CKD progression were 25.0% (95% confidence interval (CI): 24.7-25.3) and 46.0% (95% CI: 45.6-46.4), respectively. The risk of a drop in GFR category was 6.9% (95% CI: 6.8-7.1) after 1 year and 16.6% (95% CI: 16.4-16.8) after 3 years. The risks of kidney failure/renal replacement therapy were 0.1% (95% CI: 0.1-0.1) and 0.3% (95% CI: 0.3-0.4) after 1 and 3 years, respectively. All-cause mortality was 6.8% (95% CI: 6.7-6.9) in the first year and the 3-year mortality was 18.1% (95% CI: 17.9-18.4) (Table 1).

Background and Aims: Many uremic toxins (UTs) originate from gut microbiome, and contribute to chronic kidney disease (CKD) progression and cardiovascular morbidity. In order to reduce uremic symptoms and CKD progression, patients have several dietary restrictions, which may influence gut microbiome composition, and impact UTs production. An altered microbiome may contribute to UTs increase in those patients. However, the role of key bacterial taxa in producing UTs and the impact of diet on UTs variance in non-dialysis patients are not well known. The objectives of this study were, first, to compare microbial features between CKD patients and healthy controls, and, second, to investigate the relation of gut microbiome with uremic toxicity, as well as the potential impact of diet on such relationship.

Method: Characterization of gut metagenomes, 10 UTs and 3 precursors’ serum concentrations by LC-MS/MS, host characteristics and diet were obtained from 240 non-dialysis CKD patients from the CKD-REIN cohort (mean ± SD): age: 68 ± 11 years, 71% male, estimated glomerular filtration rate (eGFR): 33.2 ± 12.7 ml/min/1.73m². First, to identify microbial biomarkers characterizing the gut microbiome-related toxicity in CKD, we compared microbiome features between 78 CKD patients and 78 age-, sex-, and BMI-matched healthy controls from the Milieu Interieur (MI) cohort: age: 58 ± 13 years, 71% male, eGFR: 89 ± 13. Second, we performed a multomics’ data integration analysis via a supervised modelling to investigate cross-sectionally the association between host characteristics, gut microbiome, UTs, and diet-related features according to CKD severity (eGFR <30, n = 110 vs eGFR ≥30 ml/min/1.73m², n = 130).
Results: Compared to healthy controls, CKD patients had a significant reduced gut microbiome health index. Several Metagenomic Species Pan-genomes (MSPs) were significantly contrasted between M1 and CKD cohorts: 43 species were enriched in CKD patients vs 24 in controls. Species most enriched in CKD patients included several UTs producers such as Lachnospiraceae spp., Dysosmobacter – Oscillibacter spp, Butyricimonas fecalisomibins, Viciafilavis vadensis and Hungatella spp, some of which were positively correlated with the following UTs: 3-Carboxy-4-methyl-5-propyl-2-furanpropionate (CMPP), trimethylamine-N-oxide (TMAO), and indole-3-acetic acid (3-IAA). Moreover, species belonging to Enterocloster and Hungatella genera (both members of Lachnospiraceae family) were found to be negatively correlated with eGFR. Among species associated with CKD severity, species carrying genes for UTs production were observed such as Desulfovibrio faecalisomibins, Bacteroides clarus and Blautia obeum along with increasing alcohol and hot drinks consumption, CRP and several UTs (kynurenic acid, indoxyl sulfate and Phenylacetylglutamine) levels. In contrast, some taxa like Faecalibacterium prausnitzii and Dysosmobacter wellbi was associated with ileum intake but not with UTs.

Conclusion: Our study highlights an alteration of gut microbiome in CKD patients compared to healthy controls, with increased abundance of UTs producer species. The results of the multidimensional data integration modelling suggest a strong interplay between food intake, gut microbiome modifications, UTs accumulation and clinical features. These findings might open to promising therapeutic strategies to reduce microbiome-related toxicity.

METABOLIC BLOOD BIOMARKER PROFILING FOR CHRONIC KIDNEY DISEASE PREDICTION – EVIDENCE FROM 275,000 INDIVIDUALS IN THE UK BIOBANK

Heli Julkunen
Nightingale Health Plc, Finland

Background and Aims: Early identification of individuals at high risk of developing chronic kidney disease and other chronic conditions is essential for targeted prevention. Here, we assess the utility of metabolic blood biomarkers in predicting the onset of chronic kidney disease in over 250,000 individuals from UK Biobank, beyond established risk factors and polygenic risk scores.

Method: Circulating blood biomarkers, including lipids, fatty acids, amino acids, glycolysis metabolites and inflammation markers were measured by a low-cost nuclear magnetic resonance (NMR) metabolomics assay in around 275,000 plasma samples from the UK Biobank. During a prospective 10-year follow-up, over 6000 incident chronic kidney disease events were obtained from national health registries. Using multivariable regression modelling, we derived a 10-year risk score for chronic kidney disease onset. We assessed the predictive performance of the biomarker risk score in comparison to standard risk factors (age, sex, prevalent diabetes, body mass index, systolic and diastolic blood pressure, smoking status and use of cholesterol lowering medication), clinical chemistry measurements (HbA1c, LDL and HDL cholesterol, total cholesterol and eGFR) and polygenic risk scores. We evaluated the performance of the risk score in two practical scenarios: in a general population screening setting and in a clinical use case of stratifying kidney disease risk among prevalent type 2 diabetics. Among diabetics with mildly to moderately decreased kidney function at the time of blood sampling (eGFR 60-90), adding the metabolic biomarkers in a comprehensive model including standard risk factors, clinical chemistry measurements and polygenic risk scores increased the AUC from 0.60 to 0.70.

Conclusion: Circulating metabolic biomarkers enhanced the prediction of chronic kidney disease onset beyond standard risk factors and polygenic risk scores. From a translational perspective, this may complement the identification of high-risk individuals in both general population and clinical settings beyond current risk factor assessment, while simultaneously informing on the risk of other chronic diseases.

CARDIOVASCULAR AND MORTALITY RISKS IN YOUNG HEALTH SCREENING EXAMINEES WITH MARGINAL ESTIMATED GLOMERULAR FILTRATION RATE

Minsang Kim1, Dong Ki Kim2, Jung-Hyun Kim3, Kwon Wook Joo2 and Sehoon Park1

1Seoul National University Hospital, Rep. of South Korea, 2Seoul National University Hospital, Rep. of South Korea and 3PaiChai University, Rep. of South Korea

Background and Aims: Additional evidence is necessary to interpret the kidney function parameters in young adults, particularly in those with marginal eGFR values. We aimed to study the clinical significance of marginal eGFR values in large-scale general health screening examinees of young age (20-39 years).
Method: We performed a nationwide retrospective cohort study using the health screening database of South Korea. We included young adults aged 20-39 years without a history of major cardiovascular events (MACE) or end-stage kidney disease who underwent a nationwide health screening in 2012. The study exposure was eGFR categorized into 15 mL/min/1.73 m² intervals, with a reference group and a main group of interest: < 30, 30-45, 45-60, 60-75, 75-90 (reference), 90-105, 105-120, and ≥ 120 mL/min/1.73 m². The risks of all-cause mortality and MACE were calculated using Cox regression analysis adjusted for various clinicodemographic characteristics.

Results: In total, 3,132,409 young adults were included in this study. During a median follow-up of 7.3 years, marginal eGFR (60-75 mL/min/1.73 m²) was not significantly associated with a higher risk of all-cause mortality [adjusted HR 0.92 (0.86-0.99)]. The results were similarly identified for the MACE outcome [adjusted HR 1.01 (0.94-1.07)]. On the other hand, those with presence of albuminuria, even the marginal eGFR range was significantly associated with higher risks of all-cause mortality [adjusted HR 1.52 (1.01-1.29)] and ischemic stroke [adjusted HR 1.73 (1.10-2.74)].

Conclusion: Marginal eGFR alone was not associated with higher risks of all-cause mortality and MACE in general young adults. However, in those with albuminuria, the mortality risk was higher even in eGFR of 60-75 mL/min/1.73 m².

THE ASSOCIATION OF INTERLEUKIN-6 TO ALBUMIN RATIO WITH MORTALITY IN PATIENTS WITH KIDNEY FAILURE
Xiejia Li1,2, Abdul Rashid Tony Qureshi1, Mohamed Suliman1, Olof Heimbürger1, Franz Peter Barany1, Peter Stenvinkel1 and Bengt Lindholm1

1Karolinska Institutet, Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden and 2The 2nd Xiangya Hospital of Central South University, Department of Nephrology, Changsha, P.R. China

Background and Aims: Systemic inflammation - characterized by high interleukin-6 (IL-6) and low albumin circulating concentrations - associates with worse outcomes in patients with kidney failure (KF). We examined the value of IL-6 to albumin ratio (IAR) to stratify risk of death in KF patients.

Method: In 435 incident dialysis patients (median age 56 years, 61.8% male, 31% diabetes mellitus (DM), 38.4% cardiovascular (CV) disease (CVD)), plasma IL-6 and albumin were measured at baseline to calculate IAR. We performed receiver operating characteristic curve (ROC) to compare the discriminatory performance of albumin, IL-6 and IAR for predicting all-cause and CV mortality. We divided patients into IAR tertiles and analysed: 1) cumulative incidence of all-cause mortality and CV mortality censored for renal transplantation during follow up of up to 60 months; 2) the association of IAR and all-cause and CV mortality risk according to Fine-Gray analysis taking renal transplantation as competing risk; and 3) the restricted mean survival time (RMST) and differences of RMST (ΔRMST) between IAR tertiles to describe quantitative differences of survival time.

Results: Among 435 patients, 146 patients (33.6%) died, and 175 (40.2%) patients underwent renal transplantation during median 24.9 months of follow-up; 83 (56.8%) of the 146 deaths were due to CVD. The area under the ROC curve (AUC) of IAR (0.696 for all-cause mortality; 0.657 for CV mortality) was higher than that of both albumin and IL-6. As shown in Fig. 1 A and B: 1) the cumulative incidence of all-cause and CV mortality of patients in middle and high IAR tertiles was significantly higher than in low IAR tertile; 2) higher IAR associated with higher risk of all-cause (sub-hazard ratio (shR) 1.93, 95% confidence interval (CI) 1.22-3.06 for high IAR tertile) and CV mortality (shR 1.99, 95% CI 1.03-3.87 for middle IAR tertile) risk after adjusting for age, sex, DM, CVD, and smoking; and 3) ΔRMST at 59 months showed shorter survival time in middle and high IAR tertiles compared with low IAR tertile for all-cause (ΔRMST -6.21 months for middle vs low tertile; ΔRMST -11.4 months for high vs low tertile) and CV mortality (ΔRMST -4.73 months for middle vs low tertile; ΔRMST -7.49 months for high vs low tertile).

Conclusion: Higher IAR was independently associated with significantly higher all-cause and CV mortality risk in KF patients. These results suggest that IAR may provide useful prognostic information in patients with KF.
**Figure 1:** Cumulative incidence of all-cause mortality (A) and CV mortality (B) censored for renal transplantation in IAR tertiles. Taking LT as reference, sHR of HT and MT, $\Delta$RMST at 59 months for HT and MT after adjusting for age, sex, DM, CVD and smoking are shown. Abbreviations: IAR, interleukin-6 to albumin ratio; LT, low tertile; MT, middle tertile; HT, high tertile; CV, cardiovascular; DM, diabetes mellitus; CVD, cardiovascular disease; $\Delta$RMST, difference in restricted mean survival time.

**REVEAL-CKD: PREVALENCE OF UNDIAGNOSED STAGE 3 CHRONIC KIDNEY DISEASE IN AUSTRALIA, BRAZIL, CANADA AND SPAIN**

Roberto Pecoits-Filho¹, Maria Cristina Ribeiro de Castro¹, Ana Cebrian³, Rafael Santamaría³, Kean-Seng Lim⁵, Eric Wittbrodt⁶, Salvatore Barone⁷, Matthew Arnold⁸ and Navdeep Tangri⁹

¹Pontifical Catholic University of Paraná, Curitiba Campus, Brazil, ²Hospital das Clínicas of the University of São Paulo, Brazil, ³Cartagena Casco Health Center, Servicio Murciano de Salud, Murcia, Spain, ⁴Hospital Universitario Reina Sofia, Córdoba, Spain, ⁵Mount Druitt Medical Centre, Mount Druitt, Australia, ⁶AstraZeneca, Wilmington, United States of America, ⁷AstraZeneca, Gaithersburg, United States of America, ⁸AstraZeneca, Cambridge, United Kingdom and ⁹University of Manitoba, Winnipeg, Canada

**Background and Aims:** Chronic kidney disease (CKD) is a progressive condition that affects >850 million people globally. Global clinical guidelines from KDIGO recommend early CKD identification and management to mitigate disease progression. The REVEAL-CKD study aims to assess the prevalence of, and factors associated with, undiagnosed stage 3 CKD across 11 countries. Here we report data from 4 countries in 4 continents.

**Method:** REVEAL-CKD is a multi-national, observational study, using secondary data from electronic medical records (EMR) and claims data. For this analysis, data were extracted from Australian General Practices through Pen CS (Australia), University of Sao Paulo (Brazil), the Canadian Primary Care Sentinel Surveillance Network (CPCSSN) (Canada), and BIGPAC (Spain). The study cohort included patients aged ≥18 years with two consecutive estimated glomerular filtration rate (eGFR) values ≥30 and <60 mL/min/1.73 m² recorded 91-730 days apart. The date of the second qualifying eGFR was the index date. Patients with no CKD diagnosis code before and up to 6 months after their index date were considered undiagnosed. The prevalence of undiagnosed CKD was calculated as the ratio of undiagnosed patients to all patients meeting the study inclusion criteria.

**Results:** The prevalence and baseline characteristics of undiagnosed Stage 3 CKD appear in Table 1. In all 4 countries, the undiagnosed prevalence was >80% and predominantly was more commonly observed in female patients, in patients aged >65y, and remained high in patients with baseline comorbidities, particularly for those at highest risk of CKD (DM, CVD, HTN). Underreporting of CKD diagnosis in Brazil may be due to the inability to code for >1 condition in a patient.

**Conclusion:** These results indicate that a large proportion of patients across four world regions and who have biochemical evidence of early CKD lack a recorded diagnosis. An opportunity exists to identify, diagnose, and implement guideline-directed management for early CKD in order to delay its complications and improve clinical outcomes.

GENETIC SUSCEPTIBILITY AS AN EFFECT MODIFIER FOR THE ASSOCIATION BETWEEN CHRONIC KIDNEY DISEASE AND RISK OF VENOUS THROMBOEMBOLISM

Jingwen Zhang1, Ying Shan2, Beini Liu3, Liang Dai2, Congying Song2, Juan Jesus Carrero4, Zuying Xiong1 and Xiaoyan Huang1

1Peking University Shenzhen Hospital, Renal Division, Shenzhen, P.R. China, 2Peking University Shenzhen Hospital, Clinical Research Academy, Shenzhen, P.R. China, 3Southern University of Science and Technology, Department of Statistics and Data Science, Shenzhen, P.R. China and 4Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden

Background and Aims: The association between chronic kidney disease (CKD) and the risk of developing venous thromboembolism (VTE) is still controversial. Further, it is unknown if genetic predisposition modifies this relationship. This study was conducted to investigate plausible effect modification of genetic factors on the association between CKD and incident VTE.

Method: Population-based cohort study of the UK Biobank, including 397,658 participants of European ancestry that were free of VTE at recruitment. We used cystatin C combining creatinine estimated glomerular filtration rate (eGFR) and albuminuria to classify participants with CKD stages 1-5 according to the low, intermediate, and high/very high-risk groups suggested by KDIGO (Kidney Disease: Improving Global Outcomes). Cox proportional hazards model was applied to evaluate the associations of CKD with incident VTE. In addition, we used externally validated polygenic risk score (PRS) for VTE to evaluate whether the genetic predisposition modified the associations of interest.

Results: During median follow-up of 12.7 years, 11,372 participants developed VTE. As compared with low KDIGO risk category, covariate-adjusted hazard ratios (HR) and 95% confidence intervals (CI) for future VTE risk with intermediate and high/very high KDIGO risk categories at baseline were 1.278 (1.191-1.372) and 1.892 (1.658-2.159), respectively. Participants at high/very high risk of CKD prognosis and in the highest tertile of PRS had the highest risk of developing VTE (HR, 4.397; 95% CI, 3.639-5.313), and this group had shown the most conspicuous additive interactions between CKD and the genetic predisposition, which responsible for 1.389-fold relative excess risk and accounted for 31.6% of incident VTE. Also, when either eGFR or urine albumin-creatinine ratio (ACR) was treated as the exposure, similar associations and supra-additive interactions were yielded.

Conclusion: CKD is associated with future VTE, especially in those with high genetic risk.
Additive interaction between the KDIGO risk category and genetic susceptibility on venous thromboembolism risk. Abbreviations: AP, attributable proportion; CKD, chronic kidney disease; PRS, polygenic risk score; RERI, relative excess risk due to interaction; VTE, venous thromboembolism. Reference was the group of low polygenic risk score and low risk of chronic kidney disease prognosis. All models were adjusted for age, sex, highest attained education, Townsend deprivation index, smoking, alcohol consumption, metabolic equivalents of physical activity, body mass index, hypertension, diabetes, cardiovascular diseases other than hypertension, cancer, cholesterol-lowering medications, anticoagulants, antiplatelet agents, top 20 principal components of ancestry, and genotyping batch.

THE GROWING BURDEN OF CHRONIC KIDNEY DISEASE IN THE UK: AN IMPACT CKD ANALYSIS
Juan Jose Garcia Sanchez1, David C. Wheeler2, Stephen Brown1, Stacey Priest3, Hannah Guiang3, Charlotte Johnston Webber4, George Wharton4, Salvatore Barone1 and Daniel Grima3
1BioPharmaceuticals, AstraZeneca, Cambridge, United Kingdom, 2University College London, Department of Renal Medicine, London, United Kingdom, 3EVERSANA, Value & Evidence, Burlington, Canada and 4London School of Economics and Political Sciences, London, United Kingdom

Background and Aims: Chronic kidney disease (CKD) is a major source of morbidity and mortality, with an increasing incidence and prevalence worldwide. Patients with CKD experience diminished quality of life associated with increased risk of cardiovascular (CV) events, acute kidney injury (AKI), and reduced renal function. Late-stage CKD (stage 5) is also associated with significant economic burden related to renal replacement therapy (RRT). Public health and policy planning should consider the broader burden of CKD, including its societal and environmental burden, in addition to its clinical impacts and direct costs. Hence, IMPACT CKD aims to quantify the clinical, economic, humanistic, societal, and environmental burden of CKD in the United Kingdom (UK).

Method: A patient-level simulation model was developed to simulate the UK population using parameter data from published literature, national statistics, and health surveys. Individuals were assigned key characteristics associated with CKD, such as estimated glomerular filtration rate (eGFR), albuminuria, co-morbidities (e.g., diabetes, hypertension, heart failure), and prior CV events (e.g., myocardial infarction and stroke). Individuals were categorized as not having CKD (i.e., non-CKD) or CKD stage 1, 2, 3a, 3b, 4 or 5, based on their eGFR and albuminuria levels. Among those with CKD, patients were either classified as diagnosed or undiagnosed. Progression through the CKD stages was predicted by the simulated patient’s annual eGFR rate of decline. Risk of CV and AKI events, as well as co-morbidity development were also considered in the model. Clinical progression and outcomes for the CKD population were simulated over 10 years. CKD prevalence was projected by stage and diagnosis status, as well as associated CKD and RRT costs, productivity losses from patients and caregivers, and environmental impacts as determined by CO2 emissions. Extensive validation and calibration was conducted.

Results: From 2022 to 2032, the prevalence of CKD is expected to increase by 4% from 8.27 million to 8.61 million people in the UK. Growth in the CKD population is driven by eGFR decline and increases in albuminuria, related to kidney function decline and AKI as the model population ages. In 2032, the prevalence of CKD by stage is projected to be 30.36%, 21.07%, 29.78%, 11.86%, 4.15%, and 2.78% in stage 1, 2, 3a, 3b, 4, and 5 patients, respectively. The diagnosed CKD population is projected to be 32.43% of the total CKD population and is primarily composed of CKD stage 3a/b, 4, and 5 patients in 2032. Patients with CKD receiving RRT are projected to increase by 4% from 73,365 in 2022 to 105,860 in 2032. The increase in late-stage CKD population is associated with an increase in RRT costs from £1.09 billion in 2022 to £1.85 billion in 2032. Over the 10-year time horizon, CKD is projected to result in 81.60 million missed workdays in diagnosed patients with CKD, and 11.89 million missed workdays by caregivers of patients with CKD. Environmental impacts equivalent to 1.35 million tonnes of CO2 emissions for patients receiving in-centre hemodialysis are predicted; however, the total environmental impact would likely be larger if the total CKD care pathway was included.

Conclusion: The IMPACT CKD model forecasts the prevalence and burden of CKD to remain high in the UK over the next ten years. In addition to the significant clinical burden and direct costs, CKD was also associated with extensive productivity loss and detrimental environmental impact. The model provides a validated framework for testing the sensitivity of the projections to data uncertainty, thereby identifying areas for further research.
THE ASSOCIATION BETWEEN POTASSIUM INTAKE AND RISK OF
CHRONIC KIDNEY DISEASE
Seung Hyeok Han, Hae-Ryong Yun and Hyo Jeong Kim
Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Rep. of South Korea

Background and Aims: High potassium intake is closely related to lower risk of cardiovascular disease. However, the association between potassium intake and chronic kidney disease (CKD) development in the general population is uncertain.

Method: From UK biobank cohort, we included 317,162 participants without CKD between 2006 and 2010. The main predictor was spot urine potassium-to-creatinine ratio (KCR) as a surrogate of potassium intake. The primary outcome was incident CKD, defined based on ICD-10 and OPCS-4 codes. For secondary analysis, we included 141,180 participants who completed 24-h dietary recall questionnaire and dietary potassium intake was an additional predictor.

Results: At baseline, individuals with higher KCR had lower levels of blood pressure, BMI, and inflammation, and were less likely to have diabetes and hypertension than those with lower KCR. During a median follow-up of 11.9 years, the primary outcome events occurred in 15,255 (4.8%) participants. In competing risk model, adjusted hazard ratio (aHR) per 1-SD increase in KCR for incident CKD was 0.90 (95% confidence interval [CI], 0.89-0.92). In addition, compared with quartile 1 of KCR, the aHRs (95% CIs) for second, third, and fourth quartile were 0.98 (0.94–1.02), 0.90 (0.86–0.95), and 0.80 (0.76–0.84), respectively. In secondary analysis, higher potassium consumption was also inversely associated with risk of CKD. Compared with quartile 1 of dietary potassium intake, the corresponding aHRs (95% CIs) for each quartile were 0.85 (0.78–0.92), 0.73 (0.67–0.81), and 0.67 (0.60–0.75), respectively.

Conclusion: Higher urinary potassium excretion and potassium intake were associated with lower risk of incident CKD.

| Model 3                         | 0.88 (0.86 – 0.91)              | <0.001                          | Reference                       | 0.89 (0.82 – 0.96)              | 0.002                           | 0.78 (0.72 – 0.85)              | <0.001                          | 0.74 (0.68 – 0.81)              | <0.001                          |
| Model 4                         | 0.83 (0.79 – 0.87)              | <0.001                          | Reference                       | 0.85 (0.78 – 0.92)              | <0.001                          | 0.73 (0.67 – 0.81)              | <0.001                          | 0.67 (0.60 – 0.75)              | <0.001                          |

Model 1: unadjusted.
Model 2: age, sex, race, town deprivation index, alcohol, smoking, handgrip strength, systolic blood pressure, medical history of cardiovascular disease, and diabetes, medications including RAAS blockers, diuretics, and statin.
Model 3: Model 2 plus laboratory parameters including hemoglobin, albumin, total cholesterol, log transformed hs-CRP
Model 4: Model 3 plus dietary intake including energy, fiber, protein, sodium.
PATIENT-REPORTED MENTAL HEALTH PROBLEMS, SUICIDE IDEATION, AND CLINICAL OUTCOMES IN ADULTS WITH NON-DIALYSIS CKD: RESULTS OF THE KNOW-CKD STUDY

Kyu-Beck Lee, Jihyun Yang and Young Youl Hyun

Division of Nephrology, Department of Internal Medicine, Seoul, Rep. of South Korea

Background and Aims: Mental health is important for health and well-being at every stage of life and disease. Mental health problems are common and bothersome in chronic kidney disease (CKD). Mental health problems of CKD are poorly understood and evaluated. To address the importance of mental health in CKD, we analyzed a prospective cohort database from prospective CKD cohort.

Method: We analyzed 1897 participants from the KNOW-CKD cohort. We evaluated 4 items as indicators of patient-reported mental health: sleep duration, perceived stress, depressive symptoms, and suicidal ideation. To facilitate interpretation of the mental health problems in CKD, we measure a scaled effect size (ES) for the Kidney Disease Quality of Life Short Form (KDQOL-SF) differences among the groups of mental health problems. We investigated the association between patient-reported mental health problems and clinical outcomes of incident end-stage kidney disease (ESKD) all-cause death in non-dialysis CKD.

Results: The mean age was 53 ± 12 years and 62% were male. The participants had mental health problems of inadequate sleep duration (17.4%), subject distress (27.3%), experience of depression (13.2%), and suicide ideation (16.8%), but had not well taken care (psychiatric counselling 1.9%, antidepressant therapy 2.8%). The 4 item indicators of mental health showed large effect size between-groups KDQOL mental component summary (ES = 1.67). In the fully adjusted Cox proportional model, poor mental health (≥2 mental health problems) was associated with high risk of ESKD [HR = 1.46; 95% CI (1.18~1.08)] and death [HR = 1.55; 95% CI (1.04~2.32)] compared to good mental health (no mental health problems). Among 4 item indicators of patient-reported mental health, suicide ideation was the most predictive indicator of clinical outcomes.

Conclusion: Mental health problem is common and undertreated in CKD. Poor mental health is associated with high risk of ESKD and death in non-dialysis CKD and the single question of suicide ideation is significantly associated with high risk of ESKD and death. It suggests that the evaluation and management of mental health problem is important to the clinical outcomes in CKD.

THE 2021 CKD EPI GLOMERULAR FILTRATION RATE ESTIMATING EQUATION AND RISK OF HOSPITALIZATION FOR KIDNEY DISEASE

Cynthia Lim1, Ngiap Chuan Tan2, Jason Choo1, Hanis Abdul Kadir3, Andrew Ang2 and Chieh Suai Tan1

1Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore, 2SingHealth Polyclinics - Pasir Ris, Singapore, Singapore and 3Singapore General Hospital, Health Services Research Unit, Singapore, Singapore

Background and Aims: The revised Chronic Kidney Disease Epidemiology Collaboration (CKD EPI) equation for estimated glomerular filtration rate (eGFR) reduced CKD prevalence among Asians, but few studies have evaluated its impact on healthcare utilization. We aimed to evaluate the impact of the 2009-eGFRcr(ASR) [1] and 2021-eGFRcr(AS) [2] equations on the risk of hospitalization for kidney disease among multi-ethnic Asians.

Method: Retrospective cohort study of adults who consulted at Singapore's largest healthcare cluster of public healthcare institutions and had a baseline serum creatinine performed in 2014. eGFR was calculated using both eGFRcr(ASR) [1] and 2021-eGFRcr(AS) [2] equations and categorized as G1 (≥ 90 ml/min/1.73 m²), G2 (60-89 mL/min/1.73 m²), G3A (45-59 mL/min/1.73 m²), G3B (30-44 mL/min/1.73 m²), G4 (15-29 mL/min/1.73 m²), G5 (< 15 mL/min/1.73 m²). Electronic medical records were used to identify baseline demographic and clinical information, and the outcome of hospitalization for kidney disease including acute kidney injury, chronic kidney disease, dialysis or transplant in the next three years until December 2017. Multi-variable logistic regression models were used to compare the impact of the eGFR equations on risk of hospitalization for kidney disease. Model discrimination was assessed using the area (AUC) under a receiver operating characteristic (ROC) curve.

Results: Among 33007 Asian adults included in the study, the median age was 69.0 years (interquartile range 63.0, 76.0). The majority were Chinese (79.5%; Indian 7.2%, Malay 10.2% and other race 3.2%), female (53.3%), had diabetes (56.4%) and received statin therapy (71.6%) at baseline. Hospitalization for kidney disease occurred in 1915 (7.1% of 26874 individuals) after excluding those with missing covariates (n = 5133). Hospitalization incidence increased with worsening kidney function (Table 1) regardless of the estimation equation used. After adjusting for age, sex, ethnicity, comorbidities (cardiovascular disease, diabetes, hypertension, cancer, systolic and diastolic blood pressure, body mass index) and medications (statin, ACE inhibitor, angiotensin receptor blocker, loop and thiazide diuretic), eGFR categories were independently associated with hospitalization for both eGFR equations (Table 2). Compared
to G1, the risks of hospitalization for G2, G3A, G3B and G4 were incremental
at approximately 2, 6, 10 and 20 times, respectively, while the risk of
hospitalization for G5 was 100 times that of G1. The AUCs were 0.859 (95% CI:
0.849-0.869) for the model with eGFRcr (ASR) and 0.861 (95% CI: 0.852-
0.871) for 2021-eGFRcr (AS) but the difference was not significant (p = 0.11).
Conclusion: Lower eGFRs ascertained by both the 2009 eGFRcr(ASR) and
2021-eGFRcr(AS) equations were independently associated with greater risks
of hospitalization for kidney disease. The revised 2021-eGFRcr(AS) equation
did not significantly alter model discrimination.

PRE-DIALYSIS TRAJECTORIES OF ESTIMATED GFR AND
CONCURRENT TRENDS OF CKD-RELEVANT BIOMARKERS
Hsiao-Mei Tsao1, Tai-Shuan Lai 1, Shuei-Liong Lin 2, Yu-Hsiang Chou1 and Yung-Ming Chen1
1 National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, Rep.
of China and 2 National Taiwan University College of Medicine, Physiology,
Taipei, Taiwan, Rep. of China

Background and Aims: The glomerular filtration rate (GFR) decline varies
in patients with advanced chronic kidney disease (CKD), and the concurrent
changes in CKD-related biomarkers are unclear.
Method: We adopted a group-based trajectory model to categorize CKD patients by their pre-dialysis eGFR trajectory and then analyzed the concurrent changing trends of CKD-relevant biomarkers, including urine protein-creatinine ratio (UPCR), albumin, and uric acid.
Results: Using longitudinal data from two years before dialysis initiation, 1,758 CKD patients were included. We identified three distinct eGFR trajectories: persistently low eGFR levels, progressive loss of eGFR, and accelerated loss of eGFR. Eight of the 15 biomarkers showed distinct patterns among the trajectory groups. Compared to the group with persistently low eGFR values, the other two groups were associated with a more rapid increase in the serum urea level and UPCR, especially in the year before dialysis initiation, and a more rapid decline in hemoglobin and platelet counts. Rapid eGFR decline was associated with lower levels of albumin and potassium, and higher levels of MCHC and WBC. The albumin level in the group with an accelerated loss of eGFR was below the normal range. Rapid eGFR decline was associated with lower levels of albumin and potassium, and higher levels of MCHC and WBC. The albumin level in the group with an accelerated loss of eGFR was below the normal range. Overall, there was a total of 691 (39.3%) deaths observed during the follow-up period. In the 2-year and 5-year follow-up, 302 (17.2%) and 549 (31.2%) deaths were observed, respectively. The corresponding median follow-up times were 2 years (IQR:1.6 – 2.0) and 3.3 years (IQR:1.6 –5.0). Kaplan–Meier survival plots showed that the eGFR trajectory was significantly associated with the risk of mortality two years and five years after dialysis, with the log-rank test P = .0057 and P = .0001, respectively.
Conclusion: The changes in CKD biomarkers were delineated with disease progression. The results provide information to clinicians and clues to elucidate the mechanism of CKD progression.
Table 1: Event rates for ESKD were low in general (0.03 to 0.51 per 100 PY) except for individuals with eGFR < 30 ml/min (2.1 to 3.5 per 100 PY). Annual monitoring of eGFR was high in all groups (>90%) with increasing frequency in individuals with impaired kidney function, and measurement of UACR was low in groups with non-diabetic CKD (10-30%). Antihypertensive treatment was frequently prescribed in eGFR < 30 ml/min; overall 87.6% and 94.8% with coexisting diabetes and 92.8% with coexisting heart failure. The use of RAS inhibition was more used in diabetes and in heart failure (>50%) but less with low eGFR. Statin therapy was used in approximately 50% of individuals with diabetes, regardless of CKD group, but was used to a much less extent in non-diabetic CKD (20-24%).

CHRONIC KIDNEY DISEASE WITH COMORBIDITY IN PRIMARY CARE: CARDIORENAL TREATMENT, QUALITY OF CARE AND PROGNOSIS
Rikke Borg1,2, Margit Kriegbaum3, Christen Lykkegaard Andersen1,3,4 and Frederik Persson5
1Zealand University Hospital, Department of Nephrology, Roskilde, Denmark, 2Institute of Clinical Medicine, University of Copenhagen, København N, Denmark, 3The Research Unit for General Practice and Section of General Practice, Department of Public Health, København Ø, Denmark, 4Copenhagen University Hospital, Department of Hematology, København Ø, Denmark and 5Steno Diabetes Center Copenhagen, Herlev, Denmark

Background and Aims: Diabetes, heart failure, hypertension and cardiovascular disease are common in primary care, and frequently coexist with impaired kidney function (CKD), further increasing risk of cardiovascular and renal events as well as premature death. These comorbidities therefore call for more complex treatment regimens and monitoring. Our aim was to describe the prevalence, management, and prognosis of individuals with CKD and additional comorbidity in a large primary care cohort.

Method: Individuals were included from the Copenhagen Primary Care Laboratory (CopLab) Database, which contains 112 million biochemistry results from persons followed in primary care between 2000 and 2015 and divided into three groups based on (CKD-EPI) eGFR (>60 ml/min, 30-59 ml/min and <30 ml/min) with or without comorbidity in the form of diabetes or heart failure. We included all individuals with at least two measurements of creatinine. The date of the second measurement of creatinine was considered index date (baseline). The database has been combined with pharmacological data (The Danish National Prescription Registry), outpatient clinic visits and hospitalizations (The Danish National Patient Registry - NPR), and mortality information (The Danish Civil Registration System). Heart Failure was defined by ICD-codes in NPR from outpatient clinic visits and hospitalizations and we calculated crude event rates for a range of outcomes according to comorbidity. Diabetes was defined as at least one measurement of plasma or serum glucose ≥11 mmol/l or HbA1c ≥48 mmol/mol in CopLab. We evaluated monitoring of eGFR, albuminuria (UACR) and use of guideline-recommended pharmacological therapy (i.e. RAS-blockers and statins) in each group.

Results: In the total primary care population of 171,134 individuals of which 63.8% were female, 8.3% had impaired kidney function (eGFR <60 ml/min), and measurement of UACR was high in all groups (>90%) with increasing frequency in individuals with impaired kidney function, and measurement of UACR was low in groups with non-diabetic CKD (10-30%). Antihypertensive treatment was frequently prescribed in eGFR < 30 ml/min; overall 87.6% and 94.8% with coexisting diabetes and 92.8% with coexisting heart failure. The use of RAS inhibition was more used in diabetes and in heart failure (>50%) but less with low eGFR. Statin therapy was used in approximately 50% of individuals with diabetes, regardless of CKD group, but was used to a much less extent in non-diabetic CKD (20-24%).

Conclusion: Our data from a large primary care cohort demonstrate a high prevalence of coexisting diabetes and/or heart failure with CKD, increasing the risk for adverse outcomes. The quality of CKD care in general practice may be improved, especially in the non-diabetic population.
ASSOCIATION BETWEEN BODY MASS INDEX, WAIST CIRCUMFERENCE AND CLINICAL OUTCOMES IN KOREAN ADVANCED CHRONIC KIDNEY DISEASE PATIENTS

Ji Hye Kim, Dha Woon Im, Yeongwon Park, Minsang Kim, Eunjee Kang, Yujin Jeong, Hyanglim Lee and Kook-Hwan Oh

1Chungbuk National University Hospital, Cheongju, Rep. of South Korea, 2Seoul National University Hospital, Rep. of South Korea and 3Korea University, Rep. of South Korea

Background and Aims: This study analysed the association between body mass index (BMI) and waist circumference (WC) with all-cause death, 3-point major cardiovascular event (MACE), end-stage kidney disease (ESKD) and total composite events in nation-wide cohort of Korean advanced chronic kidney disease (CKD) patients.

Method: This nationwide cohort study, using the National Health Insurance Database, included adult health examinees who received two or more check-ups from 2009 to 2012. Among them, CKD patients (N = 325,657, stage G3a, G3b and 4) were identified. Patients were classified into three groups for BMI (<18.5, 18.5-25 [reference] and ≥25) and four groups for WC (female; <75 cm or male; <85 cm [WC1], male; 75 cm ≤ WC <85 cm or male; 85 cm ≤ WC <95 cm [reference], female; 85 cm ≤ WC <95 cm, male; 95 cm ≤ WC <105 cm [WC2] and male; ≥95 cm, male; ≥105 cm [WC3]). Risks were evaluated using Cox proportional hazard analysis.

Results: Patients (58.6±7.7 years) had mean eGFR of 54.32±5.83mL/min/1.73 m². The underweight (BMI<18.5) group had increased risks of death [HR 1.75%, 95% CI (1.573-1.964)] and total events [HR 1.24, (1.144-1.353)]. Overweight (BMI≥25) group showed lower risks of death [HR 0.888, (0.86-0.917)], ESKD [HR 0.855, (0.788-0.927)] and total events [HR 0.975, (0.956-0.995)]. However, the risk was increased for 3-point MACE [HR 1.056, (1.031-1.081)]. For the association between WC and clinical outcomes, the low WC group (WC1) had increased risk of death [HR 1.129, (1.089-1.171)] and reduced risk for 3-point MACE [HR 0.92, (0.894-0.947)]. In higher WC groups, increased risks were observed for death [WC2: HR 1.052, (1.008-1.098), WC3: HR 1.32, (1.213-1.437)], 3-point MACE [WC2: HR 1.071, (1.038-1.104), WC3: HR 1.104, (1.036-1.176)] and total events [WC2: HR 1.049, (1.022-1.077), WC3: HR 1.12, (1.062-1.181)].

Conclusion: In CKD patients, both lower BMI and WC were risk factors for mortality and ESKD. However, compared to the reference group, higher BMI group exhibited better outcomes while higher WC groups exhibited poorer outcomes. As increased WC is more specifically related to central obesity, we need different approaches to interpreting clinical risks associated with different BMI and WC criteria.

PRIMARY GLOMERULAR DISEASES AND LONG-TERM RISKS OF CKD PROGRESSION, CARDIOVASCULAR EVENTS AND DEATH: A SWEDISH NATIONWIDE COHORT STUDY

Anne-Laure Faucon, Stefania Landolino, Rino Bellocco, Märten Segelmark, Marie Evans and Juan Jesus Carrero

1Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, 2Inserm U1018, Department of Clinical Epidemiology, Paris, France, 3University of Milano-Bicocca, Milano, Italy, 4Skåne University Hospital, Department of Nephrology, Malmö, Sweden, 5Lund University, Department of Clinical Sciences, Lund, Sweden, 6Karolinska Institutet, Department of Nephrology, Huddinge, Sweden, 7Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Huddinge, Sweden and 8Danderyd Hospital, Division of Nephrology, Department of Clinical Sciences, Stockholm, Sweden

Background and Aims: Although glomerular diseases are the third most frequent cause of end-stage kidney disease worldwide (after diabetes and hypertension), little is known about their long-term risks and complications.

Method: Using data from the Swedish Renal Registry (SRR-CKD) 2005-2021, we compared clinical outcomes between patients with the four most frequent primary glomerular diseases (IgA nephropathy [IgAN], focal segmental glomerulosclerosis [FSGS], minimal change disease [MCD] and membranous nephropathy [MN]) and patients with CKD attributed to non-inflammatory etiologies (i.e. without systemic auto-immune, inflammatory, infectious, hematologic malignancy, genetic disease, or polycystic kidney disease). Poisson models were used to estimate adjusted incidence rate ratios (IRR) of all-cause and cause-specific hospitalizations (cardiovascular-, acute kidney injury-, thromboembolism- and infection-related). Cox proportional hazards models were used to estimate adjusted hazard ratios (HR) of kidney replacement therapy (KRT), major adverse cardiovascular events (MACE) and death.

Results: We identified 2967 patients with primary glomerular disease (71% men, age 57 years, eGFR 28 mL/min/1.73 m², uACR 63 mg/mmol) and 40026 patients with a non-inflammatory CKD (64% men, age 74 years, eGFR 22 mL/min/1.73 m², uACR 20 mg/mmol). As compared to non-inflammatory CKD, patients with primary glomerular diseases were younger, had a lower prevalence of cardiovascular disease, higher eGFR but higher albuminuria. Over median follow-up of 6.3 [3.3-9.9] years, there were median 0.3 [1.07.0] hospitalizations per patient, 9890 (23%) KRT, 11708 (27%) MACE, and 21091 (49%) deaths. As compared to non-inflammatory CKD, patients with primary glomerular disease had a lower risk of all-cause (IRR 0.77 [0.75-0.79]), and all-cause-specific hospitalizations, MACE (HR 0.56 [0.58-0.63]) and death
Figure 1: Adjusted hazard ratios of long-term outcomes associated with primary glomerular disease vs non-inflammatory CKD.
needed to see where we currently stand, and how to progress from here. With this overview we can identify current knowledge gaps, and potential implementation opportunities. Moreover, it will provide guidance as to where future research should be directed. Therefore, the aim of this study was to map the body of existing prognostic models within nephrology and detail the range in outcomes and populations that they cover, as well as their methodological rigour. To do so, we performed a scoping review of studies developing, validating or updating a prognostic model for patients with chronic kidney disease (CKD) or those receiving kidney replacement therapy (KRT).

**Method:** A framework for scoping reviews by Arksey and O'Malley was used and the PRISMA extension for Scoping Reviews was adhered to for transparent reporting. A systematic search yielded 3728 studies for screening, of which 596 were finally included. Of these, 29.5% concerned a CKD population, 31.4% a dialysis population, and 39.1% a kidney transplantation population. Many studies had a sample size of less than 500 participants (41.4%). Although a measure of discrimination of the model was usually presented (79.5%), a measure of calibration was presented in less than half of the studies (43.5%). Of the 411 studies in which a prognostic model was developed, most performed only internal validation (57.9%) or no validation at all (27.7%). Moreover, in almost half of the development studies (43.5%) no usable version of the model was reported, meaning that insufficient information was reported to apply the model in a new setting. For CKD populations, the majority of models predicted disease progression (n = 78), followed by models predicting mortality (n = 22) and cardiovascular events (n = 13). For dialysis populations, most models predicted mortality (n = 79), cardiovascular events (n = 20), and vascular access related outcomes (n = 15). Finally, models originally developed for kidney transplantation populations mainly predicted graft survival (n = 59), recipient survival (n = 39), and delayed graft function (n = 24). Models for non-traditional clinical outcomes, like health-related quality of life and symptom burden, were scarce. If validated or updated at all (n = 199), most models (n = 123) were externally validated and/or updated only once. The rest (n = 76) were validated and/or updated more, with a median (IQR) of 2 (2-3), 2 (2-3), and 3 (2-4) within the CKD, dialysis, and transplantation populations, respectively.

**Conclusion:** A substantial amount of nephrological prognostic research has been performed, but to minimize the gap between research and patient care additional steps have to be undertaken. Methodological rigour, external validation, updating, and impact assessment are of paramount importance. In addition, the current body of literature focuses on traditional clinical outcomes, and models for patient-reported outcomes are scarce. Opportunities to improve implementation of prognostic models in nephrological care are described in Box 1.

Box 1: Implementation opportunities and future suggestions.

FACTORS ASSOCIATED WITH QUALITY OF LIFE IN KIDNEY FAILURE MANAGED CONSERVATIVE AND WITH DIALYSIS: A RETROSPECTIVE CROSS-SECTIONAL STUDY

Sarah So¹ and Kelly Li²

¹Nepean Hospital, Renal Department, Kingswood, Australia and ²St George Hospital, Renal Department, Kogarah, Australia

**Background and Aims:** Internationally, chronic kidney disease (CKD) affects over 10% of the general population. As patients approach CKD Stage 5, they are faced with the decision of whether to proceed with dialysis or conservative, non-dialysis, kidney management (CKM). Regardless of pathway, worsening CKD is associated with poorer self-perceived health-related quality of life (HRQOL). Psychological factors such as depression and anxiety have been linked with poorer HRQOL. Quality of life is a major consideration for many patients. Patients’ experiences of disease and significant contributors to HRQOL should be recognised as an important area for healthcare providers to identify, understand and target. The primary aim is to determine if anxiety or depressive symptoms are significantly associated with HRQOL, in patients with CKD Stage 5. The secondary aim is to determine which patient-associated factors (such as comorbidities, symptoms or biochemical parameters) are associated with HRQOL in patients with CKD Stage 5.

**Method:** Patients that attend the St George Hospital Kidney Supportive Care (KSC) clinic complete surveys of their functional ‘domains’ and quality of life (EQ-5D-5L, EuroQOL Research Foundation, 2019) and symptom surveys (IPOS-Renal, Cicely Saunders Institute, 2016) at the beginning of each clinic visit. Demographic data, comorbidities and biochemical data are also obtained from the St George Hospital electronic medical records system and entered into the KSC database, with corresponding survey data. We included all patients from St George and Sutherland Hospitals that attended the KSC Clinic between 1 July 2015 and 30 June 2022 with CKD Stage 5, who were managed with either CKM or dialysis, and completed EQ5D5L and IPOS-Renal surveys at their first KSC visit. The primary outcome is self-perceived health-related quality of life score, measured using EQ-VAS, a continuous 100-point scale on the EQ-5D-5L survey. We performed multivariable linear regression analysis with pre-specified variables including age, sex, eGFR (for those on CKM), "Feeling depressed," (IPOS-Renal) “Feeling anxious” (IPOS-Renal) and “Anxiety/depression" (EQ5DSL), for the CKM and dialysis pathways. Statistical analyses were performed with IBM SPSS Statistics V26.0. P-values of <0.05 were regarded as significant.

**Results:** We included 339 patients (216 patients on CKM and 123 patients on dialysis). Patients receiving CKM were significantly older than those on dialysis, with a median age of 83 years, compared to 73 years. Most patients on dialysis received haemodialysis (85.4%). For patients receiving CKM, variables independently associated with poorer EQ-VAS were difficulty performing usual activities (EQ5DSL), drowsiness (IPOS-Renal) and shortness of breath (IPOS-Renal) (Figure 1). For patients receiving dialysis, variables independently associated with poorer EQ-VAS were reduced ability to perform self-care (EQ5DSL) and lack of energy (IPOS-Renal) (Figure 2). Anxiety and depressive symptoms were not significantly associated with poorer EQ-VAS for either CKM or dialysis patients.

**Conclusion:** We did not find an association between anxiety and depressive symptoms and poorer EQ-VAS for patients with CKD Stage 5. For patients receiving CKM, symptoms that significantly reduce EQ-VAS include shortness of breath, difficulty performing usual activities, drowsiness and lack of energy.
of breath and drowsiness. Impaired functional ability significantly reduced EQ-VAS in patients with CKD Stage 5 managed with and without dialysis. Optimization of multidisciplinary teams within KSC units are likely to be of benefit.

**Figure 1:** Factors associated with HRQOL in CKD Stage 5 not on dialysis.

**Background and Aims:** Whether early eGFR declines (eGFR below age-expected values) in younger adults are associated with adverse outcomes is unknown. We aim to estimate the association of an early eGFR decline with adverse outcomes by age group (18-39, 40-49, 50-65 years).

**Methods:** We included 8.9 million adults (aged 18-65) with ≥1 eGFR value using linked healthcare datasets in Ontario from January 2008-March 2020. The association of eGFR categories from <60 to >120 mL/min/1.73 m² and adverse outcomes (death, cardiovascular outcomes, end-stage kidney disease) was examined using adjusted Cox models. Comparisons were relative to age normalized measured GFR categories (100-110 mL/min for 18-39, 90-100 mL/min for 40-49, 80-90 mL/min for 50-65).

**Results:** The mean age, eGFR and median followup were 41 years, 104 mL/min and 9.2 years, respectively. 17.3%, 18.9%, and 17.7% had an eGFR below normal for ages 18-39, 40-49, and 50-65, respectively. The risk of an adverse event increased in a stepwise manner with eGFR values below the referent and occurred at higher eGFR values in those 18 to 39 [eGFR 70-80, age 18-39: incidence 4.37 events per 1000 person-years [p-y], HR 1.54 (1.46-1.61); age 40-49: incidence 9.78 per 1000 p-y, HR 1.18 (1.15-1.21); age 50-65: incidence 24.0 per 1000 p-y, HR 1.11 (1.10-1.12)] (see Figure 1). Results persisted for each outcome individually, and after using repeated eGFR, using a common referent, and adjusting for multiple covariates.

**Conclusion:** Young adults (18-39) with an early eGFR decline were at a higher risk of adverse events and this occurred at higher eGFR levels relative to middle-aged and older adults.
Figure 1: Incidence rates (events per 1000 person-years) and adjusted hazard ratios (HRs, 95% CI) for any adverse outcome (first of all-cause mortality, cardiovascular outcomes, end-stage kidney disease) relative to age-specific eGFR reference ranges, by age-group.
ASSOCIATION BETWEEN INCIDENT DEPRESSION AND CLINICAL OUTCOMES IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Nanbo Zhu 1, Suvi Virtanen 1, Hong Xu 2, Juan Jesus Carrero 1 and Zheng Chang 1

1Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Solna, Sweden and 2Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Huddinge, Sweden

Background and Aims: Depression is highly prevalent and related to increased morbidity and mortality in patients on dialysis, but less is known among patients with earlier stages of CKD. This study investigated the associations between depression and clinical outcomes in patients with CKD not receiving dialysis.

Method: We identified 157,398 adults with CKD stages 3–5 not previously diagnosed with depression from the Stockholm CREAtinine Measurements (SCREAM) project. The primary outcomes included hospitalization, CKD progression (>40% decline in eGFR, initiation of kidney replacement therapy, or death due to CKD), major adverse cardiovascular events (MACE; myocardial infarction, stroke, or cardiovascular death), and all-cause mortality. Survival analyses were used to estimate the associations between incident depression and adverse health outcomes, adjusting for socio-demographics, kidney disease severity, healthcare utilization, comorbidities, and concurrent use of medications.

Results: During a median follow-up of 5.1 (interquartile range: 2.3–8.5) years, 12,712 (8.1%) patients received an incident diagnosis of depression. A total of 634,471 hospitalizations (4,600,935 hospitalized days), 42,866 MACEs, and 66,635 deaths were recorded, and 9,795 individuals met the criteria for CKD progression. In the multivariable-adjusted analyses, incident depression was associated with an elevated rate of hospitalized days (rate ratio: 1.77, 95% confidence interval [CI]: 1.71–1.83), as well as an increased rate of CKD progression (hazard ratio [HR]: 1.38, 95% CI: 1.28–1.48), MACE (HR: 1.22, 95% CI: 1.18–1.27), and all-cause mortality (HR: 1.41; 95% CI: 1.37–1.45). The association with CKD progression was more evident after one year of depression diagnosis (HR: 1.47, 95% CI: 1.36–1.59). Results were consistent across a range of sensitivity analyses.

Conclusion: Among patients with non-dialysis-dependent CKD stages 3–5, incident depression is associated with poor prognosis, including hospitalization, CKD progression, MACE, and all-cause mortality.

ACCURACY OF ESTIMATED GLOMERULAR FILTRATION RATE EQUATIONS IN PATIENTS WITH DISCORDANCES BETWEEN CREATININE AND CYSTATIN C-BASED ESTIMATIONS

Edouard Fu1,2,3, Andrew Levey4, Josef Coresh5, Carl-Gustaf Elinder6, Joris Rottmans7, Friedo W. Dekker2, Julie Paik1, Franz Peter Barany6, Morgan Grams8, Lesley Inker4 and Juan Jesus Carrero9

Background and Aims: Cystatin C is recommended for use along with creatinine in estimating glomerular filtration rate (eGFR) when precise estimates are needed for clinical decision-making. Although eGFR based on both creatinine and cystatin (eGFRcr-cys) is the most accurate in research studies, it is uncertain as to whether this remains true in real-world settings, particularly when there are large discordances between eGFR based on creatinine (eGFRcr) and that based on cystatin C (eGFRcys).

Method: We included 6185 adults from the Stockholm Creatinine Measurements (SCREAM) project referred for plasma clearance of iohexol in Stockholm, Sweden, who had 9404 concurrent measurements of creatinine, cystatin C and iohexol clearance. The performance of eGFRcr, eGFRcys and eGFRcr-cys was assessed against mGFR with bias, P30 and correct classification of GFR strata. We stratified analyses within three categories: eGFRcys at least 20% lower than eGFRcr (eGFRcys < eGFRcr), eGFRcys within 20% of eGFRcr (eGFRcys ≈ eGFRcr) and eGFRcys at least 20% higher than eGFRcr (eGFRcys > eGFRcr). Bias was expressed as the median difference in estimated GFR minus mGFR, with negative biases indicating underestimation of mGFR. P30 described the percentage of individuals with eGFR within 30% of mGFR. Correct classification of GFR categories was defined as agreement of eGFR and mGFR categories using the KDIGO GFR categories (<15, 15-29, 30-44, 45-59, 60-89 and ≥90 ml/min/1.73 m²).

Results: eGFRcr and eGFRcys were similar in 4226 (45%) of samples, and there all three estimating equations displayed similar performance (Table 1). In contrast, eGFRcr-cys was much more accurate in cases of discordance. For example, when eGFRcys < eGFRcr (47% of samples), median biases were 15.0 (overestimation), −8.5 (underestimation) and 0.8 ml/min/1.73 m² for eGFRcr, eGFRcys and eGFRcr-cys, respectively; P30 was 50%/73%/84%, respectively; and correct classification was 38%/45%/62%, respectively. When eGFRcys > eGFRcr (8% of samples), median biases were −4.5, 8.4, and 1.4 ml/min/1.73 m². Findings were consistent among individuals with cardiovascular disease, heart failure, diabetes mellitus, liver disease and cancer (Figure 1).

Conclusion: When large discordances between eGFRcr and eGFRcys are found in clinical practice, eGFRcr-cys is more accurate than either eGFRcr or eGFRcys.

**Background and Aims:** Chronic kidney disease (CKD) negatively impacts patients’ psychological and social wellbeing. Prior studies have suggested that CKD progression is associated with worsening of health-related quality of life (HRQoL), but these studies were limited in terms of racial and geographic composition. We compared patient-reported outcomes, including symptom (HRQoL), but these studies were limited in terms of racial and geographic composition. We compared patient-reported outcomes, including symptom burden, work productivity and HRQoL of patients with early versus advanced CKD, based on contemporary data from DISCOVER CKD, a multinational non-interventional cohort study of patients with CKD.

**Methods:** DISCOVER CKD (clinicaltrials.gov identifier: NCT04034992) is an ongoing study that aims to generate real-world evidence on the clinical management and experiences of patients with CKD. The study adopted a hybrid design comprising both retrospective and prospective cohorts. For the prospective phase, patients were recruited from the USA, Japan, Sweden, Italy, Spain, and the UK. Clinical data were extracted manually from existing patients’ health records into a standardised case report form. HRQoL was measured via the Short Form (SF)-36 questionnaire, work productivity was assessed with the Work Productivity and Activity Impairment (WPAI)-CKD questionnaire. Symptoms were recorded using a mobile phone application. In this analysis, early CKD was defined as stages 2-3 CKD and advanced CKD as stages 4-5 CKD (inclusive of dialysis patients). For each outcome, baseline scores were compared between patients with early and advanced CKD using an ANCOVA model with adjustment for age, sex, diabetes, hypertension and renin-angiotensin-aldosterone system inhibitor use. P<0.05 was considered statistically significant. DISCOVER CKD received research ethics board approval and informed consent was obtained from all patients.

**Results:** A total of 1051 patients with CKD (early CKD, 69.2% [N = 727]; advanced CKD, 30.8% [N = 324]) were enrolled in the prospective phase of DISCOVER CKD. The population was racially diverse with approximately one-third being non-White. The mean age was 62.5 years (early CKD, 63.4 years: advanced CKD, 60.6 years) and 37% (early CKD, 37.7%; advanced CKD, 35.2%) were female. The mean WPAI-CKD scores for percentage work time missed, activity impairment, impairment at work and overall work productivity loss were significantly higher in patients with advanced CKD compared to those with early CKD, suggesting greater work and activity impairment (Figure 1). The mean symptom scores for fatigue, pruritis, problems with sleep, nausea, muscle cramping and overall feel about health were all significantly higher in the advanced CKD population (Table 1). Of note, anxious and depressed feelings were similar for early and advanced CKD.

**Conclusion:** In this multinational cohort of patients with CKD, those with advanced disease appeared to experience greater symptom burden, lower HRQoL, and higher work and activity impairment. These findings highlight the need for early detection and treatment of CKD and its reported symptoms to reduce the likelihood of disease progression, which could adversely impact patients’ QoL.

![Figure 1: Comparison of baseline work productivity and activity impairment scores for patients with early and advanced CKD.](image)

*Statistically significant difference based on ANCOVA model adjusting for age, sex, diabetes, hypertension, and renin-angiotensin-aldosterone system inhibitor use; Scores range from 0 to 100% with higher scores indicating greater impairment and less productivity. CKD, chronic kidney disease; WPAI, Work Productivity and Activity Impairment.*
INFLUENCE OF CHRONIC KIDNEY DISEASE AND GLOMERULAR FILTRATION RATE ON THE COURSE OF ACUTE SARS-COV-2 INFECTION AND POST-COVID PERIOD

Alexander Arutyunov1,2, Marina Trubnikova3, Gregory Arutyunov4, Ekaterina Tarlovskaia5, Mikhail Batyushin6, Roman Bashkinov7, Evgenii Melnikov7, Tatiana Batluk4 and Elizaveta Gordychuk4

1National Institute of Health after academician S. Avdabekyan, Erevan, Armenia, 2Eurasian Association of Internal Medicine, “ACTIV SARS-CoV-2” Working Group, Erevan, Armenia, 3Eurasian Association of Internal Medicine, “ACTIV SARS-CoV-2” Working Group, Sochi, Russia, 4Eurasian Association of Internal Medicine, “ACTIV SARS-CoV-2” Working Group, Moscow, Russia, 5Eurasian Association of Internal Medicine, “ACTIV SARS-CoV-2” Working Group, Nizhny Novgorod, Russia, 6Eurasian Association of Internal Medicine, “ACTIV SARS-CoV-2” Working Group, Saint Petersburg, Russia

Background and Aims: According to international data available in the literature, chronic kidney disease (CKD) may have a significant impact on the course and outcome of COVID-19. Moreover, kidney pathology have been suggested to aggravate the course of the post-COVID period. The aim of the study was to investigate the effect of CKD and glomerular filtration rate (GFR) on the course of acute infection and post-COVID period.

Method: An international register “Dynamics analysis of comorbidities in SAES-CoV-2 survivors” (ACTIV) (NCT04492384) was established to assess the characteristics of the course of NCI in the Eurasian region. Specialists from 7 countries participated in the register. ACTIV is a multicenter, non-interventional, real-world clinical practice registry that included men and women over 18 years of age with a confirmed diagnosis of COVID-19. The analysis presented is based on data from 4946 patients with an estimated GFR of ≥90 ml/min/1.73 m² - 3591 (42.3%) patients, 89-60 ml/min/1.73 m² - 141 (1.7%) patients, <60 ml/min/1.73 m² - 94 (1.1%) patients. GFR was calculated using the 2021 CKD-EPI formula. The post-COVID period was analyzed using data from telephone interviews that included 3099 patients at 3 months, 2493 patients at 6 months, and 1782 patients at 12 months after recovery from COVID-19.

Results: During the acute infection, patients with a GFR of 59-15 ml/min/1.73 m², had more severe lung tissue damage (stage 3-4 according to computed tomography (CT), p < 0.001) and worse oxygenation (SpO2 75-94% and less than 75%, p < 0.001); increased respiratory rate (over 22 per minute, p < 0.001); and higher body temperature (more than 38.6°C, p < 0.001) compared with patients with GFR over 60 ml/min/1.73 m². In addition, CKD increased the odds of death in hospitalized patients by 3.94-fold compared with patients without CKD (95% confidence interval (CI) 3.15-4.89, p < 0.001). The data of the deceased patients showed that most of them had a GFR of 89-60 ml/min/1.73 m², which corresponds to stage 2 CKD (Table 1). CKD was a risk factor for increased odds of death in the post-COVID period: 4.88-fold (95% CI 2.49-9.13; p < 0.001) within 3 months; 4.24-fold (95% CI 0.60-16.3; p = 0.126) within 6 months and 8.36-fold (95% CI 1.73-29.3; p = 0.012) within 12 months after recovery from SARS-CoV-2.

Influenza of chronic kidney disease and glomerular filtration rate on the course of acute SARS-CoV-2 infection and post-COVID period
Conclusion: CKD could be a predictor of a more severe acute period of COVID-19 and also significantly impact mortality within 12 months after recovery from SARS-CoV-2.

Background and Aims: Immunoglobulin A nephropathy (IgAN) is the most prevalent form of primary glomerulonephritis worldwide with an estimated annual incidence of 25 cases per million people. Many patients are not diagnosed until they develop kidney dysfunction, such as hematuria and proteinuria. Proteinuria >1 g/day is associated with a high risk of progression. The aim of the present study is to describe symptom control and consider treatment satisfaction for patients undergoing treatment for IgAN.

Method: Data were drawn from the Adelphi IgAN Disease Specific Programme (DSP)7,8, a point-in-time survey of IgAN-treating nephrologists and their consulting patients conducted in the United States (US), Europe (EU: France, Germany, Italy, Spain, United Kingdom [UK]), Japan, and China, from June to October 2021. Nephrologists completed structured online patient record forms for successive patients presenting with IgAN including demographics, clinical characteristics and treatment patterns. Patients voluntarily completed questionnaires that corresponded with the nephrologist records, with questions about their IgAN on that day regarding symptoms experienced, disease severity, and treatment satisfaction. Patients who were receiving IgAN treatment at the time of survey are included in the presented analysis.

Results: The mean (standard deviation [SD]) age of patients (n = 869) was 42 (13.7) years and 57% were male. IgAN symptoms were deemed severe by 10% of patients at the time of survey and 14% before the initiation of their current treatment. Overall, 91% of patients reported having symptoms of IgAN at the time of survey, the most common were: foamy urine, feeling tired or lack of energy, and swelling, with many patients in China reporting hematuria. The top reported most bothersome symptoms were fatigue, swelling, and high blood pressure, with many patients in China also reporting proteinuria. Satisfaction with their current treatment was reported by patients; 61% reported that they were satisfied, 27% said they were neither satisfied or dissatisfied, and 12% said they were dissatisfied with their medication. This dissatisfaction was due to their current medication not working quickly enough (54%, n = 103) or that it had not helped with their IgAN symptoms (45%, n = 103). This was consistent with the physician-reported data; where proteinuria was reported across treatment lines (L), levels remained high amongst patients (mean [SD] proteinuria [g/day]) at L1: 2.2 (2.3), n = 629; L2: 1.8 (2.0), n = 257; L3: 1.9 (1.4), n = 95) and estimated glomerular filtration rate (eGFR) continued to fall (mean [SD] eGFR [mL/min/1.73m²]) at L1: 77.1 (29.6), n = 615; L2: 72.2 (30.3), n = 246; L3: 66.9 (31.1), n = 96).

Conclusion: Despite treatment, most patients with IgAN continued to experience symptoms. Many of these symptoms were considered bothersome by patients, including fatigue, swelling and high blood pressure which may have an impact on their everyday lives. These data highlight an unmet need for effective IgAN management and future treatments should aim to target better symptom relief and disease progression.

REAL-WORLD SIGNS AND SYMPTOMS AT DIAGNOSIS IN PATIENTS WITH C3 GLOMERULOPATHY - INTERIM RESULTS FROM A MULTI-COUNTRY STUDY
Clare Proudfoot1, Katharina Pannagl2, Jennifer Nguyen3, Andrea King1, Kathleen Murphy4, Jonathan Decourcy2 and Richard Lafayette3
1Novartis Pharma AG, Switzerland; 2Novartis Pharmaceuticals UK Ltd., London, United Kingdom; 3Novartis Pharmaceuticals Corporation, East Hanover, United States of America, 4Adelphi Real World, United Kingdom and 5Stanford University Medical Center, Stanford, United States of America

Background and Aims: C3 glomerulopathy (C3G) is a rare form of glomerulonephritis, with an estimated incidence of 1 – 2 million per year. C3G is associated with a high risk of disease progression with approximately 50% of patients reaching kidney failure within 10 years of diagnosis. Common signs and symptoms include proteinuria, hematuria, edema and hypertension. The aim of this analysis was to better understand the clinical characteristics of C3G patients from the US, Europe and Asia, at the time of diagnosis.

Method: An analysis was conducted using interim data from the Adelphi C3G Disease Specific Programme (DSP), a cross-sectional survey of C3G-treating nephrologists in US, EUS (France, Germany, Italy, Spain, UK), China and Japan (study ongoing since August 2022; interim analysis based on data until November). Nephrologists completed structured forms administered via online links for consecutive patients presenting with C3G. The forms included demographic and clinical information including signs, symptoms, and lab values amongst others.

Results: In this interim analysis, 88 nephrologists had completed records for 277 patients in this survey, including 95 in US, 120 in EU5, 39 in China and 23 in Japan. Median patient age at diagnosis was 40.9, and 60% were male. 80% had C3 glomerulonephritis (C3GN) and 19% had dense deposit disease (DDD). Median proteinuria at diagnosis was 2.9 g/day, and was ≥1 g/day in 82% of patients. Median eGFR at diagnosis was 50 mL/min/1.73m² (Table 1). In addition to proteinuria, the main clinical signs and symptoms at diagnosis were hematuria, edema, hypertension and fatigue. Pain, appetite loss and sleep problems were also reported. Physicians described disease severity at diagnosis as moderate in 53% and severe in 31% of patients.

Conclusion: This study allows evaluation of a rare disease across geographies. C3G patients experience substantial symptomatic and clinical burden at diagnosis. This symptom burden, high proteinuria, and relatively low eGFR is consistent with physician assessment that the disease is moderate or severe by the time of diagnosis. Facilitating early diagnosis of C3G and rapid initiation of treatment could be beneficial for patients in slowing disease progression.

ESTIMATING AND VALIDATING MEASURES OF CKD PREVALENCE AND INCIDENCE USING OBSERVATIONAL AND CLAIMS DATA IN PERSONS AGED 70+
Tim Bothe¹, Anne-Katrin Fietz², Anna Pöhmann³, Elke Schaeffner¹, Nina Mielke¹ and Natalie Ebert¹
¹Charité - Universitätsmedizin Berlin, Institute of Public Health, Berlin, Germany and ²Charité - Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany

Background and Aims: Estimating prevalence and incidence of chronic kidney disease (CKD) based on claims data often underlies bias and limitations due to uncertainty of diagnostic validity. We investigated CKD prevalence and incidence over time using data from a community-dwelling cohort of individuals aged 70+ linked to individual claims data. We assessed the diagnostic validity of claims-based compared with the eGFR-based CKD definition.

Method: We assessed CKD prevalence and incidence in two data sources: 1) eGFR values of participants aged 70+ (n = 2,069) of the Berlin Initiative Study (BIS), including five biennial study visits from 2009-2019, and 2) claims data of BIS participants matched on person-level. Using eGFR, we defined CKD prevalence as eGFR < 60 ml/min/1.73m² calculated with the creatinine-based CKD-EPI (2009) equation. For each study visit, prevalent CKD cases were considered as incident if eGFR was >60 ml/min/1.73m² in the respective previous study visit. In claims data, in- and outpatient ICD-10 diagnoses (N18.3, N18.4, N18.5, N18.8, N18.9, N19) in the year preceding and/or following the study visit date were used to determine CKD prevalence. Incidence was defined as prevalent cases without a diagnosis in the year preceding the first CKD diagnosis. The denominator for incidence was defined as all persons at risk, i.e., who were not prevalent in a respective previous study visit and still under observation. We assessed the diagnostic validity of claims-based CKD prevalence and incidence using eGFR data as a reference. Analyses were stratified by sex.

Results: Between 2009 and 2019, CKD prevalence increased from 0.42 to 0.51 based on eGFR and from 0.30 to 0.43 based on claims data. Incidence varied between 0.16–0.22 using eGFR and 0.07–0.13 using BIS claims data. There was no clear time trend for incidence in any data source. Diagnostic validity of claims-based CKD prevalence and incidence detection is displayed in Table 1. Sensitivity for prevalence increased while other indicators remained stable over time. Detection of incident cases showed lower sensitivity (0.18–0.30 vs. 0.58–0.70) and PPVs (0.40–0.60 vs. 0.79–0.83) compared to prevalence, respectively. Prevalence and incidence based on claims data were slightly higher in males compared to females (Figure 1).

Conclusion: Using the eGFR-based or claims-based definition of CKD we found an increase in prevalence between 2009 and 2019. This might be due to the introduction of the KDIGO guidelines in 2012. During the same time, CKD incidence rates were stable. Comparing the claims-based with eGFR-based CKD definition, we found a sensitivity of 0.58-0.70 for prevalence and 0.18-0.30 for incidence, indicating that there is a risk of underdetection of CKD when using solely claims data, in particular for incident cases.
Table 1: Sociodemographics, prevalence, and incidence estimates of CKD using individual BIS data (n = 2,069 at baseline; presented are results for follow-ups (FU) 1-4) based on eGFR assessed with the creatinine-based CKD-EPI 2009 equation, and claims data. Results of diagnostic validity of claims-based prevalence and incidence with eGFR as reference are shown as well.

LONG-TERM PROGNOSIS OF HYPOPROTEIC DIET SUPPLEMENTED WITH KETOANALOGUES IN PATIENTS WITH ADVANCED DIABETIC KIDNEY DISEASE AND SEVERE PROTEINURIA

Carmen-Antonia Mocanu¹, Gabriel Mircescu¹,² and Liliana Garneata¹,²

¹Carol Davila University of Medicine and Pharmacy, Internal Medicine and Nephrology, Bucharest, Romania and ²“Dr Carol Davila” Teaching Hospital of Nephrology, Nephrology, Bucharest, Romania

Background and Aims: Studies support the role of low-protein regimens in managing chronic kidney disease (CKD). In addition, some data emphasize the role of low-protein diets (LPDs) in postponing kidney replacement therapy (KRT) in patients with CKD, even in diabetic patients with heavy proteinuria. Although most results seem to be in favor of a LPD in CKD, even in patients with advanced diabetic kidney disease (DKD), there is insufficient data on long-term kidney and patient outcomes. This is a follow-up study aimed to determine the outcomes in kidney survival and patient survival in patients with DKD and severe proteinuria.

Method: The follow-up study included all patients with advanced DKD and severe proteinuria who previously participated in a twelve-month multicentric prospective study looking to assess variations in kidney function and proteinuria. At baseline, 97 patients with DKD, with stable stage 4+ CKD and proteinuria of nephrotic-range, who proved adherent to protein restriction were enrolled and received LPD (0.6 g mixed protein/kg-day) supplemented with ketoanalogues of essential amino acids (Ketosteril®, Bad Homburg, Germany, 1 tb/10 kg dry ideal body weight per day) for 12 months. Ninety-two patients completed the study (5 patients received kidney transplant). The efficacy outcomes were assessed by the decline of kidney function and proteinuria. Safety parameters were evaluated by anthropometric measurements (Body Mass Index), Subjective Global Assessment score and serum albumin. Compliance to the LPD was assessed by urinary urea from a 24-hour urine collection to estimate protein intake (ePI) and a 3-day food diary to estimate the energy intake. After the end of the study, the patients continued to remain compliant to the nutritional intervention. The primary composite endpoint was the need for KRT or patient death. The census moment was either the occurrence of the primary endpoint or the 31st of January, 2023.

Results: At baseline, patients had a median age of 61 years (95% CI 58 to 67), 66% were men, with poorly controlled diabetes assessed by the level of the glycated hemoglobin [8.1% (95% CI 8.0 to 8.3)]. All patients had a good nutritional status (SGA A). The median estimated glomerular filtration rate (eGF) was 12.6 mL/min (95% CI 11.7 to 13.1) and the median proteinuria was 5.2 g/g creatininuria (95% CI 5.0 to 5.2). After 12 months, a significant reduction in proteinuria was observed (67%), as well as a reduction in the kidney function decline by almost 80% compared to the period before the inclusion and a preserved good nutritional status (SGA A). The median follow-up was 105 months (95% CI 103 to 106). After almost 9 years of follow-up, 83.7% of patients remained alive, despite significant comorbidities. The median

Figure 1: Estimates of prevalence and incidence based on eGFR and claims data stratified by sex over all study visits.
survival was 62 months (95% CI 47 to 85). Seventy-six percent of patients required KRT, with a predilection for hemodialysis. The median period of time until KRT was 26 months (95% CI 24 to 29). In a Kaplan-Meier survival analysis, the compliance to the LPD was associated with better kidney survival ($p = 0.03$).

Conclusion: Low-protein diets supplemented with ketoanalogues of essential amino acids seem to be associated with a better kidney outcome on long-term in patients with advanced diabetic kidney disease and heavy proteinuria.

#4188

PREFERENCES FOR PROGNOSTIC INFORMATION PROVISION AMONGST PATIENTS WITH CHRONIC KIDNEY DISEASE: A SURVEY

Jet Milders, Chava Ramspek, Friedo W. Dekker and Merel Van Diepen

Leiden University Medical Center (LUMC), Leiden, Netherlands

Background and Aims: Patients with chronic kidney disease (CKD) often experience various symptoms and have an increased risk for many adverse outcomes. The varying nature of the course of the disease comes with much prognostic uncertainty, and patients have expressed a wish for more information about their future with the disease. However, the extent to which patients want to know more about their future with CKD varies highly per individual. By identifying which topics patients are interested in regarding their prognosis, more attention can be given to these topics in clinical practice and future research. Therefore, the aim of this study was to explore whether CKD patients want to know more about their future, and if so, which topics they find most important in regards to their prognosis.

Method: To gather information on what CKD patients want to know regarding their future, a survey was constructed by an expert panel of researchers and nephrologists. Before distributing the survey, it was tested during a two-phase pilot, in which volunteers of the Dutch patients association provided detailed feedback. Feedback was incorporated into a final version, available both on paper and online in Castor EDC. The survey was developed in Dutch, and was fully anonymous. The final survey consisted of three main sections containing multiple questions: 1) demographic questions, 2) ‘do you think about your future with a kidney disease?’, 3) ‘what would you want to know about your future with CKD?’. The survey was specifically developed for all patients that currently have chronic kidney disease, including patients undergoing any form of dialysis or those that have received a kidney transplant in the past. Descriptive statistics were used to summarize the results.

Results: A total of 145 patients filled in the survey. Respondents had a mean age of 63.0 (SD 14.1) and 49.7% was male. The majority of patients (57.9%) had undergone a kidney transplant in the past and 23 (15.9%) patients were undergoing dialysis at the time of responding. When asked whether patients ever thought about their future with CKD, most replied that they think about it every now and then (57.2%) or often (36.6%), and only nine (6.2%) patients reported that they never think about it. Half of the patients (50.3%) reported that they do not want to discuss their future at all. Furthermore, patients were asked in which scenarios they would be interested in knowing more about their future. Most patients (77.9%) mentioned they currently do not discuss it, but would like to, and 23 (15.9%) patients stated that they do not want to discuss their future at all. They were asked in which scenarios they would be interested in knowing more about their future. Most patients (77.9%) mentioned they always wanted to know more about their future, regardless of whether the information is positive or negative. Contrarily, two patients (1.4%) only wanted to know in case of good news, 32 (22.1%) when the outcomes in question can be prevented, and 37 (25.5%) if it would help them make a treatment decision. Four patients (2.8%) were not sure whether they wanted more prognostic information and four patients (2.8%) preferred not to know anything in terms of prognosis at all. Patients were asked to rate the importance of receiving more prognostic information for nine outcome categories on a scale from 0 to 100. Outcome categories that were rated the highest were laboratory measurements, health complaints, and physical well-being. Per category, patients chose specific subjects that they deemed important in terms of prognosis. The top ten most chosen subjects per patient group (CKD, dialysis, kidney transplantation, and all patients) are presented in Figure 1.

Conclusion: Most patients with chronic kidney disease think about their future, and there is interest in receiving individualised prognostic information on what to expect for a variety of subjects. Based on these research results more attention can be paid to specific prognostic information provision tailored to the preferences of and based on subjects that matter to patients, both in future research and clinical practice.

Figure 1: Top ten outcomes patients wished to receive more prognostic information about.

*CKD = all patients that are not receiving dialysis and have not undergone a kidney transplant, KTx = kidney transplantation
PACE-CKD: FINANCIAL BURDEN AND WORK PRODUCTIVITY OF PATIENTS WITH CKD AND CAREGIVERS: RESULTS FROM A US SURVEY

Steven Chadban1, Ciro Esposito2, Janani Rangaswami3, Mai-Szu Wu4, Richard Hult5, Hesham Elsayed6, Helmut Reichel7, Juan Jose Garcia Sanchez8, Surendra Pentakota9, Thames Kularatne9 and Simon Fifer9

1 Royal Prince Alfred Hospital, Department of Renal Medicine, Sydney, Australia, 2 University of Pennsylvania, Nephrology, USA, 3 George Washington University School of Medicine, Nephrology Division, Washington DC, United States of America, 4 Taipei Medical University, College of Medicine, Taipei, Taiwan, Rep. of China, 5 St George’s Hospitals NHS Foundation Trust, Renal and Transplantation Unit, London, United Kingdom, 6 AIN Shams University, Department of Internal Medicine and Nephrology, Cairo, Egypt, 7 Nephrology Center Villingen-Schwenningen, Villingen-Schwenningen, Germany, 8 AstraZeneca, Biopharmaceuticals Medical, Cambridge, United Kingdom and 9 CaPPr: Community and Patient Preference Research, Sydney, Australia

Background and Aims: Chronic kidney disease (CKD) is a progressive condition, conferring serious mortality and morbidity in patients with advanced disease. Upon reaching end-stage kidney disease (ESKD), dialysis or kidney transplantation is typically required, leading to considerable burden to health care systems worldwide. There is a paucity of data assessing the financial wellbeing and work productivity of patients with CKD and their caregivers, compared to the general population. Therefore, the objective of this study was to conduct a quantitative online survey to estimate the financial burden and work productivity of patients with CKD and their caregivers relative to the general population.

Method: This non-interventional survey included adult patients with a diagnosis of CKD for at least 3 months and unpaid caregivers of CKD patients for a minimum of 1 hour per week in the previous 4 weeks. This study was supported by AstraZeneca.

Funding: This study was supported by AstraZeneca.

The study enrolled 199 patients (median age: 58 years) with CKD and 113 caregivers (median age: 38 years) in the United States. Candidates were enrolled between June and July 2022. In the patient cohort, 32.2% of participants were dialysis-dependent, who predominately received treatment in a clinic or hospital (79.7%) rather than at home. Caregivers most commonly cared for their parent (45.1%) or partner (25.7%); the most frequent role for caregivers was providing transport to/from medical appointments (89.4%). Patients were considered to have 17.8% worse financial wellbeing compared to the general population according to the CFPB scale (52.0 vs 63.2, respectively). Patients receiving dialysis experienced a similar financial burden to non-dialysis dependent patients, with slightly worse FACIT-COST scores (22.9 vs 23.4, respectively). Further, patients and caregivers reported losses to work productivity with dialysis patients (21.6%) reporting higher absenteeism from work than non-dialysis patients (9.6%) when compared to the general population (3.6%). Similarly, care of dialysis-dependent patients reported a higher rate of absenteeism (14.8%) compared to non-dialysis dependent patients (10.6%) and the general population (5.2%). Total activity impairment was higher for dialysis dependent patients (55.5%) than for non-dialysis dependent patients (43.7%) and considerably higher versus the general population (5.7%). Caregivers for dialysis dependent patients had greater total activity impairment (44.3%) than caregivers for non-dialysis dependent patients (34.3%) and the general population (17.3%). Results for patients and caregivers in other countries (United Kingdom, Germany, and Mexico) will also be presented at the congress.

Conclusion: The results of this survey suggest that work productivity is impaired in both CKD patients and their caregivers and is also exacerbated further in patients who progress to dialysis and their caregivers. The survey also provides indications that the financial wellbeing in patients with CKD may be affected in comparison to the general population. Evidence based policy interventions ought to consider the progressive nature of CKD and should aim to reduce the societal burden of disease for patients and caregivers.

#5059

EXTERNAL VALIDATION OF THE KFRE AND GRAMS PREDICTION MODELS FOR DEATH AND KRT IN A SPANISH POPULATION WITH ADVANCED CHRONIC KIDNEY DISEASE

Eduardo Gallego Valcarce, Amira Shabaka, Ana Maria Tato Ribera, Eugenia Landaluce-Triska, Mariana León-Póo, Deborah Roldan and Enrique Gruss

Hospital Universitario Fundacion Alcorcon, Spain

Background and Aims: The Kidney Failure Risk Equation (KFRE) is used to predict the risk of kidney replacement therapy (KRT) initiation in the following 2 and 5 years, in patients with chronic kidney disease (CKD) stages G3-G5. The Grams model is applied exclusively to stage G4-G5 patients who have a higher risk of dying or requiring KRT. This model predicts both events, KRT and death, at 2 and 4 years, but unlike the KFRE, it considers the patient’s death as a competing event with respect to the start of KRT. It has been suggested that the Grams model makes a more accurate prediction of the onset of KRT in the long term, since by including mortality as a competing event it does not overestimate the risk of KRT. However, there are few external validations of the Grams model to predict mortality in patients with CKD G4+. We performed an external validation of both models with respect to the start of KRT and mortality in a Spanish population with CKD G4+, followed up prospectively during 4-9 years.

Method: We conducted a prospective cohort analysis of incident patients followed in the Advanced Chronic Kidney Disease clinic of the Hospital Universitario Fundacion Alcorcon, Spain between 1-1-2014 and 31-12-2018 who had CKD G4-G5. Clinical data was registered prospectively in a database at each visit to the clinic. Follow-up ended on 31-12-2022. For each patient, the follow-up time ranged from 4 to 9 years. The outcomes were: observed incidence of KRT (haemodialysis, peritoneal dialysis, or pre-emptive kidney transplantation) by 2, 4 and 5 years and death at 2 and 4 years before starting KRT.

Results: We studied 347 patients, 31.1% were women, with a mean age of 72.1 ± 12.7 years, 52.4% with cardiovascular disease and 58.8% diabetics. At the start, the mean eGFR was 20.7 ± 5.0 ml/min and the median urine albumin-to-creatinine ratio was 327 (IQR 52-1118) mg/g. At 2, 4 and 5 years the percentage of patients who required KRT was 20.2%, 38.3% and 45.7% respectively, while 12.7% and 23.6% died at 2 and 4 years respectively, before starting KRT. For KTR both models had an excellent discrimination. For KFRE-2 and Grams-2, the AUC was 0.842 (95% CI 0.801-0.884), and for KFRE-5 the AUC was 0.805 (95% CI 0.751-0.859). For death before KRT the Grams model demonstrated an acceptable discrimination, with an AUC of 0.726 (95% CI 0.646-0.806) and 0.749 (95% CI 0.690-0.809) respectively, for Grams-4 the AUC was 0.842 (95% CI 0.801-0.884), and for KFRE-5 the AUC was 0.805 (95% CI 0.751-0.859).

Conclusion: In a Spanish cohort of patients with CKD G4+, the Grams and KFRE models adequately estimate the risk of KRT. The Grams model provides an acceptable estimate of the risk of death before starting KRT at both 2 and 4 years. It can be considered for treatment planning and information for patients with CKD G4+.
CHANGES IN SERUM CREATININE DURING AND AFTER PREGNANCY IN WOMEN WITH OR WITHOUT CHRONIC KIDNEY DISEASE: AN OBSERVATIONAL STUDY

Carole Marxer1,2, Julie Paik3,4, Min Zhuo4,5, Rishi Desai3, Katrina Wilcox Hagberg6, Susan Jick6,7, Christoph Meier1,2 and Julia Spoendlin1,2

1University Hospital Basel, Hospital Pharmacy, Basel, Switzerland, 2University of Basel, Department of Pharmaceutical Sciences, Basel, Switzerland, 3Brigham and Women’s Hospital, Harvard Medical School, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, United States of America, 4Brigham and Women’s Hospital, Harvard Medical School, Division of Renal (Kidney) Medicine, Department of Medicine, Boston, United States of America, 5Beth Israel Deaconess Medical Center, Harvard Medical School, Division of Nephrology, Department of Medicine, United States of America, 6Boston Collaborative Drug Surveillance Program, Lexington, United States of America and 7Boston University School of Public Health, Boston, United States of America

Background and Aims: In women with chronic kidney disease (CKD), kidneys may not sufficiently adapt to physiological changes during pregnancy, which may accelerate postpartum loss in renal function. We aimed to characterize pregnant women with or without renal impairment and to describe changes in renal filtration during and until one year after pregnancy.

Method: We performed a descriptive study using primary care data from the United Kingdom-based Clinical Practice Research Datalink (CRPD) GOLD and linked hospital data (2000–2019) in 14’401 pregnancies with ≥2 serum creatinine (Scr) measurements between the year before and after pregnancy. Pregnancies were categorized by means of the median estimated glomerular filtration rate (eGFR) during baseline (proteinuria is not reliably recorded). We captured risk factors for CKD and described changes in Scr levels over time as proxies for renal filtration.

Results: Of 14’401 pregnancies, 84% had a baseline eGFR [ml/min/1.73m^2] of ≥90, 13% between 75–89, 13% between 60–74, and <1% between 15–59. Pre-existing hypertension, diabetes, and/or overweight was prevalent in 66.0% of women with an eGFR < 60 (versus 51.3–54.4% in eGFR ≥ 60). Preterm delivery was recorded in 30.2% of women with an eGFR < 60 (versus 9.4–9.8% in eGFR ≥ 60). In women with a low-normal eGFR between 75–89, median baseline Scr levels (mg/dL [μmol/L]) were 0.92 [81.33] (interquartile range (IQR) = 0.88–0.96 [77.79–84.86]), which decreased by 0.25 [22.1] by week 14/15, remained stable until week 30/31, increased to 0.94 [84.0] [IQR = 0.83–0.99 [73.37–87.52]] until week 3/4 postpartum, and decreased back to baseline by one year postpartum. In women with a moderately low baseline eGFR between 60–74, median baseline Scr levels were 1.05 [92.82] [IQR = 1.01–1.10 [89.28–97.24]] and patterns during pregnancy followed those of women with low-normal
eGFR (decreased by 0.28 [24.7] until week 18/19, plateau until week 38/39). However, Scr levels increased slower in trimester 3 and early postpartum and reached baseline levels at week 9/10 postpartum. Women with a baseline eGFR between 15–59 (median baseline Scr levels = 1.43 mg/dL [126.41 μmol/L], IQR = 1.26–1.72 mg/dL [111.38–152.05 μmol/L]) showed renal adaptation in trimester 1 and 2, but increased Scr levels of 1.71 [151.16] (IQR = 1.32–2.36 [116.69–208.62]) in trimester 3, but sample size was small.

Conclusion: Adaptations of renal filtration were not impaired during or after pregnancy in 1’932 pregnancies of women with a low-normal eGFR between 75–89. In women with a moderately low eGFR between 60–74, the pattern was similar, but potentially prolonged hyperfiltration in trimester 3 and early postpartum requires further investigation. The pattern of renal adaptation in eGFR between 15–59 was similar in trimester 1 and 2. Increased Scr levels in trimester 3 may indicate insufficient renal function but results have to be interpreted cautiously due to small sample size and potentially selective measurements.

THE ASSOCIATION OF EGF SLOPE WITH VISUAL IMPAIRMENT, RETINAL VESSEL DENSITY, AND EYE PATHOLOGIES IN THE EYE DETERMINANTS OF COGNITION (EYEDOC) STUDY

Johannes Scheppach1, Lubaina Arsiwala2, XinXing Guo2, Pradeep Ramulu2 and Alison Abraham3

1Charité – Universitätsmedizin Berlin, Department of Nephrology, Berlin, Germany, 2Johns Hopkins University, Wilmer Eye Institute, United States of America and 3University of Colorado, Department of Ophthalmology, United States of America

Background and Aims: Previous studies have identified chronic kidney disease (CKD) as a risk factor for poor ocular health. However, the effect of faster decline in estimated glomerular filtration rate (eGFR) on visual function, retinal markers, and eye conditions is unclear. We therefore examined the association of eGFR slope with visual function measures, retinal vessel density (VD), and common ocular pathologies in a bi-racial general population cohort.

Method: We studied 823 participants with normal kidney function or mild CKD (eGFR ≥ 60 ml/min per 1.73 m^2) at baseline from the Eye Determinants of Cognition (EYEDOC) Study. Exposure was change in eGFR (ml/min per 1.73 m^2 per year) over 4 study visits between 1996 and 2019, calculated using linear mixed-effect models with unstructured covariance matrix. Outcomes (recorded between 2017 and 2019) were visual function (near visual acuity, presenting distance visual acuity, contrast sensitivity), retinal VD in the superficial, intermediate, and deep capillary plexus layers, and common ocular pathologies, such as retinopathy, age-related macular degeneration, and
glaucoma. We used linear regression to model the associations of eGFR slope with visual function and retinal VD. We used logistic regression to study the association of eGFR slope with ocular pathologies. All models were adjusted for age, sex, race, education, smoking, body mass index, diabetes, hypertension, and hyperlipidemia. The models for retinal VD were additionally adjusted for signal strength index.

**Results:** In our study cohort, the mean age was 79 (±4) years with 62% females and 48% African Americans. The prevalence of diabetes and hypertension was 38% and 82%, respectively. The mean [SD] eGFR slope was −1.6 (0.6) ml/min per 1.73 m² per year. A faster eGFR decline of 1 ml/min per 1.73 m² per year was significantly associated with worse near visual acuity (0.04 logMAR [95% CI: 0.00; 0.08], p = 0.03), worse contrast sensitivity (−0.03 log [−0.05; −0.001], p = 0.01), lower VD in the deep capillary plexus layer (−0.99% per mm² [−1.96; −0.02], p = 0.04), and higher odds of retinopathy (odds ratio 2.44 [1.06; 6.63], p = 0.04). Associations of eGFR slope with the remaining measures of visual function and eye conditions were not significant.

**Conclusion:** In our bi-racial general population cohort with an eGFR ≥ 60 ml/min per 1.73 m² at baseline, a faster decline in eGFR was associated with worse visual function, reduced retinal vascular health, and higher odds of retinopathy. Our results support the potential usefulness of eGFR slope for risk assessment of ocular outcomes, even in patients with normal kidney function or mild CKD.

**HIGHER DIETARY NA/K RATIO IS ASSOCIATED WITH AN INCREASED RISK OF CARDIOVASCULAR OUTCOMES IN THE GENERAL POPULATION, BUT NOT IN CKD PATIENTS**

Charlotte Zwager1,2, Malik Esseghir1,2, Anne Myrthe van Vliet1,2, Joost Daams1, Liffert Vogt1,2 and Rik Olde Engberink1,2

1Amsterdam UMC location University of Amsterdam, Nephrology, Amsterdam, Netherlands and 2Amsterdam Cardiovascular Sciences, Microcirculation, Amsterdam, Netherlands

**Background and Aims:** High sodium and low potassium intake have been recognized as cardiovascular risk factors. The combined effect of sodium and potassium intake, reflected by the dietary sodium-to-potassium ratio (Na/K ratio), may be an even better predictor of cardiovascular disease (CVD). The primary objective of this meta-analysis is to investigate the effect of the estimated dietary Na/K ratio on the composite outcome of cardiovascular events (CVE) and all-cause mortality. As the ideal sodium and potassium intake may be different for chronic kidney disease (CKD) patients, we will compare subjects with and without CKD.

**Method:** We performed a systematic search in MEDLINE and EMBASE databases from January 1946 to December 2022. We included randomized controlled trials and cohort studies with a mean follow-up duration of ≥ 1 year, which reported the association between the estimated dietary Na/K ratio and CVE and/or all-cause mortality. Two reviewers independently assessed the eligibility of identified studies, extracted data, and assessed the risk of bias according to the Cochrane Handbook Guidelines. We compared hazard ratios (HRs) among subgroups with increasing dietary Na/K ratio using the group with lowest estimated dietary Na/K ratio as a reference. We performed a random-effects meta-analysis using these HRs. A sensitivity analysis was performed using the leave-one-out approach. In a subgroup analysis, we compared CKD patients with the general population and adults with a history of CVD. We performed a meta-regression analysis to investigate the impact of the absolute increase in estimated dietary Na/K ratio (Δ Na/K) on the composite outcome, when adjusted for the mean estimated dietary Na/K ratio of the reference group and the follow-up duration of the studies.

**Results:** Of the 8,249 studies initially identified, 16 studies with 404,301 subjects were included in our main analysis. Mean age was 55.2 years, and 49% were male. For estimation of dietary Na/K ratio, 3 studies used spot urines, 3 studies used 24-hour urine collections, and 10 studies used food frequency questionnaires. Mean follow-up duration was 12 years. Higher estimated dietary Na/K ratio was associated with a significant higher risk for the composite endpoint of CVE and all-cause mortality (HR 1.16 [95% CI: 1.10-1.23], p < 0.00001, I² = 41%) (Figure 1). We observed no significant changes in our results using the leave-one-out approach. In the subgroup analysis, we observed that increased estimated dietary Na/K ratio associated with significantly higher CVE and all-cause mortality risk in the general population (10 studies; 387,679 subjects; HR 1.17 [1.10-1.25], p < 0.00001, I² = 48%), and in adults with a history of CVD (5 studies; 15,779 subjects; HR 1.18 [1.11-1.25], p < 0.00001, I² = 49%).

**Figure 1:** Forest plot of the association between the estimated dietary Na/K ratio and the composite outcome of CVE and all-cause mortality in CKD patients, subjects with a history of CVD and the general population. CI, confidence interval.
knowledge gaps by providing observational data on patients' characteristics, risk factors, management patterns, disease progression, and outcomes related to CKD and associated comorbidities namely: T2D, HTN, and HF.

**Method:** The iCaReMe Global Registry (NCT03549754) is a prospective, investigator-led, multinational, observational registry relying on voluntary participation by treating physicians to assess the management and quality of care through socio-demographic and clinical characteristics, disease management patterns (including screening, diagnosis, treatment approaches), healthcare resource utilization and clinical outcomes in patients with CKD, T2D, HTN, and/or HF. Eligible and consented patients were enrolled during routine clinical practice based on the physician's discretion and were followed up per routine clinical care. We present the descriptive analysis of baseline clinical and demographic characteristics of the CKD cohort enrolled in the iCaReMe Global Registry from February 2018 to December 2022.

**Results:** Overall 2977 patients with CKD have been enrolled from 21 countries (Argentina, Costa Rica, Egypt, Ethiopia, Georgia, Greece, Hong Kong, Indonesia, India, Jordan, Kenya, Lebanon, Malaysia, Mexico, Russia, South Africa, Thailand, The Philippines, Turkey, Ukraine, and the United Arab Emirates). At baseline, the mean ± standard deviation (SD) age was 60.4 ± 13.8 years and 54.6% were males. The mean ± SD systolic and diastolic blood pressures of the cohort were 120.4 ± 43.6 and 70.5 ± 25.6 mmHg and the mean ± SD body mass index was 21.6 ± 12.9 kg/m². 68.9% had T2D and 68.3% had hypertension. Diabetic kidney disease and hypertensive kidney disease were the most common etiologies in 78.8% of the patients (Figure 2). Serum creatinine was reported in 85.3% of patients and urine albumin-creatinine ratio (UACR) in 30.5% and only 25.9% had both. The prevalence of KDIGO GFR categories G3-5 based on estimated glomerular filtration rate (eGFR) using CKD-EPI was 72.5% and the prevalence of albuminuria A2/A3 was 75.9%. In total, 7.9% patients were undergoing dialysis. In patients with T2D (n = 2051); 69.1% (1250/1808) had G3-5 GFR category and 76.1% (484/636) had albuminuria stage A2 and A3. In patients with HTN (n = 2033); 77.6% (1367/1761) had G3-5 GFR category and 76.6% (485/633) had albuminuria stage A2 and A3.

**Conclusion:** At baseline most of iCaReMe Registry CKD cohort fall within the KDIGO high or very high risk of outcomes associated with a high prevalence of T2D and HTN. Our results also indicate an underutilization of albuminuria testing despite its critical role in diagnosis, risk stratification and follow up which raises concerns about CKD early detection, management, and prognosis.

**CLINICAL CHARACTERISTICS AND RENAL RISK OF PATIENTS WITH CHRONIC KIDNEY DISEASE: REAL-WORLD EVIDENCE FROM THE ICAReME GLOBAL REGISTRY**

Mustafa Arici1, Carol Pollock2, Susana Goncalves3, Hardik Vasnawala4 and Ahmed Hadaoui5

1 Hacettepe University Faculty of Medicine, Department of Nephrology, Turkey, 2 Kolling institute, Royal North Shore Hospital, University of Sydney, Australia, 3 AstraZeneca International, Medical Affairs, Argentina, 4 AstraZeneca International, Medical Affairs, India and 5 AstraZeneca Algeria, Medical Affairs, Algeria

**Background and Aims:** Chronic kidney disease (CKD) has emerged as a leading global public health concern due to its growing prevalence and associated morbidity and mortality. Throughout the disease progression, CKD is associated with a substantial health and socio-economic burden on patients, families, and healthcare systems worsened by complex interactions with type 2 diabetes (T2D), hypertension (HTN), and heart failure (HF). To help current and future patients get the best possible care, it is of the greatest importance to better understand how they are managed routinely, but real-world data on coexisting cardiovascular, renal, and metabolic diseases are scarce or non-existent in many countries. The iCaReMe Global Registry aims to address these
MARKERS OF SUBCLINICAL LEFT VENTRICULAR DYSFUNCTION ARE ASSOCIATED WITH MORTALITY IN CHRONIC KIDNEY DISEASE PATIENTS WITH PRESERVED EJECTION FRACTION
Diana-Silvia Zilisteana1, Monica Rosca2, Andreea Calin2 and Elena Emanuela Rusu1

1Carol Davila University of Medicine and Pharmacy, Nephrology, Fundeni Clinical Institute, Bucharest, Romania and 2Carol Davila University of Medicine and Pharmacy, Cardiology, “Prof Dr CC Iliescu” Institute for Cardiovascular Diseases, Bucharest, Romania

Background and Aims: Cardiac dysfunction is frequent in chronic kidney disease (CKD) patients and contributes to high morbidity and mortality in this category. The aim of our study is to evaluate the association between markers of subclinical left ventricular (LV) dysfunction and mortality in CKD patients with preserved left ventricular ejection fraction.

Method: We prospectively enrolled CKD patients (pts) in pre-dialysis. Parameters of cardiac structure and function were evaluated by echocardiography: systolic and diastolic left ventricular (LV) volumes, LV mass index (LVMI), left atrial volume index (LAVI), LV ejection fraction (LVEF), global longitudinal strain (GLS), ratio of mitral velocity to early diastolic velocity of the mitral annulus (E/E’) and ratio between the early maximal ventricular filling velocity and the late filling velocity (E/A). Cardiac functional status was stratified according to NYHA criteria. All patients were followed until death or loss from records. Primary endpoint was all-cause mortality. Secondary endpoints were cardiovascular mortality and a composite cardiac endpoint comprising coronary heart disease, heart failure hospitalization and new-onset arrhythmia.

Results: We prospectively enrolled 39 CKD patients (5 pts CKD stage 2, 27 pts CKD stage 3, 7 pts CKD stage 4) mean age 64.3 ± 10.2 years, men = 28 (71.8%).
At baseline all pts had LVEF >50%; 11 pts (28.2%) were classified as NYHA I, 18 (46.2%) as NYHA II, and 10 pts (25.6%) as NYHA III. endpoint was significantly correlated with LVMI (p < 0.05), in pts with symptomatic heart failure (−15.6 ± 2.6 vs 18.9 ± 2.8, p = 0.05), and in pts with diabetes mellitus (−15.8 ± 1.9) and hypertensive nephropathy (−16.8 ± 2.8) compared with patients with tubulointerstitial diseases (−18.1 ± 2.5) and chronic glomerulonephritis (vs −21.1 ± 3.6) (p < 0.05). E/E’ as a marker of subclinical LV diastolic dysfunction, was significantly higher in pts with symptomatic heart failure (12.2± 3.4 vs 9.5 ± 1.9, p < 0.05), in pts with diabetes mellitus (13.3± 3.5 vs 10.2 ± 2.5, p < 0.05). All-cause mortality was 17.9% (7 events), while cardiovascular mortality was 10.3% (4 events). Composite cardiac endpoint was recorded in 13 pts (33.3%). Baseline profile in patients who died during follow up period included significantly lower eGFR (30.1 ± 10.5 vs 46.1 ± 16.9 mL/min/1.73 m², p < 0.05), higher LAVI (55.5 ± 11.1 vs 37.4 ± 11.9 mm²/m², p < 0.05), higher LVMI (149.8 ±36.1 vs 115 ±28.5 g/m², p < 0.05), and higher E/E’ (15.2 ±3.3 vs 10.7 ± 2.8, p < 0.05). Death was significantly correlated with GLS (p = 0.042), E/E’ (p = 0.002), LVMi (p = 0.008) and LAVi (p = 0.007), while CV mortality was correlated with E/E’ (p = 0.019) and LVMi (p = 0.041). Composite cardiac event was significantly correlated with LVMI (p = 0.01) and LAVI (p = 0.006). Cox regression analysis identified only E/E’ as a predictor for all-cause mortality (p = 0.002) and also for cardiovascular mortality (p = 0.015).

**Conclusion:** In our study population of CKD patients, cardiac imaging parameters of subclinical LV dysfunction (GLS and E/E’) were associated with all-cause mortality. Marker of LV diastolic dysfunction E/E’ proved to be the only predictor of all-cause and cardiovascular mortality. Thus, in CKD patients, evaluation of the cardiac function should focus not only on ejection fraction measurement, but also on the parameters of subclinical LV dysfunction.

**#6774 CAUSAL ASSOCIATION OF COVID-19 AND KIDNEY FUNCTION: A MENDELIAN RANDOMIZATION ANALYSIS**

Li Chunyang and Xiaoli Zeng

West China Hospital, Kidney Research Institute, Biomedical Big Data Center, Chengdu, P.R. China

**Background and Aims:** Previous observational studies suggest that there are potential associations between COVID-19 and kidney functions. However, whether COVID-19 had causal effects on different kidney traits is currently unclear. We aimed to investigate the causal link between genetically determined COVID-19 and following kidney traits.

**Method:** We performed univariate Mendelian randomization (MR) studies using summary genome-wide association studies (GWAS) statistics of COVID-19 severity (n case/n control: 32,519/2,062,805 for European, n case/n control: 2882/31,200 for Asian) and COVID-19 susceptibility (n case/n control: 122,616/2,475,240 for European, n case/n control: 4459/36,121 for Asian) derived from THE COVID-19 Host Genetics Initiative (r7) as exposure. Phenotypic outcomes analyzed for COVID-19 and following kidney traits. More deeply explorations focused on the association between COVID-19 and kidney traits should be performed with more data would be available in the future.

**#4016 MENTAL HEALTH OF PEOPLE WITH KIDNEY DISEASE AND THEIR SIGNIFICANT OTHERS BEFORE AND AFTER THE COVID-19 VACCINE PROGRAMME**

Naeema A. Patel1,2, Gurneet K. Sohansoha 1,2, Ella Ford1,2, Thomas Wilkinson1,3, Courtney J. Lightfoot1,2 and Alice Smith1,2

1University of Leicester, Leicester Kidney Lifestyle Team, Department of Population Health Sciences, Leicester, United Kingdom, 2Leicester NIHR Biomedical Research Centre, Leicester, United Kingdom and 3NIHR Applied Research Collaboration East Midlands, Leicester Diabetes Centre, Leicester, United Kingdom

**Background and Aims:** The COVID-19 pandemic resulted in widespread psychological experiences, including depression, anxiety, and stress, especially in clinically vulnerable people such as those with chronic kidney disease (CKD). The UK, high rates of infection, severe illness and death, and profound changes to usual activities and healthcare delivery imposed by social distancing and isolation persisted throughout 2020 and only began to abate after the introduction of the COVID-19 vaccination programme early in 2021. We conducted a survey to assess levels of general depression, anxiety, stress and health anxiety in people with non-dialysis CKD (ND-CKD), kidney transplant recipients (KTRs), and their significant others (SOs) at two timepoints: during the Autumn of 2020 when COVID-19 levels and social restrictions were high, and in May 2021 after the majority of the population had been vaccinated. We hypothesised that the mental health status of people affected by CKD would improve after receiving the vaccine.

**Method:** 11 hospital sites in England invited local patients and their SOs to complete an online survey in Autumn 2020, and a follow-up in May 2021. The survey included two validated mental health questionnaires: the Depression, Anxiety and Stress Scale (DASS-21) and the Short Health Anxiety Index (SHAI). Higher scores are indicative of higher levels of depression, stress and anxiety, and health anxiety respectively. One-way ANOVA was used to compare questionnaire scores between the three participant groups, and paired sample t-tests were used to assess changes between the two timepoints for each group.

**Results:** 381 participants completed the Autumn 2020 survey: 123 ND-CKD (61% male, mean age 64 [SD:14] years), 150 KTRs (51% male, 59 [SD:12] years), and 108 SOs (39% male, 60 [SD:13] years). 318 completed the May 2021 follow-up survey. 87 participant groups completed both surveys. In Autumn 2020, people with ND-CKD had significantly higher DASS-21 anxiety scores than SOs (p = 0.029). Both ND-CKD and KTRs had significantly higher health anxiety scores than SOs at baseline (P <0.001), and at follow-up (ND-CKD, P = 0.006; KTR, P = 0.010). In May 2021, 95% of participants had received the COVID-19 vaccine. There were no significant changes in DASS-21 subscale scores or SHAI scores between the Autumn 2020 and May 2021 timepoints for any of the participant groups.

**Conclusion:** Our results show that during the COVID-19 pandemic, people living with ND-CKD and KTRs had higher levels of health-related anxiety than their SOs. As the COVID-19 vaccine programme reduced health risks and allowed relaxation of social restrictions, it may be expected to result in improved population mental health. However, in May 2021, we found no improvement in depression, anxiety, stress, or health anxiety among people living with CKD or their SOs despite nearly all the participants having received the vaccine. It is likely that increased social mixing and marked reduction in public mask-wearing led to persistently high anxiety levels in clinically vulnerable people and those who live with them. Today, the majority of the public have returned to “normal” social behaviour and masks are rarely worn, but COVID-19 remains a threat to people with CKD. There is an urgent need for better mental health support among the kidney community.
SEX DIFFERENCE IN CARDIOVASCULAR RISK IN PATIENTS WITH CHRONIC KIDNEY DISEASE: A POOLED ANALYSIS OF FOUR COHORT STUDIES

Silvio Borrelli, Carlo Garofalo, Valentina Pirozzi, Felicia Palumbo, Francesco Cascone, Luigi Di Martino, Andrea Foderini, Luca De Nicola and Roberto Minutolo

University of Campania “Luigi Vanvitelli”, Nephrology, Italy

Background and Aims: Progression of chronic kidney disease (CKD) has proven to be faster in men than in women [1-3]. Whether the same holds true for cardiovascular risk remains ill-defined.

Method: We conducted a pooled analysis of 4 cohort studies from 40 nephrology clinics in Italy including patients with CKD (estimated GFR<60 mL/min/1.73 m2 or higher if proteinuria >0.15 g/day). The aim was to compare multivariable-adjusted risk (Hazard Ratio, 95% Confidence Interval) of a composite cardiovascular endpoint (cardiovascular death and non-fatal myocardial infarction, congestive heart failure, stroke, revascularization, peripheral vascular disease, and nontraumatic amputation) in women (n = 1,192) versus men (n = 1,635).

Results: At baseline, women had slightly higher systolic blood pressure (SBP) as compared with men (139±19 vs 138±18 mmHg, P = 0.049), lower eGFR (33.4 vs 35.7 mL/min/1.73 m2, P = 0.001) and lower urine protein excretion (0.30 g/day vs 0.45 g/day in men, P<0.001). Women did not differ from men in age and prevalence of diabetes while having a lower prevalence of cardiovascular disease, left ventricular hypertrophy and smoking habit. During a median follow-up of 4.0 years, 517 fatal and non-fatal cardiovascular events were registered (199 in women and 318 in men). The adjusted risk of cardiovascular events was lower in women (0.73, 0.60-0.89, P = 0.002) than in men; however, the cardiovascular risk advantage of women progressively diminished as SBP (as continuous variable) increased (P for interaction = 0.021; Figure 1). Similar results were obtained when considering SBP categories; when compared to men, women had a lower cardiovascular risk for SBP <130 mmHg (0.50, 0.31-0.80; P = 0.004) and between 130–140 mmHg (0.72, 0.53-0.99; P = 0.038), while no difference was observed for SBP >140 mmHg (0.85, 0.64-1.11; P = 0.232).

Conclusion: Higher BP levels abolish the cardiovascular protection seen in female vs male patients with overt CKD. This finding supports the need for higher awareness of hypertensive burden in women with CKD.

REFERENCES

Abstracts
and ESKD was higher at all stages in Cohort 1 vs. Cohort 2, particularly ESKD which was markedly higher for stage 5 (91.4% vs. 13.6%). Proportion of death was similar in both cohorts and was the highest in stages 4–5.

Conclusion: Substantial differences in kidney outcomes were noted between CKD classifications derived from ICD codes vs. KDIGO criteria, except all-cause mortality which was comparable across both cohorts and increased notably with stage. Changes in kidney function, both progression, regression, and ESKD occurred more frequently in Cohort 1. Our analysis suggests ICD diagnosis and KDIGO criteria might not be used interchangeably in the context of utilizing real-world data sources.

#6871
RISK FACTORS FOR SHORT-TERM CHRONIC KIDNEY DISEASE AFTER A CUTE KIDNEY INJURY WITH RECOVERY OF NORMAL RENAL FUNCTION

Nouha Ben Mahmoud, Rania Lahouimeil, Mouna Hammouda, Meriem Ben Salem, Manel Ben Salah, Ahmed Letaief, Aloui Sabra and Habib Skhiri

Background and Aims: Acute kidney injury (AKI) is a clinic-biological syndrome encompassing the entire spectrum of acute renal failure that is responsible for a higher short-term risk of developing chronic kidney disease (CKD) even after recovery of normal renal function. The risk of developing new CKD has been estimated at 4 times that of the population without an episode of AKI in several studies. Our objective was to identify its risk factors

Method: We conducted a retrospective descriptive study that included patients hospitalized for AKI with recovery of normal renal function between January 2002 and December 2015 who were followed up to one year after discharge. In order to achieve our objective, we collected data related to the patients’ age, history, multitargeted or not, mechanism of AKI, KDIGO stage, glomerular filtration rate (GFR) at hospital discharge, using a pre-designed form.

Substantial differences in kidney outcomes were noted between CKD classifications derived from ICD codes vs. KDIGO criteria, except all-cause mortality which was comparable across both cohorts and increased notably with stage. Changes in kidney function, both progression, regression, and ESKD occurred more frequently in Cohort 1. Our analysis suggests ICD diagnosis and KDIGO criteria might not be used interchangeably in the context of utilizing real-world data sources.

#4018
CHARACTERISATION OF THE CLINICAL, HUMANISTIC AND ECONOMIC BURDEN OF ANAEMIA IN CHRONIC KIDNEY DISEASE: A SYSTEMATIC LITERATURE REVIEW

Alfred Sackeyfiyo1, Digant Gupta2, Amandeep Kaur2, and Rodrigo Refoios Camejo3

1GSK, Stevenage, Hertfordshire, United Kingdom, 2Bridge Medical Consulting, Richmond, London, United Kingdom and 3GSK, Brentford, London, United Kingdom

Background and Aims: Chronic kidney disease (CKD) is defined as structural kidney damage and/or decreased kidney function (glomerular filtration rate <60 mL/min/1.73 m²) persisting for ≥3 months [1]. Anaemia is a frequent CKD comorbidity associated with increased cardiovascular (CV) morbidity, mortality, reduced health-related quality of life (HRQoL) and greater healthcare resource utilisation (HRU) [2]. Our systematic literature review provided an overview of the clinical, humanistic and economic burden of anaemia of CKD.

Method: A search was performed in MEDLINE, EMBASE, MEDLINE IN-PROCESS, Cochrane Controlled Trials Register and the Cochrane Database of Systematic Reviews from database inception to 10 April 2022, using predefined criteria to identify cohort, cross-sectional, observational and cost studies, economic evaluations, conceptual model studies, systematic and literature reviews (complemented by grey literature and congress abstract searches and back-referencing relevant review papers [2016–2021]). Full-text selected citations were examined by two independent reviewers. Clinical burden parameters included CKD progression, differences in progression between patients with/without CKD anaemia, time to blood transfusion and association of CKD stage/progression with CV outcomes or mortality. Humanistic burden included HRQoL and caregiver burden. Economic burden was determined by HRU and direct/indirect costs.

Results: Data were extracted from 115 studies (12,109 database records, 79 supplementary items; Figure 1), including patients: pre- or non-dialysis (n = 61), on dialysis (n = 21), mixed non-/on dialysis (n = 19) and unknown dialysis status (n = 14). Incidence of advanced CKD was significantly higher in adult non-dialysis dependent (NDD) patients with anaemia of CKD vs those without (incidence per 1000 person-years: 15 to ∼85 vs 3 to ∼25). Patients with CKD anaemia had a higher risk of disease progression than those without anaemia (n = 21), e.g. non-dialysis stage 1–5 adults with CKD anaemia had ∼double the risk of developing end-stage CKD (hazard ratio [95% confidence interval] CI) = 2.08 [1.50–2.89]). Median time to dialysis initiation was significantly lower in adult NDD stage 1–5 patients with anaemia of CKD vs those without anaemia (45.5 vs 68.3 months p <0.01). A higher proportion of stage 3 adult NDD patients with anaemia of CKD progressed to stage 4 or 5 over follow-up periods of 1, 2 and 3 years vs those without anaemia (40% vs 20%; 60% vs 25%; 75% vs 30%, respectively). Available data from the 43 studies reporting humanistic burden suggested significantly worse HRQoL in patients with vs without CKD anaemia; e.g. non-dialysis adults with CKD anaemia had worse 36-item kidney disease and QoL scores for symptoms/problems, effect- and burden-of CKD. Comparative caregiver burden data in patients with/without CKD anaemia were limited. Limited available evidence from an economic perspective suggested higher HRU in patients with anaemia of CKD vs those without. Patients with anaemia of CKD has ∼2 times greater risk of hospitalisation due to heart failure vs those without (crude incidence rate ratio [95% CI] = 1.9 [1.6–2.1]). Similarly, patients with anaemia of CKD has significantly higher risk of hospitalisations (adjusted relative risk [ARR] [95% CI] = 1.33 [1.31–1.34]) and emergency department visits (ARR [95% CI] = 1.14 [1.12–1.15]) in a multivariate logistic regressions model. No data were available on change in economic parameters over time or on inter-relationships between humanistic/economic burden parameters. There were no published disease models in CKD anaemia; Figure 2 illustrates identified relationships between clinical, humanistic and economic burden parameters.

*excluding transplant and dialysis; **excluding ESKD.
As the same publication may provide data for different burden domains, the total of clinical, humanistic and economic publications exceeds the total of 115. HRQoL, health-related quality of life; HRU, healthcare resource utilisation; PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

No inter-relationships exist for humanistic and economic burden parameters; caregiver burden was reported among all CKD patients regardless of Hb levels. Positive relationships, i.e. if one variable increases the other also increases: green (+); Negative relationships, i.e. if one variable increases the other decreases: red (-). CKD, chronic kidney disease; CV, cardiovascular; Hb, haemoglobin; HRQoL, health-related quality of life; HRU, healthcare resource utilisation.

Based on limited moderate-to-good quality data, we found that patients with CKD anaemia face greater clinical, humanistic and economic burdens than those without anaemia, with significantly worse HRQoL and greater HRU. CKD anaemia was also associated with a higher risk of CKD progression.

FRAILTY ASSESSMENT TOOLS, SURVIVAL TIME AND TIME TO INITIATE DIALYSIS IN OLDER PATIENTS WITH ADVANCED CHRONIC KIDNEY DISEASE

Hani Hussien, Mihai Onofriescu, Andra Nastasa, Cristina Popa, Iuliana Teodor, Irina Apascaritei, Andreea Covic, Silvia Corina Cusai and Adrian Covic

University of Medicine and Pharmacy “Grigore T. Popa, Renal medicine, Iași, Romania

Background and Aims: Chronic Kidney Disease (CKD) patients with frailty have been shown to have a shorter survival time compared to non-frail individuals. Additionally, frailty has been linked to earlier initiation of dialysis among CKD patients. Despite the availability of over 50 frailty assessment tools in the literature, few have been applied in studies of older adults with CKD. There is a need for a comprehensive analysis of different frailty tools to identify the most accurate tools that could predict survival time and time to start dialysis in older adults with CKD. The present study compares four commonly used assessment tools of frailty from different categories (self-reporting tools, clinical judgment tools and complex instruments) regarding their association with survival time and time to start dialysis.

Method: Two hundred forty patients with biochemical evidence of CKD Stages 4–5 were included in this prospective cohort study. The inclusion criteria included patients 65 years old or more with two consecutive measurements of estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m² separated by more than three months, while exclusion criteria included dialysis dependence, history of kidney transplantation, recent acute kidney injury, initial visit with the provider, amputation, or cerebrovascular accident. The four frailty assessment tools used in the study were Prisma-7 and FRAIL Scale, Clinical Frailty Scale (CFS), and Frailty Phenotype (FP). Patients were followed-up for 36 months for death events or dialysis initiation.

Results: The study population (240 patients) comprised 46% male patients with a mean age of 73.8 ± 6.6 years. Approximately 25% of patients were considered frail using the FRAIL scale, 69% using Prisma-7, and almost 40% using CFS and FP. Except for Prisma-7, “frail” patients, as determined by the FRAIL, CFS, and FP scores (Fig. 1), had significantly shorter survival times, with a mean survival of 24.9 months (Log-rank p < 0.001), 27.3 months (Log-rank p = 0.041), and 26.6 months (Log-rank p = 0.004) respectively. No significant differences were observed in time to dialysis initiation when comparing frail and non-frail patients using any of the frailty assessment tools (Table 1).

Conclusion: The findings suggest that the frailty scores derived from the FRAIL, CFS, and FP tools are better predictors of survival time in frail elderly patients with CKD, while further research is required to determine the most appropriate frailty tool to predict the time to start dialysis in this population.

Table 1: Percentage of frail patients according to different scores and mean survival/ time to dialysis (log-rank p where significantly different); NS - non-significant.

PERFORMANCES OF THE 5-YEAR KIDNEY FAILURE RISK EQUATION IN A TERTIARY SINGLE CENTER CHRONIC KIDNEY DISEASE COHORT (CKD CAREMEAU)

Julien Prouvot1,2, Marion Gerbal1, Pedram AhmadiPoor1, Florian Garo1, Sylvain Cariou1, Sophie Renaud1, Emilie Pambrun1, Pascal Reboul1 and Olivier Moranne1,2

1University Hospital of Nimes, Nephrology, Nîmes, France and 2Institut Desbrest d’Épidémiologie et de Santé Publique, UMR UA11 INSERM – UM, Montpellier, France

Background and Aims: Chronic kidney disease (CKD) is a common disease with a heterogeneous course. The Kidney Failure Risk Equation (KFRE) is designed to predict 5-year End stage renal disease (ESRD). This score has shown poor performance in predicting 5-years ESRD in elderly patients, probably because of a competitive risk with death. Indeed, patients with type 2 diabetes are numerous and older than non-diabetic patients, with higher risks of death, and thus a higher competitive risk. In this context, we aimed to evaluate the performance of the KFRE score at 5 years, in a cohort from a tertiary center, according to diabetic status.

Method: The CKD Caremeau (CKDC) cohort is a single-center tertiary cohort of adults seen by a nephrologist for CKD. We studied CKDC patients included between January 2008 and December 2017 and followed them. We excluded patients younger than 45 years. KFRE score covariates were collected at the first visit, and Renal replacement therapy (RRT) (dialysis or kidney transplantation) and death before ESRD were collected during follow-up through December 2022. Multiple imputation (Monte Carlo) was used for missing albuminuria. Score performance was calculated with discrimination (area under curve (AUC)) and calibration (observed versus predicted risks), according to diabetic status, at 5 years.

Results: Of the 3046 patients included, 1288 (42%) had diabetes. 558 (18%) albuminuria were missing and imputed. For diabetic patients, median follow-up time was 5.3 [3.0–7.6] years, median age was 73 [66–80] years, 843 (65%) patients were males, median eGFR was 38 [27–50], median albuminuria was 204 [57–671] mg/g, 177 (14%) developed ESRD, and 398 (30%) died, with a median 5-years KFRE score of 4 [0.65–17.6] %. For non-diabetic patients, median time of follow-up was 5.5 [3.3–8.2] years, median age was 72 [63–81] years old, 1027 (58%) were males, median eGFR was 40 [27–53], median albuminuria was 113 [38–399] mg/g, 205 (12%) experimented ESRD, and 501 (29%) died, with a median 5-year KFRE score of 2 [0.18–14] %. Discrimination was not modified by diabetic status at 5 years (p = 0.67). Calibration was also unaffected by diabetic status, with an overall overestimation at 5 years.

Conclusion: The performance of the KFRE score was not modified by diabetic status, meaning that age is probably more important than diabetic status for the competitive risk of death in CKD patients.
PROPOSING A NEW RENAL OUTCOME WHEN REACHING ESTIMATED GFR OF 30—SIMULATION STUDY USING REAL-WORLD STRATIFIED DATA

Hiroshi Tanaka
Mihara Red Cross Hospital, Internal Medicine/Nephrology, Mihara, Hiroshima, Japan

Background and Aims: Patients with renal diseases often have progressive decline in eGFR, with many clinical researches having outcomes of reaching renal death/renal replacement therapy. In the real life, however, patients with eGFR under 15 mL/min/1.73m² (the same unit hereafter) lose their lives more often by cardiovascular diseases before reaching endstage renal disease. Moreover, patients with eGFR below 30 are known to have miscellaneous metabolic derangements including phosphate retention, parathyroid hormone excess, metabolic acidosis, hyperkalaemia and renal anaemia. It appears to be extremely important to recognize that, in order to avoid enfacing plethora of metabolic alterations and cardiovascular disorders that progress after renal function falls below 30, we physicians need to take a step to find ways how to keep patients’ eGFR above 30 for as long time as possible. At the same time, renal clinics are fully booked already; we need to prioritize the patients who have the highest risks in reaching eGFR below 30. This simulation study was performed to draw a trajectory to clarify who are the most eligible patients for nephrologists to intervene.

Method: Before performing the simulations using an inverse transform sampling, a priori statistical distributions were retrieved from the real-world data, i.e., a whole-hospital-wide survey over 4 years; (a) distribution of eGFR: obtained from patients with at least 3 measurements of eGFR over 366 days or more, where a median of eGFR values was used to represent the patient’s renal function, (b) distribution of eGFR slopes: similarly retrieved, which were then stratified in 6 strata with each eGFR range of [30,35)/[35,40)/[40,45)/[45,50)/[50,55)/[55,60). The simulation was performed in 4 steps. In the first step (“random number generating step”), 65,000 pairs of random numbers U1, U2 were generated using a continuous uniform distribution, U[0,1]. In the second step (“eGFR generating step”), eGFR was generated using the clinically-retrieved distribution (a, above) from a random number U1. In the third step (“slope generating step”), a slope in eGFR decline was generated using the a priori stratified distribution (b, above) from a random number U2. In the final step (“estimation step”), renal prognosis, especially an eGFR value 10 years later, was estimated in each of the “65,000 simulated patients”, with or without an effect of nephrology consults. The primary outcome was defined as reaching the eGFR below 30 within 10 years. If this occurred, time until the eGFR 30 was also calculated.

Results: In the strata of simulated patients with eGFR’s [50,55) and [55,60), 35.3% and 34.9% reached their eGFR below 30, over the periods of 4.78 and 4.95 years in average. In these strata, there were marked differences in renal prognosis based on the eGFR slope, where all the patients with the fastest quartile (annual rate of decline faster than 3.09) reached the outcome, while only 4–11% of the patients with slower decline (the remaining 3/4) reached eGFR <30. The number of patients was the largest in the stratum of [55, 60). In the stratum of eGFR [45,50), 45.3% patients, including 100% of faster quartile and 24.5% of slower 3 quartiles, reached eGFR of <30. Assuming the effect of nephrology consultation as attenuating the slope by 1/3, nephrologist intervention most prominently influenced the prognosis of the patients in strata [40,45) and [45,50) in terms of proportion of patients reaching outcomes (decreases by 10.5% and 12.5%).

Conclusion: 1) Reaching an eGFR of <30 mL/min/1.73m² is a newly proposed outcome in clinical research with substantial significance such as avoiding cardiovascular events and metabolic derangements that occur frequently at eGFR below 30. 2) Patients in the fastest quartile in eGFR slope, even those whose baseline eGFR 50–60, are the candidates who merit nephrology consultation.

HEART FAILURE AND DIABETES IN CHRONIC KIDNEY DISEASE

Joakim Österman1, Franz Peter Barany1, Ida Löfman2 and Marie Evans1

1Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Division of Renal Medicine, Stockholm, Sweden and 2Karolinska Institutet, Department of medicine, Solna, Division of Cardiology, Stockholm, Sweden

#2569

Abstracts
Background and Aims: Few studies have investigated the prognosis in chronic kidney disease (CKD) patients with heart failure (HF) and diabetes (DM). In the clinical setting, treating a combination of these conditions is challenging but novel treatments such as SGLT2-inhibitors are now emerging. The aim of this study is to investigate the prevalence and outcomes of survival and major cardiovascular events (MACE) in CKD patients with HF and/or DM before these new treatments were commonly used.

Method: In this retrospective observational study, we extracted data from 26,647 nephrology-referred patients ≥18 years old with eGFR 60 ≤ ml/min/1.73 m² from the Swedish Renal Registry – Chronic Kidney Disease (SRR-CKD) and health registers at the National Board of Health and Welfare in Sweden during an observational period of January 2005 – June 2017. HF and DM was categorized based on International Classification of Disease 10 (ICD-10) diagnostic codes prior to inclusion in the SRR-CKD. Outcomes were death by any cause and MACE, defined as a composite of hospitalization for nonfatal myocardial infarction, coronary heart disease, congestive heart failure, nonfatal stroke or cardiovascular death. Secondary outcome was start of kidney replacement therapy (KRT) defined as start of dialysis or kidney transplantation.

Results: There were 12,910 (47.7%) patients with CKD, 3,458 (12.5%) with CKD + HF, 7,595 (27.3%) with CKD+DM and 3,684 (13.3%) with CKD + HF + DM. Median age was higher in the cohorts with heart failure (CKD + HF and CKD + HF + DM), 77 and 74 years vs 67 and 69 years (CKD and CKD + DM). Most patients were men in all four groups (62-66%). The use of evidence based therapies such as ACE-inhibitors/ARBs, varied across the groups between 62.9, 66.6, 78.5 and 73.7% (CKD, CKD + HF, CKD + DM, CKD + HF + DM). Statins were used in 42.0, 50.7, 71.1 and 73.7% and beta blockers in 53.9, 83.7, 65.9, and 86.1%. Survival data is presented in a Kaplan-Meier curve (Figure 1). Adjusted hazard ratio (HR) for all cause-death was highest in the cohorts with heart failure CKD + HF (2.54 [95% CI 2.40–2.68]) and CKD + DM + HF (3.22 [3.05–3.39]) followed by CKD + DM (HR 1.53 [1.45–1.60]) compared to patients with only CKD. The cumulative incidence of MACE is illustrated below (Figure 2). Adjusted HR for MACE was substantially higher in patients with heart failure, 3.82 (3.62–4.03) and 4.82 (4.59–5.08) for CKD + HF and CKD + HF + DM respectively while it was 1.63 (1.56–1.72) for CKD + DM. The risk of initiation of KRT was similar in all four groups, but risk of death before start of KRT was higher in patients with HF.

Conclusion: In CKD-patients, a heart failure diagnosis comprises approximately three to four times greater risk of death and MACE compared to patients with only CKD. The combination of CKD + HF + DM is the most severe. In all patient groups the use of evidence-based therapies was surprisingly low. This may reflect both deviation from guidelines for CKD-patients and the clinical challenge in treating comorbidities in CKD-patients. The results underlie the importance of identifying CKD-patients with HF and DM early to optimize treatment.

Figure 1: Kaplan-Meier survival curves of survival data. The figure shows the probability of survival in all four groups during the analysis time 10 years. CKD = Chronic kidney disease, HF = Heart failure, DM = Diabetes Mellitus.

Figure 2: Cumulative incidence curve. The figure is showing the cumulative incidence of major cardiovascular events in the four groups. CKD = Chronic kidney disease, HF = Heart failure, DM = Diabetes Mellitus.
**Background and Aims:** The presence of chronic kidney disease (CKD) in patients with type 2 diabetes mellitus (T2DM) leads to elevated medical and economic burden, and with CKD progression, the medical expenditure increases substantially. Information about healthcare utilization and medical expenditures of this patient population is limited in China. This study aims to describe the medical cost and healthcare utilization of patients with CKD and T2DM in a regional database in China.

**Method:** A retrospective, regional EHR-based serial cross-sectional study was conducted in Yinzhou Regional Healthcare Database (YRHCD), Ningbo, China. All adult patients (age \( \geq 18 \) years) with CKD and T2DM were collected between 1st Jan 2017 and 31st Dec 2020, patients were excluded if they did not have serum creatinine (SCr) values or initiated renal replacement therapy. Eligible patients were identified at each calendar year and categorized by CKD stages (G1-G5). Data on demographics, comorbidities and drug prescription were presented for all included patients at baseline and from 2017 to 2020. Annual medical costs and healthcare utilization were described among different CKD stages. Two-part models were built to estimate the medical costs and healthcare utilization in each CKD stage.

**Results:** A total of 16,521 patients with CKD and T2DM were included with a substantial increase between 2017 and 2020. Among all patients, the majority of them were classified in CKD stage 1 and 2. Over 70% of patients aged 65 years or older and approximately 55% were female. >90% of patients had hypertension, followed by peripheral vascular diseases, which increased from 69.2% in 2017 to 82.2% in 2020. Renin–angiotensin system inhibitors (RASI) were the most prescribed medication and metformin ranked the second. In general, the age, proportion of having comorbidities and proportion of drug prescription presented an increasing trend from 2017 to 2020. The proportion of eGFR value \( > 25 \) and \( \leq 75 \text{ mL/min/1.73m}^2 \) in G1 to G4 was 64.4% for baseline and decreased from 58.2% in 2017 to 48.7% in 2020. The general trend of medical costs in all CKD stages increased from 2017 to 2020; for healthcare utilization, the average number of outpatient visits per person per year was over 10.0 times per each CKD stage. The medical cost and healthcare utilization increased substantially in patients with more advanced CKD stages. Mean annual medical costs per patients were 6,084, 8,675, 14,291, and 24,571 CNY (908, 1,294, 2,132, and 3,726 USD) and the mean length of stay were 2.2, 3.3, 6.2, 12.6 and 16.1 days for G1-5 patients respectively in 2020. Patients in G1 and G2 had more outpatient visits compared with hospitalization, the cost of hospitalization raised dramatically in patients with G4-G5 and became a main contributor of total medical cost.

**Conclusion:** Our contemporary study revealed the medical cost and use of healthcare resources increased moderately over time in earlier CKD stages but grew remarkably from G4 stage onwards. The estimates suggested significant correlation between CKD stages and medical costs and healthcare utilization. Our findings further suggest earlier CKD identification and timely treatment may reduce the overall medical and economic burden in this population.

RISK FACTORS FOR INPATIENT MORTALITY IN PATIENTS WITH NON-DIALYSIS CHRONIC KIDNEY DISEASE ADMITTED FOR COVID-19 USING A US NATIONAL SAMPLE

Sae Morita¹, Akshay Agrawal², Nehemias Guevara², Arias Carlos¹ and Bessy Flores²

¹SBH Health System, New York, United States of America and ²SBH Health System, United States of America

Background and Aims: Several studies reported that the COVID-19 pandemic has disproportionately affected socioeconomically vulnerable populations. No study evaluated risk factors for inpatient mortality in patients with non-dialysis chronic kidney disease (CKD) admitted with the diagnosis of Covid-19, using a US nationwide sample. This study aimed to elucidate risk factors for mortality in patients with CKD during Covid-19 admissions.

Method: We extracted data from the National Inpatient Sample year 2020, the largest nationally representative inpatient-care database in the US. We created a cohort of all adults with CKD hospitalized for Covid-19 by ICD-10 codes. The outcome was inpatient mortality. We excluded patients with end stage kidney disease on maintenance dialysis and transplant patients. We compared baseline characteristics and used multiple logistic regression to determine risk factors for inpatient mortality in this cohort.

Results: Total of 201,460 admissions with a diagnosis of Covid-19 were detected in patients with non-dialysis CKD. Table 1 showed the baseline characteristics. The mean age was 72.8±0.2 years and females accounted for 43.6%. Of all, White accounted for 52.3%, followed by Black (26.1%) and Hispanic (14.6%). Inpatient mortality was 20.9%. Table 2 showed the results of the multivariable logistic model. Older patients, Males, higher Charlson Comorbidity Index scores were associated with a higher risk of inpatient mortality. White patients had a higher risk compared to Black patients and Native Americans had the highest risk, followed by other ethnic minorities, Hispanic, and Asians. Those from the lowest income households had the highest risk. Admission to a rural, publicly owned hospital and those located in the West and Northeast had higher odds of inpatient mortality.

Conclusion: Our study showed males, race, commercial payment type, lower income, and hospital settings such as regions and location were risk factors for inpatient mortality in patients with non-dialysis CKD. Further studies are needed to evaluate whether differences in clinical practice underly some of these risks.

Abstracts
Background and Aims: Immunoglobulin A nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide, with an estimated annual incidence of 25 cases per million people. Hematuria (tea coloured urine) and proteinuria (foamy urine) are among the most common clinical manifestations of IgAN, however the burden of such symptoms on diagnosis and disease severity is not fully understood. The aim of this analysis was to better understand patient reported symptoms prior to the first nephrologist consultation and diagnosis of patients with IgAN, in the United States, Europe, Japan, and China.

Method: Data were drawn from the Adelphi IgAN Disease Specific Programme (DSP), a point-in-time survey of IgAN-treating nephrologists and their consulting patients, conducted in the United States (US), Europe (EU5: France, Germany, Italy, Spain, United Kingdom [UK]), Japan, and China, between June and October 2021. Nephrologists completed structured online patient report forms for successive patients presenting with IgAN. Patients voluntarily completed questionnaires that corresponded with the nephrologist records, with questions about their IgAN on that day regarding demographics, clinical data, and signs and symptoms.

Results: A total of 991 patients with a nephrologist confirmed IgAN diagnosis completed a self-reported questionnaire. Mean (standard deviation [SD]) patient age was 42.1 (13.8) years, and 57% were male. Patients first noticed their IgAN symptoms at a mean (SD) age of 37.1 (13.1) years. Proteinuria (58%), hematuria (56%), and fatigue (36%) were the top patient-reported symptoms that prompted patients to see a doctor (n = 979). In the EU5, 64% of patients, and in the US 55% of patients, also reported high blood pressure as a sign that prompted them to see a doctor. Patients reported a median (interquartile range [IQR]) time of 12.9 (4.3-25.7) weeks from first experiencing IgAN symptoms to consulting with a doctor, ranging from 8.6 (4.3-25.7) weeks in Europe to 21.4 (4.3-52.1) weeks in Japan. Of those patients who reported a delay between experiencing symptoms and when they visited a doctor, 52% said that they were waiting to see if their symptoms would go away on their own (US: 64%, EU5: 68%, Japan: 34%, China: 49%) and 35% assumed they were just feeling tired or run down (US: 36%, EU5: 22%, Japan: 39%, China: 39%). Most patients reported first visiting either a family doctor/GP (49%) or a nephrologist (34%) for their IgAN symptoms. In China, 20% of patients reported seeing a urologist for their IgAN symptoms (US 0%, EU5 1%, Japan 6%). Median (IQR) patient-reported time from first doctor visit to IgAN diagnosis was 8.0 (4.0-16.0) weeks. This finding was consistent across geographical regions except in Japan, where median (IQR) duration was 12.0 (4.0-24.0) weeks. Waiting for test results (US: 31%, EU5: 35%, Japan: 34%, China: 68%), waiting to be tested (US: 52%, EU5: 59%, Japan: 37%, China: 54%), and waiting for a referral (US: 48%, EU5: 32%, Japan: 48%, China: 32%) were the top patient-reported reasons for a delay in the patient’s IgAN diagnosis. At time of diagnosis, 47% of patients reported ‘mild’, 43% ‘moderate’, and 10% described ‘severe’ IgAN severity (n = 983). 23% of patients in the US reported severe IgAN severity at diagnosis (EU5 14%, Japan 11%, China 7%).

Conclusion: Despite experiencing symptoms, patients with IgAN waited several weeks before consulting a physician. Of those with a delayed diagnosis, over half described their IgAN as moderate or severe. Greater awareness of symptoms of kidney disease may lead to patients seeking help for their symptoms and getting a confirmed diagnosis more quickly. Improvement of the IgAN patient journey pathway in a health care system is important to expedite timely diagnosis of IgAN and subsequent management of the disease.

*Estimates were standardized by age and sex based on nationwide demographic distributions (Destatis).
Obesity was defined as body mass index < 25 kg/m² and metabolic syndrome (age-dependent PedsQL for parents as proxies and EQ-5D for adults). PREM questionnaires consisted of 12 questions with 5-point Likert scale answers, encompassing experiences throughout all patient journey (including primary, secondary and tertiary care, and social/rehabilitation services). Higher scores in PREM questionnaire and in EQ-5D indicated worse experiences or worse PROMs evaluation (except for overall health), while higher score in PedsQL indicated better PROMs assessment. Surveys were generated and sent using REDCap system with the entire process integrated into hospital’s electronic medical record system.

Results: 48 (52%) parents and 60 (45%) adult patients completed both questionnaires. In adult patients, median completion times of PREM and PROM surveys were 5.0 and 2.2 minutes, respectively. Among parents, median PREM survey filling time was 1.7 minutes and PBM surveys filling time ranged between 2.7 and 3.8 minutes. Adult patients, who evaluated their mobility worse, reported experiencing more problems throughout diagnosis establishment process ($r = 0.3$, $p = 0.049$) and better experiences in rehabilitation ($r = 0.57$, $p = 0.015$). Worse self-care evaluation and reporting more pain/anxiety correlated with better experiences in psychological support ($r = -0.3$, $p = 0.049$ and $r = -0.34$, $p = 0.026$). Worse overall health self-evaluation associated with worse experiences in diagnosis establishment process ($r = -0.37$, $p = 0.035$). Parents evaluating their children’s physical health as worse reported more negative experiences in diagnosis establishment process ($r = -0.31$, $p = 0.028$), more technical difficulties in the healthcare process ($r = -0.47$, $p = 0.001$) and worse information provision ($r = -0.31$, $p = 0.031$). Similar associations with PREMs were observed with social and global PROMs domains (all $p < 0.05$).

Conclusion: Electronic integrated collection of PREMs and PROMs in patients with chronic kidney disorders is feasible but attempts to promote higher patient engagement are needed. Observed associations between PROMs and PREMs point towards potential benefits of long-term integrated patient feedback collection for targeted healthcare services quality improvement.

OBESITY, METABOLIC SYNDROME AND THE RISK OF ADVERSE CLINICAL OUTCOMES IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Shinyeong Kang, Hyeon Seok Hwang, Jin Sug Kim and Kyungwhan Jeong
Kyuong Hee University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South Korea

Background and Aims: Obesity and metabolic syndrome are prevalent disorder in patients with chronic kidney disease (CKD). However, it is unclear whether obesity without metabolic syndrome is associated with higher risk of adverse clinical outcomes in patients with CKD.

Method: We reviewed the National Health Insurance Service database of Korea for people who received ≥2 national health screenings between 2009 and 2011. A total of 68,464 chronic kidney disease patients were identified with consecutive estimated glomerular filtration rate <60 mL/min per 1.73 m². Obesity was defined as body mass index ≥25 kg/m² and metabolic syndrome status was considered as the presence of three or more of the following metabolic factors; waist circumference, blood pressure, fasting blood sugar, triglyceride level, high-density lipoprotein cholesterol level. The primary outcomes were cardiovascular events, end-stage renal disease progression (ESRD) and all-cause mortality.

Results: Compared to non-obese patients without metabolic syndrome, obesity without metabolic syndrome did not increase the risk of cardiovascular event (HR 1.02, 95% CI 0.95–1.11) and progression to ESRD (HR 0.86, 95% CI 0.73–1.02). Risk of all-cause mortality was significantly decreased in these patients (HR 0.88, 95% CI 0.81–0.96). These findings were consistently observed in overweight, obese, morbid obese patients without metabolic syndrome. In addition, while linear increase of HRs for each additional metabolic abnormality was observed, HRs increase for cardiovascular event was significantly slower in obese patients than in non-obese (P for interaction = 0.035).

Conclusion: Obesity without metabolic syndrome did not confer excess risk for cardiovascular complication or ESRD progression and decreased the risk of all-cause mortality. Healthy effect of obesity against mortality risk and metabolic hazard on cardiovascular event is better to be considered in CKD patients.

CHARACTERISTICS OF MEDICATION-INITIATOR COHORTS OF PATIENTS WITH CHRONIC KIDNEY DISEASE AND TYPE 2 DIABETES IN JAPAN: A REPORT FROM FOUNTAIN PLATFORM

Yuichiro Yano1, Hiroshi Kanegasu2, Suguru Okami3, Nikolaus Obergriesser4, Manel Pladevall-Vila5, Alain Gay6, Satoshi Yamashita7, Catherine Johannes8, Natalie Ebert9, Csaba Kovessy9, David Vizzaya10 and Naoki Kashiha11

8Charité-Universitätsmedizin, Institute for Public Health, Berlin, Germany, 9University of Tennessee Health Science Center, Department of Medicine, MEMPHIS, United States of America, 10Bayer AG, Integrated Evidence Generation & Business Innovation, Sant Joan Despi, Spain and 11Kawasaki Medical School, Department of Nephrology and Hypertension, Kureashiki, Japan

Background and Aims: The clinical landscape for the treatment of patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) is rapidly evolving with the introduction of new treatments such as sodium-glucose cotransporter-2 inhibitors (SGLT2i), glucagon-like peptide-1 receptor agonist (GLP-1 RA), and non-steroidal mineralocorticoid receptor antagonists (nsMRA). However, limited information is available regarding the utilization patterns of these new therapies in worldwide clinical practice. The FINEGUST study (EUPAS84188, NCT05526157) is a multinational observational cohort study and part of the FOUNTAIN multi-database research platform. It aims to describe drug utilization and temporal changes of different treatments in adults with CKD and T2D in two time periods (before and after finerenone approval) using secondary data from population-based data sources in Europe, Japan, China, the United Kingdom, and the United States.

Method: In this country-specific analysis, four separate medication-specific cohorts of adults with CKD and T2D, including new users of SGLT2i, GLP-1 RA, steroidal MRA (sMRA), or esaxerenone as a nsMRA available in the study period, were retrospectively identified from the Japan Chronic Kidney Disease Database Extension (J-CKD-DB-Ex) between January 1st 2014 and June 30th 2021 (pre-finerenone period). The presence of T2D and CKD was assessed based on ICD-10 diagnostic codes, and lab measurement values, i.e., serum creatinine to calculate estimated glomerular filtration rate (CKD-EPI) or urine albumin-creatinine ratio (UACR). The CKD stage was categorized based on the KDIGO definition. Patients with type 1 diabetes, kidney cancer or kidney failure at baseline were excluded. The index date was the date of initial prescription of each drug class. Patient characteristics and baseline medication patterns were summarized overall and by presence or absence of UACR results in the previous year.

Results: Of 251,659 patients recorded in J-CKD-DB-Ex in the study period, we identified 6,934, 2,991, 18,974, and 301 patients with recorded use of SGLT2i, GLP-1 RA, sMRA, and nsMRA, respectively. After applying inclusion and exclusion criteria, 1,157 SGLT2-1 (16.7%), 329 GLP-1 RA (11.0%), 1,769 sMRA (9.3%), and 63 nsMRA (20.9%) new users were included in the analysis. The mean age ranged from 66 years in the GLP-1 RA cohort to 74 years in the sMRA cohort (Table 1). All medication classes were most prescribed in patients with CKD stage 3 followed by patients with CKD stage 2. Insulin was most frequently prescribed in the GLP-1 RA cohort (65.3%). Patients in the sMRA cohort were most comorbid based on the prevalence of congestive heart failure (40.2%), coronary heart disease (26.9%), and cerebrovascular disease (16.1%). Compared to patients without UACR measurements, those with a UACR measurement in year prior to the index date were more likely to receive other treatments of interest in combination during the 90 days prior to index (Figure 1). Among the drug classes summarized, angiotensin-converting enzyme inhibitors or angiotensin-receptor blockers were the most prescribed drug class in all cohorts (43.0% in SGLT2i cohort, 28.9% in GLP-1 RA cohort, 30.6% in sMRA cohort, and 50.8% in nsMRA cohort, respectively).

Conclusion: Treatment initiation with either SGLT2i, GLP-1RA, sMRA or nsMRA occurred most frequently in patients with CKD stage 2–3 with variations in characteristics for each medication class, including the patterns of anti-hyperglycemic therapies and cardiovascular complications. Differences by UACR test result availability 1-year prior to index may indicate a possible association between treatment choice and the availability of UACR test results. Subsequent analyses from the FOUNTAIN program, including longitudinal drug utilization patterns and geographic variations across regions, will provide

**ARB:** angiotensin receptor blocker; **ACEi:** angiotensin-converting-enzyme inhibitors; **CKD:** chronic kidney disease; **SD:** standard deviation; **UACR:** urine albumin-creatinine ratio. *Based on the International Classification of Disease 10th revision codes and estimated glomerular filtration rate in accordance with KDIGO definition.

Figure 1: Number of additional drug classes* used 90 days prior to index in patients with or without UACR results in year prior to index.

Further insights about the clinical use of different treatment options for patients with CKD and T2D.

**Background and Aims:** Individuals receiving kidney replacement therapy (KRT) are at higher risk of cardiac arrest than the general population. The aim of this systematic review was to evaluate survival outcomes in individuals on different forms of KRT (haemodialysis, peritoneal dialysis or kidney transplantation) following cardiopulmonary resuscitation (CPR) within healthcare settings (hospital or outpatient clinics).

**Method:** A comprehensive literature search of EMBASE, MEDLINE, CINAHL, Web of Science and Central was carried using a pre-defined search strategy with no date or language restrictions. Retrospective and prospective observational studies reporting outcomes following CPR in adults on kidney replacement therapy were included. The study protocol was prospectively registered on PROSPERO: CRD42022336363.

**Results:** Thirteen eligible studies were identified. Due to the heterogeneity of study populations, lack of a standardised outcome set and inconsistent use of control groups, a narrative review was conducted, and a meta-analysis was

Figure 1: Bar chart of % Survival following CPR in healthcare setting. Y axis denotes first author, year of publication and number of study participants in corresponding group. Where a control group was used, p-value was taken from publication. Saeed et al (2015) did not report a p-value for unadjusted univariate analysis. Yanget al reported unadjusted annual survival between 2004–2012—the value presented represents the mean of the annual % survival to discharge. Studies by Lafrance et al, Davis et al and Pun et al refer to CPR outcomes in outpatient dialysis clinic settings, the remainder of the presented studies evaluated outcomes following in-hospital CPR. Median % survival was calculated at 22%.

not performed. Crude unadjusted survival rate to discharge from hospital was reported in 11 studies and ranged from 0%—75%. Only two studies reported neurological outcome at discharge, with rates of a favourable cerebral performance category score (CPC 1 or 2) on discharge between 17–20%.

Conclusion: The current evidence is insufficient to guide clinical decision-making regarding resuscitation due to a lack of up-to-date data, uncertainty about outcomes and inconsistent reporting of neurological status after CPR. Additionally, there is a lack of data comparing survival outcomes for people on different types of KRT. There remain unanswered questions regarding the likelihood of favourable outcomes for the KRT population and whether these can be accurately predicted using clinical and demographic features.

Background and Aims: The substantial mortality and morbidity burden of chronic kidney disease (CKD) is well described, with the highest burden associated with progression to end-stage kidney disease (ESKD), where kidney replacement therapy (dialysis or kidney transplantation) is indicated. CKD is known to have a detrimental effect on patient health-related quality of life (HRQoL). However, there is a lack of data comparing the impact of CKD on patient and caregiver HRQoL versus the general population. This study aimed to administer validated HRQoL instruments using a quantitative online survey to estimate the HRQoL of patients with CKD and their caregivers compared to the general population.

Method: A non-interventional survey enrolled adult patients with CKD and caregivers. Patients with a diagnosis of CKD for at least 3 months were included. ESKD was defined as patients with CKD stage 5 or receiving dialysis or a kidney transplant. Caregivers were required not to receive formal payment and must have cared for a CKD patient for a minimum of 1 hour a week in the previous 4 weeks. A general population cohort was also enrolled, matching key patient and caregiver demographic characteristics (e.g. age, sex, and area of residence). Patient and caregiver HRQoL were assessed using the EQ-5D-5L instrument. Caregiver HRQoL was also measured by the CarerQoL-7D carer-specific instrument.

Results: This analysis is based on 199 patients with CKD and 113 caregivers in the United States who were enrolled between June and July 2022. Patient and caregiver median age was 58 years and 38 years, respectively. There were 32.2% patients who were on dialysis, while 81.4% caregivers were caring for a patient on dialysis. Most dialysis patients (79.7%) were receiving treatment in a clinic or hospital, with 20.4% of patients receiving it at home. Caregivers typically cared for their parent (45.1%) or partner (25.7%) and their duties would most commonly include driving to/from medical appointments (89.4%). When comparing mean [SD] EQ-5D-5L index scores for patients with CKD with the general population, patients had 33.7% lower utility (0.63 [0.27] vs 0.95 [0.08]) and caregivers had 13.8% lower utility (0.81 [0.22]) vs 0.94 [0.11]) versus the general population. EQ-5D-5L index scores were lower in dialysis-dependent patients (0.59 [0.27]) versus non dialysis-dependent patients (0.65 [0.27]). Patients and caregivers reported problems across all EQ-5D domains (anxiety and depression, mobility, pain/discomfort, selfcare and usual activities) when compared to the general population, with anxiety and depression domains scoring highest. According to the CarerQoL-7D index, caregivers for patients with CKD had worse HRQoL than caregivers for other major illnesses, including hip fractures, breast cancer and dementia, according to published

In total, 3,738 patients were enrolled for analysis from 5,299 patients and fulfilled the inclusion criteria among 12,742 patients who underwent coronary angiography.

Method: C-reactive protein (hs-CRP) levels. As well as potential mediators, including serum albumin and high-sensitivity C-reactive protein (hs-CRP) levels.

Background and Aims: Decreased kidney function is a risk factor for the development of contrast-associated acute kidney injury (CA-AKI) in chronic kidney disease (CKD). Although the relationship between CKD and CA-AKI is well established, the mechanistic link between the two, particularly the extent to which this interaction is mediated by inflammation, remains poorly understood. We examined the association between CKD and CA-AKI, as well as potential mediators, including serum albumin and high-sensitivity C-reactive protein (hs-CRP) levels.

Method: A total of 3,738 patients were enrolled for analysis from 5,299 patients and fulfilled the inclusion criteria among 12,742 patients who underwent coronary angiography (CAG) between 1 January 2007, and 31 December 2016. Multivariable logistic regression and mediation analyses were performed. In addition to the effect as risk factors, direct and indirect effects were also estimated.

Results: Among 3,738 subjects, 414 developed AKI (11.1%). Pre-procedural albumin and Lnhs-CRP (log-transformed) were independently associated with CA-AKI (odds ratio [OR], 95% confidence interval [CI]): 0.320 (0.272–0.378), P < 0.001 and 1.211 (1.132–1.296), P < 0.001, respectively. Direct, and indirect effects were also estimated. Patients with CKD were found to be more likely to exhibit lower serum albumin and higher serum hs-CRP levels. Simple mediation analyses showed that 38.8% and 52.3% of the relationship between CKD and CA-AKI was mediated by the serum albumin and hs-CRP levels, respectively with co-mediation being 13.9%.

Conclusion: These results represent that, in addition to reduced kidney function, inflammatory parameters are also risk factors and mediators of CA-AKI in patients with CKD.

Conclusion: These results represent that, in addition to reduced kidney function, inflammatory parameters are also risk factors and mediators of CA-AKI in patients with CKD.

#4866 PREVALENCE AND SEVERITY OF CHRONIC KIDNEY DISEASE ASSOCIATED PRURITUS IN A DIALYSIS NETWORK IN WEST GERMANY
Thilo Krüger1 and Bastian Schunk2
1 University Clinic of the RWTH Aachen, Division of Nephrology and Rheumatology, Aachen, Germany and 2 RWTH Aachen, Medical Faculty, Aachen, Germany

Background and Aims: Chronic kidney disease-associated pruritus (CKD-aP) is a troubling and in some cases debilitating problem for patients with CKD and end-stage renal disease with potential impact on patients’ quality of life (QoL). Frequency of CKD-aP with at least a medium intensity has been reported to be present in approximately 40% of dialysis dependent patients in European countries and 26% in Germany. This work intended to update prevalence and disease severity in a large dialysis network in West Germany.

Method: We performed a cross-sectional study addressing maintenance dialysis patients (both hemodialysis and peritoneal dialysis) in 23 dialysis facilities in West Germany with a total of approximately 1,500 dialysis patients. After ethical approval, a questionnaire was distributed to all dialysis patients asking for presence of pruritus and if present about itch duration, dialysis vintage, pruritus severity, communication patterns, therapeutic attempts and impact on quality of life (QoL). Pruritus intensity was assessed using the worst itch numeral rating scale (WI-NRS).

Results: From May to July 2022, 919 patients completed and returned the questionnaire. 31.9% were female, 55.4% male and 12.7% did not disclose their gender. Overall, 223 (23.7%) reported presence of pruritus of any severity with 90.1% having pruritus for at least 6 weeks duration. 159 (17.4%) of all patients reported at least moderate itch intensity (WI-NRS ≥ 4) and 70 (7.7%) a severe itch intensity (WI-NRS ≥ 7). Dialysis vintages of <1 year, 1–2 years, 2–4 years and >4 years were reported by 15.8%, 16.2%, 25.7% and 36.9% of patients with pruritus, respectively. Approx. 71% of all patients with any intensity of pruritus reported to be unaware of origin of pruritus, the remainder gave various reasons with a majority mentioning CKD or dialysis associated reasons. 62 of the 223 with pruritus (27.4%) reported having received treatments of which 14 (22.6%) stated no, 27 (43.5%) partial and 17 (27.4%) good response. Most frequent therapy category mentioned was emollients (14) with a mixed effect; 4 reported no effect, 6 some and 2 a good effect. Of those having received antihistamines, all reported good response (4), 132 (59.2%) of patients with pruritus communicated the presence with someone, 89 of those (67.4%) with their nephrologist. Of the 223 patients with pruritus 214 (96.0%) reported any stage of impact on their QoL in at least one of the categories sleep, social life, household, or work. Highest frequency given was in social life (180/223) and lowest frequency in sleep disturbances (74/223).

Conclusion: Prevalence of CKD-aP of at least medium intensity was lower than previously reported for Germany, continuing the previous trend seen in DOPPS for decreasing prevalences. The patient awareness of association of pruritus to CKD is still low. A positive correlation of itch prevalence in CKD may exist to dialysis vintage. Compared to DOPPS data from 2015, fewer patients communicated itch at all but in case the nephrologist was most frequently addressed. Treatment attempts seem to be still rare and were conducted only in a minority of patients with CKD-aP. Impact of CKD-aP on QoL was usually present.

#5293 THE IMPACT OF SEVERE DEPRESSION ON THE SURVIVAL OF OLDER PATIENTS WITH END-STAGE KIDNEY DISEASE
Background and Aims: Incidence of depression increases in patients with end-stage kidney disease (ESKD). We evaluated the association between depression and mortality among older patients with ESKD, which has not been studied previously.

Method: This nationwide prospective cohort study included 487 patients with ESKD aged > 65 years, who were categorized into minimal, mild-to-moderate, and severe depression groups based on their Beck Depression Inventory-II (BDI-II) scores. BDI-II scores were separated into three symptom domains: affective, cognitive, and somatic depressive symptoms. The association between the depression groups and survival were analyzed using multivariate Cox proportional hazard regression models. Predisposing factors for high BDI-II scores were evaluated using logistic regression analysis. The associations among the three depressive-symptom domains and survival were also analyzed.

Results: The severe depression group showed a higher modified Charlson comorbidity index value and lower serum albumin, phosphate, and uric acid levels than the other depression groups. The Kaplan-Meier curve revealed a significantly lower survival in the severe depression group than in the minimal and mild-to-moderate depression groups (P = 0.011). Multivariate Cox regression analysis confirmed that severe depression was an independent risk factor for mortality in the study cohort (hazard ratio (HR), 1.39; 95% confidence interval (CI), 1.01–1.91; P = 0.041). BDI-II scores were associated with modified Charlson comorbidity index (P = 0.009) and serum albumin level (P = 0.004) in multivariate linear regression. Among the three depressive symptoms, higher somatic symptom scores were associated with increased mortality (HR, 2.45; 95% CI, 1.25–4.79; P = 0.009).

Figure 1: Kaplan-Meier curve for mortality in depression groups.

Model 1: unadjusted.
Model 2: adjusted for age and sex.
Model 3: adjusted for age, sex, and mCCI.
Model 4: adjusted for age, sex, mCCI, albumin, phosphate, and uric acid.
Abbreviations: BDI-II, Beck Depression Inventory-II; HR, hazard ratio; CI, confidence interval; mCCI, modified Charlson comorbidity index.
Conclusion: Among older patients with ESKD, severe depression increases mortality compared with minimal or mild-to-moderate depression. And patients with concomitant somatic symptoms require careful management of their comorbidities and nutritional status.

#5392
THE DIAGNOSTIC JOURNEY OF PATIENTS WITH IMMUNOGLOBULIN A NEPHROPATHY: DATA ANALYSIS OF A REAL-WORLD SURVEY
Michel Kroes1, Serge Sweerts1, Aneesh Thomas George2, Luis Prieto3, Jonathan Decourcy4, and Jade Garratt-Wheeldon4
1Novartis Pharma AG, Basel, Switzerland, 2Novartis Healthcare Private Limited, Hyderabad, India, 3Novartis Pharma AG, Basel, Switzerland and 4Adelphi Real World, Bollington, United Kingdom

Background and Aims: Although rare (estimated global annual incidence of 25 cases per million people), immunoglobulin A nephropathy (IgAN) is the most common form of primary glomerulonephritis. IgAN is associated with a poor prognosis, with 30% or more of patients with >1g/day of proteinuria progressing to kidney failure within 10 years. As poor prognosis is partly due to delayed diagnosis, this analysis aims to describe aspects of the diagnostic pathway for patients with IgAN.

Method: Data were drawn from the Adelphi IgAN Disease Specific Programme (DSP)1,2, a point-in-time survey of IgAN-treating nephrologists and their consulting patients, conducted in the United States (US), Europe (EU5: France, Germany, Italy, Spain, United Kingdom [UK]), Japan, and China, between June and October 2021. Nephrologists completed structured online patient record forms for successive patients presenting with IgAN, including demographics, clinical data, time to diagnosis, reasons for delayed diagnosis, and treatment history. A duration of greater than four weeks between first consultation with a physician and diagnosis was considered a delayed diagnosis.

Results: A total of 295 nephrologists completed records for 1537 patients which had data characterizing the time from first consultation and diagnosis. Mean (standard deviation (SD)) patient age was 43.0 (15.0) years, and 59% were male. At diagnosis, mean (SD) proteinuria (n = 1254) was 2.3 (2.4). Median time from first physician consultation to confirmed IgAN diagnosis varied by physician speciality. When patients initially consulted a nephrologist regarding their IgAN symptoms, median (interquartile range) duration from first consultation to diagnosis was 2.4 (0.7-5.6) weeks (n = 582). For family doctors/ General Practitioners (GPs)/ Primary Care Physicians (PCPs) (n = 656), this was 6.6 (3.0-13.8) weeks, for internal medicine/ internists (n = 120) and urologists (n = 113) the duration was 4.4 (1.3-9.4) and 1.5-12.5) weeks. Most patients were diagnosed by a nephrologist (US 95%, n = 263; EU5 96%, n = 491; Japan 99%, n = 236; China 85%, n = 547) and these were typically performed by a nephrologist in most countries (US 99%, n = 233; EU5 81%, n = 397; Japan 95%, n = 231; China 97%, n = 464) except in the US, where 40% of cases were done by a radiologist. However, some patients were unable to undergo a biopsy (6%, n = 1531) and in some cases the physician chose to diagnose the patient using non-invasive methods (8%, n = 1531).

Conclusion: Most of the patients with IgAN in this survey were diagnosed by a nephrologist using a kidney biopsy. These data suggest that initially consulting a family doctor/ GP/ PCP led to a delayed diagnosis for patients. This may be due to the time taken for onward referral to a nephrologist. China had the highest proportion of patients diagnosed within 4 weeks from the first consultation (57%) and the highest proportion of patients who first visited a nephrologist regarding their symptoms. The results from this study suggest that speeding up referral from PCPs to nephrologists may reduce the amount of time taken to confirm IgAN diagnosis.

#5807
FACTORS ASSOCIATED WITH KALEMIA IN RENAL DISEASE
Granal Maelys, Denis Fouque, Ducher Michel and Jean Pierre Fauvel
Hospices Civils de Lyon - HCL, Nephrology, Lyon, France

Background and Aims: International recommendations promote a strict potassium diet in order to avoid hyperkalemia in chronic kidney disease patients. However, efficiency of such a dietary counseling has never been demonstrated. The objectives of this study were to define the relationship between kalemia, dietary potassium intake estimated by kaliuresis and renal function and to define the factors associated with kalemia in patients using artificial intelligence.

Method: To this extent, data from patients followed in a nephrology unit, included in the UniverSel study and whose kalemia (measured on the day of urine collection; n = 367) were analyzed. The association between kalemia and thirty-four variables concerning the patients’ characteristics, their biological work-up, their medications and their answers to the UniverSel dietary self-questionnaire on kalemia were assessed using a Bayesian network.

Results: The patients included had a wide range of estimated glomerular filtration rate, but few had stage 5 chronic kidney disease (CKD). Kalemia was negatively and linearly correlated to estimated glomerular filtration rate (p<0.001) but was not correlated to kaliuresis (p = 0.55). Kaliuresis was not correlated to estimated glomerular filtration rate (p = 0.08). Factors associated with kalemia were analyzed using a Bayesian network. The 5 variables most associated with kalemia were, in descending order, estimated glomerular filtration rate, original nephropathy, age, diabetes, and plasma bicarbonate level. RAS-blockers prescription was also associated to kalemia. Consumption of potassium rich food were poorly associated to kalemia.

Conclusion: Our results do not support a strict control of potassium intake in stage 1 to 4 CKD patients. Our results reinforce the interest of a multidimensional management including personalized therapy and strict correction of metabolic acidosis. Lightning dietary restrictions in potassium would improve the quality of life of patients with CKD who are often multi-pathological and already subject to multiple dietary constraints.
#6758
THE CASUAL ASSOCIATION OF ALCOHOL CONSUMPTION AND CHRONIC KIDNEY DISEASE: A MENDELIAN RANDOMIZATION STUDY
Liu Dekai, Lei Tang, Xiaoxi Zeng and Ping Fu
West China Hospital, Sichuan University, Division of Nephrology, Kidney Research Institute, Chengdu, PR. China

Background and Aims: Many previous views believed that alcohol intake increases the risk of chronic kidney disease progression. Even in the previous KDIGO guidelines, alcohol restriction was included in the guidelines. However, in recent years, some research contradicted these views and removed alcohol restriction from the KDIGO guidelines. The causal relationship between alcohol intake and the risk of progression of chronic kidney disease was explored using the methods of Mendelian randomized studies.

Method: Using data from a large sample of genome-wide association studies, the Society for Genome-wide Association Analysis and Sequencing of alcohol and nicotine consumption or use (GSCAN) database (1.2 million individuals) was used to identify independent genetic loci strongly associated with alcohol consumption. Then select the corresponding genetic loci in the CKDGen consortium database (one million individuals) as instrumental variables. One is not to use "MR-PRESSO" package for analysis. Then, two sample Mendelian random methods, such as inverse variance weighting method, approximate maximum method, MR-Egger regression method, weighted median method and weighted model method, are adopted. The other one is to use "MR-PRESSO" bag to detect whether there are outlier points, remove them, and then use the inverse variance weighting method of quantity sample Mendelian random method. The causal relationship between alcohol intake and chronic kidney disease was reflected by the change in eGFR value with increased unit alcohol intake.

Results: A total of 44 single nucleotide polymorphisms (SNPs) were screened as instrumental variables. Without the use of "MR-PRESSO" package, the results obtained by using inverse variance weighting method, approximate maximum method and MR-Egger regression method were not statistically significant. The weighted median method showed that alcohol intake increased by one unit per week. The glomerular filtration rate (eGFR) was increased by 0.015 ml/min (95% CI 0.005-0.026, P = 0.004). Weighted model results showed that an increase of one unit per week in alcohol intake was associated with an increase of 0.017 ml/min in estimated glomerular filtration rate (eGFR) (95% CI 0.005-0.026, P = 0.002). The MR-Egger regression result showed that the genetic pleiotropy did not bias the result (intercept = 0.009, P = 0.507). However, with the removal of six outliers using MR-PRESSO, the inverse variance weighting method showed that an increase of one unit of alcohol intake per week increased the estimated glomerular filtration rate (eGFR) by 0.014 ml/min (95% CI 0.010-0.020, P = 0.004).

Conclusion: This study provides an association between alcohol intake and progression of chronic kidney disease. Overall, increased alcohol intake is protective against progression of chronic kidney disease. Clinically, alcohol intake is associated with many diseases. Although this study concluded that alcohol has a protective effect on the progression of chronic kidney disease, whether increasing alcohol intake can protect kidney function needs to be treated with caution. In addition, the long-term effects of alcohol intake on the progression of chronic kidney disease also need to be studied.

#6904
EVALUATION OF KIDNEY FUNCTION GRAPH SURVEILLANCE ACROSS SOUTH WALES, UK
Owain Brooks1, Aled Richards1, Robert Greening1, Chris Brown1, Lee White1, William Ford2, Juliette Moutel-Davesne2 and Julia Phillips2
1Swansea Bay University Health Board, Department of Nephrology, Morriston Hospital, Swansea, United Kingdom and 2Cardiff University, School of Pharmacy and Pharmaceutical Sciences, Cardiff, United Kingdom

Background and Aims: For people requiring Kidney Replacement Therapy (KRT) late presentation to a nephrologist (within 90 days of initiating KRT) is associated with adverse outcomes. The ASSIST-CKD kidney function graph surveillance (KFGS) quality improvement project was adopted by the Department of Nephrology in South West (SW) Wales, UK in November 2017. Between the end of 2017 and the end of 2020, late presentation rates reduced from 19.5% [1] to 13.5% [2] across the region, having reduced to 9.7% in 2019 [3]. During KFGS, graphs of eGFR over time are generated for patients ≤65 years with eGFR ≤60 ml/min/1.73 m² and ≥65 years with eGFR ≤40 ml/min/1.73 m² with significantly deteriorating kidney function. Alerts are sent to the GP for review and/or referral to nephrology. Over 100,000 graphs have been reviewed in SW Wales. We present demographic and initial outcome data for patients identified by KFGS.

Method: An observational retrospective cohort study analysed data of patients identified through KFGS in SW Wales between 1/11/17 and 1/10/21. Data were extracted from ASSIST-CKD and renal (Vital Data) databases using SQL coding.

Results: Data pertaining to 4811 patients are included for analysis. 44% of patients were male. At initial eGFR the mean age of patients ‘flagged’ was 73 years. The mean [range] initial eGFR was 32 ml/min/1.73 m² [2-50]. The median time [range] from initial eGFR to KFGS alert was 8 days [2-113]. For
those with results within 90 days of initial eGFR the mean initial haemoglobin (HB) was 118 g/l. The mean serum potassium was 4.7 mmol/L. Data for 1144 (24%) patients were included for outcome analysis, where a clear timeline from initial eGFR to KFGS alert, first registration with the nephrology service (registration), and outcome could be established. 3667 patients were excluded from outcome analysis because they were registered before KFGS or were not registered with nephrology, had died or moved out of area after KFGS alert. The median time [range] from alert to registration was 22 days [0-1636]. 20% of patients (n = 232) received CKD education from a specialist nurse. The median time [range] from registration to first contact from a CKD education nurse was 349 days [8-1419]. 34% of patients received IV iron and 31% received an erythropoiesis-stimulating agent (ESA) after alert. The median time [range] from registration to first IV iron and first ESA was 257 [5-1705] and 277 [3-1650] days respectively. 6% (n = 71) of patients required KRT. The late presentation rate was 22%, 21% of patients needing haemodialysis (HD) received their first treatment via an arteriovenous (AV) fistula, 1% via AV graft, 59% via non-tunneled line and 19% via tunnelled line. 44% (7/16) of patients presenting late died within 90 days of starting KRT. 33% (18/55) of patients died within 90 days of starting KRT if they presented to a nephrologist >90 days before starting KRT.

Conclusion: Late presentation rates have reduced in SW Wales since implementing KFGS. The relatively high late presentation rate and low rate of initial definitive access for HD in the present data requires further analysis. eGFR values that prompted alert may denote Acute Kidney Injury (AKI) as opposed to, or as well as CKD progression; increasing the urgency of referral to nephrology. eGFR values pre and post alert will be reviewed to elucidate this. Patients presenting late were more likely to die within 90 days of starting KRT than those presenting early, emphasising the importance of early identification of progressive kidney disease. We aim to compare present data with a cohort referred to nephrology independent of KFGS to inform renal centres of the benefits of KFGS beyond headline late presentation rates, including timely access to specialists. We will consider potentially unwelcome consequences of KFGS, such as inappropriate referral. We cannot draw conclusions of causality between KFGS and outcomes. The GP may not have seen the alert, and there are several reasons why a GP may decide not to refer to nephrology following a KFGS alert.

Background and Aims: The past three decades have seen an increase in the prevalence and mortality rate of chronic kidney disease (CKD). It is estimated that between 1990 and 2017, the global all-age prevalence of CKD increased by 29.3%, whilst the mortality rate rose by 41.5%. Over this period, CKD became the 12th leading cause of death worldwide, with an estimated 1.2 million deaths attributed to the disease in 2017 [1]. With global prevalence currently estimated at 10% [2], CKD is a leading cause of disability, accounting for 35.8 million disability-adjusted life years (DALYs) in 2017 [3]. This growing burden of the disease calls for robust healthcare policy interventions to improve disparities in health, socioeconomic, and environmental outcomes. The aim of this research is to build a Healthcare Policy framework for CKD that will analyse the drivers and components of the burden of disease in terms of clinical, socioeconomic and environmental outcomes. It will also incorporate current knowledge of best practices and challenges in the organisation of healthcare services to mitigate these burdens. The framework will facilitate the analysis of the burden of disease attributable to CKD and be used to inform further research on areas in which policies could be implemented to optimise CKD prevention, early detection, and treatment at different stages of CKD and different levels of health systems. The framework presented here reflects the UK context but can be adapted for different country contexts.

Method: The framework development included two stages. First, a scoping review of the literature in this field was conducted. The literature review included peer-reviewed articles, grey literature, policy documents, academic reports and congress and conference reports. The second stage saw the validation of the framework by a multidisciplinary expert panel in the UK. This expert panel was composed of eight UK experts in the fields of nephrology, public health, primary care, organ donation and transplantation, and other disciplines.

Results: The framework outlines a holistic patient pathway from pre-CKD development to kidney failure along with the corresponding interdisciplinary level of care. The framework stresses the need to implement a population-wide approach focused on preventative care strategies, chiefly on the risk reduction of kidney failure. Underlying aetiologies and disparities in access to care were found to be inherently linked to disease progression and health outcomes. Data systems were identified as vital to ensuring continuity of care between primary and specialty care which in turn could lead to improved patient outcomes. The use of greener energies coupled with a reduction in the incidence of renal failure requiring dialysis could reduce substantially the environmental footprint of this disease. The burden of disease reflects the sum of the individual and system-level impact and outcomes of CKD which are labelled as economic, social, and environmental (Fig. 1).

Conclusion: The conceptual framework underscores how underlying aetiologies, socioeconomic factors, and fragmentation of care are reflected in disparities in healthcare access, particularly in marginalised and underserved populations. The environmental footprint of this disease could be reduced through optimal standard of care. The framework can inform future research to model the burden of CKD in terms of clinical, societal, economic, and environmental outcomes in the UK and the targeting of policy interventions to mitigate these burdens across different country contexts.

USING THE KIDNEY FAILURE RISK EQUATION TO PREDICT END-STAGE KIDNEY DISEASE IN CKD PATIENTS OF SOUTH ASIAN ETHNICITY: AN EXTERNAL VALIDATION STUDY
Francesca Maher1, Lucy Tece1, Rupert Major2, Nigel Brunskill3,4, Sarah Booth1 and Laura Gray1

1 University of Leicester, Population Health Sciences, United Kingdom, 2 University of Leicester, Department of Population Health Sciences, United Kingdom, 3 University Hospitals of Leicester NHS Trust, John Walls Renal Unit, United Kingdom and 4 University of Leicester, Department of Cardiovascular Sciences, United Kingdom

Background and Aims: The Kidney Failure Risk Equation (KFRE) predicts the 2- and 5-year risk of needing kidney replacement therapy (KRT) using four risk factors – age, sex, urine albumin-to-creatinine ratio (ACR), and creatinine-based estimated glomerular filtration rate (eGFR). Although the KFRE has been recalibrated in a UK cohort, this did not consider minority ethnic groups. Further validation of the KFRE in different ethnicities is a research priority. The KFRE also does not consider the competing risk of death, which may lead to overestimation of KRT risk. This study externally validates the KFRE for patients of South Asian ethnicity and compares methods for accounting for ethnicity and the competing event of death.

Method: Data were gathered from an established UK cohort containing 35,539 individuals diagnosed with chronic kidney disease. The KFRE was externally validated and updated in several ways taking into account ethnicity, using recognised methods for time-to-event data, including the competing risk of death. A clinical impact assessment compared the updated models through consideration of referrals made to secondary care.

Results: The external validation showed risk of KRT differed by ethnicity. Model validation performance improved when incorporating ethnicity and its interaction with ACR and eGFR as additional risk factors. Further, accounting for the competing risk of death improved prediction. Using a criteria of 5 year ≥5% predicted KRT risk, the competing risks model resulted in an extra 3 unnecessary referrals (0.59% increase) but identified an extra 1 KRT case (1.92% decrease) compared to the previous best model. A hybrid criteria of predicted risk using the competing risks model and the previous guidelines should be used in referrals to secondary care.

Conclusion: The accuracy of KFRE prediction improves when updated to consider South Asian ethnicity and to account for the competing risk of death. This may reduce referrals whilst identifying risks of KRT and could further individualise the KFRE and improve its clinical utility. Further research should consider other ethnicities.

THE CLINICAL AND ECONOMIC BURDEN OF CHRONIC KIDNEY DISEASE IN GREECE
Panos Stafylas1, Pantelis Sarafidis2, Christiana Tychala1, Eva Pella2, Marianthi Karaiskou1, Renata Valsami1, George Stergiou3 and Ioannis Boletis4

1 HealThink (Medical Research & Innovation PC), Thessaloniki, Greece, 2 Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece, 3 National and Kapodistrian University of Athens, Third Department of Medicine, Sotiria Hospital, Athens, Greece and 4 National and Kapodistrian University of Athens, Department of Nephrology and Renal Transplantation, Laiko General Hospital, Athens, Greece

Background and Aims: Chronic Kidney Disease (CKD) is a progressive disorder with a substantial clinical and economic burden. This burden is expected to grow, mainly because of the ageing population, and the increasing incidence of diabetes mellitus and arterial hypertension. The objective of this study is to provide insights into the clinical and economic burden of CKD in Greece.

Method: A cost of illness (COI) study has been performed to approximate the burden of CKD in Greece from the perspective of EOPYY (National Organization for Health Care Services Provision), with reference year 2022. The COI model employs a prevalence-based approach using national and international sources and approximates the annual direct cost of CKD. The direct costs included in this analysis are categorized into primary care, medication, hospitalization and renal replacement therapy (RRT) costs.

Results: It has been estimated that there are about 1,115,991 patients with CKD (stages 1–5) in Greece, most of them in stage 3 (about 534,694), and about 15,337 receiving RRT or having received a kidney transplant. In 2032 this population is expected to increase to approximately 1,249,475 patients. The total annual direct cost of CKD was estimated at €845,936,094. The main cost driver was RRT, which accounted for roughly 49% (417 millions) of total cost of care, followed by hospitalizations 29% (246 millions) and medications 17% (143 millions). The progression of the disease is strongly correlated with an increase in the annual management cost. About 1.4% of the CKD population (RRT group) spent about half of the total CKD budget or more than 4% of the total public health expenditure, higher than other European countries.

Conclusion: CKD is creating a high and growing clinical and economic burden, largely driven by the RRT cost. There is an urgent need for public health strategies aiming at early detection and management of CKD.
RETROSPECTIVE SINGLE-CENTER EXPERIENCE
KIDNEY DISEASES IN PATIENTS WITH MALIGNANCY: A UTILITY OF KIDNEY BIOPSY AND SPECTRUM OF BIOPSY PROVEN

Hui Zhu Han1, Pin Hui Ho1, Alwin Hwi Liang Loh3, Irene Mok1, Cynthia Lim1, Syed Salahuddin Ahmed1,3, Tze Wei Chng3, Yok Mooi Chin1, Esther Wai Teng2 and Jason Choo1

1 Singapore General Hospital, Department of Renal Medicine, Singapore, 2 Lee Kong Chian School of Medicine Hq Building, Singapore, Singapore and 3 Singapore General Hospital, Department of Anatomical Pathology, Singapore

Background and Aims: Kidney biopsy may improve diagnostic accuracy and aid in the management of cancer patients with kidney diseases. However, literature on the utility of kidney biopsy in cancer patients and survivors is lacking. We aimed to evaluate the clinical characteristics of cancer patients who underwent kidney biopsy, as well as the histological spectrum of biopsy proven kidney diseases in this cohort.

Method: This was a single-center retrospective study of all patients who had native kidney biopsies at the Singapore General Hospital between 1st October 2015 to 31st December 2022. Demographic, clinical, laboratory and histological data were retrieved from electronic medical records to identify patients with solid-organ or hematological malignancies who underwent kidney biopsy.

Results: Out of 1208 patients who underwent kidney biopsy between 1st October 2015 to 31st December 2022, 116 (9.6%) patients had diagnoses of solid-organ or hematological malignancies. Approximately two-thirds (79/116; 68.1%) had solid-organ malignancies, of which 21.5% had metastatic disease at time of biopsy. Approximately one-third (36/116; 31.0%) had hematological malignancies, of which 10 (8.6%) had a hematological stem-cell transplant (HSCT). One (0.9%) patient had both solid-organ and hematological malignancies. Sixty-eight (58.6%) patients were in remission at time of biopsy, comprising of 52 (44.8%) and 16 (13.8%) patients with solid-organ and hematological malignancies, respectively. Median age at biopsy was 65.7 years (IQR 56.5, 71.4) and majority was female (61/116; 52.6%). Comorbidities of hypertension, type 2 diabetes mellitus, autoimmunity, and liver transplant were found in 36.2% (42/116), 23.3% (27/116), 8.6% (10/116) and 1.7% (2/116) patients respectively. Median serum creatinine at time of biopsy was 152.0 μmol/L (IQR 101.8, 220.5). Micro-hematuria was present in approximately two-thirds (66.1%) of patients. Nephrotic range proteinuria and nephrotic syndrome were observed in one-quarter (25.9%) and one-third (31.0%) of the patients, respectively. Approximately half (49.1%) of the patients had acute kidney injury at time of biopsy, while one-fifth (19.8%) had progressive chronic kidney disease. A wide spectrum of histological diagnoses was observed. Glomerulonephritides, tubulointerstitial inflammation and/or glomerular endothelial injuries were diagnosed in 60.8% (79/120) of solid-organ and 80.6% (29/37) of hematological malignancies. Amongst patients with active solid-organ malignancies (n = 20), acute tubulointerstitial nephritis (ATIN) (5/20, 25.0%), IgA nephropathy (3/20; 15.0%) and lupus nephritis (3/20; 15.0%) were the most common primary diagnoses. Amongst patients with active hematological malignancies (n = 17), dysproteinemic kidney disease and/or leukemic infiltration was most frequently diagnosed (6/17; 35.3%). Compared to remission status, active malignancy was not associated with an increased likelihood of an overall diagnosis of glomerulonephritides, tubulointerstitial inflammation and/or glomerular endothelial injuries (p = 0.16). Specifically, the incidence of membranous nephropathy was similar in patients with active malignancy and those in remission (p = 0.42). Amongst patients with HSCT, thrombotic microangiopathy (40.0%) was observed most frequently. Overall, onco-therapeutics-related kidney injuries were present in 13 (11.2%) patients, of which ATIN (38.4%) was most commonly encountered, followed by glomerular endothelial injury (30.7%).

Conclusion: Kidney biopsy provides valuable diagnostic information amongst cancer patients. While a broad spectrum of histological diagnoses can be observed, glomerular diseases and onco-therapeutics-related kidney injuries remain the most common.

IMPACT OF THE COVID-19 PANDEMIC ON THE WELL-BEING OF PATIENTS WITH CHRONIC KIDNEY DISEASE
Takuhito Moromizato1, Ryoto Sakaniwa1, Yorikazu Hashimoto1 and Kunitoshi Ikei2

1 Okinawa Prefectural Nanbu Medical Center and Children’s Medical Center, Renal and Rheumatology, Shimajiri, Japan, 2 Osaka University Graduate School of Medicine, Department of Social Medicine, Suita, Japan and 3 Nakamura Clinic, Clinical Research Support Center, Urasoe, Japan

Background and Aims: Coronavirus Disease 2019 (COVID-19) devastatingly impacted well-being, especially among the socioeconomically vulnerable population. The impacts of the pandemic on specific groups of age, sex, race, type of work, and income have been studied. However, the impacts COVID-19 pandemic on well-being of people with diseases have yet to be well evaluated. We conducted a longitudinal survey for outpatients who visited our Nephrology division and asked about their monthly well-being status for two years. Therefore, we aimed to elucidate the impacts of the pandemic especially on the well-being of patients with chronic kidney disease (CKD).

Method: We conducted a monthly survey for 358 outpatients who visited the Nephrology division of Okinawa Prefectural Nanbu Medical Center and Children’s Medical Center between February 1st, 2020, and December 31st, 2021. Out of these patients, 257 patients were included in this study. All participants were asked questions about their well-being status with a visual analog scale (0-10) regarding their health, socioeconomic satisfaction, human connections, general anxiety, and satisfaction in receiving treatment. We also collected information about their basal demographics, social situation (living with family, marriage, having children, or caregiving), educational status, income level, the activity of daily life, and active diseases. We used a mixed-effects regression model to assess the impacts of the pandemic on longitudinal changing of well-being scores especially among patients with CKD. We also described trajectories of well-being scores for CKD patients and non-CKD patients to visualize the difference in the impacts of the COVID-19 pandemic on them.

Results: Among the 257 analyzed patients, 43.9% were male, and the mean (± standard deviation) of their age was 58.9 (± 19.9). 25% were unmarried, and 59.5% had full-time job. 47.9% had G3b or higher stage CKD (eGFR < 45 ml/min/1.73 m²); 24.5% had diabetes; and 30.7% had collagenous disease. In total, 1,814 answer sheets were collected from the patients. Based on the mixed-effects regression model, especially among female patients with CKD, the pandemic has decreased the well-being regarding their human connections (Fig. 1). Contrarily, male patients with CKD showed an increase in well-being regarding human connections during the pandemic. In female patients with CKD, (1) younger, (2) married, (3) living with a family member, and (4) required caregiving status were associated with lower well-being status regarding human connections. Notably, male patients with CKD had higher well-being status regarding human connections and socioeconomic situation if married and living with family than male patients without CKD.

Conclusion: In patients with CKD, female Japanese patients showed lower well-being score regarding human connections than male patients during the early phase of pandemic. The support and caregiving among families influenced differently for male and female patients with CKD.
SAFETY OF NATIVE AND TRANSPLANT KIDNEY BIOPSY IN A NATIONAL COHORT

Background and Aims: Safety of kidney biopsy is variably reported in different published series. Since 2014, all native kidney biopsies undertaken in the 9 adult renal units in Scotland have been recorded by the Scottish Renal Registry (SRR) and since 2015 all transplant kidney biopsies were included. In this complete national dataset, we report data on safety of kidney biopsy in a current real world setting.

Method: Major complications of kidney biopsy are recorded using pre-defined terms and include: arteriography and embolisation, arteriography no embolisation, clot retention, blood transfusion only, death within 28 days directly attributable to biopsy, nephrectomy and other. Biopsies are undertaken under ultrasound guidance using 16G or 18G spring loaded biopsy guns. All centres discontinue clopidogrel, DOACs and warfarin. Some centres continue

aspirin. In some centres biopsy is performed by nephrologists and in others by radiologists.

**Results:** In total, 6979 biopsies in 5755 patients were recorded between 2014 and 2021 (5095 native biopsies and 1884 transplant biopsies), with an adequacy for diagnosis of 98.1%. Table 1 describes the demographics, indications, operator and diagnoses made by biopsy type. Overall, in patients undergoing native kidney biopsy 2.4% suffered a major complication and 1.4% of patients undergoing transplant biopsy. The commonest complication was the requirement for arteriography, with or without embolisation. We included CT angiography in this group. There were 8 deaths within 28 days attributable to renal biopsy.

**Conclusion:** Kidney biopsy remains safe for the vast majority of patients and complications are less likely with transplant biopsy.

**Abstracts**
Epidemiology Collaboration in 2021. We projected the changes of eGFR, CKD prevalence, and incidence of end stage renal disease (ESRD) and mortality in a large prospective cohort of adult Koreans who had voluntary health check-ups, using current (CKD-EPI 2009) and new equation (CKD-EPI 2021).

**Method:** We included 112,772 adult participants, aged 18 years or older, who had voluntary routine health check-ups including serum creatinine at three medical centers in Korea from 2003 to 2009. We compared the difference of eGFR and predictability of mortality and ESRD between eGFR values calculated by CKD-EPI 2009 and CKD-EPI 2021. Serum creatinine was expressed as the IDMS-traceable creatinine according to the manufacturer’s conversion formula from the original value measured by the alkaline picrate Jaffe kinetic method. The incidence of mortality data was extracted from Statistics Korea and the ESRD data from the ESRD registry of the Korean Society of Nephrology.

**Results:** At baseline study, there were 60,723 males (53.8%). Age was 48.9 ± 12.0 years. The value of IDMS-traceable serum creatinine was 0.86 ± 0.21 mg/dL. Levels of eGFR at baseline study was 93.5 ± 15.6 ml/min/1.73 m² by CKD-EPI2009, and 97.1 ± 15.0 ml/min/1.73 m² by CKD-EPI2021. Values subtracted eGFRs by CKD-EPI2009 from eGFR by CKD-EPI2021 were 3.6 ± 3.2 range: -32.9 to 6.1) ml/min/1.73 m². The difference of eGFR was higher in males compared to females (p<0.001), was the highest in the oldest group among participants aged 18–44 years, 45–64 years, and 65 years or more (p<0.001). Patients with diabetes mellitus (DM) or hypertension showed higher difference of eGFR compared patients without DM or hypertension, respectively (each p<0.001). Patients with eGFR >120.0 ml/min/1.73 m² by CKD-EPI 2009 showed the highest difference between two eGFRs compared to patients with the other values. CKD stage was improved in 11,828 (10.5%) participants using eGFR calculated by CKD-EPI 2021 instead of CKD-EPI 2009, however, only 0.63% of participants with eGFR <60 ml/min/1.73 m² by CKD-EPI equation was reclassified into eGFR ≥60 ml/min/1.73 m² by CKD-EPI 2021.During 11.6 ± 2.0 years, 3354 (3.00%) subjects were dead and 151 (0.13%) subjects had end stage renal disease (ESRD) before death. Any eGFR or stage of CKD was an independent risk factors to ESRD or mortality estimated by Cox’s hazard proportional model adjusted by related factors. AUC to estimate renal survival by eGFRs was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009 [0.739 (0.687-0.790)] vs 0.740 (0.688-0.792), p = 0.170]. AUC to estimate survival by eGFRs calculated through CKD-EPI equation was slightly higher than that by CKD-EPI2021 equation [0.673 (0.604-0.682) vs 0.667 (0.658-0.676), p<0.001], however, the difference of AUC was negligible (standard error of AUC difference by two eGFRs: 0.3% [95% CI: 0.006-0.01])

**Conclusion:** The eGFR calculated by CKD-EPI2021 was higher compared to eGFR calculated by CKD-EPI2009. The power to estimate renal survival was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009.

#4026
ECONOMIC EVALUATION OF ANAEMIA OF CHRONIC KIDNEY DISEASE (CKD): A SYSTEMATIC LITERATURE REVIEW AND MODEL CONCEPTUALISATION

Alfred Sackeyfio, Juliette Thompson, Edit Remak and Rodrigo Reifos-Camejo

1GSK, Stevenage, Hertfordshire, United Kingdom, 2Bridge Medical Consulting, Oxford, United Kingdom and 3GSK, Brentford, London, United Kingdom

**Background and Aims:** Anaemia is a common complication of chronic kidney disease (CKD), affecting up to 33% of patients with Stage 5 CKD compared to 8.4% of patients with Stage 1 CKD [1]. Anaemia of CKD is associated with increased risk of cardiovascular events and death, increased healthcare resource utilisation (HRU), and reduced health-related quality of life (HRQoL) [2]. Established treatments for anaemia of CKD include erythropoiesis-stimulating agents (ESAs) [1,2]; however, hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHIs), targeting both erythropoietin production and iron metabolism (the two key mechanisms of anaemia of CKD), are an emerging class of agents in this indication [3]. The cost and HRQoL burden associated with anaemia of CKD treatment is not well characterised.1 Thus, we conducted a systematic literature review (SLR) to evaluate published economic models (including the cost inputs, time horizon, subgroups, and clinical assumptions used) and HRU data in patients with anaemia of CKD. Findings of the SLR will help guide future economic model development and inform economic evaluation strategies as part of health technology assessment submissions to support daprodustat, an HIF-PHI under development for use in both dialysis-dependent and non-dialysis-dependent patients.

**Method:** Relevant publications were identified using structured searching of MEDLINE, Embase, MEDLINE In-Process, Cochrane Controlled Trials Register, and the Cochrane Database of Systematic Reviews from database inception to 10 April 2022 using disease- (e.g. CKD, chronic kidney failure, anaemia) and economic-associated (e.g. economics, economic evaluation, quality-adjusted life-years, model structure) search terms. Additional supplemental searches (conference proceedings [2016–2021], grey literature, and bibliographies) were conducted. Studies were assessed for inclusion or exclusion by two independent reviewers, with any discrepancies resolved by a third reviewer. Objectives were to determine the structure of any published economic models and the availability of health utility data in patients with anaemia and additional complications of CKD, and to examine what cost inputs, time horizons, subgroups, and clinical assumptions are used to inform economic modelling.

**Results:** From 1397 citations identified in the searches, 40 primary studies were included in the final analysis. Review of the data revealed an established approach for modelling the ESA cost-effectiveness (i.e. a Markov model with health states defined according to CKD treatment received or anaemia status): most studies were conducted from a North American or European perspective, time horizons varied, and reporting of cycle length was poor. Only one economic evaluation included an HIF-PHI model: given the different mechanisms of action of ESAs and newer treatments, a modelling strategy focused mainly on a Markov approach may not be the most optimal way of assessing cost-effectiveness in anaemia of CKD where HIF-PHIs are used. Considerations of modelling factors that could influence cost-effectiveness of HIF-PHIs are shown in Fig. 1. While existing models typically only stratified patient populations according to age (<65 vs >65 years), for appropriate modelling of treatment effectiveness, the impact of prior treatments (including response to prior ESAs) was also considered. As in every model, comorbidities may also have a role in effect modification and this impact will need to be considered in economic models of anaemia of CKD treatment. Due to the natural history of anaemia in CKD, innovative modelling techniques that retain the Markov approach and which account for respective haemoglobin levels, CKD stage, and potential kidney transplantation should be incorporated into the economic evaluation (Fig. 2).

**Conclusion:** Adjustment of existing models using the approaches described may provide more reliable estimates of treatment efficacy in a highly heterogenous population of patients with anaemia of CKD.

BURDEN OF KIDNEY DISEASES IN THE GENERAL POPULATION OF THE VAL VENOSTA/VINSCHGAU DISTRICT

Giulia Barbieri1,2, Lucia Cazzoletti1, Roberto Melotti2, Essi Marjatta Hantikainen2, Laura Barin2, Giovanni Gambaro3, Pramstaller Peter4, Maria Elisabetta Zanolin1 and Cristian Pattaro2

1University of Verona, Unit of Epidemiology and Medical Statistics, Department of Diagnostics and Public Health, Italy, 2Eurac Research, Institute for Biomedicine, Italy and 3University of Verona, Medicine, Italy

Background and Aims: Chronic kidney disease (CKD) is a public health burden affecting >10% of the population worldwide. Population-based studies are essential to assess CKD prevalence and its determinants. However, questionnaires to survey CKD and other kidney diseases in the general population are scarce. We developed a novel questionnaire to identify several types of kidney disease in the general population and implemented it in a large central-European population study. We integrated questionnaire responses with standard renal biochemical measurements to estimate CKD prevalence in the Val Venosta/Vinschgau district. We aimed to assess the degree of CKD underdiagnosis and to describe the kidney health status of study participants.

Method: Within the Cooperative Health Research In South Tyrol (CHRIS) study, we conducted a cross-sectional assessment of kidney health on 11684 adults (mean age 45 years; females 53.8%) with interviewer-administered kidney questionnaire and measured fasting serum creatinine and albuminuria. The questionnaire covered retrospectively various kidney diseases, including reduced renal function and renal surgeries (Fig. 1). Questions asked if a doctor had ever diagnosed the specific condition and the age at diagnosis. We defined CKD based on combinations of self-reported diagnosis of reduced kidney function (Q6), CKD-EPI 2021 estimated glomerular filtration rate (eGFR) levels, and microalbuminuria (Table 1). Prevalence was estimated via the Clopper-Pearson method and adjusted to the general target population via relative sampling weights. Using factor analysis we explored the underlying correlation structures within and between questionnaire items and laboratory markers.

Results: Participants had median eGFR and urinary albumin-to-creatinine ratio (UACR) of 98.4 ml/min/1.73 m² (IQR: 87.8-108.8) and 5.7 mg/g (IQR: 3.8-10.0), respectively. Overall, 744 reported only one and 179 reported at least two types of kidney diseases (Fig. 1). Glomerulonephritis (n = 359; 3.14%), kidney stones (n = 311; 2.93%) and other kidney diseases (n = 200; 1.91%) were the most frequent types. Males reported kidney stones (M: 3.2%; F: 2.2%; p-value = 0.0116) and renal surgeries (M: 0.9%; F: 0.5%; p-value = 0.0013) more frequently than females. Females reported a higher proportion of glomerulonephritis (M: 0.6%; F: 5.2%; p-value <0.0001). The population-weighted CKD prevalence varied between 0.71% to 9.29% depending on the definition (Table 1), with a KDIGO estimate of 8.79% (95%CI 8.28%-9.31%).
Figure 1: Summary of the responses to the kidney questionnaire. Combinations reported by ≤2 participants were excluded.

Questionnaire items showed low sensitivity and high specificity to identify low eGFR or high UACR levels. Factor analysis revealed two clearly separated latent factors: one representing “reduced renal function”, which included eGFR, UACR, and the question Q6 on reduced kidney function; and one representing “all other kidney diseases”.

Conclusion: In the Val Venosta/Vinschgau district, CKD prevalence is aligned to Western-European countries. In general population studies, questionnaire-based CKD assessment may severely underestimate CKD prevalence as compared to eGFR- and UACR-based estimates. Our analysis highlights that the large majority of individuals with CKD according to KDIGO guidelines were unaware of the disease. On the other hand, the questionnaire has allowed identifying several specific kidney diseases that usually go undetected in population studies. The limited discriminant ability of questionnaire items and the identifiable correlation structure support the use of the survey questionnaire as an integrative tool to study the kidney health status in general population.

PHASE ANGLE (PA), AGE AND MIS AS MORTALITY PREDICTORS IN PATIENTS WITH ADVANCED CKD

Guillermina Barril, Graciela Alvarez, Almudena Núñez, Carmen Sanchez Glez and Ángel Nogueira

Hospital de La Princesa, Nefrología, Madrid, Spain

Background and Aims: Survival study in Advanced CKD patients according to age, MIS and phase angle

Method: We studied 225 patients with ACKD, 153 men (68.3%), xage 70.09±12.72 years. We analyze survival at 120 months and how the Phase angle (PA) and MIS scale influence mortality. We chose these parameters, one of body composition (BIA-vector) and the MIS malnutrition-inflammation scale, since they are described as independent predictive factors.

Results: We defined the cut-off point for PA with the ROC curve, appearing as 3.75 (sensitivity 67% and specificity 55%). With 83 (37.1%) ≤3.75 and 141 (62.9%) greater than 3.75, PA, with significance between men and women p<0.001. Analyzing the % of deaths with PA with PC- 3.75 there is a significant difference between groups p<0.001, Sig difference between men and women p<0.021. We define with COR cut-off point age = 70.5 years sens 85% spec 63% 79 patients (64.6%) died in 120 months, 53/152 (65.1%) men and 45/71 (63.4%) women xage deceased 76.39±9.16 vs 66.63±13.14 years p<0.001. The survival curves for the 3 variables by Kaplan Meier are significant with the established cut-off points (Fig. 1). In the univariate analysis we found that age (CP-70.5 years) p<0.001, and PA (CP-3.75) p<0.04 are significant, but not MIS(CP-5). In the Cox analysis we evaluated age, PA and MIS, with age as a priority, followed by PA and finally the MIS Wald 18.73, 3.77 and 2.26 respectively.

Conclusion: 1-Age, phase angle and MIS are independent mortality risk factors for ACKD patients. 2-In the multivariate model Age and phase angle are predictors of mortality. 3-Independent of age, the phase angle is the best predictor of mortality.
INCIDENCE AND FREQUENCIES OF HYPERKALEMIA IN PATIENTS WITH CHRONIC KIDNEY DISEASE: A RETROSPECTIVE DATABASE STUDY FROM US CLINICAL CARE

Sascha van Boemmel-Wegmann1, Chris Bauer2, Johannes Schuchhardt2, Alexander Hartenstein1, Glen James3, Elena Pessina4, Scott Beeman5 and Roberto Pecoits-Filho6,7

1 Bayer AG, Integrated Evidence Generation & Business Innovation, Berlin, Germany, 2 MicroDiscovery GmbH, Berlin, Germany, 3 Bayer plc, Integrated Evidence Generation & Business Innovation, Reading, United Kingdom, 4 Bayer S.p.A., Integrated Evidence Generation & Business Innovation, Milano, Italy, 5 Bayer Corporation, Integrated Evidence Generation & Business Innovation, Hanover, United States of America, 6 Arbor Research Collaborative for Health, Ann Arbor, United States of America and 7 Pontifical Catholic University of Paraná, Curitiba, Brazil

Background and Aims: Hyperkalemia (HK) is associated with significant risks for premature mortality, adverse clinical outcomes, and with a potentially more rapid decline of renal function. Reported numbers on the epidemiology of HK in patients diagnosed with chronic kidney disease (CKD) vary significantly and are unclear in real-world patients across different CKD stages, eGFR and UACR strata. We aimed to evaluate the occurrence of moderate to severe hyperkalemia episodes among a large, representative sample of patients with CKD from the US between 2009 and 2020.

Method: Using Optum Electronic Health Records data, we included patients with CKD between January 2009 and December 2020, who had at least two qualifying estimated glomerular filtration rate (eGFR) (15-60 ml/min/1.73 m²) and/or UACR values ≥ 30 mg/g between 90 and 365 days apart. The second qualifying value was considered confirmatory and set as the index date. Patients had to have 365 days of baseline activity prior to index, be ≥ 18 years of age, and not show any diagnoses, procedures, or lab values of kidney failure or hemodialysis or kidney transplant during baseline. A HK episode was defined in two ways, (1.) as either a combination of two elevated inpatient or outpatient serum potassium values (sK+ ≥ 5.5 mmol/L, not longer than 7 days apart, or (2.) a combination of one elevated sK+ and the initiation of pharmacotherapy (e.g., i.v. calcium or insulin-glucose, nebulized albuterol, potassium binders) or a diagnostic code for HK, not longer than 3 days apart. We calculated relative frequencies and incidences of HK in the overall CKD study population and specific subgroups of interest.

Results: 1,771,900 patients met our selection criteria for CKD, with advanced stages 3 and 4 predominantly represented (85.7% and 10.2%, respectively). The cohort consisted of 57.7% females, 83.8% Caucasian and 9.8% African American. Most common baseline comorbidities were hypertension (68.5%), hyperlipidemia (55.1%) and T2D (34.2%). 69.3% of patients were prescribed antihypertensives, 45.7% statins and 45.6% antiarrhythmics. 99.1% of patients had at least one baseline potassium measurement with values averaging 4.3 mmol/L (median, 4.3; IQR: 4.0-4.55). During an average follow up 3.9 years, 220,339 (12.4%) patients experienced at least one episode of hyperkalemia. Of those, 69.3%, 17.5%, and 13.2% showed one, two, and three or more HK episodes, respectively. Across all patients with CKD, the mean incidence rate was 3.37 (95% CI, 3.36-3.38) cases per 100 patient years (PYs). HK incidence correlated with lower eGFR and increased UACR values, with rates of 1.32 (1.25-1.39), 2.48 (2.40-2.55), 3.00 (2.99-3.01) and 8.80 (8.71-8.88) cases/100 PYs for patients with CKD stage 1, stage 2, stage 3 and stage 4, respectively. Highest incidence rates (13.81; 12.96-14.70) were found in patients with UACR values ≥ 3500, irrespective of their eGFR value. In addition, across disease-related subgroups, significantly higher incidence rates were found in patients co-diagnosed with T2D (5.43; 95% CI, 5.40-5.47) and HF (8.70; 8.62-8.77), and sMRA users (7.66; 7.57-7.76) at baseline.

Conclusion: Our contemporary findings demonstrate that HK is common in patients with CKD undergoing routine clinical care in the US, and it is notable in patients with reduced eGFR and elevated UACR. In addition, HK was more predominant in patients with T2D, heart failure or sMRA use, emphasizing a need for more routine sK+ monitoring in patients with these risk factors. Further research is needed to assess additional intrinsic risks, clinical consequences and management approaches of HK in patients with CKD to further inform clinical practice.

T2DM MODIFIES THE RELATIONSHIP BETWEEN CAC AND ADVERSE KIDNEY OUTCOME IN PATIENTS WITH CKD

Hae-Ryong Yun and Seung Hyeok Han

Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Rep. of South Korea

Background and Aims: Kidney function decline faster in patients with type 2 diabetes mellitus (T2DM) than in those without. We previously showed that coronary artery calcification (CAC) is a strong risk of adverse kidney outcome. Here, we examined whether T2DM could modify the relationship between CAC and the progression of chronic kidney disease (CKD).

Method: 2067 participants from the KoreaN Cohort Study for Outcome in Patients With CKD were enrolled. The main exposures were T2DM and CAC. The primary outcome was CKD progression defined as a composite of a 50% decline in estimated glomerular filtration rate or kidney failure with replacement therapy. Multivariable cause-specific hazard function was

T2DM MODIFIES THE RELATIONSHIP BETWEEN CAC AND ADVERSE KIDNEY OUTCOME IN PATIENTS WITH CKD

Hae-Ryong Yun and Seung Hyeok Han

Yonsei University College of Medicine, Department of Internal Medicine, Seoul, Rep. of South Korea

Background and Aims: Kidney function decline faster in patients with type 2 diabetes mellitus (T2DM) than in those without. We previously showed that coronary artery calcification (CAC) is a strong risk of adverse kidney outcome. Here, we examined whether T2DM could modify the relationship between CAC and the progression of chronic kidney disease (CKD).

Method: 2067 participants from the KoreaN Cohort Study for Outcome in Patients With CKD were enrolled. The main exposures were T2DM and CAC. The primary outcome was CKD progression defined as a composite of a 50% decline in estimated glomerular filtration rate or kidney failure with replacement therapy. Multivariable cause-specific hazard function was
employed to determine the association between the main exposures and the primary outcome.

Results: During 8633 person-years of follow-up, the primary outcome occurred in 565 (27.3%) participants. In the multivariable cause-specific hazard model, both T2DM and CAC Agatston score (CACS) > 0 were associated with a 1.80- and a 1.41-fold increased risk of CKD progression compared with counterparts. There was a significant interaction between T2DM and CAC for the primary outcome. In patients without T2DM, CACS > 0 was not associated with the primary outcome compared with CACS of 0. However, in patients with T2DM, CACS > 0 was associated with a significantly higher risk of CKD progression (adjusted hazard ratio 2.12; 95% confidence interval, 1.64–2.75). In addition, a 1-SD increase in CACS was associated with 1.11-fold higher risk of CKD progression. Notably, this association was also significant in patients with T2DM who had CACS of 0. The slope of eGFR decline was steeper in patients with T2DM and the magnitude of decline was greater when CACS > 0.

Conclusion: CAC were more strongly associated with risk of CKD progression in patients with T2DM than in those without. Thus, clinical implication of CAC may differ depending on the presence of T2DM.

Method: SS patients have two kinds of photographs in literatures, before SS nondeformed and after SS deformed. We studied to create face map in SS by using technic in soil survey. 10 face images (5 before SS and 5 after SS) were used. Unsupervised Classification (UC) system of Erdas 8.4 software was used to classify images. Methodology had 3 phases in this research. In first phase, we got the images at same scale by cutting them around faces images. In final phase, we applied coloring on 10 classes of images. We used same color for same class number both ClbSS and ClaSS images. If color classes are in same structure of face (on cheek, forehead, etc), they may be combined.

Results: We have very important results on deformed faces photos in SS (ClaSS). First finding is all ClaSS have specific “hourglass” shapes (figure 4). “Hourglass” is enclosing red area for sample A and B Figure 3, Column 1: photos of patients before SS (raw images), column 2: classified photos of column 1, column 3: classified photos of patients after SS, Figure 5. “Hourglass” is conformity of “Hourglass” form for all ClaSS curved face.

Conclusion: Image processing plays very important role in clinical practices and biomedical researches. SS is a kidney disease and derived from inside of the body but its effects are appearance outside of human body, such as head, face, skull deformations. These symptoms can be put forward by using Image Classification for SS. Moreover, shape of “hourglass” can be an index for SS and this is very specific for SS. “Hourglass” can be an indicator for grading SS. Finally, “hourglass” should be carefully evaluated in SS.
TERTIARY HOSPITAL EXPERIENCE IN AN ESSENTIAL SUBSPECIALTY: ONCONEPHROLOGY
Sheila Bermejo Garcia, Mónica Bolufer, Davide Viggiano, Ana Callejo, Enriqueta Felip, Marina López, Ander Vergara, Irene Agraz Pamplona, Oriol Bestard Matamoros and Maria Jose Soler Romeo
Vall d’Hebron University Hospital, Nephrology, Barcelona, Spain, Vall d’Hebron University Hospital, Oncology, Barcelona, Spain and University of Turin - Campus Luigi Einaudi, Nephrology, Torino, Italy

Background and Aims: Kidney complications of cancer patients and cancer in renal patients have increased in recent years. The objective of this study is to evaluate the characteristics of the patients referred to the Onconephrology Unit from January 2021 to December 2021, studying the cognitive and mood status of these patients.

Method: This is a prospective observational study of the Onconephrology consultation at a University Hospital Center during 2021. Clinical and analytical characteristics of the patients and clinical indication for referral were analyzed. In addition, sleep quality, mood and cognitive status were assessed using validated rating scales (Epsworth, Geriatric Depression Scale and Montreal).

Results: Seventy-four patients were evaluated, mean age was 69.6(±11) years, 41(55.4%) men, 47(63.5%) had hypertension, 18(24.3%) diabetics, and 11(14.9%) were affected by heart disease. In addition, creatinine 1.93(±1.1)mg/dl, eGFR 39.97(±20.3)ml/min, proteinuria 187[29-515.9]mg/g, and 4(5.4%) had microhematuria. The most frequent cancers were intestinal, gynecological and mammary with 12.16%(n = 9) each. The most frequent indication for referral was acute kidney injury (n = 36; 48.7%), followed by chronic kidney disease (n = 27; 36.49%) and proteinuria (n = 5; 6.76%). Rating scales were obtained in 51 patients: 49% (n = 25) were snorers, followed by 17.6% (n = 9) with insomnia and 11.8% (n = 6) with OSAS. 27 patients (36.5%) had cognitive impairment. Mild depression was detected in 13 cases (25.5%) and moderate depression in 11.6% (n = 6). 21 renal biopsies were performed, the most frequent diagnosis was acute interstitial nephritis (71.4%, n = 15) followed by thrombotic microangiopathy (19%; n = 4). A total of 15 patients (20.3%) died during the year.

Conclusion: Most patients referred to Onconephrology are affected by advanced oncological disease and consequently had a high mortality. The most frequent indication for referral was acute kidney injury (48.7%). Comprehensive patient care is important, given the prevalence of depressive syndrome. Onconephrology is an example of a comprehensive and multidisciplinary approach to improve the survival and quality of life of patients with advanced cancer and renal disease.
Method: We obtained data from the 2011–2014 and 2019–2020 Korea National Health and Nutrition Examination Survey (KNHANES). Microalbuminuria was measured based on spot urine albumin-creatinine ratio (UACR). The Framingham risk score (FRS) model was implemented to evaluate the CVD risk. Linear and logistic regression models were used to identify the associations of microalbuminuria status with cardiometabolic predictors and CVD status determined by the FRS score.

Results: Among 19,340 representative Korean participants, the (UACR) in Korean women and men with history of CVD was higher than in those without history of CVD. Among patients without history of CVD, multivariate regression analysis showed that a high UACR was related to older age, lower high-density lipoprotein cholesterol level, higher total cholesterol level, higher systolic blood pressure, higher prevalence of current smoking, higher prevalence of diabetes, and higher anti-hypertensive medication use in both women and men. The UACR showed a positive linear correlation with the Framingham risk score in both women and men.

Conclusion: The presence of microalbuminuria was significantly associated with the cardiometabolic risk factors and the increased risk of CVD evaluated by FRS model in both women and men in a nationally representative sample of Korea.

Results: 271 patients who met the inclusion criteria were analyzed. The clinical characteristics are shown in Table 1. The Grams model showed good discrimination for initiating KRT at 2 and 4 years, AUC 0.84 [95%CI 0.77-0.91] and AUC 0.81 [95%CI 0.75-0.87], respectively. The ROC curves presented by both equations showed good discrimination, AUC 0.82 [95%CI 0.74-0.91] and AUC 0.80 [95%CI 0.74-0.87]. When comparing the need for 2-year KRT with both equations, we observed both ROC curves were similar (p < 0.05). Table 2 shows results from logistic regression analysis. For the 2-year KRT event by Grams, patients with a score ≥ 17.85% were 11.53 [95%CI 5.16-27.78] times more likely to initiate KRT. However, compared to KFRE with a score ≥ 20.77%, they had 17.53 [95%CI 7.59-40.47] times higher probability of KRT (both p < 0.001). When we compared both equations in multivariate analysis only the KFRE was significant (ODR 0.217 [95%CI 0.87-0.54]).

Conclusion: In our population, both prognostic equations showed good discrimination to program initiation of KRT. However, the GS could underestimate this need while the KFRE seems to discriminate it better.
ACUTE KIDNEY DISEASE FOLLOWING COVID-19 VACCINATION: A RETROSPECTIVE, SINGLE-CENTER STUDY
Chien-Chou Chen1, Sung-Sen Yang2, Yu-Juei Hsu1, Chih-Chien Sung1, Pauling Chu1, Chia-Chao Wu2, Shun-Neng Hsu1, Han-En Wang1, and Shih-Hua Lin1
1Tri-Service General Hospital, Division of Nephrology, Department of Medicine, Taipei, Taiwan, Rep. of China and 2Tri-Service General Hospital, Division of Nephrology, Department of Medicine, Taiwan, Rep. of China

Background and Aims: The rare de novo or relapsed kidney diseases associated with coronavirus disease 2019 (COVID-19) vaccination have been increasingly reported. The aim of the study was to investigate the incidence, characteristics, and outcome of acute kidney disease (AKD) following COVID-19 vaccination.

Method: This retrospective study scrutinized the data from renal registry in a single academic medical center from Jan. 1st, 2020, to Apr. 30th, 2022. Patients who developed AKD within 90 days after COVID-19 vaccination were first included. Naranjo score as a causality assessment tool for adverse vaccination reaction and charts review by peer nephrologists were utilized for the exclusion of other causes. The etiologies of AKD, their characteristics, treatment, and outcome attributing to the COVID-19 vaccines were examined (Fig. 1).

Results: Twenty-seven aged 23 to 80 patients with AKD were identified from 1897 patients (incidence of 6.3 per 1000 patient-years). Their Naranjo score was 7.7±1.5, and 14 of 27 patients (51.9%) had definite diagnosis (Naranjo score ≥ 9). They incorporated both glomerular disease (n = 16) including IgA nephropathy (n = 7), anti-neutrophil cytoplasmic antibodies-associated glomerulonephritis (AAN) (n = 4), membranous glomerulonephritis (n = 3), minimal change disease (MCD) (n = 2), and chronic kidney disease (CKD) with acute deterioration (n = 11). The majority (21 of 27, 77.8%) of COVID-19 vaccination was messenger RNA (mRNA)-based regimen. Four patients (14.8%) rapidly progressed to end stage kidney disease (ESKD) requiring dialysis despite aggressive management. Extra-renal features such as pulmonary hemorrhage, myopericarditis and hepatitis/pancreatitis were observed in 4 patients.

Conclusion: In summary, AKD after COVID-19 vaccination may occur with more alarm in this renal registry. In addition to GN, patients with pre-existing moderate to severe CKD should also receive more intensive evaluation before vaccination despite the established benefits of vaccination in this vulnerable population likely outweigh the risk.

RAPID DECLINE IN KIDNEY FUNCTION IS ASSOCIATED WITH HIGHER HEMOGLOBIN VARIABILITY IN CHRONIC KIDNEY DISEASE
Hyo Jin Kim, Da Woon Kim, Harin Rhee, Sang Heon Song and Eun Young Seong
Pusan National University Hospital, Internal Medicine, Rep. of Korea

Background and Aims: Hemoglobin decrease and anemia are common in chronic kidney disease (CKD). This study aimed to evaluate hemoglobin variability in patients with CKD according to decline in kidney function.

Method: We analyzed patients from the KoreaN cohort study for Outcome in patients With CKD (KNOW-CKD). The rates of renal function decline per year were determined using the slope of estimated glomerular filtration rate (eGFR) analyzed using a generalized linear mixed model. Rapid decline in kidney function was defined as a decline in the eGFR of >3 mL/min/1.73 m²/year. Hemoglobin value was measured at 0, 6, and 12 month and annually for up to 8 years. Hemoglobin variability was calculated by standard deviation. Higher hemoglobin variability was defined as a hemoglobin variability value greater than the median.

Results: Among 1895 patients, 736 patients (38.8%) were in the rapid kidney function decline group. In 1472 patients who were 1:1 propensity score-matched, the baseline eGFR was not significantly different between the non-rapid kidney function decline group (48.2±26.9 vs 46.9±26.2 mL/min/1.73 m², P = 0.345). The use of iron supplements (P = 0.536) or erythropoiesis stimulating agents (P = 0.689) was similar in both groups. In multivariable logistic regression analysis, rapid decline in kidney function was significantly associated with higher hemoglobin variability (odds ratio [OR]: 1.81; 95% confidence interval [CI]: 1.43–2.28; P < 0.001). This association was prominent in the group without anemia at baseline (OR: 2.82; 95% CI: 1.99–4.01; P < 0.001).

Conclusion: Rapid decline in kidney function is associated with higher hemoglobin variability in patients with CKD. Attention should be paid to hemoglobin variability in patients with a rapid decline in kidney function.
ml/min/1.73 m² by CKD-EPI2021. Values subtracted eGFRs by MDRD or CKD-EPI2009 from eGFR by CKD-EPI2021 were 2.5 ± 10.1 ml/min/1.73 m² and 4.5 ± 1.0 ml/min/1.73 m², respectively. Between eGFRs by CKD-EPI2009 and CKD-EPI2021, the difference of eGFR was higher in females compared to males (p < 0.001), was not different between subjects aged less than 75 years and more than 75 years (p = 0.139), and lowest in subject with <45 ml/min/1.73 m² of eGFR by CKD-EPI2009 compared to subjects with other eGFR values (p < 0.001). CKD stage was improved in 241 (24.5%) participants and was not changed in 743 (75.5%) using eGFR calculated by CKD-EPI2021 instead of CKD-EPI2009. Similar trend of eGFR difference between eGFRs calculated by MDRD and CKD-EPI2021. During 8.3 ± 6.2 years, 255 (25.9%) subjects were dead and 7 (0.7%) subjects had end stage renal disease (ESRD) before death. Any eGFR was an independent risk factors to mortality estimated by Cox’s hazard proportional model adjusted by related factors. AUC to estimate survival by eGFRs was not different between eGFRs by CKD-EPI2009 and CKD-EPI2021 (0.662 ± 0.620-0.695), however, different between eGFRs by CKD-EPI2009 and MDRD [0.662 (0.625-0.699) vs 0584 (0.543-0.626), p < 0.001]. AUC to estimate renal survival by eGFRs was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009, also.

Conclusion: The eGFR calculated by CKD-EPI2021 showed higher value compared to eGFR calculated by CKD-EPI2009 or MDRD. The power to estimate mortality or renal survival was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009.

DIETARY BEHAVIOR OF CKD PATIENTS BEFORE AND AFTER THE COVID-19 PANDEMIC PERIOD
Son Seong Min1, Kwon Sung Ok2, Sunhwa Lee1,4, Back Hyunjeong1,4, Hwang Duck-Jin1,6 and Ji In Park1,4
1 Kangwon National University Hospital, Internal Medicine, Chuncheon-si, Rep. of South Korea, 2 Seoul National University, Research Institute of Human Ecology, Gwangan-gu, Seoul, Rep. of South Korea, 3 Kangwon National University Hospital, Nephrology, Chuncheon-si. Gangwon-do, Rep. of South Korea, 4 Kangwon National University School of Medicine, Nephrology, Chuncheon-si. Gangwon-do, Rep. of South Korea, 5 Hangi Eye Hospital, Ophthalmology, Bupyeong-gu, Incheon, Rep. of South Korea and 6 Catholic Kwandong University College of Medicine, Ophthalmology, Incheon, Rep. of South Korea

Background and Aims: As the COVID-19 infection went global pandemic in 2020, many governments around the world have carried out social lockdown policies. It resulted in changes in lifestyles such as diet, physical activity, and social interaction. This study aimed to investigate the changes of lifestyles focusing on diet, especially in patients with chronic kidney disease (CKD) during the COVID-19 pandemic period.

Method: We compared data from 2019 and 2020 of the Korea National Health and Nutrition Examination Survey (KNHANES) before and after COVID-19, because COVID-19 was first detected in January 2020 in South Korea. CKD was defined as albumin to creatinine ratio > 30 mg/g or estimated glomerular filtration rate (eGFR) < 60 ml/min/1.73 m². CKD was categorized into two groups, CKD stage 1–2 and CKD 3–5; eGFR over 60 with albuminuria and eGFR below 60 ml/min/1.73 m². We compared changes in diet behavior, nutrients, and food intake between 2019 and 2020 in normal, CKD stage 1–2, and CKD stage 3–5 groups.

Results: This analysis included a total of 5,084 and 4,338 participants from 2019 and 2020. When compared to normal group in the post-COVID-19, CKD group showed lower energy intake (p = 0.038), but the proportion of carbohydrates, proteins, and lipids did not differ. In the pre-COVID-19, CKD stage 3–5 group ate significantly lower sodium (1893.5 ± 109.2 mg/1000 kcal, p = 0.015), and the urine Na/Cr ratio also increased (from 19.5 ± 1.4 to 26.0 ± 1.5, p = 0.001). The main source food of sodium was kimchi in every group, but the proportion changed in the post-COVID-19 period. In CKD stage 3–5 group, compared to the pre-COVID-19 period, the intake of noodles and Ramen increased 35% and 91%, respectively. Interestingly, the potassium intake increased from pre-COVID-19 to post-COVID-19 in all three groups.

Conclusion: The COVID-19 pandemic affects CKD patients’ diets in terms of sodium intake. We need to pay attention to diet and nutritional education for CKD stage 3–5 patients.
THE CARE TRAJECTORY LEADING TO EMERGENCY DIALYSIS START: CROSSING PATIENTS’, GENERAL PRACTITIONERS’ AND NEPHROLOGISTS’ PERSPECTIVES

Maxime Raffray¹, Cécile Vigneau², Laetitia Laude¹, Campeon Arnaud³ and Sahar Bayat¹

¹Univ Rennes, EHESS, CNRS, Inserm, Arènes - UMR 6051, RSMS (Recherche sur les Services et Management en Santé) - U 1309, Rennes, France,  ²Univ Rennes, CHU Rennes, Inserm, EHESS, Irset (Institut de recherche en santé, environnement et travail) - UMR_S 1085, Rennes, France and ³EHESP, Arènes, CNRS, UMR 6051, Rennes, France

Background and Aims: Emergency dialysis start (EDS) is an important issue to understand and tackle in CKD care. Late referral, absent previous nephrology care and higher comorbidity scores have been associated with EDS. However, how those quantitative risk factors happen and contribute to EDS remains unexplored. We conducted a qualitative study in France to identify and describe the mechanisms that shape the trajectories that lead to EDS, using patients, GPs and nephrologists perspectives.

Method: Three groups of participants were recruited in Brittany, north-west France: Patients who started dialysis in emergency between 2017 and 2019, GPs and nephrologists. Maximum variation sampling approach was used based on patients’ socio-economic profiles and GPs’ and nephrologists’ years and settings of practice. Semi-structured interviews were conducted between 2017 and 2020. A crossed thematic analysis between the 3 groups of transcripts was performed, informing how EDS trajectories come to be.

Results: Twenty patients, 12 GPs and 18 nephrologists were interviewed. Five main themes were identified: 1) Learning about dialysis, 2) Dialysis and nephrology care representations: a) an unacceptable biographical disruption, b) a dreadful invasive machinery, c) a straw that breaks the camel’s back, 3) The gap between the “illness” perceived and the “disease” treated, 4) Slipping through the primary care prevention net, 5) the unavoidable unpredictability of CKD course.

Conclusion: This study shows how quantitative risk factors of EDS such as low or absent previous nephrology care are, in part, the results of an interplay between patients’ constructed representations of dialysis, relation with the medical sphere and CKD physiopathology. The results suggest a need for evaluation of kidney replacement therapy education programs and

Figure 1: Flow diagram of the study and definition of the socioeconomic status score. SES was defined as a score incorporating income, education, occupation, and marital status, ranging from 0 to 4. Abbreviation: SES, socioeconomic score.

Figure 2: Forest plots of subgroup analyses according to the presence or absence of renal dysfunction and smoking, as reference one group SES = 0: risk of myocardial infarction (A&D), stroke (B&E), and death (C&F), Abbreviations: RD, renal dysfunction; SES, socioeconomic status score; HR, hazard ratio; CI, confidence interval.
The decision-making process in this regard for clinicians, patients, and their families may be ameliorated by the Thamer Risk Scoring tool which uses simple variables such as age, albumin level, nursing home residence, need for assistance in daily living, cancer, heart failure, and hospitalization to predict early mortality in elderly patients after initiating dialysis [1]. This tool has not been validated in the Philippine setting, hence this study aimed to validate the prognostic property of the Thamer Risk Scoring tool in predicting early death among elderly patients initiated on dialysis in a tertiary institution, in Davao City, Philippines.

Method: A retrospective cohort research design was used. All the charts of patients diagnosed with end-stage renal disease aged 60 years and above, who were admitted and initiated on either hemodialysis or peritoneal dialysis within a 4-year period from 2018 to 2021 were reviewed. Patients with periods of dialysis lasting less than 90 days or who died of recovery of kidney function, and patients with missing data that meet all pre-requisite variables for the risk scoring were excluded.

Results: A review of 1,583 patient charts was done, with 1,402 omitted based on the exclusion criteria. A total of 181 patients were included in the study. Most of the patients were male (56.35%), and initiated on hemodialysis (97.24%). The mean age of the population was 67.34 years with majority in the 60–69 year age group (66.3%). Those who survived had a mean age of 66.53 years and those who expired had a mean age of 68.63 years. All-cause mortality was 38.12% at 3 months, and 3.57% at 6 months after dialysis initiation. The all-cause mortality at 3 months in this study was three times higher than the Thamer study with a mortality of 12.5%. Patients with heart failure (p-value = 0.007), cancer (p-value = 0.040), asthma (p-value = 0.040), and need for assistance in daily living (p-value = 0.022), had significantly higher mortality rates, while patients who had higher albumin (p-value = 0.010), and creatinine (p-value = 0.014) had higher survival rates. Similar to the Thamer study, this study also showed that the tool becomes less sensitive and more specific as the scores increased for the 3-month, 6-month, and over-all mortality groups. The accuracy of the tool rises with a higher score as well. In the Thamer study, their validation cohort had an area under the receiver operating characteristic curve (AUROC) = 0.691 for their risk scoring tool while this study showed an AUROC = 0.6245, 0.2847, and 0.5993 in the 3-month, 6-month, and over-all mortality groups respectively which does not show statistical strength.

Conclusion: Patients with older age, comorbidities such as heart failure, cancer, asthma, and those who need assistance in daily living had higher mortality rates. Despite the poor performance of the Thamer risk scoring tool in predicting mortality in terms of AUROC in this study, the sensitivity, and specificity had a similar performance in the Thamer study. Furthermore, the consistent trend of accuracy of predicting mortality in these groups reflect that a higher score portends to a higher accuracy in predicting mortality.

**“SURPRISE QUESTION”: IS IT A USEFUL TOOL IN CKD STAGES 4 TO 5?**

Bruno Pepe1, Teresa Prazeres2, Andrea Carnevale1, Rita Calça1, Patricia Matias1, Patricia Branco1, Sofia Azeredo-Lopes3, Sofia Azeredo Pereira2 and Ana Rita Martins4

1Hospital Santa Cruz, Nefrologia, Carnaxide, Portugal. 2iNova4Health, Nova Medical School Faculdade Ciências Médicas, NMS; Faculdade de Ciências Médicas, Universidade Nova Lisboa, Portugal and 3Department of Statistics and Operational Research, Faculty of Sciences, University of Lisbon, Portugal

**Background and Aims:** The “Surprise Question” (SQ) (“would you be surprised if this patient died in 6 months/year?”) has proven to be an interesting prognostication tool in a range of settings. However, its reliability in non-dialysis-dependent CKD is still unclear. Our aim was to study the applicability of the SQ to an outpatient CKD-EPI stages 4 to 5 and correlate it with mortality.

**Method:** Observational, prospective and single center study. Baseline comorbid conditions, cause of CKD, degree of autonomy, literacy, social support and baseline laboratory values (i.e., serum creatinine/estimated glomerular filtration rate, serum albumin and hemoglobin) were collected.

**Results:** A total of 269 patients completed the study; mean age 65 years old; 256 patients (85.3%) had hypertension and 124 (41.3%) had diabetes. The main causes of renal disease were diabetic kidney disease (n = 53; 17.7%), hypertension (n = 15; 5%) and IgA nephropathy (n = 11; 3.7%). The etiology of kidney disease was undetermined for 24 patients (8.0%). Average CKD-EPI was 15.5 ± 7.4 mL/min/1.73 m². A total of 188 patients (63%) were independent for daily living activities and 68 (23%) were professionally active and 45 (16%) were accompanied by family members or caregivers in outpatient consultation to discuss and define the care of plan regarding end stage renal disease. Mean follow up time of the study was 365 ± 254 days, and 27 (9%) patients died during this time period. Using the SQ, providers responded Yes and No for 162 (54%) and 92 (31%) patients, respectively. There were no differences in CKD-EPI stage, arterial hypertension, cerebrovascular disease and dyslipidemia. The No group was older (73 ± 16 vs. 63 ± 16, p = 0.001) and had more diabetes (n = 46, 55%, p = 0.015). About 8 (30%) and 18 (67%) of Yes and No patients died, respectively (P > 0.001). In the Cox-proportional hazard model adjusted to diabetes, the risk of all-cause mortality was significantly increased by around 55%, p = 0.001. Among patients on chronic dialysis therapy (KRT), cardiovascular events, risk of requiring kidney replacement therapy (KRT), cardiovascular events and death. Our aims was validation of the Grams score as a prognostic tool in patients with CKD G4 aged over 65 years old in our hospital area.

**Conclusion:** SQ proved to be a support tool in order to identify patients at high risk of death, who might not have a full benefit of starting dialysis. The choice around kidney replacement therapy is a shared decision-making process, in which competing risks and benefits must be considered. It is essential and urgent to identify means of support for patients, caregivers and health providers to provide and discuss personalized prognostic information.

Soo-Young Yoon, Hyo Jin Lee, Dae Kyu Kim, Jong Ho Kim, So Jin Lim, Jin Sug Kim, Hyeon Seok Hwang and Kyunghwan Jeong

Kyung Hee University Hospital, Division of Nephrology, Department of Internal Medicine, Seoul, Rep. of South Korea

**Background and Aims:** Little is known about the prevalence of chronic kidney disease (CKD) during the coronavirus disease 2019 (COVID-19) pandemic, as well as the pandemics’ impact on CKD diagnosis. We aimed to investigate the long-term trends in CKD prevalence throughout the pre- and early pandemic periods in adults using a nationwide serial survey from South Korea.

**Method:** We used data from 108,152 Korean adults from 2007 to 2020 obtained from a representative longitudinal serial study. We defined CKD as a condition when the participant's estimated glomerular filtration rate was < 60 mL/min/1.73 m², one-time point proteinuria was ≥ 1+ on a urinary dipstick test according to recent guidelines, or previous diagnosis of CKD. We examined the overall trends in the prevalence of CKD during the study period and the impact of the early pandemic on the prevalence of CKD.

**Results:** Among the included adults (n = 80,010), the overall national prevalence of CKD was 6.2%. The trend slope gradually increased from 2007 to 2019, however, there was a sudden decrease in 2020 (2007–2010, 5.1%; 95% confidence interval (CI), 4.7–5.5%; 2017–2019, 7.1% [95% CI, 6.6–7.6]; pandemic period, 6.5% [95% CI, 5.7–7.3]; and βdiff, -0.19; 95% CI, -0.24–0.13). The prevalence of CKD among younger adults and those with poor medical utilization significantly decreased during the early pandemic.

**Conclusion:** This study was the first large-scale study to investigate the longitudinal prevalence of CKD from 2007 to 2020. Our results improve the understanding of outpatient health service utilization during the COVID-19 pandemic and suggest the need for governmental support to prevent the aggravation of CKD in society. Consequently, the nephrology community has a potential role in pertinent policies to reduce the public health burden of CKD by properly allocating limited medical resources.

**VALIDATION OF THE GRAMS MODEL AS A PROGNOSTIC TOOL IN ADVANCED CHRONIC KIDNEY DISEASE (ACKD)**

Alba Temprado Collado, Marisa Vidal Blandin, Gema Montilla Cosano, Cristina Andrades Gómez and Francisco Javier Toro Prieto

Spain

**Background and Aims:** Elderly patients with Advanced Chronic Kidney Disease (ACKD) present high cardiovascular comorbidity and increased mortality risk. The CKD-G4+ risk calculator was developed by Grams specifically for the population with CKD-G4 and analyzes the risk of requiring kidney replacement therapy (KRT), cardiovascular events and death. Our aims was validation of the Grams score as a prognostic tool in patients with CKD G4 aged over 65 years old in our hospital area.

**Method:** Descriptive and retrospective non-randomized study of a cohort of patients older than 65 years with CKD G4 attending for the first time for consultation during 2016 and 2017. Follow-up for 4 years or first clinical event defined as need for KRT, eGFR < 8 mL/min/1.72 m² or death. Demographic and clinical data were collected for Grams model risk calculation (age, sex, CKD-EPI eGFR, urine albumin/creatinine ratio (CAC), systolic blood pressure (SBP), diabetes, smoking, cardiovascular history, non-fatal cardiovascular event (CHF, AMI, stroke) and death). SPSS statistical analysis.

**Results:** Of 663 patients who started follow-up in ACKD consultations in our hospital area between 2016 and 2017, 303 patients who met inclusion criteria were analyzed, 31 were excluded due to loss to follow-up. The clinical characteristics of the studied population are collected in Table 1. The results are collected in Table 2, they include predicted and observed incidences of death, KRT onset and cardiovascular events in 2 and 4 years from the first visit. Predictors used in this study included Grams calculator risk scores at 2 and 4 years (Grams-2 and Grams-4, respectively) for any KRT, cardiovascular events, and death.

**Conclusion:** In our cohort of patients with G4 ACKD older than 65 years old, the Grams score provides good discrimination to significantly predict the onset of KRT and cardiovascular events. The risk of death was moderately accurate and should be taken into account for care planning. Further external validation studies are required.
Erectile dysfunction is a frequent problem and is associated with an increase in arterial stiffness and an increase in the incidence of erectile dysfunction. Moreover, erectile dysfunction was more common in patients with increased PWV.

#4112 PULSE WAVE VELOCITY AND ERECTILE DYSPNFUNCTION IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Adamantia Bratsiakou, Georgia Andriana Georgopoulou, Maria Triviza, Theodoros Ntrinias, Dimitrios Goumenos, Konstantinos Giannitsas, Adamantia Bratsiakou, Georgia Andriana Georgopoulou, Maria Triviza, Theodoros Ntrinias, Dimitrios Goumenos, Konstantinos Giannitsas, Evangelos Papachristou and Marios Papasotiriou

General University Hospital of Patras, Nephrology, Rio, Greece

**Background and Aims:** Erectile dysfunction is a frequent problem and adversely affects quality of life. In recent years, it has been shown to be an early indicator of cardiovascular disease and endothelial damage. For patients with chronic kidney disease, the incidence of cardiovascular events is increased, and erectile dysfunction is also more frequent. In this study, we evaluated patients with chronic kidney disease and the incidence and the association of erectile dysfunction with pulse wave velocity (PWV) and reflection wave parameters.

**Method:** The incidence of erectile dysfunction was examined with the use of IIEF (5) Sexual Health Questionnaire in adult male patients aged less than 65 years with chronic kidney disease stage I-V or a history of kidney transplantation that were actively monitored or treated as outpatients. Peripheral blood pressure, central blood pressure, PWV and reflection wave parameters (augmentation pressure and augmentation index) were evaluated using the Mobil-o-graph device in office measurements.

**Results:** Overall, 69 men with a mean age of 46.5 ± 11.79 years were included in the study. Chronic kidney disease (CKD) classification according to baseline eGFR calculation was as follows: 12 patients with CKD-I, 27 with CKD-II, 12 with CKD-III, 6 with CKD-IV and 12 with CKD-V on maintenance hemodialysis. Erectile dysfunction of all degrees (mild to severe) was detected in 52% of patients. From the correlation of the various parameters assessed with the degree of erectile function, as calculated by the IIEF questionnaires, it was found that the renal function as estimated by eGFR showed a positive correlation (r = 0.24, p = 0.047), while age and PWV showed a negative correlation (r = -0.384, p = 0.002 and r = -0.474, p < 0.001 respectively). Moreover, pulse wave velocity was the only parameter which could predict erectile dysfunction (β = -0.995, 95% CI -0.465 to -10.074, p = 0.032).

**Conclusion:** The results of the study showed that worsening kidney function is associated with an increase in arterial stiffness and an increase in the incidence of erectile dysfunction. Moreover, erectile dysfunction was more common in patients with increased PWV.

#5340 ASSOCIATION BETWEEN PARABEN EXPOSURE AND INDEX OF CHRONIC KIDNEY DISEASE (CKD) AMONG THE GENERAL TAIWANESE POPULATION

Jung-Wei Chang1, Hsin-Chang Chen2, Wan-Ting Chang3 and Po-Chin Huang4

1Institute of Environmental and Occupational Health Sciences, National Yang Ming Chiao Tung University, Taipei, Taiwan, Rep. of China, 2Tunghai University, Department of Chemistry, Taichung, Taiwan, Rep. of China and 3Department of Medicine, National Taiwan University Hospital, Taipei, Taiwan, Rep. of China
Background and Aims: Exposure to consumer chemicals has been associated with chronic kidney disease (CKD) among humans, but their associations with estimated glomerular filtration rate (eGFR) are inconsistent. We aimed to assess the relationship between paraben exposure and renal function including the serum level of blood urea nitrogen (BUN), and the urinary levels of microalbumin, albumin, protein, and creatinine from a population-based study.

Method: We enrolled 310 participants (≥18 y, N = 240; <18 y, N = 70) who provided questionnaire information as well as blood and urine samples from a nationally representative study. Urinary parabens including methylparaben (MeP), ethylparaben (EtP), propylparaben (PrP), and butylparaben (BuP) are measured by liquid chromatography/tandem mass spectrometry. From the renal function index, we measured the serum level of blood urea nitrogen (BUN), and the urinary levels of microalbumin, albumin, protein, and creatinine. We used multiple logistic regressions to evaluate the relationship between paraben exposure and renal function in our participants.

Results: Median levels of urinary MeP; EtP; PrP and BuP in adults were 399 [interquartile range (IQR) = 257–611], 38.3 (IQR = 25.9–62.2), 115 (IQR = 74.6–160) and 6.60 (IQR = 4.42–9.42) ng/mL, respectively, which were significantly lower than those in children/adolescents (MeP: 186 (IQR = 6.92–453); EtP: 13.0 (IQR = 0.05–38.1); 60.3 (IQR = 0.62–101); 2.65 (IQR = 0.73–7.84) ng/mL (all P <0.001). Multivariate regression models adjusted for the same confounding factors confirmed the association of BUN and eGFR with urinary EtP with a log-linear relationship (β: 0.137; 95% CI = 0.003 to 0.272; β: -0.101; 95% CI = -0.202 to -0.001), which means BUN increased by 0.137 × 10^-2 mg/dL and eGFR decreased by 0.0 × 10^-2 mL/min/1.73 m^2 with a 1% increase in urinary EtP level, respectively. The multiple logistic regression showed that the adjusted odds ratio of the higher EtP and PrP level (median) in participants ≥18 y for lower eGFR (eGFR <90 mL/min/1.73 m^2) was 1.86 and 1.87 times (95% CI = 1.03–3.34 and 1.04–3.37) than the lower group, respectively.

Conclusion: Our findings suggested that daily exposure to EtP were significantly positively associated with an increased risk of higher BUN and lower eGFR in Taiwanese ≥18 y. Comprehensive or mechanistic studies are required to elucidate these associations.

#3922 CLINICOPATHOLOGICAL CHARACTERISTICS OF LIGHT AND HEAVY CHAIN DEPOSITION DISEASE: A CASE SERIES FROM A SINGLE CENTER

Yujie Wang, Shaoshan Liang, Dandan Liang, Feng Xu, Xiaodong Zhang, Dacheng Chen, Yao Lin and Caihong Zeng

National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, P.R. China

Background and Aims: Light and heavy chain deposition disease (LHCDD) is the rarest form of monoclonal immunoglobulin deposition disease (MIDD) characterized by the deposition of the monoclonal light chain and heavy chain. At present, the large-scale clinical research data of LHCDD is limited. We explore the clinicopathological characteristics and outcome of LHCDD in a single center of China, to obtain a better understanding of this disease.

Method: We reviewed 65291 native kidney biopsies from January 2008 to December 2022. Ten patients with biopsy-proven LHCDD diagnosed were studied retrospectively.

Results: 4 males and 6 females, with an average age of 52.5 ± 8.9 years were enrolled. The patients were presented with hypertension (80%), anemia (90%), elevated serum creatinine (70%), proteinuria (100%), nephrotic syndrome (30%) and microscopic hematuria (90%). Serum immunofixation electrophoresis showed that 8 (80%) patients were positive for monoclonal immunoglobulin (IgG-κ/IgG-λ/IgA-κ/IgA-λ: 3/2/3). Serum free light chain (FLC) ratio was abnormal in 9 (90%) patients. Among them, 5 patients had an Elevated FLC ratio (κ:χ > 1.65), and an FLC ratio χ<0.20 was observed in 1 patient. Two patients were diagnosed with multiple myeloma. Histologically, nodular mesangial sclerosis was identified in 9 (90%) patients. Immunofluorescence showed that 6 patients had deposits of heavy chain IgG (γ-κ/κ-γ/κ-λ/κ-κ/λ-κ/λ-κ: 2/1/1/1/1/1), and 4 patients of heavy chain IgA (κ-κ/κ-κ/κ-κ/κ-κ/κ-κ: 2/1/1/1/1/1). During a median of 28 months of follow-up (range, 6–104 months) in 9 patients, 8 patients received chemotherapy. Three (33%) patients had complete hematologic remission (CR), 2 (22%) had very good partial hematologic response (VGPR) or partial hematologic response (PR), and 4 (44%) had no response (NR). One (11%) had stable/improved renal function, 6 (67%) had worsening renal function, and 3 (33%) progressed to ESRD. All 9 patients survived.

Conclusion: In this case series of LHCDD in a single center in China, light and heavy chain deposition in renal tissues was most frequent with IgG-κ, followed by IgA-κ, IgG-λ and IgA-κ. More than half patients had hematologic response but poor renal prognosis.

#5932 BALKAN ENDEMIC NEPHROPATHY AND MALIGNANT TUMOR OF THE UPPER TRACT UROTELIUM: AFTER 45 YEARS

Stevan Glogovac1, Danijela Tasic2, Branislav Apostolovic2, Zorica Dimitrijevic4, Miomir Stojanovic1, Milan Petrovic2, Srđjan Sterovic2, Karolina Paunovic3, Miomir Prokopovic2, Branka Mitic1, Ljubomir Dinić, Slavoljub Mladenovic2, Aleksandar Skakic3 and Dragoslav Basic4

1UCC, Clinic of nephrology, Nis, Serbia, 2General Hospital, Urology Department, Leskovac, Serbia, 3University of Nis, Faculty of Medicine, Clinic of nephrology, Nis, Serbia, 4University of Nis, Faculty of Medicine, UCC, Clinic of nephrology, Nis, Serbia, 5University of Nis, Faculty of Medicine, UCC, General Hospital, Nis, Serbia and 6University of Nis, Faculty of Medicine, Clinic of urology, Nis, Serbia

Background and Aims: Balkan endemic nephropathy (DEN) is a chronic progressive tubulo-interstitial kidney disease of unknown etiopathogenesis described more than 65 years ago. One of the general importance of the disease is the association with malignant tumors of the upper urothelium (MUUT). Epidemiological monitoring of BEN and MUUT plays a particularly important role. In the works published so far, there is a large discrepancy in the results of epidemiological works in relation to the researchers, the period and the region of observation. The aim of this paper was to examine the occurrence of MUUT in endemic settlements for BEN and the ratio of tumor frequency in endemic and non-endemic settlements of the Jablanica district.

Method: The observed research period is from 1978 to 2022. During the study of the frequency of MUUT (malignant tumors of the upper urothelium), the operative material of the urological service of the Leskovac General Hospital was used. The patients were divided according to their place of residence from individual settlements in the Jablanica district, and data from the Nephrology Clinic of the Urgent Clinical Center of Nis were used to classify the settlements: A: endemic settlements of patients with BEN (Balkan endemic nephropathy); B: hypoendemic settlements; C: non-endemic urban and D: non-endemic rural settlements. Some of the analyzes in this work were carried out so that groups A, B are unique endemic and C, D are non-endemic settlements. Data on the total number of inhabitants of the Jablanica district were obtained based on official data from the population census in 1981, 1991, 2002, 2011 and 2022. The incidence rate was calculated per 100,000 inhabitants. For practical reasons, the observed period is divided into the first (1978-2002) and the second (2003-2022).

Results: In the period from 1978 to 2022, 106 MUUT (55 men and 51 women) were registered in the Jablanica district, and the PGSI was 0.924. In endemic settlements (A) there were 14, hypoendemic (B) 10, non-endemic urban (C) 25 and in non-endemic rural (D) 57 MUUT. In the first observation period, the PGSI in Jablanica district was 1.3, and in the second, 0.93. In endemic settlements (A) in the first period, the frequency of MUUT was 9.1 times higher than in the second (17.56/1.93), while in hypoendemic ones (B) the frequency was 3.2 times higher in the first compared to the second observation period (5.06/1.58). In the last five years of observation (2018-2022), not a single MUUT was registered in the Jablanica district, and in the endemic settlements (A,B) only three tumors were registered in the last 25 years. In the observed period, the linear trend in endemic settlements (A) was in a statistically significant decline (y = -0.0276+55.691; r2 = 0.2128), while in the first period (1978-2002) it was in a statistically weak decline (y = -0.0054+0.59; r2 = 0.0031) and in the second period (2003-2022) it is not valid because only one tumor was registered. In the observed period, the linear trend of BEN incidence was in a statistically significant decrease (y = -0.164×+6.0669; r2 = 0.5788).

Conclusion: The high frequency of MUUT in endemic settlements for BEN in the first period of observation, perhaps indicates a common nephropathogenic and carcinogenic etiological factor, and therefore the more correct name of the disease may be Balkan nephroprourophy. In the observed period, we have a large discrepancy in results compared to the observation periods, and one of the main reasons is the drastic decrease of patients with BEN in endemic settlements, and the reasons should be sought in the lower toxicity of the causative agent, better water supply, better health awareness of patients, health and construction prevention and not having marriage between-at-risk patients. Is BEN disappearing?
"PRIMUM NON NOCERE": DIGITAL TOOLS AND MENTAL LOAD IN CLINICIANS AND PATIENTS: THE "E3 TASK FORCE" PROJECT
Corinne Isnard Bagnis1,2

1APHP, Nephrology Department, Paris, France and 2Sorbonne University Pierre and Marie Curie Campus, Paris, France

Background and Aims: The Covid 19 pandemia has been an extremely potent enhancer of digital health solutions spreading. Telemedicine was already available in France before SARS-COV2, but not used as a standard of care. It seems like when sticking to the expressed needs and objectives, the implementation of digital solutions became a reality with a high level of acceptability. Since e-health is spreading and the commercial offer of digital solutions dramatically increasing, it seems critical to predict the impact of those new tools on mental load of users in order to make sure digital solutions really bring better quality of care together with quality of life (patients) or professional life (health care professionals).

Method: Assistance publique - Hôpitaux de Paris launched in 2022 an ambitious project focusing on digital innovation at Hotel Dieu, making the largest hospital in Europe also an active promotor of digital health. This project includes an Innovation Hub, a large incubator for Start-ups, and (among others) the Digital Medical Hub (DMH). DMH is combining an academic platform dedicated to promoting scientific research on E-health and an open innovation structure promoting transformation strategies for e-health projects. Academic DMH initiated (March 2022) an innovative project aiming at defining what are the critical parameters involved into the lived experience of e-health users (clinicians and patients) with regard to mental load. This project included 3 steps: 1) a "consensus of experts" strategy conducted through meetings allowing the group to provide a list of the main dimensions impacting the (positive or negative) changes observed on daily life and mental load. The group includes neurosciences experts, clinicians (nephrologist, cardiologist, psychiatrist), e-health and digital solution experts, neuroergonomics and ergonomics experts, work psychologists, health economy specialist, market access experts). The following task of the group is to identify among those dimensions, those that are measurable or propose a way to evaluate them. 2) In parallel, a large opinion barometer is spread among health care professionals (HCP), digital entrepreneurs, and stakeholders in the field of health in order to collect over 500 answers allowing to describe expectations, fears and representations about e-Health implementation in France. 3) The last step of our research project is experimental with semi structured interviewing of health care professionals in two different hospitals to explore the experience of actors exposed to digital solutions usage daily. The expert group conducting this research has turned into a Task Force to build the research plan for the next steps, after publishing the first conclusions of this work in the form of a "white book".

Results: A white paper is under review describing the dimensions identified by the consensus of experts group as impacting mental load of HCP and, when available, the tools for quantitative assessment of impact. The result of the opinion barometers will be available in June and the qualitative study if ongoing.

Conclusion: Sharing this experience is shedding light on the importance for the Nephrology community to think about how to take part to the digital revolution in the field of Nephrology. There is incredible need for training and teaching to develop a commun culture about digital health. Patients and professionals should explore and express needs for digital tools in order to act as promoters of the digital transformation of health system.
in unadjusted (HR 2.35; CI 95% 0.61–9.15) and adjusted (HR 1.29; CI 95% 0.30–5.56) Cox proportional hazard models. As a continuous variable, each mL·kg\(^{-1} \cdot \text{min}^{-1}\) increase in VO\(_2\text{peak}\) was not associated with mortality risk (HR 0.94; CI 95% 0.79–1.11). Univariate Kaplan-Meier analysis showed that severe CRF patients did not have significantly worse survival rates than those with mild-moderate CRF (p = 0.186).

**Conclusion:** Our findings indicated that severe CRF was not associated with all-cause mortality in patients receiving HD. Despite severe CRF being prevalent, larger cohort studies are needed to establish strong conclusions on its association with all-cause mortality.

Advanced Medical and Surgical Sciences, Naples, Italy, 2National Medical Science and Nutrition Institute Salvador Zubiran, Nephrology and Mineral Metabolism, Mexico City, Mexico, 3National Autonomous University of Mexico, Medicine and Nephrology, Mexico City, Mexico, 4Hospital Universitario Nuestra Señora de Candelaria, Santa Cruz de Tenerife, Spain, 5North Bristol NHS Trust, Southmead Hospital, Renal Medicine, Bristol, United Kingdom, 6AstraZeneca, BioPharmaceuticals Medical, Cambridge, United Kingdom, 7Medical University of Łódź, Łódź, Poland, 8AstraZeneca, Gothenburg, Sweden, 9AstraZeneca, Gaithersburg, United States of America, 10Internal Medicine Department II at University of Pécs, Hungary and 11HealthLumen Ltd, London, United Kingdom

**Background and Aims:** Chronic kidney disease (CKD) and its associated complications constitute a major challenge for healthcare systems worldwide. Albuminuria, measured as albumin-to-creatinine ratio (uACR), is a critical marker of glomerular injury and endothelial dysfunction. Elevated uACR is an independent predictor of CKD progression and cardio-renal mortality [1,2]. However, there is a paucity of data translating the burden of CKD at the population level according to uACR categories, in order to promote evidence-based policies. This study aims to assess the future epidemiological and financial burden of CKD using the Inside CKD microsimulation [3]. Specifically, we report CKD population level projections for cardio-renal complications, progression to end stage kidney disease (ESKD), and death due to any cause according to uACR categories.

**Method:** The Inside CKD microsimulation was used to simulate virtual individuals from 28 countries and regions. Individuals were assigned baseline characteristics such as age or sex based on national statistics, and estimated glomerular filtration rate (eGFR), uACR, CKD stage, and cardio-renal complications based on data from national health surveys or epidemiological studies. The following cardio-renal complications were projected between 2022 and 2027 according to uACR categories (normo-, micro-, macro-albuminuria): myocardial infarction (MI), stroke, heart failure (HF), CKD transition from stage 3 to 4 and from 4 to 5 (defined as a change in either eGFR or uACR category), and death due to any cause.

**Results:** Projected estimates for the total CKD population (all stages) with macro-albuminuria varied by country and region for 2023 (mean = 9.8%, range = 1.6% – 40.2%). The lowest percentages of macro-albuminuria (< 5%) were in Romania, Belgium, and the UK, compared to the highest (≥ 27%) in Brazil, Philippines and Mexico. Macro-albuminuria is associated with a higher relative risk of cardio-renal outcomes on a per person basis, but according to these estimates only a small proportion of the population have macro-albuminuria. Hence, the predominant CKD population with normo- or micro-albuminuria would be expected to account for most of the clinical burden. Accordingly, most of the cardio-renal incident events projected to occur by 2027 will be in the population with normo- or micro-albuminuria in all countries and regions (Figure 1): MI (97.9%), stroke (96.5%), HF (98.0%), the transition from CKD stage 3 to 4 (94.9%) and from stage 4 to 5 (97.5%), and death due to any cause (95.6%) (percentages represent mean and included the combined normo- and micro-albuminuria populations).

**Conclusion:** Although, macro-albuminuria is associated with a higher relative risk of cardio-renal outcomes on a per patient basis, the total CKD population should be considered with regards to the clinical burden in absolute terms. The Inside CKD microsimulation supports early intervention in the total CKD population, including individuals with normo- or micro-albuminuria, to reduce cardio-renal outcomes, delay progression to ESKD, and therefore the requirement for costly interventions, including heart related hospitalisations, transplantation and dialysis.

MANAGEMENT OF TUBULOINTERSTITIAL DISEASE IN PREGNANCY: TEN-YEARS EXPERIENCE OF A NEPHRO-OBSTETRIC CLINIC
Estela Nogueira1, Nadiesda Peres1, Jolanda Godinho1, Sofia Jorge1, Mónica Centeno2, Luísa Pinto2 and José António Lopes1
1 Centro Hospitalar Universitário de Lisboa Norte, Serviço de Nefrologia e Transplantação Renal, Lisboa, Portugal and 2 Centro Hospitalar Universitário de Lisboa Norte, Serviço de Obstetricia, Departamento de Obstetricia, Ginecologia e Medicina da Reprodução, Lisboa, Portugal

Equal contribution: Estela Nogueira and Nadiesda Peres

Background and Aims: Tubular renal acidosis and salt losing nephropathies are rare conditions but their management during pregnancy that can be challenging due to the physiological adaptation of kidney function. Herein, the authors report the management and outcomes of 7 gestations in patients with Gitelman disease (GS) and renal tubular acidosis (RTA).

Method: Retrospective analysis of maternal, obstetric and perinatal outcomes of pregnant women with tubulo-interstitial diseases surveilled at our Nephro-Obstetric clinic from 2011 to 2021.

Results: We evaluated 7 pregnancies in 5 women. Mean age was 29 years [21-36]. They were all caucasian. Genetic diagnosis was performed during pregnancy in only one patient. Tubular disorder was caused by Gitelman disease in 3 patients and by renal tubular acidosis in 2 patients (ATP6VA4 and REN genes mutations). There were 4/1 patients in CKD G1/G3a, respectively, and none developed renal function deterioration. Only one patient developed transient proteinuria during both gestations and all patients had a low blood pressure profile. Management during the first trimester was especially challenging in GS patients, due to nausea, vomiting and hyperemesis gravidarum, which required hospital admission for intravenous potassium chloride therapy in all GS patients during the first trimester. Potassium levels in GS patients were generally below normal levels throughout pregnancy (mean 3 meq/L, 2.2-3.4 meq/L), even with progressive increase in therapy. Pre-pregnancy potassium chloride replacement increased from 4–10 tablets of 600 mg/day to a maximum of 9–21 tablets/day. One patient was also treated with spironolactone. The need for oral magnesium slightly increased from 2–3 ampoules of 1500mg/day to 2–4 ampoules/day. GS patients frequently developed transient proteinuria during both gestations and all patients had a low blood pressure profile. Management during the first gestation was especially challenging in GS patients, due to nausea, vomiting and hyperemesis gravidarum, which required hospital admission for intravenous potassium chloride therapy in all GS patients during the first trimester. Potassium levels in GS patients were generally below normal levels throughout pregnancy (mean 3 meq/L, 2.2-3.4 meq/L), even with progressive increase in therapy. Pre-pregnancy potassium chloride replacement increased from 4–10 tablets of 600 mg/day to a maximum of 9–21 tablets/day. One patient was also treated with spironolactone. The need for oral magnesium slightly increased from 2–3 ampoules of 1500mg/day to 2–4 ampoules/day. GS patients frequently complained of astenia and cramps. Regarding RTA patients, there was also a need to increase sodium bicarbonate dosage from 3–4.5g/day to a maximum of 2–3g/day. Regarding obstetric and perinatal outcomes, none of the patients developed preclampsia, mean gestational age at delivery was 40 weeks (38-41), mean birth weight was 3233g (2775-3825) and mean Apgar score was 10/10/10 at 1st, 5th and 10th minutes respectively.

Conclusion: In GS patients, management in the first trimester of pregnancy can be challenging due to nausea and vomiting, generally requiring admission for therapy with iv potassium. In spite of increasing doses in oral supplementation, ionic and acid base homeostasis during pregnancy is difficult to achieve. In our small series, maternal, obstetric and perinatal outcomes do not seem to be affected by this unbalance.

Efficacy and Safety of Roxadustat in Non-Dialysis-Dependent CKD Patients With or Without Inflammation: A Pooled Analysis of Four Phase 3 Studies

Gabriel Choukrour1, Alexander Harkavyi2, Vicki Santos3, Alina Jiletcovici3 and Lucia Del Vecchio4

1CHU Amiens Picardie and Jules Verne University, Amiens, France, France, 2Astellas Pharma Europe, Addlestone, Surrey UK, United Kingdom, 3Astellas Pharma, Inc., Northbrook, IL, USA, United States of America and 4Sant’Anna Hospital, ASST Lariana, Como, Italy

Background and Aims: Chronic kidney disease (CKD)-associated anemia is commonly treated with erythropoiesis-stimulating agents (ESAs); however, some patients respond inadequately to ESAs. Inflammation may be a cause of ESA hyporesponsiveness. Roxadustat, an oral medication, is a hypoxia-inducible factor prolyl hydroxylase inhibitor that has shown efficacy in patients with anemia of CKD. This pooled analysis examined the efficacy and safety of roxadustat in correcting hemoglobin (Hb) levels in subgroups of patients with anemia of CKD regardless of inflammation status.

Method: Data from four phase 3, randomized, placebo-controlled (OLYMPUS [NCT02174627], ALPS [NCT01887600], ANDES [NCT01750190]) or erythropoiesis-stimulating agent–controlled (ESA; DOLOMITES [NCT02021381]) studies in patients with NDD CKD were pooled for this analysis. Mean Hb change from baseline to Weeks 28–52 was greater with roxadustat than with placebo, and comparable between roxadustat and ESA, regardless of inflammation at baseline (Fig. 1). At Week 24, roxadustat dose was not increased in patients across hsCRP quintiles (hsCRP quintiles 1–5: 3.3, 3.0, 2.7, 3.1, 3.1 mg/kg, respectively). Roxadustat dose was not significantly higher at Week 24 for patients with moderate-to-high baseline hsCRP levels (quintile 4, >3.48 to ≤5.17 mg/L; least squares mean [LSM], 3.05; 95% CI, 2.83–3.36) compared with patients with low baseline hsCRP levels (quintile 1, <0.71 mg/L; LSM, 3.04–3.56; treatment comparison between quintile 1 and quintile 4: LSM difference, 0.25; 95% CI, −0.11 to 0.61; treatment comparison between quintile 1 and quintile 5: LSM difference, 0.20; 95% CI, −0.17 to 0.57; Fig. 2), indicating that patients with increased inflammation at baseline did not consistently require a higher roxadustat dose. The overall percentages of patients responding inadequately to ESAs (≥1.5 g/dL for roxadustat (hsCRP quintiles 1–5: 9.17 [0.82], 9.26 [0.68], 9.18 [0.75], 9.15 [0.74], 9.08 [0.82]), placebo (hsCRP quintiles 1–5: 9.09 [0.74], 9.20 [0.71], 9.15 [0.69], 9.09 [0.71], 9.01 [0.76]), and ESA (hsCRP quintiles 1–5: 9.53 [0.69], 9.53 [0.64], 9.54 [0.73], 9.60 [0.66], 9.53 [0.71]) were similar across hsCRP quintiles. The mean Hb change from baseline to Weeks 28–52 was greater with roxadustat than with placebo, and comparable between roxadustat and ESA, regardless of inflammation at baseline (Fig. 1). At Week 24, roxadustat dose was not increased in patients across hsCRP quintiles (hsCRP quintiles 1–5: 3.3, 3.0, 2.7, 3.1, 3.1 mg/kg, respectively). Roxadustat dose was not significantly higher at Week 24 for patients with moderate-to-high baseline hsCRP levels (quintile 4, >3.48 to ≤5.17 mg/L; least squares mean [LSM], 3.05; 95% CI, 2.83–3.36) compared with patients with low baseline hsCRP levels (quintile 1, <0.71 mg/L; LSM, 3.04–3.56; treatment comparison between quintile 1 and quintile 4: LSM difference, 0.25; 95% CI, −0.11 to 0.61; treatment comparison between quintile 1 and quintile 5: LSM difference, 0.20; 95% CI, −0.17 to 0.57; Fig. 2), indicating that patients with increased inflammation at baseline did not consistently require a higher roxadustat dose. The overall percentages of patients with at least one treatment-emergent adverse event were similar across hsCRP quintiles for patients treated with roxadustat (hsCRP quintiles 1–5: 88.5, 87.9, 87.5, 87.7, 87.9, and ESA (hsCRP quintiles 1–5: 90.9, 91.4, 91.7, 91.9, 91.7). The most common treatment-emergent adverse events were hypertension (hsCRP quintiles 1–5 [%]; roxadustat: 16.8, 16.5, 17.4, 22.2, 18.9; placebo: 7.9, 9.5, 11.8, 9.3, 8.5; ESA: 45.7, 36.4, 39.7, 22.1, 31.2), end-stage renal disease (hsCRP quintiles 1–5 [%]; roxadustat: 21.3, 22.7, 21.1, 24.6, 23.1; placebo: 13.8, 15.9, 15.3, 18.1, 16.5; ESA: 32.6, 36.4, 34.5, 39.7, 36.4), and decreased glomerular filtration rate (hsCRP quintiles 1–5 [%]; roxadustat: 4.6, 5.0, 4.3, 5.3, 5.1; placebo: 2.0, 2.0, 2.4, 1.3, 3.1; ESA: 13.0, 22.7, 19.0, 13.2, 16.9).

Conclusion: Independent of baseline inflammation status, roxadustat increased Hb levels greater than placebo and comparable to ESA with a similar safety profile. Patients with high baseline hsCRP did not require increased roxadustat doses to maintain Hb levels up to Week 24. These data suggest that roxadustat is effective in patients with anemia of NDD CKD regardless of inflammation status.
PREVALENCE OF ELECTROCARDIOGRAPHIC ABNORMALITIES IN PATIENTS WITH CHRONIC KIDNEY DISEASE

1 Aalborg University Hospital, Department of Nephrology, Aalborg, Denmark, 2 Aalborg University Hospital, Renal Research Group, Aalborg, Denmark, 3 Copenhagen University Hospital, Department of Nephrology, Copenhagen, Denmark, 4 Aalborg University, Department of Health Science and Technology, Aalborg, Denmark, 5 Copenhagen University Hospital, Laboratory for Molecular Cardiology, The Heart Centre, Copenhagen, Denmark, 6 Copenhagen General Practitioners’ Laboratory, Kongens Lyngby, Denmark, 7 North Zealand Hospital, Department of Cardiology, Hillerød, Denmark and 8 Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark

Background and Aims: The presence of electrocardiogram (ECG) abnormalities is high in patients with end-stage kidney disease, but no studies have examined the prevalence of ECG abnormalities according to different strata of estimated glomerular filtration rate (eGFR) in a population-based setting.

Method: This was a retrospective cross-sectional study including 310,060 individuals from the Copenhagen General Practitioners’ Laboratory who had an available digital ECG recorded between 2001 and 2015 and a creatinine measurement within 7 days of the ECG. eGFR was calculated using the The Chronic Kidney Disease Epidemiology Collaboration equation. ECG abnormalities were categorized as no, minor or major, as done previously [1]. Patients with both minor and major ECG abnormalities were assigned as major ECG abnormalities. The prevalence of ECG abnormalities was examined according to different strata of renal function [eGFR (ml/min/1.73 m²) >90, 61–90, 46–60, 31–45, 30-16 and ≤15]. Ordinal logistic regression was used to illustrate the probability of ECG abnormalities as a function of eGFR.

Results: The median age was 55 [IQR, 41-69] years and 46% were male. A total of 47,249 (17.9%) of the included patients had an eGFR <60. The prevalence of major ECG abnormalities increased with declining eGFR: >90 (16.5%), 61–90 (21.6%), 46–60 (36.5%) 31–45 (52.1%), 30-16 (57.9%) and ≤15 (60.1%). Ordinal logistic regression, the risk of having major ECG abnormalities compared to minor/no abnormalities significantly decreased pr. 5 ml/min increase in eGFR, OR 0.90 (95% CI, 0.85-0.90), Fig. 1. The most common major ECG abnormalities were left ventricular hypertrophy and ST-T deviations. The prevalence of all ECG abnormalities is shown in Table 1.

Conclusion: ECG abnormalities are common in patients with chronic kidney disease, and the probability of major ECG abnormalities increases with declining eGFR.

RENAI OSTEODYSTROPHY AND CLINICAL OUTCOMES: RESULTS FROM THE BRAZILIAN REGISTRY OF BONE BIOPSY

Cinthia Carbonara1, Kelcia Quadros1, Noemi Roza1, Joaquim Barreto2, Luciene Reis3, Aluizio Carvalho4, Vanda Jogetti3 and Rodrigo de Oliveira4

1 University of Campinas, Nephrology Division, School of Medical Sciences, Campinas, Brazil, 2University of Campinas, Laboratory of Atherosclerosis and Vascular Biology, Campinas, Brazil, 3University of São Paulo, Laboratory of Renal Pathophysiology, São Paulo, Brazil and 4Federal University of São Paulo, São Paulo, Brazil

Background and Aims: Mineral and bone disorders caused by chronic kidney disease (CKD-MBD) encompass biochemical/hormonal abnormalities, soft tissue calcifications and bone morphological changes known as renal osteodystrophy (ROD). Data from prior studies have consistently shown that patients with CKD-MBD are susceptible to an increased risk of mortality, bone fractures and major cardiovascular outcomes. This study is a sub-analysis of the Brazilian Registry of Bone Biopsy (REBRABO), a prospective, national multicenter cohort of patients with CKD who underwent bone biopsy, aimed at addressing the relationship between ROD type and the occurrence of bone fractures, hospitalizations, cardiovascular events, and a composite of all-cause mortality.

Method: During the period from August 2015 to December 2021, 511 patients with CKD who underwent bone biopsy and with diagnosis of ROD were included in REBRABO. Bone biopsy was indicated by medical reasons or research protocol. Were excluded from this analysis patients who lost their follow-up (N = 111), had no bone biopsy report (N = 40), had an estimated glomerular filtration rate > 90 mL/min (N = 28), not signed their consent (N = 24), had bone fragments inadequate for diagnosis (N = 23), had a bone biopsy indicated by a specialty other than nephrology (N = 6), or were < 18 years old (N = 4). Baseline was defined as the time when the patient underwent bone biopsy. The prospective analysis included data from patients who completed at least 12 months of follow-up. The mean follow-up was 1242 (693-1508) days. The following events were adjudicated: bone fractures, hospitalization, major cardiovascular events - MACES (unstable angina, nonfatal acute myocardial infarction, elective or emergency coronary revascularization, transient ischemic attack, stroke, and cardiovascular death), and death. Bone fragments were obtained via transiliac bone biopsies using an electrical trephine after prelabeling with tetracycline (3 days) administered over two separate periods. The samples were classified as osteitis fibrosa (OF), mixed uremic osteodystrophy (MUO), adynamic bone disease (ABD), osteomalacia (OM) and normal/minor alterations, according to TMV system. Cox regression analysis was performed to detect independent determinants of clinical outcomes.

Figure 1: Effects of bone turnover, mineralization, and volume on death outcome.

Cox regression analysis survival curves for death outcome. Variables tested in the models: age, previous cardiovascular disease, previous parathyroidectomy, proportion of patients out of the normal range for serum phosphate levels, plus: bone turnover (reference: high bone turnover) in (A), or bone mineralization (reference: abnormal bone mineralization) in (B), or bone volume (reference: low bone volume) in (C). Overall p = 0.0001.
Results: A total of 275 patients were included. This was a population with a mean age of 52 (42–60) years, 143 (52%) were men, 39 (14%) had diabetes, and 248 (90%) were on dialysis. During follow-up, a total of 28 bone fractures, 97 hospitalization events, 44 MACEs, and 70 deaths were reported, with incidence of 15.1% (4.4%/year), 49.5% (14.6%/year), 23.3% (6.85%/year) and 25.5% (7.5%/year), respectively. Patients who presented MACEs had lower serum hemoglobin levels [11.1 (9.6-12.6) vs. 12 (10.8-13.5; p = 0.026), higher prevalence of diabetes mellitus [11 (25%) vs. 15 (10%); p = 0.013] and previous cardiovascular disease [8 (18%) vs. 8 (5%); p = 0.008]. Age, previous cardiovascular disease, and proportion of serum phosphate levels out of the normal range were independent predictors for death [OR 1.046 (CI: 1.024-1.069), p = 0.0001; OR 1.856 (CI: 1.009-3.413), p = 0.04; OR 1.942 (CI: 1.116-3.379), p = 0.019; respectively]. Participants were grouped according to the ROD subtype as: OF (n = 113; 41%), ABD (n = 79; 29%), MUO (n = 59; 21%), OM (n = 12; 4%), and normal/Minor alterations (n = 12; 4%). ROD subtypes were not related to incident outcomes.

Conclusion: The incidence of bone fractures, hospitalizations, cardiovascular events, and of a composite of all-cause mortality did not differ between the types of ROD.

#5603
HYPERKALAEMIA MAY LIMIT POTENTIAL PARENTERAL INTERVENTIONS IN PATIENTS WITH LOW GFR AND SIGNIFICANT PROTEINURIA
Hyewon Nina Koo1, Fredrik Thoren2, Peter Greasley3, Shardul Chandankhede4, Afrah Khayyam5 and Philip Ambery2
1AstraZeneca, Data Science & Artificial Intelligence, Mölndal, Sweden, 2AstraZeneca, Late-stage Development, Cardiovascular, Renal and Metabolism, Mölndal, Sweden, 3AstraZeneca, Research and Early Development, Cardiovascular, Renal and Metabolism, Mölndal, Sweden, 4ZS Associates, Real World Data & Insights, Pune, India and 5AstraZeneca, Biopharmaceuticals Medical, Cambridge, United Kingdom

Background and Aims: Evidence-based therapies including ACE inhibitors, ARBs and mineralocorticoid receptor antagonists (MRA) can significantly delay progression of CKD, yet their use is potentially limited by hyperkalaemia risk. In this study, we describe hyperkalaemia events among CKD patients to provide a better understanding of the current unmet need.

Method: This was a retrospective secondary data analysis from electronic medical records (EMR) in the US TriNeXa analytics data CKD subset from Jan 2015-Dec 2019. Patients with ≥1 uACR measure were included, whereby the first date of the uACR measure was considered the index date. The study cohort included patients aged > 18 years with a) two consecutive estimated glomerular filtration rate (eGFR) values between 20 and 90 mL/min/1.73m² recorded 91–730 days apart prior to the index date, or b) at least one CKD diagnosis code before the index date. Patient demographics, ACE/ARB, MRA and SGLT2i treatments on index were described. The frequency of HK (defined as serum potassium > 5.5 mmol/L or a diagnosis code) during a 1-year baseline period and 1-year follow-up period was described by uACR (<700mg/g, 300–700mg/g, <300mg/g) and eGFR (<20mL/min/1.73m², 20–45mL/min/1.73m², 45–60mL/min/1.73m², 60–90mL/min/1.73m² and >90mL/min/1.73m²) categories.

Results: Baseline characteristics of the included patients are described in the table below. During the 1-year follow-up period, HK events were more frequently recorded for patients with uACR>700mg/g (15.3%), eGFR<60mL/min/1.73m² (9.3%) and combined uACR>700mg/g and eGFR<60mL/min/1.73m² (18.3%).

Conclusion: The preliminary results of this analysis shows that HK occurs more frequently among patients with low eGFR and/or high uACR. Despite guidelines, uACR testing is not done frequently in clinical practice and likely performed more frequently among patients with high uACR. Further analyses and more conservative study definitions will be applied to more comprehensively clarify the unmet need among patients at risk of HK. Of particular interest are the patients who discontinued RAASi treatment after a hyperkalaemia event during baseline and were not on renoprotective treatment, yet who had recurrent hyperkalaemia. Adequate treatment options for these patients are currently limited, and there is a need for more renoprotective treatments with limited hyperkalaemia risk.

ALBUMINURIA IN PATIENTS ADMITTED WITH HEART FAILURE IS ASSOCIATED WITH MORE SYSTEMIC CONGESTION ASSESSED BY ULTRASOUND

Natalia Kontareva, Yulia Khruuleva, Robinson Tsimine Andriamanohery, Irina Misan, Rena Aslan, Marina Efremovtsve, Svyatoslav Galochkin and Zhanna Kobalava

Russia

Background and Aims: Albuminuria is frequently observed in patients with heart failure (HF) and is associated with worse outcomes. New instrumental methods of congestion assessment in HF are superior in accuracy to physical examination and, therefore, are becoming the new standards for congestion registration. The relationship of albuminuria with congestion assessed by ultrasound in HF population is unclear. We aimed to investigate the relationship between albuminuria level and congestion measured by lung ultrasound (LUS) and Venous Excess Ultrasound (VExUS) at admission in patients with ADHF.

Method: In this prospective study we included 58 patients which were admitted with ADHF (typical signs and symptoms with NT-proBNP > 300 pg/ml). Patients with end-stage chronic kidney disease (CKD), malignancy were excluded. Routine clinical examination and laboratory tests, echocardiography, eight-zone LUS, and VExUS assessment of veins: caval inferior, hepatic, portal, and renal were performed. Patients were divided into two groups according to albumin/creatinine ratio at hospitalization: without albuminuria (uACR<30 mg/gCr) and with albuminuria (uACR>30 mg/gCr).

Results: 72% were male, mean age was 72 (55;79) (Me (IQR) years, 52% (n = 30) had reduced ejection fraction (EF), 77% - hypertension (HTN), 66% - atrial fibrillation (AF), 37% - diabetes mellitus (DM), 58% - coronary artery disease (CAD), 17% (n = 10) - previously known CKD. On physical examination at admission 67% (n = 39) patients had orthopnea,69% (n = 40) - exertional dyspnea, 53.4% (n = 31) - elevated jugular venous pressure, 91.4% (n = 53) - ankle edema, 50% (n = 29) - hepatomegaly and 82.8% (n = 48) pulmonary crepitations. Mean NT-proBNP was 2062 (13443246) (Me (IQR) pg/ml 49 (84%) had pulmonary congestion assessed by LUS (mean number of B-lines 34 (25;48)), 86% (n = 50) - congestion by VExUS, from which the majority of patients had the most severe, 3rd grade (1< - 32%, 2nd - 16%, 3rd - 52%). The prevalence of albuminuria was 65.5% (n = 38): 92% (n = 35/38) patients had albuminuria categories A2 and 8% (n = 3/38) had A3 category. Groups with and without albuminuria were similar in gender, age, prevalence of EF<40%, comorbidities, exertional dyspnea, orthopnea, elevated jugular venous pressure, hepatomegaly, pulmonary crepitations, levels of NT-proBNP and serum creatinine. Differences between groups with and without albuminuria were detected in the frequency of ankle swelling (100% (n =38/38) vs 75% (n = 15/20), p = 0.003). Patients with albuminuria had a trend to more frequently having pulmonary congestion than without albuminuria (89% (n = 34/38) and 75% (n = 15/20), p = 0.15 respectively). The prevalence of congestion assessed by VExUS was higher in patients with albuminuria (95% (n = 36/38) and 70% (n = 14/20), p = 0.090 respectively).

Conclusion: In patients hospitalized with ADHF albuminuria is associated with systemic congestion assessed by VExUS. The relationship between pulmonary congestion by LUS and albuminuria should be a matter of future studies.

RESULTS

ALBUMINURIA VS. SYSTEMIC CONGESTION ASSESSED BY LUS AND VEXUS

Comparison of patients with and without albuminuria and their congestive scores assessed by LUS and VExUS are shown in Table 1.

### Discussion

The results of this study suggest a significant association between albuminuria and systemic congestion assessed by LUS and VExUS. This association is independent of conventional clinical variables such as age, sex, and EF. The higher prevalence of pulmonary congestion and lower EF in patients with albuminuria is consistent with previous findings [1, 2]. The higher prevalence of pulmonary edema in patients with albuminuria may be due to increased capillary permeability or decreased clearance of albumin. These findings support the hypothesis that albuminuria is a marker of increased capillary permeability and decreased clearance of albumin, which may contribute to the development of pulmonary congestion in patients with ADHF.

ACTIVATION OF HYPOXIA-INDUCIBLE FACTORS IN ERYTHROID PROGENITOR CELLS RESULTS IN DEFECTIVE ERYTHROPOIESIS

Pei-Zhen Tsai1, Suzu-Yu Pan2 and Shuei-Liong Lin1,2

1National Taiwan University College of Medicine, Graduate Institute of Physiology, Taipei, Taiwan, Rep. of China and 2National Taiwan University Hospital, Taipei, Taiwan, Rep. of China

Background and Aims: Hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) activates HIF in renal pericytes and fibroblasts to promote erythropoietin production and erythropoiesis. However, the effects of HIF stabilization in the erythroid lineage are not clear. We aim to study the effects of erythroid lineage-specific stabilization of HIF on erythropoiesis by preclinical models.

Method: EpoGFP-Cre/+;VhIF/F mice were used to achieve erythroid lineage-specific stabilization of HIF. Surface expression of TER-119, CD44, and forward scatter (FSC) were used to define erythroblast, reticulocyte, and red blood cell in the bone marrow. Expression of propidium iodide and surface annexin V were used to define apoptosis. Stress erythropoiesis was induced by subcutaneous administration of phenylhydrazine.

RESULTS

Compared with littermate VhIF/F mice, EpoGFP-Cre/+;VhIF/F mice had decreased hematocrit, decreased percentage of erythroblasts in the bone marrow, and increased apoptosis of erythroblasts in the bone marrow under steady state. These phenotypes of defective erythropoiesis were normalized in mice harboring concomitant Vhl, Hif1a, and Hif2a deletion (EpoGFP-Cre/+; VhIF/F;Hif1a-/-;Hif2a-/- mice). Although macrophages in the bone marrow also express Epor, macrophage-specific Vh deletion in either Tg(Cay1r-CreERSt1);VhIF/F or Lyz2Cre-/-;VhIF/F mice did not result in defective erythropoiesis. During stress erythropoiesis, compared with littermate VhIF/F mice, EpoGFP-Cre/+;VhIF/F mice had similar hematocrit, lower percentage of erythroblast in the bone marrow, and increased percentage of erythroblast in the spleen.

Conclusion: Vh deletion in erythroid progenitor cells impairs erythropoiesis in murine bone marrow in the steady state. The phenotypes of defective erythropoiesis were partially reversed during stress erythropoiesis.
Conclusion: The results indicate the high P exposure could lead to an impairment of vascular health by causing decrease in miR-145 levels with the α-tocopherol supplementation. The results indicate the high P exposure could lead to an impairment of vascular health by causing decrease in miR-145 levels with the α-tocopherol supplementation.

EFFECT OF IV FERRIC CARBOXYMALTOSE ON PHYSICAL PERFORMANCE AND QOL IN PATIENTS WITH CKD NOT ON DIALYSIS, MILD ANEMIA AND IRON DEFICIENCY

Maria Jesús Puchades Montesa1, Juan Casas Todolí2, Aleix Cases Amenos3, Claudia Forquet4, Elena Gimenez-Civera3, Elisa Pérez Bernat1, Camila Solano Rivera1, Andrea Muñozsenberg Alcalá1, Adriana Acosta Barrios1 and José Luis Gorriz Teruel6

1Servicio de Nefrología. Hospital Clínico Universitario, Valencia, Spain, 2Hospital Francesc de Borja, Gandia, Spain, 3Nephrology Unit. Hospital Clinic. Universitat de Barcelona, Barcelona, Spain, 4Hospital Clínico Universitario. Servicio de Nefrología, Valencia, Spain, 5Servicio de Nefrología. Hospital Clínico Universitario, Valencia, Spain and 6Servicio de Nefrología. Hospital Clínico Universitario. Universidad de Valencia, Valencia, Spain

Background and Aims: Iron deficiency (ID) in patients with chronic kidney disease (CKD) is highly prevalent and contributes to a poorer quality of life. According to current guidelines, treatment with intravenous (IV) iron is limited to CKD patients with ID and anemia to avoid/delay the use of erythropoiesis-stimulating agents (ESAs) or the reduce the doses of ESA in patients treated with these drugs. Considering the effects of the correction of ID in other settings, we hypothetized that treatment with IV iron in patients with ID and borderline anemia can improve physical performance and their quality of life, independent of the effects on hemoglobin.

Method: Prospective, uncenteric, single-arm study in CKD patients with ID, mild anemia and with-out heart failure. The inclusion criteria were: age ≥ 18 years, CKD patients stages 3–5 not on dialysis, iron deficiency (ferritin <100 ng/ml or ferritin <200 ng/ml if TSAT <20%), mild anemia (Hb 10.5–11.5 g/dL). At the baseline visit, after all the studies were performed, IV ferric carboxymaltose was administered in a single dose, according to the degree of ID calculated by the Ganzoni’s formula. The co-primary outcome was the change in physical performance, evaluated through the 6 minute-walk test (6MWT) at one week and at four weeks. Secondary end-points: Patient’s global assessment (PGA) and quality of life (EQ-5D), Piper’s fatigue test, serum phosphorous at four week. Laboratory data, PGA, EQ-5D and Piper test questionnaires were evaluated at baseline, and at weeks 1 and 4 after receiving IV ferric carboxymaltose.

Results: 41 patients completed the study. Primary end-point: the 6MWT increased significantly from 296 ± 101 m to 314 ± 106 m at week 1 (p < 0.01), and to 325 ± 111 meters at week 4 (p < 0.01), at week 6 (p = 0.083). A significant improvement in the PGA test values was detected when compared baseline vs 4 weeks (adjusted p value = 0.031). No significant differences were found between the baseline and week 1 (adjusted p value = 0.083), and week 1 and week 4 visits (adjusted p value = 0.086). No significant differences were found between the initial, 1-week, and 4-week visits in the EQ-5D quality of life questionnaire nor Piper’s fatigue test. Phosphorus levels decreased significantly at week 1 from baseline (3.16 ± 0.7 vs 3.72 ± 0.6) (adjusted p <0.01), with a partial recovery of serum levels in week 4 (3.57 ± 0.7 mg/dL). There were no significant increases in hemoglobin concentration between the different time periods.

Conclusion: IV ferric carboxymaltose administration significantly improved the functional capacity of CKD patients with ID in short term. PGA also improved slightly but significantly. Effects that were independent of the functional capacity of CKD patients with ID in short term. PGA

Abstracts

i593
substantial variation across countries, from 7.3 in the UK to 45.6 in Thailand. For HD, the RBCT rate was 23.9 (95% CI: 23.3, 24.5), also higher than in ND-CKD, with international variation observed. In the HD cohort, RBCT rates were lower in China (6.3) compared to the US (8.9), Canada (17.4), and the Gulf Cooperation Council region (21.6). Within HD-Europe, RBCT rates were highest in Belgium (48.1) and Sweden (40.4), and lowest in Germany (15.4), France (19.0), and Italy (20.4).

As expected, however, rates of VAT were higher in IDD patients than PDD patients. Mean ages of the IDD and PDD cohorts were 70.3 and 63.3 years, respectively. Compared with the PDD cohort, patients in the IDD cohort were more likely be female (48.2% vs 45.7%), of non-Hispanic White race (61.6% vs 40.4%), less likely be of lower-income status (33.0% vs 47.4% for Medicare/Medicaid dual enrollment and 38.6% vs 57.0% for Part D low-income subsidy) and with higher proportion of comorbidities. First event rates are shown in the Table for the IDD and PDD cohorts. Compared with the PDD cohort, patients in the IDD cohort had higher rates of all-cause mortality (17.3 vs 16.8 per 100 patient-years), stroke (1.8 vs 1.4), VAT (109.4 vs 67.2 per 100 patient-years), and MACE (20.9 vs 20.3); however, they had lower rates of MI (3.1 vs 3.5), HF (7.1 vs 8.9), DVT (3.2 vs 4.0), and MACE+HF (25.6 vs 26.9). For non-CV events, patients in the IDD cohort had lower event rates for nearly all events except malignancies.

Conclusion: ESA-treated IDD patients had higher event rates for some CV events but lower rates for most non-CV events compared with PDD patients. As expected, however, rates of VAT were higher in IDD patients than PDD patients. These background event rates in real-world populations with wide ESA use provide context when considering potential alternative treatments for anemia. Limitation of this descriptive study includes the reporting of crude (unadjusted) rates, and therefore should be interpreted with caution. Funding: GSK (study 217316).

Background and Aims: Patients with advanced chronic kidney disease (CKD) typically develop a constellation of various non-specific symptoms known as the uremic syndrome. This symptom burden affects patients’ quality of life and is one of the most relevant reasons for initiating dialysis. Several factors are thought to be involved in symptoms development, including mineral bone disorder (CKD-MBD). However, evidence linking deranged mineral biomarkers and CKD symptoms is mostly limited to few symptoms in dialysis patients. We studied the association between PTH, phosphate and calcium and the overall symptom burden in a cohort of elderly non-dialysis patients with advanced CKD, during 5 years of follow up. Secondly, we investigated whether these biomarkers are specifically associated with a wide spectrum of CKD-related signs and symptoms.

Method: We used data from the EQUAL study, which included patients aged ≥65 with eGFR ≤20 ml/min/1.73m² from six European countries. Symptoms were repeatedly assessed at 6-month intervals through a questionnaire on 33 CKD-related signs and symptoms. Generalized linear mixed models were used to study the association between mineral biomarkers and the overall symptom number (range 0–33), the overall symptom severity (range 0–165, with higher scores indicating higher severity), the probability of having each symptom and its severity (range 1–5). Models were adjusted for age, sex, Charlson Comorbidity Index, kidney function, albumin, hemoglobin and CKD-MBD medications.

Results: At baseline, the 1396 patients included in the study had a mean (SD) of 12.6 (±6.4) symptoms and a median symptom severity score of 32 (19–50), with the most prevalent symptoms being fatigue, loss of strength, muscle cramps, bone pain, swelling in legs, dry skin, and sexual disorders. Among the mineral biomarkers, only PTH had a significant association with the overall symptom number and severity. Furthermore, a doubling in PTH was associated with an increased probability of reporting shortness of breath (OR 1.13 [1.01, 1.27], p 0.03) and decreased probability of loss of strength (OR 0.90 [0.81, 1.00], p 0.05). Both PTH and phosphate had significant U-shaped associations with gastrointestinal symptoms (decreased appetite, nausea, and vomiting). A doubling in phosphate level was linearly associated to the severity of muscle cramps (β 0.20 [0.06, 0.36], p 0.007) and bone pain (β 0.24 [0.09, 0.39], p 0.002), in patients who experienced these symptoms. Phosphate was also non-linearly associated with the probability of having trouble falling asleep. One mmol/L increase in calcium was associated with both a decreased probability of having muscle cramps (OR 0.50 [0.25, 0.98], p 0.04) and its severity (β -0.43 [-0.69, -0.17], p 0.001).

Conclusion: Serum levels of PTH are associated with the overall symptom burden in older non-dialysis patients with advanced CKD, and PTH, phosphate, and calcium are specifically and independently associated with some of the individual symptoms in this population.
Background and Aims: COVID-19 is associated with myocardial injury and in previous studies, patients with right ventricular dysfunction had an increased risk of all-cause death. In the general population, there is evidence that right ventricular strain improves at 6 months after COVID-19, but data about the course of other myocardial performance parameters are limited. 

Method: CARDIO-SCARS in CKD is a currently ongoing observational cohort study that aims to assess the cardiovascular risk in a CKD (stages 3 to 5), dialysis and kidney transplant population following SARS-CoV2 infection, by using clinical evaluation, various techniques and both endothelial dysfunction and myocardial injury biomarkers (ClinicalTrial.gov Identifier NCT05125913). We hereby report the evolution of the main echocardiographic myocardial performance parameters at 6 months from COVID-19 disease.

Results: Our study included 222 patients (134 in the COVID-19 group and 88 in the control group). In the COVID-19 group, the echocardiography was performed at a mean distance of 2.21±1.9 months after testing positive for SARS-CoV-2. The mean age at baseline was 58.81±15.2 years and 53.41±14.14 years for the COVID-19 group and control group respectively. Atrial fibrillation, heart failure, ischemic heart disease and diabetes were more prevalent in the COVID-19 group. When analyzing the mean absolute difference between baseline and 6 months echocardiographic parameters using a two-sample t-Test, statistically significant results were observed for the left ventricular (LV) ejection fraction (EF), LV Tei Index, right ventricular (RV) Tei Index and RV free wall longitudinal strain (RVFWLS) as follows: Δ LVEF was 0.70±7.97% and -2.44±7.30% (p = 0.005), Δ LV Tei index was -0.04±0.19 and 0.0007±0.111 (p = 0.024), Δ RV Tei index was -0.04±0.17 and 0.0007±0.20 (p = 0.034) and Δ RVFWLS was 1.68±4.36% and -0.32±3.34% (p = 0.039) for the COVID-19 group and the control group respectively.

Conclusion: Our study is the first to describe the evolution of echocardiographic parameters post-COVID in a CKD population. Despite worse demographic and echocardiographic characteristics at baseline, patients from the COVID-19 group had a better evolution at 6 months, when compared to the control group. Both right and left ventricular myocardial performance indices improved for the COVID-19 patients and worsened for the control group.
Furthermore, group D had a higher positive rate of screening tests for CAD compared to the other three groups.

Conclusion: In patients with advanced CKD, ECG and TTE abnormalities were significantly associated with the occurrence of CVD events. Additionally, those with both ECG and TTE abnormalities may be at high risk for the presence of CAD.

**Conclusion:** CKD was associated with smaller initial ischemic lesions for equivalent neurological severity, and more recanalization failures. CKD was not an independent risk factor for mortality or poor functional prognosis at 3 months. CKD patients seem to benefit from thrombectomy and should not be contraindicated to this technique. AKI is associated with greater initial neurological severity, poorer functional prognosis and increased mortality at 3 months and is an independent risk factor for poor prognosis.

**Impact of mechanical thrombectomy on outcomes after an ischemic stroke.**

**Method:** Multicenter cohort study. Patients with at the acute phase of ischemic stroke following a large artery occlusion managed with mechanical thrombectomy were included. CKD was defined as eGFR < 60 mL/min/1.73m² for more than 3 months, AKI by 2012 KDIGO score, infarcted volume by ASPECTS and functional prognosis at 3 month by modified Rankin Scale (mRS).

**Results:** 296 patients were included. Sixty-three patients (22.8%) had CKD. In univariate analysis, patients with CKD had more white matter vascular lesions (Fazekas 1.7±0.8 vs. 1.0±0.8, p<0.001), had lower initial infarcted volume (ASPECTS 7.6±1.7 vs. 6.7±1.8, p = 0.003), for equivalent severity (NIHSS: 9.2±7.0 vs. 10.1±7.7, p = 0.404), and had more thrombectomy failure (12.7% vs. 3.8%, p = 0.008) compared to non-CKD patients. At 3 months, CKD was associated with equivalent functional prognosis (mRS 3–6: 51.6% vs. 42.2%, p = 0.193) but higher mortality: 24.2% vs. 9.5%, p = 0.004. Forty-eight patients (19.6%) developed an AKI. AKI was associated with increased initial gravity (NIHSS 18.8±5.2 vs. 16.7±5.7, p = 0.014, equivalent stroke volume (ASPECTS 7.3±1.9 vs. 6.8±1.8, p = 0.234). At 3 months, CKD was associated with poorer functional prognosis (mRS 3–6: 64.6% vs. 39.4%, p = 0.002) and mortality: 25.0% vs. 8.4%, p = 0.003. In multivariate analysis, AKI appeared as an independent risk factor of poor neurological outcome (OR 2.16 [1.05-4.46], p = 0.036 and mortality: OR 2.47 [0.96-6.35], p = 0.059 at 3 month, as CKD was not.

**Figure 1:** Occurrence of CVD events among study patients according to findings of ECG and TTE.
patients without diabetes, obesity may play a protective role. Diabetes is a potent predictor of outcomes irrespective of BMI, however, in group 3 (CKD and DM, n = 227) showed that patients with obesity had significant lower rates of combined outcomes compared to patients with normal BMI (HR 0.75; 95%CI = 0.63-0.89; p = 0.001 and HR 0.56; 95%CI = 0.38-0.82; p = 0.003 for group 1 and group 2 respectively). In multivariate models, obesity consistently proved to be a strong protective factor against combined outcomes (HR 0.77; 95%CI = 0.65-0.92; p = 0.005 for group 1 and HR 0.53; 95%CI = 0.34-0.83; p = 0.005 for group 2). This was independent of age, gender, HTN, angina, stroke, MI, and prescription of statins and angiotensin converting enzyme inhibitors. For group 3 (CKD and DM, n = 614), and group 4 (CKD, DM, and HF, n = 190), there was no significant difference in the combined outcomes between the different BMI groups when using univariate Cox regression analysis (for patients with obesity: HR 0.78; 95%CI = 0.61-1.01; p = 0.060 and HR 0.70; 95%CI = 0.43-1.16; p = 0.166 for both groups respectively). There was no significant difference in the incidence of RRT in any of the four groups.

Conclusion: In our largely white NDD-CKD cohort of patients, there was evidence of increasing risk of RRT or ACM as comorbidity increased irrespective of BMI. This is not surprising as ACM would be expected to increase as the burden of disease increases. However, when comparing the effect of BMI within groups, obesity was protective against combined outcomes in group 1 (CKD only) and group 2 (CKD+HF). This 'protective' effect was not seen in patients who had concomitant diabetes. These data suggest that diabetes is a potent predictor of outcomes irrespective of BMI, however, in patients without diabetes, obesity may play a protective role.

25 HYDROXYVITAMIN D ASSOCIATES WITH GASTROINTESTINAL BLEEDING IN DIALYSIS
John Larkin1, Yue Jiao1, Suman Lama1, Sheetal Chaudhuri1, Joanna Willetts1, Anke Winter2, Manuela Stauss-Grabo2, Len Usayt1, Jeffrey Hymes3, Franklin Maddux4, David C. Wheeler4, Peter Stevininkel5 and Jürgen Floege6

1Fresenius Medical Care, Global Medical Office, Waltham, United States of America, 2Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany, 3University College London, London, United Kingdom, 4Karolinska University Hospital, Dept of Renal Medicine, Stockholm, Sweden and 5University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany

Background and Aims: The INSPIRE collaborative group built a prediction model that showed serum 25 hydroxyvitamin D concentration (25OH Vit D) may be a predictor of gastrointestinal bleeding (GIB) hospitalizations in dialysis patients [1]. Unexpectedly, 25OH Vit D levels in the target range (i.e., >30 ng/mL) were most associated with GIB hospitalization risk. We aimed to further investigate the association between GIB episodes and 25OH Vit D levels, considering the onset of a GIB comorbidity or a GIB hospitalization event in the next 180 days.

Method: Analysis used data from adult (age ≥18 years) dialysis patients in the United States who had one or more 25OH Vit D lab measurement between 01-Jan-2018 to 31-Mar-2021. We identified GIB episodes (comorbidity or hospitalization observations) that were within ≤180 days after a 25OH Vit D measurement. GIB episodes and types were based on ICD-10 diagnosis code clusters defined by the United States Healthcare Cost and Utilization Project [2]. We calculated the percent of GIB comorbidities that onset, or GIB hospitalizations that occurred, by categories of 25OH Vit D levels (<15, ≥15 to <30, ≥30 to <50, ≥50 to <100, or ≥100 ng/mL).

Results: Among 347,165 adult dialysis patients who had a 25OH Vit D lab measurement(s), 3.2% (n = 11,038) experienced ≥1 GIB comorbidity and 6.7% (n = 23,389) experienced ≥1 GIB hospitalization. In total, 16.5% (n = 4,873) of these patients had ≥1 GIB comorbidity and hospitalization. GIB episodes were within ≤180 days after a 25OH Vit D measurement for 5,358 GIB comorbidity and 21,862 GIB hospitalization observations. We found patients with 25OH Vit D levels that were ≥15 ng/mL or ≥50 ng/mL exhibited the lowest GIB comorbidity and GIB hospitalization rates (Figure 1A & B). Patients with 25OH Vit D levels that were between ≥15 ng/mL and <50 ng/mL had the highest GIB comorbidity and GIB hospitalization rates. This observation was consistently observed for all GIB types, including upper, lower, and unspecified GIB episodes.

Conclusion: Findings showed serum 25OH Vit D levels are associated with 180-day GIB episodes in dialysis patients. The highest GIB rates were found in patients with a 25OH Vit D level between 15–50 ng/mL versus all other levels. This finding was consistent for the onset of a GIB comorbidity and the occurrence of a GIB hospitalization, and in both cases was associated with 2-fold higher GIB rates. Outside the kidney failure population, 25OH vitamin D levels in the range of 30–100 ng/mL have been shown to be associated to higher GIB risk in warfarin users [3]. These findings may question recommendations in kidney disease that suggest repletion of 25OH Vit D levels to ≥30 ng/mL, which has been a controversy for more than a decade. Nonetheless, further analyses are needed and should consider adjustments for patient factors (e.g. age, sex, medications) and competing risks (non-GIB hospitalization events).

CHARACTERISTICS OF PATIENTS WITH CKD WHO USE HYPOXIA-INDUCIBLE FACTOR PROLYL HYDROXYLASE INHIBITORS: A JAPAN MEDICAL DATA CENTER DATABASE STUDY

Timothy Pham, George Mu, Jake Hunnicutt and Liyuan Ma

GSK, Collegeville, PA, United States of America

Background and Aims: Anemia is common among patients with chronic kidney disease (CKD) and is reported to be associated with increased cardiovascular disease and all-cause mortality, as well as reduced quality of life. The incidence of anemia increases as kidney function declines and affects approximately 32% of Japanese patients with stage 3–5 CKD.

Hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHIs) have been approved in the Japan since Sept 2019 for patients with anemia of chronic kidney disease. Available HIF-PHIs include roxadustat (approved Sept 2019), daprodustat (approved June 2020), enarodustat (approved June 2020), vadadustat (approved Sept 2020) and molidustat (approved Jan 2021). This analysis aims to provide a real-world account of patient characteristics of those initiating HIF-PHIs since the approval of HIF-PHIs in Japan, overall and by individual treatments.

Method: This retrospective cohort study leveraged data from the Japan Medical Data Center (JMDC) database from Nov 2018 – May 2022 and included patients over 18 years of age with documented CKD who initiated any HIF-PHI from Nov 2019 – Nov 2021. JMDC is a health insurance database aggregating administrative claims data, medical examination data, and ledger information of patients who are on employer-based insurance and <75 years of age. The study index date was defined as the first observed claim for any HIF-PHI during the identification period. Patients were required to have baseline period of 1 year prior to the index date and a minimum of six months of follow-up after the index date, with continuous insurance enrollment. This study assessed patient demographics, clinical characteristics, and previous anemia of CKD treatment in the baseline period.

Results: Overall, 500 patients initiated HIF-PHIs, with 47.8% (n = 239) patients initiating roxadustat, 40.8% (n = 204) patients initiating roxadustat, and 11.4% (n = 57) patients initiating other HIF-PHIs. Table 1 illustrates the patient demographic characteristics overall and by index HIF-PHI. Overall, 60.2% (n = 301) of patients were male; the mean age was 55.7 years (SD = 10.8). More than a third (37.2%) of overall patients received dialysis in the baseline period. Within the 184 patients on specified types of dialysis, 67.9% (n = 125)
had received hemodialysis and 32.1% (n = 59) had received peritoneal dialysis. In terms of prior anemia of CKD treatments, 61.8% (n = 309) of patients had any rhEPO use in the baseline period. Further breakdown is in Table 2. Nearly a third (31.6%, n = 158) of patients received any iron treatment in the baseline period, with 19.2% (n = 96) receiving oral iron and 13.8% (n = 69) receiving injectable iron. At baseline, almost all of patients initiating on HIF-PHIs had baseline comorbidities of hypertension (95.8%; n = 479) and diabetes (77.0%; n = 385).

Conclusion: Evaluating a real-world database for patients initiating HIF-PHIs within Japan allows for a more comprehensive picture of patient clinical and demographic characteristics. Our analysis found most patients initiating on HIF-PHIs were male, had previous rhEPO use, and had history of hypertension and diabetes. Understanding patient profiles in a real-world setting may guide treatment decisions in clinical practice.

RATES OF SELECTED CARDIOVASCULAR AND NON-CARDIOVASCULAR EVENTS AMONG DIALYSIS PATIENTS WITH ANEMIA IN THE US MEDICARE POPULATION
James Wetmore1, Julie Rouette2, Haifeng Guo3, Gema Requena4, Suying Li3, George Mu1, Liyuan Ma5, Jolyon Fairburn-Beech6, Anna Richards2, David Gilbertson3, Sally Wetten8 and Jiannong Liu3
1Hennepin Healthcare, Division of Nephrology, Minneapolis, United States of America, 2GSK, Montreal, Canada, 3Hennepin Healthcare Research Institute, Chronic Disease Research Group, Minneapolis, United States of America, 4GSK, Brentford, United Kingdom, 5GSK, Collegeville, United States of America, 6GSK, Collegeville, United States of America, 7GSK, Brentford, United Kingdom and 8GSK, Brentford, United Kingdom
Background and Aims: The safety and efficacy of daprodustat in patients on dialysis were reported in ASCEND-D/ID trials [1,2]. Trials impose strict criteria for enrollment, making participants more narrowly selected than a broader population with disease who might benefit from treatment. We describe events, of which most were noted as safety events in ASCEND-D/ID trials, among general anemia “treatment eligible” (TE) patients on dialysis and patients similar to those in ASCEND-D/ID trials (“clinical trial-like” [CTL]) in the US.

Method: Using United States Renal Data System data, we conducted a retrospective cohort study of incident dialysis-dependent (IDD) patients from 2017–2019 and, separately, point prevalent dialysis-dependent (PDD) patients as of Jan 1 2018. Dialysis initiation date was the index date for IDD patients and Jan 1 2018 for PDD patients. We also required patients to have ≥ 6 months of continuous Medicare coverage before, and be aged ≥ 18 years on, index date. Patients with a history of kidney transplant or who had cancer during the year prior, and those who had a hospitalization for heart failure (HF), myocardial infarction (MI), or stroke in the 4 weeks before, the index date were excluded. For IDD patients, we required use of ESAs at the index date to support comparability to the PDD patients. The CTL cohort was a subset of the TE cohort, approximating eligibility in the ASCEND-D/ID trials. Patients were followed from index date to the earliest date of death, loss of Medicare coverage, kidney transplantation, or Dec 31 2019. We assessed cardiovascular (CV: all-cause death, HF, MI, stroke, thromboembolic events [TEEs], major cardiovascular events [MACE: death, MI, stroke] and MACE+HF) and non-CV (cancer, gastric erosions, ocular events, seizures, serious infections) events, derived from medical claims in the follow-up period using ICD-10 diagnosis, Healthcare Common Procedure Coding System, and Current Procedural Terminology codes. HF, MI, stroke, and serious infections were defined as inpatient events. First event rates for TE and CTL cohorts were calculated separately for IDD and PDD patients and expressed as number of events per 100 patient-years (PYs).

Results: Of IDD patients, 23,909 were in the TE and 6,962 in the CTL cohorts; corresponding numbers were 230,055 and 41,980 for PDD patients. Median follow-up was 12.6 and 13.8 months for the TE and CTL cohorts, respectively, in IDD patients; and 24 months for both TE and CTL cohorts in PDD patients. Mean ages were 70.3 and 71.0 years for the TE and CTL cohorts in IDD patients; and 63.3 and 64.1 years for the TE and CTL cohorts in PDD patients. For both IDD and PDD patients, the TE and CTL cohorts had similar demographics, but the TE cohorts had a slightly higher proportion of patients with comorbidities. First event rates are shown in the Table. TE cohorts had higher rates than CTL cohorts for most CV events (mortality, 17.3 vs 14.0 per 100 PYs in IDD and 16.8 vs 15.1 in PDD; MACE: 20.9 vs 17.5 in IDD and 20.3 vs 18.6 in PDD; MACE+HF: 25.6 vs 21.8 in IDD, 26.9 vs 25.1 in PDD). In IDD patients, HF was more common in the TE than the CTL cohort (7.1 vs 6.1) but was similar in PDD patients. MI, stroke, and TEEs (vascular access thrombosis [in hemodialysis patients only], deep venous thrombosis, and pulmonary embolism) had similar rates in the TE and CTL cohorts for both IDD and PDD patients. Serious infections were higher in the TE than the CTL cohort in both IDD and PDD patients. In PDD patients, gastric erosions were higher in the TE than the CTL cohort (40.0 vs 38.5) while ocular events and retinal hemorrhage were lower in the TE cohort.

Conclusion: Rates for most CV events were higher in TE cohorts, comprised of patients eligible for anemia treatment, compared with CTL cohorts mimicking trial participants. Rates of non-CV events did not show a consistent pattern. As expected, rates of VAT were higher in IDD than PDD patients. These findings further contextualize real-world event rates of interest in dialysis populations. Reported rates were crude (unadjusted) and should be interpreted with caution. Funding: GSK (study 217316).

BONE MATERIAL STRENGTH INDEX AND DUAL ENERGY X-RAY ABSORPTIOMETRY IN EVALUATION OF BONE HEALTH IN AUTOSOMAL POLYCYSTIC KIDNEY DISEASE

Magdalena Jankowska1, Piotr Wisniewski2, Pieter Evenepoel1, Bengt Lindholm4, Alicja Debeka-Slizien1, Peter Stenvinkel1 and Mathias Loberg Haarhaus4

1Medical University of Gdańsk, Department of Nephrology, Transplantology and Internal Medicine, Gdańsk, Poland, 2Medical University of Gdańsk, Department of Endocrinology and Internal Medicine, Gdańsk, Poland, 3UZ Leuven, Department of Nephrology and Renal Transplantation, Leuven, Belgium and 4Karolinska Institutet Cliniec, Division of Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden

Background and Aims: Bone material strength measured with the use of impact microindentation technique (OsteoProbe®) has emerged recently as potentially beneficial tool in evaluating bone quality in metabolic bone disorders. Patients with autosomal polycystic kidney disease (ADPKD) carry an increased risk of skeletal complications, both due to deficiency of polycystins and development of chronic kidney disease-mineral bone disorder (CKD-MBD). In our preliminary study, we found that bone material strength index (BMSi) associated with bone mineral density (BMD) measured with the use of dual energy X-ray absorptiometry (DXA) in chronic kidney disease patients (CKD). The aim of the present study was to find if the same applies to patients with ADPKD. We evaluated bone health by measuring BMSi and performing DXA in patients with ADPKD.

Method: BMSi was measured (OsteoProbe®, Active Life Scientific, USA) performing DXA in patients with ADPKD.

Results: Mean values of BMSi, TBS and BMD are presented in the Table 1. BMSi in ADPKD patients was lower than average value observed in healthy individuals (85 men and 80 women). A positive linear relationship between BMSi and BMD was found in all of the examined sites with the highest standardized regression coefficient for 1/3 distal forearm (R² = 0.315, beta = 0.57, p < 0.001) and weakest for lumbar spine (R² = 0.003, beta = 0.33, p = 0.003). There was no association between BMSi and TBS.

Conclusion: This is the first report on BMSi in ADPKD patients. In agreement with the notion of a distinct bone phenotype in ADPKD, we observed a median bone material strength index in patients with ADPKD that was lower than the reference value. BMSi associated with BMD, but not with TBS. However, the association with BMD overall is weak, with BMD explaining only 3 to 31% of the variability of BMSi. This observation suggests complementarity and warrants additional studies investigating whether BMSi associates with hard bone endpoints, independent of BMD.

EXPERIENCE IN A GERIATRIC NEPHROLOGY CONSULTATION

Orlando Siverio Morales1, Maria Adela Davilla2, Edduin Miguel Martin Izquierdo3, María José Reguera4, Patricia Garcia1, Alejandro Alonso Bethencourt1, Carla Rodriguez1, Ana Aragao1, Rosa Perez1, Virginia Dominguez1 and Manuel Macia1

1HU Nuestra Señora de Candelaria, Nephrology, Santa Cruz de Tenerife, Spain and 2HU Nuestra Señora de Candelaria, Geriatrics, Santa Cruz de Tenerife, Spain

Background and Aims: In the last two decades, the Spanish population over 65 years of age has increased by more than two million people. This has made the coexistence of comorbidities such as arterial hypertension (AHT) and diabetes (DM) more frequent, which act as risk factors in the onset of chronic kidney disease (CKD). This circumstance is conditioned by the presence of other factors associated with aging that condition greater frailty and a greater degree of dependency. Due to this, the application of the comprehensive geriatric assessment could be useful for its adequate stratification, obtaining a better evaluation of kidney disease and, with it, trying to improve the functionality of the patient.

Method: To analyze the parameters associated with CKD and their possible relationship with the degree of frailty and/or functionality in patients older than 75 years referred to a specific Nephrology consultation.

Material and methods: Descriptive and observational epidemiological study corresponding to a series of cases, which includes patients from the southern area of Tenerife who were referred for evaluation by the HUNSC Nephrology Service over a period of 8 months.

Results: It was obtained that, of 1263 patients referred, 41.1% of patients were older than 75 years. Of these, 19.1% of patients required face-to-face assessment in the Nephrogeriatrics consultation. When analyzing the relationship between frailty and functionality, we observed that the groups with greater frailty had both older ages and lower hemoglobin and albumin values. Likewise, it was observed that patients classified as frail had a higher risk of mortality than those who were not frail. Regarding functionality, when comparing the means of the parameters associated with CKD in relation to the degree of functionality (Barthel), it was obtained that age, creatinine, hemoglobin and albumin presented statistical significance.

Conclusion: The geriatric population represents a significant number of all consultations referred to Nephrology. The high prevalence of associated diseases that affect renal function (HBP and DM) together with the physiological changes that occur in aging make CKD an important public health problem. Carrying out adequate frailty and functionality scales may constitute one of the most important parameters to assess in nephrogeriatric patients, since it would allow us to improve the efficiency of the care process in CKD.

Background and Aims: Erythropoiesis-stimulating agents (ESAs) are commonly used to treat anemia of chronic kidney disease (CKD). ESA hyporesponsiveness is prevalent in a significant portion of patients with CKD, especially those with end-stage renal disease on dialysis. Inflammation has been reported to contribute to ESA hyporesponsiveness and is associated with poor outcomes in patients with CKD. Roxadustat, an oral medication, is a hypoxia-inducible factor prolyl hydroxylase inhibitor that has previously demonstrated efficacy in patients with anemia of CKD. This pooled analysis evaluated the efficacy and safety of roxadustat in correcting hemoglobin (Hb) levels in subgroups of patients with dialysis-dependent (DD) CKD with or without inflammation at baseline.

Method: Data for this analysis were pooled from four phase 3, randomized, open-label, active comparator–controlled studies (HIMALAYAS [NCT02052310], ROCKIES [NCT02174731], PYRENEES [NCT02278341], SIERRAS [NCT02273726]) in patients with DD CKD. Outcomes evaluated were mean Hb change from baseline to Weeks 28–52 and mean weekly roxadustat dose (mg/kg) at Week 24 in patients with or without baseline inflammation (as determined by high-sensitivity C-reactive protein [hsCRP] level, divided into quintiles). Data were analyzed with an analysis of covariance model with baseline Hb as a covariate. Adjusted least-squares means, their difference, and corresponding confidence intervals were generated from datasets where missing data were imputed using missing at random-based multiple imputation, by treatment group, with baseline Hb, cardiovascular/cerebrovascular/thromboembolic history, geographical region (United States vs non–United States) and incident vs stable dialysis (<4 vs >4 months) as predictor variables. Safety data were summarized descriptively.

Results: In total, 4072 patients with DD CKD (roxadustat N = 2022; ESA N = 2050) were evaluated. At baseline, mean Hb levels (g/dL [SD]) were similar in the roxadustat (9.80 [1.29]) and ESA (9.83 [1.29]) groups, regardless of baseline hsCRP levels (roxadustat hsCRP quintiles 1–5: 9.72 [1.43], 9.78 [1.27], 9.80 [1.32], 9.90 [1.18], and 9.79 [1.23], respectively; ESA hsCRP quintiles 1–5: 9.75 [1.34], 9.92 [1.23], 9.90 [1.23], 9.96 [1.23], and 9.62 [1.38], respectively). Hb change from baseline was greater in patients treated with roxadustat compared with ESA, regardless of baseline hsCRP levels (Fig. 1). At Week 24, patients with higher baseline hsCRP levels did not require higher doses of roxadustat compared to patients with lower baseline hsCRP levels (Fig. 2). The overall percentages of patients with at least one treatment-emergent adverse event were similar for patients treated with roxadustat (hsCRP quintiles 1–5: 86.7, 88.1, 86.6, 88.7, and 90.0, respectively) or ESA (hsCRP quintiles 1–5: 83.5, 84.6, 90.5, 88.2, and 87.9, respectively) across hsCRP quintiles.

Conclusion: In patients with anemia of DD CKD, roxadustat increased Hb levels without requiring increased doses of roxadustat in patients with or without baseline inflammation. Results from the current analysis suggest that roxadustat is effective, with a comparable safety profile to ESA, regardless of inflammation status.
ASSOCIATION BETWEEN CKD-MBD AND MORTALITY IN OLDER PATIENTS WITH ADVANCED CKD – RESULTS FROM THE EQUAL STUDY

Lorenza Magagnoli¹,², Mario Gennaro Cozzolino¹,², Fergus Caskey³,⁴, Marie Evans⁵, Claudia Torino⁶, Maciej Szymczak⁷, Friedo W. Dekker⁸, Christoph Wanner⁹, Nicholas Chesnaye¹⁰,¹¹ and Kitty J. Jager¹⁰,¹¹

Background and Aims: Chronic Kidney Disease - Mineral and Bone Disorder (CKD-MBD) is a common complication of CKD, associated with higher mortality in dialysis patients. Its impact in non-dialysis patients remains mostly unknown. We investigate the associations between parathyroid hormone (PTH), phosphate, and calcium (and their interactions) and all-cause, cardiovascular (CV), and non-CV mortality in older non-dialysis patients with advanced CKD.

Method: We used data from the EQUAL study, which included patients aged ≥65 with eGFR ≤20 ml/min/1.73 m² from six European countries. Cox models were used to assess the association between baseline and time-dependent CKD-MBD biomarkers and all-cause, CV, and non-CV mortality. Models were sequentially adjusted for other mineral biomarkers, age, sex, country, eGFR, albumin, BMI, comorbidities and medications. Effect modification between biomarkers was also assessed.

Figure 1: Effect sizes of CKD-MBD biomarkers on all outcomes. Hazard ratios (HR) for all-cause (A), CV (B) and non-CV (C) mortality associated with 1 SD increase in baseline and time-dependent biomarkers in unadjusted and sequentially adjusted models (I, unadjusted; II, adjusted for other mineral biomarkers; III, previous further adjusted for age sex and country; IV, previous further adjusted for eGFR; V, previous further adjusted for albumin; VI, previous further adjusted for BMI; VII, previous further adjusted for pre-existing comorbidities; VIII, previous further adjusted for medications). Abbreviations: BMI, body mass index; CV, cardio-vascular; eGFR, estimated glomerular filtration rate; PTH, parathyroid hormone.
**Results:** In 1294 patients, the prevalence of CKD-MBD at baseline was 94%. Both PTH (aHR 1.12, 95%CI 1.03-1.23, p 0.01) and phosphate (aHR 1.35, 95%CI 1.00-1.84, p 0.05), but not calcium (aHR 1.11, 95%CI 0.57-2.17, p 0.76), were associated with all-cause mortality. Calcium was not independently associated with mortality, but modified the effect of phosphate, with the highest mortality risk found in patients with both hypercalcemia and hyperphosphatemia. PTH level was associated with CV mortality, but not with non-CV mortality, whereas phosphate was associated with both CV and non-CV mortality.

**Conclusion:** CKD-MBD is very common in older non-dialysis patients with advanced CKD. PTH and phosphate are independently associated with all-cause mortality in this population. While PTH level is only associated with CV mortality, phosphate seems to be associated with both CV and non-CV mortality.

**STRUCTURAL AND FUNCTIONAL CHARACTERISTICS OF THE HEART IN ELDERLY AND OLD PATIENTS WITH CHRONIC KIDNEY DISEASE AND ATRIAL FIBRILLATION**

Ranokhon Igamberdieva¹ and Sherzod Abdullaev²

¹Tashkent pediatric medical institute, Internal medicine, nephrology and hemodialysis, Asian (origins of Asia, East Asia or Southeast Asia), Uzbekistan

²Republican Scientific and Practical Medical Center of Nephrology and Kidney Transplantation, Immunogenetics, Asian (origins of Asia, East Asia or Southeast Asia), Uzbekistan

**Background and Aims:** The study of cardiorenal relationships is an important area in medicine. The presence of chronic kidney disease (CKD) and atrial fibrillation (AF) in elderly and old patients requires a special integrated approach in diagnosis and treatment, taking into account the principles of patient orientation. The aim was to study of structural and functional characteristics of the heart in elderly and old patients with CKD and AF.

**Method:** 224 female and 215 male patients of elderly and old age (mean age 72.4±6.8 years) with AF were examined. Among elderly and old patients, the following types of AF were diagnosed: a permanent form was observed in 136 (30.9%), a persistent form - in 117 (26.7%), a long-term persistent form - in 98 (22.3%), a paroxysmal form - in 88 (20.1%). Glomerular filtration rate (GFR) was determined using the CKD-EPI equation. All patients underwent electrocardiography (ECG), echocardiography (EchoCG), and some patients underwent ECG monitoring by Holter with assessment of rhythm variability.

**Results:** CKD with GFR<60 ml/min/1.73m² was diagnosed in 274 (62.4%) patients with AF: stage 3a – in 184 (67.2%), stage 3b – in 82 (29.9%), 4 stage - in 8 (2.9%) patients with CKD. When analyzing the structural and functional parameters of the heart, more than half of elderly and old patients with CKD had concentric left ventricular hypertrophy - 146 (53.3%), 65 (23.7%) patients had eccentric hypertrophy. The types of remodeling in elderly and old patients did not differ depending on the presence of CKD (p=0.05). The ejection fraction (EF) of the left ventricle in elderly and old patients did not differ depending on the presence of CKD (p = 0.5). Preserved left ventricular EF
had 194 (70%) intermediate - 60 (21.7%), low - 23 (8.3%) elderly and old patients with CKD. In patients with AF and CKD, compared with patients without CKD, mitral regurgitation (p = 0.006) and aortic regurgitation (p = 0.02) were more frequently observed. Left atrial (LA) diameter, exceeding the norm, was observed in most patients regardless of the presence of CKD: in 191 (69.7%) patients with CKD and 118 (71.5%) without CKD (χ^2 = 0.03, p = 0.86). Moderate and pronounced increase in LA diameter was observed in 111 (40.1%) patients with CKD and 63 (38.1%) without CKD (χ^2 = 0.17, p = 0.67). When analyzing the LA index, an increase in size was observed significantly more often in patients with CKD than in patients without CKD: 79 (28.8%) and 25 (15.2%), respectively, χ^2 = 10.75, p = 0.001. Enlargement of the right ventricle was detected in 94 (34.3%) patients with CKD and 53 (32.1%) without CKD (χ^2 = 0.18, p = 0.67), right atrium – 35 (12.8%) patients with CKD and 19 (11.5%) without CKD (χ^2 = 0.15, p = 0.7). Attention is drawn to the differences in the spectral analysis of the heart rate in elderly and old patients with CKD compared with patients without CKD: a higher index of centralization (0.55 (0.33-0.86) and 0.36 (0.25-0.48), respectively, p = 0.03) and a lower index of vagosympathetic interaction (1.48 (0.85-2.32) and 3.16 (2.12- 4.59), p = 0.004).

Conclusion: When analyzing the structural and functional parameters of the heart in elderly and old patients with AF and CKD, there was an increase in the LA index, more frequent presence of mitral and aortic regurgitation compared to patients without CKD. Elderly and old patients with CKD had a lower index of vagosympathetic interaction compared to patients without CKD.

ESTIMATED PROXIMAL TUBULE FLUID PHOSPHATE (ePTFp) CONCENTRATION: AN EARLY MARKER OF CHRONIC KIDNEY DISEASE-MINERAL AND BONE DISORDER (CKD-MBD)?

Silverio Rotondi, Lida Tartaglione, Marzia Pasquali, Adolfo Perrotta, Chiara Romano, Francesca Tinti and Sandro Mazaferro

Sapienza University of Rome, Roma, Italy

Background and Aims: MBD develops early in CKD and is associated with kidney damage progression, but CKD-MBD markers, of initial CKD-MBD like FGF23 and α-Klotho are not available in clinical practice. Recently ePTFp has been proposed as a new early marker of MBD. In fact, the progressive reduction of nephron number, with the proportional FGF23 increments, reduce renal tubular phosphate reabsorption to maintain phosphate balance. As a consequence, PTFp concentration per single nephron progressively increases, leading to progression of kidney tubular damage. For this reason, PTFp could represent an innovative early marker of CKD-MBD. We evaluated the relationship of ePTFp with FGF23, α-Klotho and kidney damage progression.

Method: In CKD stage G2-4, we assayed serum FGF23, α-Klotho and ePTFp [ePTFp = (Phosphaturia / creatininuria) x creatininemia x 3,33]. The progression of CKD was evaluated during 5 years and the patients were splitted in two groups according to the basal ePTFp median value. 30 healthy subject provided the normal value of ePTFp.

Results: In 68 CKD patients (age 58.9 ± 15.6 y.o. eGFR 45 ± 21 mL/min), ePTFp averaged 2.4 ±1.3 mg/mg which was higher than the control group (ePTFp = 1.2±0.5; p<.01). ePTFp increased progressively along with the increasing CKD stages with values higher than the control group since stage 2 (Table 1). ePTFp showed a positive correlation with FGF23 (r: 0.69; p<.<.001) and a negative correlation with α-Klotho (r: -0.237; p<.05) and eGFR (r: -0.647; p<.001). Follow-up was available in 30 patients (Table 2) and showed a greater reduction of eGFR in the 15 patient with higher ePTFp (threshold 2 mg/dl) (Fig. 1).

Conclusion: Our data show early and progressive increments of ePTFp in CKD along with increments of FGF23 and PTH and reduction of α-Klotho, as per reciprocal pathophysiologic dependence. ePTFp values > than 2 mg/dl identified patients at highest risk of CKD progression. Accordingly, ePTFp, a surrogate of renal tubular cells phosphate overload, could represent a novel marker of CKD-MBD development and of increased risk of kidney damage potentially helpful to make therapeutic choice.

Background and Aims: Skeletal muscle composition disturbances, like sarcopenia and myosteatosis, are common in non-dialysis chronic kidney disease (ND-CKD) patients and seem to be associated with adverse clinical outcomes. Sarcopenia and myosteatosis can be evaluated by computed tomography (CT) by measuring skeletal muscle area (SMA) and muscular attenuation (MA) in Hounsfield units (HU) at the third lumbar vertebra, respectively, but the optimal cutoff points for diagnosis and outcome prediction are not established in chronic kidney disease (CKD) patients. We aimed to evaluate the prevalence of sarcopenia and myosteatosis in ND-CKD patients and to define the optimal cutoff values of SMA and MA to predict mortality.

Method: We conducted a retrospective cohort study including non-dialysis CKD patients referred to an outpatient clinic during a two-year period, who underwent a CT as part of clinical workup and with an available serum creatinine evaluation within a 90-days timeframe. Patients with a follow-up under 26 weeks after the CT were excluded. Area under the receiver operating characteristic curve (AuROC) analysis was used to evaluate the ability of SMA and MA to predict mortality and the Youden's index was used to determine the optimal cutoff point. Cox-regression analysis was employed to identify independent predictors of mortality.

Results: 167 patients (94% Caucasian, 50.9% male, 32.3% diabetics) with a mean age of 68.3 ± 16.4 years were included, most with CKD stage 3 and 4 (53.9%; mean estimated GFR 57.6 ± 33.1 ml/min/1.73m2 at baseline). During a median follow-up of 4.9 (4.2) years, 39 patients (23.4%) died. Median SMA was 127.7 (45.8) cm² and there was a trend to increased mortality across lower SMA quartiles (1st quartile 32.6%, p = 0.026; 2nd quartile 26.8%, p = 0.095; 3rd quartile 21.4%, p = 0.261; 4th quartile 21.2% - reference). SMA showed a modest ability to predict mortality (AuROC 0.623) and the best cutoff found was 140.7 cm². Median MA was 28.4 (13.8) HU and there was a statistically significant higher mortality across lower MA quartiles (1st quartile 42.9%, p<0.001; 2nd quartile 31.0%, p = 0.001; 3rd quartile 16.7%, p = 0.028; 4th quartile 2.4% - reference). MA showed a good ability to predict mortality (AuROC 0.733) and the best cutoff was 30 HU. Using the identified cutoff points, sarcopenia (SMA < 140.7 cm²) was present in 67.1% (n = 112) and myosteatosis (MA < 30 HU) in 56.3% (n = 94) of patients. In univariate Cox-regression both sarcopenia and myosteatosis were associated with increased mortality – Hazard ratio (HR) 4.34 (95% CI 1.68-11.19, p = 0.002) and 5.32 (95% CI 2.22-12.73, p<0.001), respectively. In multivariate Cox-regression models (adjusted for age, baseline estimated GFR and presence of diabetes) only myosteatosis kept its association with mortality – HR 2.87 (95% CI 1.15-7.16, p = 0.024). This association was also present when the model was adjusted for the presence of sarcopenia. Patients with myosteatosis were older (median age 77.3 [10.8] vs 62.7 [30.1], p<0.001) and had higher frequency of diabetes (42.6% vs 19.2%, p = 0.001), arterial hypertension (87.2% vs 57.5%, p<0.001), and heart failure (24.5% vs 6.8%, p<0.003). They had also higher BMI (29.3 [7.4] vs 25.1 [6.0] kg/m², p<0.001), visceral obesity (77.7% vs 43.8%, p<0.001) and frequency of sarcopenia (75.5% vs 56.2%, p = 0.008). Myosteatosis was more frequent in CKD stage 3 to 5 patients, compared to CKD stage 1 or 2 (66.3% vs 42%, p = 0.002).

Conclusion: Sarcopenia and myosteatosis are prevalent in CKD patients, especially in advanced stages. However, reference values for this population are lacking. We found cutoff values for these muscle parameters using CT analysis in CKD patients, based on optimal stratification for mortality. Additionally, our study highlights that muscle quality (i.e., myosteatosis) may be more closely associated with mortality than muscle quantity (i.e., sarcopenia). Identifying patients at risk for these muscle abnormalities and early diagnosis are paramount for the subsequent implementation of therapeutic interventions.

EARLY REPEAT HOSPITALIZATION FOR FLUID OVERLOAD IN INDIVIDUALS WITH CARDIOVASCULAR RISKS

Cynthia Lim1, Hanis Abdul Kadri2, Dorothy Huang1, Zhihua Huang1, Li Choo Ng1, Ngiap Chuan Tan3, Wei Yi Tay4 and Chieh Suai Tan1

1Singapore General Hospital, Department of Renal Medicine, Singapore, 2Singapore General Hospital, Health Services Research Unit, Singapore, 3SingHealth Polyclinics - Pasir Ris, Singapore and 4Singapore General Hospital, Department of Family Medicine and Continuing Care, Singapore

Background and Aims: Fluid overload is a common manifestation of cardiovascular and kidney disease and a leading cause for hospitalizations. To identify patients at risk of recurrent severe fluid overload who can benefit from strategies to reduce hospitalizations, we evaluated the incidence and risk factors associated with early repeat hospitalization for fluid overload among individuals with cardiovascular risks.

Method: Single-center retrospective cohort study of consecutive adults with an index hospitalization for fluid overload between January 2015 and December 2017 and had cardiovascular risks (older age, diabetes mellitus, hypertension, dyslipidemia, kidney disease) and/or cardiovascular disease, but excluded if lost to follow up or eGFR <15 ml/min/1.73 m². Comorbidities, biochemistry and medications were retrieved from electronic medical records. The primary outcome was early repeat hospitalization for fluid overload within 30 days of discharge. Binary logistic regression (enter method) was used to assess factors associated with repeat hospitalizations in the literature or had p<0.25 on univariate analysis. Discrimination and calibration of the model were assessed by the area (AUC) under a receiver operating characteristic (ROC) curve and Hosmer-Lemeshow goodness-of-fit test, respectively.
Results: Among 3423 unique patients with index hospitalization for fluid overload, the mean age was 73.9 ± 11.6 years and 16.7% required high-dose intravenous (IV) furosemide. The median length of stay (LOS) was 4 (2, 9) days and 95.3% were prescribed loop diuretics at discharge. Early repeat hospitalization for fluid overload occurred in 291 patients (8.5%). After adjusting for demographic factors (age, gender, ethnicity), comorbidities (recent hospitalization, cardiovascular disease, atrial fibrillation, diabetes), medications before index hospitalization (diuretic, RAS blocker, NSAID), clinical parameters during index hospitalization (systolic BP, eGFR, IV furosemide use, LOS) and medications at discharge (diuretic, RAS blocker, statin), cardiovascular disease (adjusted OR 1.66, 95% CI 1.26-2.17, p < 0.001), prior hospitalization for fluid overload within 3 months before index hospitalization (adjusted OR 2.52, 95% CI 1.17-5.44, p = 0.02), prior hospitalization for any cause in within 6 months before index hospitalization (adjusted OR 1.33, 95% CI 1.02-1.73; p = 0.04) and IV furosemide during the index hospitalization (adjusted OR 1.58, 95% CI 1.10-2.28, p = 0.01) were associated with increased early repeat hospitalization for fluid overload. Higher systolic BP on admission (adjusted OR 0.992, 95% CI 0.986-0.998, p = 0.01) and diuretic at discharge (adjusted OR 0.50, 95% CI 0.26-0.98, p = 0.04) reduced early hospitalization for fluid overload. The model accuracy was 91.5% and the Hosmer and Lemeshow Test chi-square p was 0.25. The AUC of the ROC curve was 0.639 (95% CI 0.606 – 0.671).

Conclusion: Patients with cardiovascular disease, prior hospitalization for fluid overload within 3 months or prior hospitalization for any cause in within 6 months before index hospitalization, lower systolic BP, need for IV furosemide during the index hospitalization and lack of diuretic at discharge were associated with increased early repeat hospitalization for fluid overload.

#2901
PAIN MANAGEMENT IN PATIENTS WITH CHRONIC KIDNEY DISEASE: BEWARE OF INERTIA!
Faiza Ben Messaoud1, Nada Sellami2, Salah Saïd2, Saoussen Miladi1 and Ezzeddine Abderrahim2
1Mongi Slim Hospital, Rheumatology Department, Tunis, Tunisia and 2Charles Nicolle Hospital, Department of Internal Medicine A, Tunis, Tunisia

Background and Aims: Pain and pain management are major concerns when facing patients with chronic kidney disease (CKD), and it can be more challenging for practitioners other than nephrologists. In practice, one of the aspects of this challenge is the reluctance to initiate or adapt a treatment for this particular group of patients. With this in mind, we proposed to study pain management in patients with CKD by primary care givers by identifying the causes of therapeutic inertia.

Method: A survey, self-administered via internet and elaborated via Google-Forms (including multiple and unique choice questions) was carried out among primary care physicians in November 2022.

Results: Sixty primary care physicians answered our survey with a male-to-female gender-ratio of 0.36 and a mean age of 30.65 years [18-57]. Most of the practitioners enrolled in our survey worked in urban areas (98%). Half of them worked in university hospitals, 20% in regional hospitals, 23% in local community clinics and 6.7% in private offices. When asked about their immediate feeling when managing a patient with CKD for a reason other than their kidney disease, anxiety was mostly cited (55%), with indifference, fear and confidence reported respectively in 23%, 8% and 3% of practitioners. Forty-three (71%) of the participants admitted to have difficulties initiating treatment in CKD patients. The main reasons were lack of knowledge about dose adjustments (45%), fear of adverse effects (71%), unavailability of recommended treatments for CKD patient (13%) and lack of access to nephrologist’s opinion (26%). When asked about pain management in CKD patients, one out of three doctors did not prescribe the maximum dose of paracetamol for CKD patients when it was necessary. This was due to a fear of overdose (61%), fear of adverse effects (42%) and fear of interactions with other treatments (14%). Forty percent of the participants admitted delaying the increase of paracetamol doses if the initial dose is ineffective. Ninety per cent of participants did not prescribe non-steroidal anti-inflammatory drugs to CKD patients even if indicated. In this case, 61% preferred to use another therapeutic alternative, 55% feared the risk of long-term nephrotoxicity, 16% feared interactions with other treatments and 9.3% did not know how to monitor the tolerance of the treatment. Concerning not relieved by level 1 analgesic treatment pain, 55% did not reach the permitted dose of Tramadol when necessary. As for codeine, 60% of practitioners did not reach the maximum doses if indicated. In 94% of the cases, this was due to apprehension about side effects. Fifty-five per cent of the participants did not seek for a nephrologist’s opinion when initiating or modifying analgesic treatment in CKD patients. The main reasons were lack of knowledge about dose adjustments (45%), fear of adverse effects (71%), unavailability of recommended treatments for CKD patient (13%) and lack of access to nephrologist’s opinion (26%). When asked about pain management in CKD patients, one out of three doctors did not prescribe the maximum dose of paracetamol for CKD patients when it was necessary. This was due to a fear of overdose (61%), fear of adverse effects (42%) and fear of interactions with other treatments (14%). Forty percent of the participants admitted delaying the increase of paracetamol doses if the initial dose is ineffective. Ninety per cent of participants did not prescribe non-steroidal anti-inflammatory drugs to CKD patients even if indicated. In this case, 61% preferred to use another therapeutic alternative, 55% feared the risk of long-term nephrotoxicity, 16% feared interactions with other treatments and 9.3% did not know how to monitor the tolerance of the treatment. Figure 1: Receiver operator curve (ROC) for the clinical model to predict risk of 30-day repeat admission for fluid overload.
Abstracts

Conclusion: Managing patients with CKD calls for great caution when prescribing treatments. However, it is necessary to avoid therapeutic inertia. Our survey illustrates an example regarding a common symptom (pain) that might worsen their quality of life. We suggest that regular seminars on the topic of analgesics prescription for CKD patients should be proposed in order to improve their management.

#3258 MECHANISMS OF HEMOGLOBIN CYCLING IN ANEMIC END-STAGE RENAL DISEASE PATIENTS TREATED WITH ERYTHROPOIESIS-STIMULATING AGENTS

David Joerg1, Doris Fuertinger1 and Peter Kotanko2,3

1Fresenius Medical Care Germany, Computational Medicine Group, Global Medical Office, Bad Homburg vor der Höhe, Germany, 2Renal Research Institute, New York, United States of America and 3Icahn School of Medicine at Mount Sinai, New York, United States of America

Background and Aims: A considerable fraction of renal anemia patients treated with erythropoiesis-stimulating agents (ESAs) experience hemoglobin cycling behaviors during which levels periodically over- and undershoot a specified target range [1]. This is an undesired condition, which also necessitates frequent adjustment of the drug dose. The causes of hemoglobin cycling are not understood on a fundamental level. Through a combination of biomedical simulations and quantitative data analysis, we aimed at identifying mechanisms of hemoglobin cycling and the physiological and treatment-related factors contributing to cycling.

Method: We developed a biomedical modeling and simulation scheme that captures the essential features of ESA therapy involving a minimal feedback model for the delayed hemoglobin response after ESA administration and a stereotypic ESA dosing algorithm [2]. In this model, hemoglobin cycling emerged as a consequence of the delayed feedback between a patient's physiological response to ESA administrations and the resulting dose adjustments, which mutually maintain themselves in a causal loop. Guided by this model, we developed a set of statistical indicators that can detect this type of self-sustained hemoglobin cycling in clinical time series, including the Pearson cross correlation between hemoglobin levels and given ESA doses and hemoglobin standard deviation.

Results: A model analysis showed that physiological and treatment-related delays in hemoglobin response and ESA dose adjustment and administration were a major driver of hemoglobin cycling. Such delays are caused, e.g., by the cell cycle and maturation times of erythroid progenitors in response to ESA administration on one hand and restrictions in ESA dose changes and typical administration intervals on the other hand. In clinical time series, this was reflected by a systematic delay between bursts of ESA administrations and hemoglobin cycles. We quantified 1,134 such datasets from hemodialysis patients and found that more persistent cycling was associated with negative correlation coefficients between hemoglobin levels and given ESA doses. Using model simulations with similar behavior, we found that many patient- and therapy-related factors affect the hemoglobin dynamics in several (sometimes competing) ways, obfuscating their overall effect. For example, a larger RBC lifespan generally both entails higher hemoglobin levels but also prolongs the effect of ESA misdosings. However, model simulations suggested that longer RBC lifespan generally have a favorable effect in requiring less ESA on average and preventing hemoglobin cycling. Moreover, the model showed that for a given patient, ESA-specific properties such as its half-life may have a ‘sweet spot’ range of values within which hemoglobin cycling was suppressed while still showing a desired effect on the hemoglobin dynamics. Furthermore, the choice of the hemoglobin target window had an impact on hemoglobin stability. If the window was chosen too small, more frequent dose adjustments could initiate and maintain a cycling behavior.

Conclusion: Hemoglobin cycling in renal anemia patients often emerges from a complex interplay of multiple physiological and ESA treatment-related factors, with delays between ESA administration, hemoglobin response and subsequent ESA dose adjustment being a key driver of cycling. Biomedical modeling and simulation can aid in systematically exploring these interplays and find improved dosing strategies.

#5342 ASSOCIATION BETWEEN LONGITUDINAL GFR TRAJECTORIES AND BMD DECLINE RATE IN PATIENTS WITH CKD STAGE 2–4

Dong Hoon Kang, Hyung Woo Kim, Jung Tak Park, Seung Hyeok Han, Shin-Wook Kang and Tae-Hyun Yoo

Yonsei University College of Medicine, Rep. of South Korea

Background and Aims: Bone mineral density (BMD) predicts fracture risk in patients with chronic kidney disease (CKD). However, there are few studies regarding BMD decline rates in CKD population. In this study, we investigated whether BMD decline rate is associated with baseline estimated glomerular filtration rate (eGFR) and further evaluated with longitudinal eGFR trajectories.

Method: A prospective cohort study of 1,006 patients with CKD stages 2 through 4 who enrolled in the Korean Cohort Study for Outcome in Patients With CKD between 2011 and 2016. BMD was measured using dual-energy X-ray absorptiometry at baseline and year 4. Estimated GFR was measured 2–5 times during 4 years of follow-up. Mixed linear regression model was used for the longitudinal analysis and trajectory analysis was performed using semiparametric group-based modeling using maximum likelihood.

Results: Declined renal function was associated with increased rate of decline in total hip BMD (Stage 2: −0.23, Stage 3A: −0.39, Stage 3B: −0.80, Stage 4: −1.20 in men; −0.86, −1.19, −1.20, −1.58% change/year respectively in women). Trajectory analysis revealed two distinct trajectories of eGFR for each CKD Stages 2 through 4: Class 1, stable group; Class 2, rapid decline group. Trajectory group that represented rapid eGFR decline showed consistent trends of increased rate of decline in total hip BMD. There was significant difference between stable and rapid decline group in Stage 3A, 3B (Stage 3A: −0.18 vs. −0.67 [p = 0.009], Stage 3B: −0.36 vs. −1.10 [p = 0.031] in men; Stage 3A: −0.79 vs. −1.67 [p = 0.006], Stage 3B: −0.60 vs. −1.52% change/year [p = 0.001] in women; p for interaction).

Conclusion: Declined renal function and faster GFR decline is associated with rapid BMD decline in CKD stage 2–4.

Figure 1: Biomedical modeling scheme that embodies prototypical anemia treatment cycles of repeated hemoglobin measurement, ESA dose adjustment and administration, increase in systemic ESA levels and delayed hemoglobin response.
SELECTED CARDIOVASCULAR (CV)/NON-CV EVENT RATES IN NON-DIALYSIS-DEPENDENT PATIENTS TREATED WITH ESAS IN US MEDICARE (2017–2019), BY CKD STAGE

James Wetmore1, Julie Rouette2, Haifeng Guo3, Gema Requena4, Suying Li3, George Mu2, Liyuan Ma5, Jolyon Fairburn-Beech4, Anna Richards4, David Gilbertson3, Sally Wetten4 and Jiannong Liu3

1Hennepin Healthcare, Division of Nephrology, Minneapolis, United States of America, 2GSK, Montreal, Canada, 3Hennepin Healthcare Research Institute, Chronic Disease Research Group, Minneapolis, United States of America, 4GSK, Brentford, Middlesex, United Kingdom and 5GSK, Collegeville, United States of America

Background and Aims: The safety and efficacy of daprodustat in non-dialysis-dependent chronic kidney disease (CKD) patients have been reported in the ASCEND-ND trial [1]. However, CKD stage may affect both the need for anemia treatment as well as outcomes, including potential safety events for anemia treatment. This study describes cardiovascular (CV) and non-CV event rates by CKD stage among patients treated with erythropoietin-stimulating agents (ESAs) in the US Medicare population.

Method: Using Medicare data for all fee-for-service enrollees, we conducted a retrospective cohort study of patients who had diagnosis of CKD stages 3, 4, or 5 and a first use of ESA in 2017–2019. CKD stage was identified by ICD-10 codes; ESA use was derived using Healthcare Common Procedure Coding System (HCPCS) codes. The date of first ESA use was the index date and CKD stage was defined as the most recent diagnosis on or before index date. We further required patients to have at least 12 continuous months of Medicare Parts A and B coverage (also used as a washout period to identify new ESA users) prior to, and be aged ≥ 66 years on, the index date. Patients with a history of kidney transplant or who had cancer during the year prior, and those who had a hospitalization for heart failure (HF), myocardial infarction (MI), or stroke in the 4 weeks before, the index date were excluded. Patients were followed from index date to the earliest date of death, loss of Medicare coverage, kidney transplantation or dialysis, or December 31, 2019.

Results: This study cohort included 50,206 patients; 22,332 had stage 3, 19,177 stage 4, and 8,697 stage 5 CKD at the index date. Median follow-up time was 11.5 months for patients with CKD stage 3, 8.9 months for patients with stage 4, and 3.7 months for patients with stage 5 CKD. Patients with higher (worse) CKD stages were slightly younger (mean ages for stages 3, 4, and 5 were 79.7, 79.1, and 76.8 years); with increasingly more males (42.9%, 45.1%, and 48.5%), increasingly more individuals of non-Hispanic Black race (14.2%, 15.7%, and 19.6%), with lower income (indicated by Medicare/Medicaid dual enrolment and Medicare Part D low-income subsidy), and lower proportion of comorbidities. Rates were higher for most CV events in patients with higher (worse) CKD stages (Table): death rates were 19.5, 22.1, and 28.1 per 100 patient-years for stages 3, 4, and 5, respectively; MI rates were 2.2, 2.9, and 3.2; HF rates were 12.5, 17.2, and 19.0; MACE rates were 22.0, 25.4, and 31.8; and MACE+HF rates were 31.0, 38.7, and 47.8, respectively. Rates of stroke were similar across CKD stages; but no pattern for TEE. For non-CV events, higher (worse) CKD stage had higher rates of first ocular events (17.2, 23.3, and 27.1) and seizures (2.3, 2.7, and 3.4), but lower rates of cancer (21.8, 14.2, and 10.2) and, within this, hematological malignancies (10.4, 4.11 and 2.3).

Conclusion: Medicare-covered ESA-treated patients with higher CKD stage had higher rates for most events assessed, while malignancy rates were lower. These findings may provide important context when assessing US event rates in non-dialysis-dependent CKD patients. Further investigation could clarify some of the differences between stages, such as rates of malignancy. Rates were reported as crude (unadjusted) and so should be interpreted with caution. Limiting the analysis to ESA-treated patients may have resulted in different event rates than would be expected to occur in the general CKD population. Funding: GSK (study 217316).

Both CV (all-cause death, HF, MI, stroke, thromboembolic events [TEEs], MACE [death, stroke, MI], and MACE+HF) and non-CV (cancer, gastric erosions, ocular events, seizures, and serious infections) events were ascertained, derived from Medical claims using ICD-10 diagnosis, HCPCS, and Current Procedural Terminology codes in the follow-up period. HF, MI, stroke, and serious infection were defined as inpatient events. First event rates were calculated separately by CKD stage, expressed as number of events per 100 patient-years during the follow-up period.

HYPERKALIEMIA TREATMENT APPROACH BY THE NEPHROLOGIST: A REAL-WORLD ANALYSIS (K+RENAL STUDY)

María Marques Vidas1, Fernando Tornero Molina2, María Auxiliadora Bajo Robles3, Milagros Fernández Lucas4, Enrique Morales5, Antolina Rodriguez-Moreno6, Vicente Paraíso7, María Laura Bucalo8, José Carlos De la Flor9 and Paula López1

1Puerta de Hierro Majadahonda University Hospital, Majadahonda, Spain, 2Hospital Arganda del Rey, Arganda del Rey, Spain, 3La Paz University Hospital, Madrid, Spain, 4Ramón y Cajal Hospital, Madrid, Spain, 5University Hospital October 12, Madrid, Spain, 6Hospital Clínico Universitario San Carlos, Madrid, Spain, 7Hospital Henares, Coslada, Spain, 8Hospital Universitario de Guadalajara, Guadalajara, Spain and 9Hospital Central de La Defensa Gómez Ulla, Madrid, Spain

Background and Aims: Hyperkalemia is highly prevalent among chronic kidney disease (CKD) patients and its management is determinant to allow the maintenance of therapies of demonstrated cardiovascular and renal benefit. Attitude towards hyperkalemia is variable among different guidelines and also among different clinicians. The aim of this study was to analyze nephrologist response to K serum levels > 5.5 mmol/l between July 1st and December 11th, 2022. The only exclusion criterion was being on renal replacement therapy and not obtaining patient’s informed consent.

Results: 13 centers entered the study including 339 patients with hyperK; 331 had enough data to be included in the final analysis. 258 (78%) patients had mild hyperK (5.5-5.9), 60 (18%) moderate (6.0-6.4) and 13 (3.9%) severe hyperK (>6.5). 70.7% were males, mean age 72.0 (SD 13.4) and 87.3% and 55.6% suffered hypertension or DM, respectively. 17.3% were diagnosed from heart failure (25% NYHIA type I, 63.6% TII and 11.4% TIII). Most frequent CKD diagnoses were CKD+DM 36%, nephroangioesclerosis/vascular 25.4%, glomerulor 7.2% and unknown 16.6%. Median eGFR was 29.9 ml/min/1.73m² iQR [21-41] and 40.9% had UACR > 300 mg/g. Distribution according GFR stages was homogeneous (Pearson chi2 6.4 p 0.6). Percentage of use of ACEi, ARBs, MRA and NRIAI was 41.5%, 37.9%, 13.7% and 1.52% and showed no association with higher K levels. 33.6% of the patients that suffer hyperK were on renin angiotensin system inhibitors (RAS), 46.5% on diuretics and 62.6% on potassium binders. 33.6% of the patients that suffer hyperK were on renin angiotensin system inhibitors (RAS), 46.5% on diuretics and 62.6% on potassium binders. 33.6% of the patients that suffer hyperK were on renin angiotensin system inhibitors (RAS), 46.5% on diuretics and 62.6% on potassium binders. 33.6% of the patients that suffer hyperK were on renin angiotensin system inhibitors (RAS), 46.5% on diuretics and 62.6% on potassium binders.

Conclusion: Multicentric cross-sectional study performed in the nephrology departments of Madrid analyzing the therapeutic approach to K serum levels > 5.5 mmol/l between July 1st and December 11th, 2022. The only exclusion criteria were being on renal replacement therapy and not obtaining patient’s informed consent.

Method: Retrospective observational study, includes population under follow-up in nephrology consultations in a health area, during 2018–2021. We analyzed lipid profile, renal function and whether they received statins. IBM SPSS Statistics V24 was used.

Results: 3301 prevalent patients with kidney disease were collected, excluding those on renal replacement therapy (RRT), with glomerular filtration rate (GFR), glomerular filtration rate (GFR) <10ml/min/1.73m² and proteinuria greater than 1.5g. Of these, 112 (3.4%) patients had PKD. 51% of the total CKD patients were under treatment with statins. The average number of Total Cholesterol (TC) was 170.4+/−43mg/dl, LDL 92.3+/−37mg/dl, HDL 50.3+/−15mg/dl and triglycerides (TG) 147.3+/−92mg/dl. In 37% of CKD patients, LDL was >100mg/dl and only 35% had LDL <75mg/dl. In the CKD group with a GFR <60ml/min/1.73m² (N = 2357; 71%), there was a high prevalence of patients with LDL values >100mg/dl (N = 784; 33.5%). In the case of GFR <30ml/min/1.73m² (N = 981; 29.7%), the presence of LDL>100mg/dl 30% (N = 297) was also frequent. In the subanalysis of patients with PKD, the mean TC was 182+/−40mg/dl, LDL 101.2+/−33mg/dl, HDL 56.4+/−17mg/dl, and TG 123.7+/−59mg/dl. 76% of the PKD had GFR <60ml/min/1.73m² (N = 73), of which 45% presented LDL>100mg/dl (N = 32). In PKD patients with GFR >60ml/min/1.73m² (N = 39), half (N = 22; 56.4%) also had LDL >100mg/dl. In addition, 51% were taking a statin, despite this they had a mean TC 183mg/dl+/−46, LDL 102.7+/−39, HDL 53+/−15, and TG 142+/−69mg/dl.

Conclusion: The presence of elevated LDL was frequent in CKD, especially in the group with GFR <60ml/min/1.73m² without statin and in a quarter of patients with the same GFR with statin. It is notable in the PKD group, probably due to less awareness of strict CVR control.

THE INTERACTION EFFECT OF PHASE ANGLE AND AGE ON FEMORAL NECK BONE MINERAL DENSITY IN PATIENTS WITH NON-DIALYSIS CHRONIC KIDNEY DISEASE STAGE 5

Byoung Geun Han, Jae Seok Kim and Jae Won Yang

Yonsei University, Wonju College of Medicine, Nephrology, Wonju, Rep. of South Korea

Background and Aims: Low bone mass is common in malnourished patients with chronic kidney disease (CKD) and can lead to higher risk of fractures. Elderly and CKD patients have the same risk factors for protein energy wasting, sarcopenia, and osteoporosis. We attempted to investigate an association between phase angle (PhA) and bone mineral density (BMD) in dialysis naïve patients with stage 5 CKD, and to identify a statistical relationship between PhA and age that affects bone density.

Method: Bio-impedance spectroscopy for evaluating body composition and PhA and dual energy X-ray absorptiometry for determining the BMD were simultaneously performed in 167 consecutive patients (age: 59.65 ± 13.98 years; women: 40.1%). Two-way analysis of variance (ANOVA) was conducted to assess the potential interaction effect of PhA and two age group (young and elderly group) on femoral neck BMD (FN-BMD).

Results: Our results showed that PhA and age were independently associated with both FN-BMD and the T-score in multiple linear regressions analyses. A significant interaction effect of PhA and age on FN-BMD was found in the two-way ANOVA (P = 0.028). Average BMD values for first and second tertiles of PhA were higher in the young group than the elderly group, whereas patients in the elderly group had higher BMD in third tertiles on average.

Conclusion: A relationship between PhA and BMD in patients with advanced-stage CKD was identified in current study. The effect of PhA level on FN-BMD was different between elderly and young patients. Higher PhA levels may have protective effects on bone health in the elderly patients with stage 5 CKD and seem to be an important determinant for BMD.

ANALYSIS OF THE LIPID PROFILE IN THE RENAL PATIENT AND SUB-ANALYSIS OF THE POPULATION WITH POLYCYSTIC KIDNEY DISEASE

Alfonso Lara Ruiz1, Salia Pal Heres2, Melissa Cintra3, Teresa Arrobas Veillilla4, Rocío Molas Flores5 and Mercedes Salgueira Lazo6

1Virgen Macarena University Hospital, Nephrology, Sevilla, Spain and 2Virgen Macarena University Hospital, Clinical Biochemistry, Seville, Spain

Background and Aims: Dyslipidemia is frequent in patients with chronic kidney disease (CKD), it constitutes a factor of progression of both cardiovascular (CVR) and CKD itself. It has its own characteristics, which are modified with the ERC stadium. The subgroup of patients with Polycystic Kidney Disease (PKD) presents its own characteristics. The aim of the study was to analyze the lipid profile in the renal population and the differences in the PKD group.
Figure 1: The interaction between phase angle and age on femoral neck bone mineral density. BMD, bone mineral density.

PROGNOSTIC RELEVANCE OF ELECTROCARDIOGRAPHIC ABNORMALITIES ACCORDING TO EGFR CATEGORIES

Louis Nygaard Pedersen 1,2, Nicholas Carlson 1, Karl-Emil Nelweg-Kristensen 3, Jesper Moesgaard Rantanen 1,2, Bo Madsen 1,2, Claus Graff 4, Jonas Nielsen 5, Adrian Pietersen 6, Christian Torp 7, Sam Riahi 8, My Svensson 1,2, Jon Waast Gregersen 1,2 and Christoffer Polcwiartek 8

1 Aalborg University Hospital, Department of Nephrology, Aalborg, Denmark, 2 Aalborg University Hospital, Renal Research Group, Aalborg, Denmark, 3 Copenhagen University Hospital, Department of Nephrology, Copenhagen, Denmark, 4 Aalborg University, Department of Health Science and Technology, Aalborg, Denmark, 5 Copenhagen University Hospital, Laboratory for Molecular Cardiology, Copenhagen, Denmark, 6 Copenhagen General Practitioners' Laboratory, Kongens Lyngby, Denmark, 7 North Zealand Hospital, Department of Cardiology, Hillerød, Denmark and 8 Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark

Background and Aims: Electrocardiogram (ECG) abnormalities are associated with adverse cardiovascular outcomes in patients with chronic kidney disease (CKD), but their prognostic relevance according to estimated glomerular filtration rate (eGFR) categories remains unexplored. This study investigated the associations between no, minor, and major ECG abnormalities and fatal cardiovascular disease (CVD) according to different strata of renal function.

Method: This was a retrospective cohort study including 310,060 individuals aged ≥16 years from the Copenhagen General Practitioners' Laboratory that had an available digital ECG and creatinine measurement within 7 days from 2001–2015. eGFR was calculated using The Chronic Kidney Disease Epidemiology Collaboration equation, and data were cross-linked with...
Danish nation-wide healthcare registries to gain information on medication, comorbidity, and fatal CVD. ECG abnormalities were categorized as either no abnormalities, minor (first-degree atrioventricular block, incomplete bundle branch block or corrected QT prolongation) or major (left ventricular hypertrophy, atrial fibrillation/flutter, bundle branch block, Q waves, or ST-T deviations), as done previously [1]. Patients with both minor and major ECG abnormalities were assigned as major ECG abnormalities. ECG abnormalities and their association with fatal CVD were compared across strata of renal function [eGFR (ml/min/1.73m²) > 90, 61–90, 46–60, 31–45, 16–30 and ≤15] based on multivariable Cox-regression analysis adjusted for age, sex, and comorbidities. Counterfactual G-estimation of Hazard Ratios (HRs) standardized to age and sex was performed to estimate 5-year absolute risk of fatal CVD.

Results: The median age was 55 [IQR, 41-69] years and 46% were male. Median study follow-up time was 10.3 [IQR, 6.7-14.4] years. A total of 47,249 (17.9%) of the included patients had an eGFR < 60. The rate of fatal CVD according to ECG abnormalities and their adjusted HRs is shown in Fig.1, while 5-year standardized risk of fatal CVD is depicted in Fig.2. Generally, having minor or major ECG abnormalities, conferred a worse prognosis across all eGFR strata, with the highest 5-year absolute risk of fatal CVD being observed among patients with major ECG abnormalities and an eGFR between 31–45 [19% (95% CI, 18–20%)], eGFR 16–30 [25% (95% CI, 24–26%)] or an eGFR ≤15 [27.5% (95% CI, 24–31%)], Fig. 1–2.

Conclusion: In a population-based setting, having minor or major ECG abnormalities were associated with an increased risk of fatal CVD across all strata of renal function. Patients with an eGFR ≤45 and major ECG abnormalities represent a high-risk population, that might benefit from careful monitoring and cardiovascular risk management.

REFERENCE

Figure 2: Standardized 5-year absolute risk of fatal cardiovascular disease across no, minor and major ECG abnormalities. Absolute risks are depicted with error bars representing ± standard error.
Comparison between baseline and 6, 12 and 24 months follow-up. All other comparisons showed no statistically significant differences.

* Median value.

c-LDL, LDL-cholesterol; TC, total cholesterol; TG, triglycerides; eGFR, estimated glomerular filtration rate.

Figure 1: Percentage reduction in LDL-cholesterol, total cholesterol and triglycerides at 6, 12 and 24 months follow-up (A, B, C); median LDL-cholesterol, total cholesterol and estimated glomerular filtration rate at 6, 12 and 24 months follow-up (D, E, F).
and 48.8% at 12 months of treatment. Renal function remained stable during follow-up. No side effects or cardiovascular events were documented.

Conclusion: iPCSK9 reduce cholesterol, c-LDL and triglycerides in patients with CKD, allowing therapeutic targets to be achieved while maintaining stable renal function. Due to the apparent advantages of this drug in CKD patients, we believe that conducted clinical trials should be designed for this population.

#3394
THE VALUE OF ADVANCED CARDIAC MAGNETIC RESONANCE IN DETECTING THE CHARACTERISTICS OF CARDIAC INVOLVEMENT IN ANDERSON-FABRY DISEASE
Junlan Yang and Xiao Liang Zhang
P.R. China

Background and Aims: Anderson-Fabry disease (AFD) is a rare X-linked inherited lysosomal storage disorder caused by GLA gene mutations. With the progression of the disease, end organ damages (such as renal and cardiac) will impair quality of life. For nephrologists, it is necessary to improve the early diagnosis ability of AFD and the ability to assess the involvement of multiple organs (especially the heart). Cardiac magnetic resonance (CMR) is more accurate than echocardiography in measuring myocardial thickness and mass. Moreover, with the gradual maturation of T1 Mapping and gadolinium-enhanced cardiac magnetic resonance, CMR has also been applied to evaluate cardiomyocyte injury. In this study, clinical data of patients with AFD were collected in order to study the value and advantages of advanced CMR technologies in evaluating cardiac function, cardiac structure and cardiomyocyte injury.

Method: In this prospective observational study, clinical and echocardiography data were collected from patients with AFD diagnosed at this center from January 2022 to September 2022. T1 Mapping and gadolinium-enhanced cardiac magnetic resonance were used to evaluate the cardiac function and the degree of cardiac structural lesions, and to analyze characteristic CMR findings of cardiac involvement in AFD. To clarify the value of CMR for the assessment of cardiac involvement in AFD compared with echocardiography.

Results: 13 patients (five women, eight men) with AFD were included (Table 1). When diagnosing reduced ejection fraction, two (15.4%) met CMR, and zero (0%) met echocardiography. When diagnosing left ventricular hypertrophy, 12 (92.3%, 18.56±2.74mm) met CMR, and ten (76.9%, 16.37±2.71mm) met echocardiography. Compared with CMR, echocardiography can significantly underestimate the severity of left ventricular hypertrophy (P = 0.043). Using T1 Mapping and gadolinium-enhanced cardiac magnetic resonance, characteristic CMR findings of cardiac involvement in AFD were found in all patients (Fig.1), included decreased T1 values (12 cases, 92.3%, 1104.00±44.69ms) and late gadolinium enhancement (LGE) (six, 46.2%).

Conclusion: Characteristic CMR findings of cardiac involvement in AFD are left ventricular hypertrophy, decreased T1 values, and LGE associated with myocardial fibrosis. Advanced CMR holds promise in subclinical detection of AFD.

Table 1: Characteristics of 13 patients with AFD and genotype.

Figure 1: CMR of patients with AFD: A1-2: End-diastolic frames from cine in AFD patient (F1f): The myocardium is extensively thickened, the ventricular septal myocardium is significantly thickened, and the thickest myocardium is 19mm; B1-3: T1Mapping(3.0T) in AFD patient (F2m):Decreased T1 values, the minimum of T1 value is 1070 ms; C1-3: Gadolinium-enhanced cardiac magnetic resonance (10-15min) in AFD patient (F1f): Decreased subendocardial perfusion and LGE were observed in the apical segment, decreased myocardial perfusion and LGE in the basal inferolateral region.

Conclusion: Characteristic CMR findings of cardiac involvement in AFD are left ventricular hypertrophy, decreased T1 values, and LGE associated with myocardial fibrosis. Advanced CMR holds promise in subclinical detection of AFD.
EARLY MARKERS AND VASCULAR IMPAIRMENT IN THE PROGRESSION OF CHRONIC KIDNEY DISEASE (CKD)

Julia Martín Virgala¹, Beatriz Martín-Carro², Sara Fernández Villabrille¹, Jose Joaquin Bunde³, Belinda Fernandez-Marino³, Teresa Naves López¹, Mónica Ilaneza Faedo¹, Jorge Cannata Andía⁴, Manuel Naves Díaz¹ and Natalia Carrillo-Lopez¹

¹Metabolismo Óseo, Vascular y Enfermedades Inflamatorias Crónicas. ISPA, UGC Metabolismo Óseo. HUCA, Oviedo, Spain, ²AGC de Nefrología, HUCA, Oviedo, Spain, ³Servicio de Radiología, HUCA, Oviedo, Spain and ⁴Metabolismo Óseo, Vascular y Enfermedades Inflamatorias Crónicas. ISPA, Universidad de Oviedo, Oviedo, Spain

Background and Aims: Soluble Klotho (sKlotho) is thought to decrease early in CKD, but its use as biomarker of the CKD progression is controversial. In addition, the use of non-invasive techniques to diagnose incipient vascular damage in CKD would be of clinical interest. The aims of this study were: to assess the utility of serum and urinary sKlotho as a useful biomarker of kidney impairment and, to analyse the value of carotid adventitial neovascularization and aortic stiffness in the course of CKD.

Method: Forty-three CKD patients were classified according to their estimated glomerular filtration rate (eGFR) into 4 groups (CKD-2/3a, CKD-3b, CKD-4 and CKD-5) and 38 sex and age matched controls were studied. Carotid and femoral adventitial neovascularization was assessed by ultrasonography without contrast (Superb microvascular image, SMI). Aortic pulse wave velocity (PWV) was measured to determine stiffness.

Results: No differences in age and body mass index between control group and the four CKD stages were observed. The eGFR showed a significant decrease in the CKD stages (Table 1). No changes were observed in serum Ca and serum P increased only in CKD-5 (Table 1). Serum sKlotho displayed a progressive decrease from CKD-2/3a to CKD-5, before other CKD parameters, such as FGF23 and PTH changed. A significant correlation between serum sKlotho and serum creatinine was observed (r = -0.394, p = 0.0003). Urinary sKlotho increased in CKD-2/3a stage and remained similar up to CKD-5 (Table 1). The carotid artery of CKD patients stages 4 and 5 showed a higher number of adventitial vasa vasorum in the carotid artery (r = 2.09±0.26, p = 0.002; CKD-5 vs Control) and a greater area of adventitial neovascularization (r = 0.84±0.005 vs CKD-4). Values are expressed as Median [Interquartile range] or Mean ± Standard deviation.

Conclusion: Serum sKlotho decreased before FGF23 levels begun to rise, indicating the sKlotho decrease as the earliest marker of CKD-MBD, although it remains with no changes throughout the CKD progression. Carotid adventitial neovascularization by SMI and PWV increased in advanced CKD stages, suggesting that they have a limited clinical utility as early markers of vascular damage in CKD.

URAEMIC CARDIOMYOPATHY AS PREMATURE PRESBYCARDIA
Shanmugakumar Chinnappa and Andrew Mooney

1 Doncaster and Bassetlaw Teaching Hospitals, Nephrology, Doncaster, United Kingdom and 2 Leeds Teaching Hospitals, Nephrology, Leeds, United Kingdom

Background and Aims: Presbycardia, the age-related decline in cardiac function, has been shown in the general population by demonstrating gradual decline in peak cardiac performance with advancing age [1]. Chronic kidney disease (CKD) has shown phenotypic similarities with premature aging. Studies have shown accelerated vascular aging and skeletal muscle wasting in CKD. However, it is not known whether CKD patients show age related decline in cardiac function and whether the impairment is more pronounced for the given age (premature presbycardia). In the present study, we set out to test the hypothesis that CKD patients have premature presbycardia by measuring peak cardiac power (CPO\text{peak}) non-invasively across different age groups.

Method: A cross sectional study (n = 170) of healthy male volunteers (n = 100) and male CKD patients (n = 70) spanning ages 19 to 75 years. CKD patients were grouped into early (CKD 2–3, n = 29) and late CKD (CKD 4–5, n = 41). Patients with diabetes or any known cardiovascular diseases were excluded. CPO\text{peak} was measured using a specialised cardiopulmonary exercise test (CPX) using CO₂ rebreathing method [2]. The association between age and CPO\text{peak} was evaluated. The regression lines of CKD patients and healthy volunteers were compared using ANCOVA. P < 0.05 is considered significant.

Results: The mean eGFR of early CKD and late CKD were 57.8±17.2 ml/min and 16.8±5.8 ml/min respectively. The mean CPO\text{peak} of the study groups were 5.35±0.94 W (Control), 4.93±0.71 W (early CKD) and 4.26±0.69 W (late CKD). Fig. 1 shows the association between CPO\text{peak} and age along with the regression equations for the individual study groups. Comparison of the regression lines using ANCOVA did not show any difference in slopes between the groups (P = NS). There was a diminution in CPO\text{peak} of 0.2 W per 10 years of advancing age. However, for any given age, the CPO\text{peak} was diminished by 0.38 W in early CKD (P = 0.023) and 0.93 W in late CKD (P < 10\textsuperscript{-3}) compared to control. In other words, the cardiac age was older by 19 years in early CKD and by 46.5 years in late CKD compared to healthy volunteers.

Conclusion: The results demonstrate that CKD is associated with premature presbycardia. This phenomenon may offer explanation for the high prevalence of heart failure in advanced CKD. Further studies exploring the underlying mechanisms of premature aging in CKD may be worthwhile in the future.

REFERENCES

Figure 1: Graph showing decline in peak cardiac power with age in healthy control, early CKD (CKD2-3) and late CKD (4-5).
Background and Aims: Cardiovascular disease (CVD) is the main cause of morbidity and mortality in patients with chronic kidney disease (CKD). Novel determination of clonal expansion of hematopoietic stem cells carrying mutations in certain genes is called Clonal hematopoiesis of indeterminate potential (CHIP), which is well known the association with an increased risk of hematologic malignancies but in general population, CHIP has been associated with increased mortality and increased cardiovascular risk. The aim of our study was to analyze the influence of CHIP on the risk of CVD and heart disease in the population with CKD.

Method: 128 patients with different degrees of CKD were in our prospective study in between September 1, 2020 and January 31, 2021. All of them have followed up in Nephrology clinics and any patient have previous cardiovascular pathology. For detection of silent heart disease was realized measurement of troponin I and NT-Pro-BNP in the blood using a microparticle chemiluminescence assay and the degree of coronary calcification was calculated by the computed tomography (CT): Agaston method. All the patients were prospectively followed up for 18 months, recording the occurrence of major cardiovascular events. For detection of CHIP massive sequencing was performed with Ion Chef System On-demand recording the occurrence of major cardiovascular events. For detection of silent heart disease using a microparticle chemiluminescence assay and the degree of coronary calcification was calculated by the computed tomography (CT): Agaston method. All the patients were prospectively followed up for 18 months, recording the occurrence of major cardiovascular events.

Conclusion: The presence of CHIP was not associated with a greater risk of silent heart disease or cardiovascular events, although DNMT3a mutations, analyzed independently, were associated with a greater number of cardiovascular events in our CKD population.

MALE CHRONIC KIDNEY DISEASE IS A STATE OF PREMATURE TESTICULAR AGING

Karel David1, Nick Narinx1, Jetty De Loor1, Leen Antonio2, Dirk Vanderschueren1, Frank Claessens1, Brigitte Decallonne1 and Pieter Evenepoel2

1KU Leuven, Chrometa, Leuven, Belgium, 2KU Leuven, Microbiology, Immunology and Transplantation, Leuven, Belgium and 3KU Leuven, Cellular and Molecular Medicine, Leuven, Belgium

Background and Aims: Sex steroid levels have been reported to be decreased in male patients with chronic kidney disease (CKD), parallel to the severity of the kidney dysfunction. These studies, at large, used immuno-assays, a method that is inferior to gold standard chromatography measurements and, in addition, failed to give insights into the underlying pathophysiology as they lacked data on gonadotropin levels. The aim of this study was to comprehensively map the gonadal status in male CKD patients not yet on dialysis and age- and BMI-matched controls, using gold standard techniques.

Method: We performed a case-control study in 120 male CKD patients (age 59±7, BMI 26.8 kg/m²), matched (1:1) with non-CKD controls for age and BMI. We divided CKD patients into 3 categories based on CKDigo classification: CKD 1–2 (n = 24), CKD 3 (n = 42) and CKD 4–5 (n = 54). We measured total testosterone (T) and estradiol (E2) using liquid chromatography tandem mass-spectrometry. Sex hormone binding globulin (SHBG), prolactin, luteinizing hormone (LH) and follicle stimulating hormone (FSH) were measured on the Roche Cobas 8000 platform. Free T levels were calculated via Vermeulen formula. Inhibit B (a readout for testicular Sertoli cell function) was measured by ELISA.

Results: CKD patients showed lower total T (426.0 ng/dL [297.5-516.5] vs. 541.0 ng/dL [452.0-647.8]; P < 0.0001) and free T levels (7.4 ng/dL ± 3.2 vs. 9.4 ng/dL ± 2.2; P < 0.0001) as compared to non-CKD counterparts. SHBG and E2 levels, conversely, were comparable in cases and controls. Inhibit B levels were lower in CKD patients as well (112.7 pg/mL [38.1-189.0] vs. 181.1 [122.2-236.4]; P < 0.0001). LH and FSH levels were higher in CKD patients (9.1 IU/L [5.4-16.2] vs. 5.4 IU/L [3.6-8.1]; P < 0.0001 and 7.8 IU/L [5.0-20.2] vs. 5.6 IU/L [4.0-9.7]; P < 0.0001 respectively). Consequently, the T/LH ratio and inhibit B/FSH ratio, respectively reflecting Leydig and Sertoli cell function, were markedly depressed in CKD (1.8 mmol/ IU [0.7-3.0] vs. 4.0 mmol/IU [2.4-5.2]; P < 0.0001 and 14.4 ng/IU [1.2-33.6] vs. 32.2 ng/IU [3.2-146.3]; P < 0.0001). In the CKD cohort, regression analysis identified eGFR and age as independent determinants of T/LH ratio (R² 0.29). According to the T/LH ratio a male CKD patient of 45y old has a testicular age of an 81y old control.

Conclusion: Male patients with CKD not yet on dialysis show low total and free T levels, confirming CKD as a risk factor for male hypogonadism. The low T/LH and inhibit B/FSH ratio point to testicular failure as the underlying pathophysiological mechanism.

* Adjusted for gender, age, body mass index
b Adjusted for the above and eGFR, diabetes mellitus and established cardiovascular disease
c Adjusted for the above and Framingham risk factors (systolic blood pressure, LDL, HDL, current smoker)

P = 0.051). High bone-specific ALP was not associated with increased risk of all-cause mortality.

**Conclusion:** In patients with CKD not yet on dialysis, increased non-skeletal ALP (as opposed to skeletal ALP) is associated with inflammation and increased risk of all-cause mortality. These associations are at least partly driven by metabolic endotoxemia.

#4594 INPATIENT POLYPHARMACY AND THE AGING KIDNEY
Louise Clarkson1, Tien Khoo1, Alfred Lam1 and Anthony Griffiths2

1Griffith University, Department of Medicine, Southport, Gold Coast, Australia and 2University of Sydney, Department of Medicine, Sydney, Australia

**Background and Aims:** Individuals aged ≥80 years have been found to have some of the highest rates of polypharmacy. Nearly 50% of these people are likely to have significant renal impairment, either from chronic kidney disease or age-related decline. Since many drugs are renally excreted, reduced renal function will cause pharmacokinetic and pharmacodynamic changes. As a result, some medications are inappropriate and there is an increased risk of adverse effects which are dose-related or related to drug interactions. We aim to examine the prevalence of highly renally excreted and nephrotoxic medications taken by our oldest old medical inpatients.

**Method:** Data was obtained as part of an ongoing prospective cross-sectional observational study examining polypharmacy in elderly inpatients at Ballina Hospital, Australia. Data as of 03/01/2019 for participants aged ≥80 years were retrieved as part of this nested study involving acute medical inpatients with sufficient capacity to provide informed consent. Exclusion criteria comprised of people with insufficient working knowledge of English, cognitive impairment (including delirium) and those under the age of 80 years. Information with regards to inpatient medication use, co-morbidities and renal function (creatinine clearance, CrCl) were retrieved from inpatient medical records as part of routine clinical care. Renally excreted medications and potential nephrotoxic medications were identified via the Australian Medicines Handbook and Renal Drug Database. Cognition was assessed by the Montreal Cognitive Assessment, multimorbidity via the Charlson Co-morbidity Index and frailty using the Clinical Frailty Score. A polypharmacy questionnaire was used to further probe participant insight and aptitude towards medication use.

**Results:** One hundred and five inpatients, with mean age of 86.7 years (range 80.2 to 102.7) met the inclusion criteria and participated in the study. The patients were prescribed an average of 12 medications (range 3–26). They had multiple co-morbidities (mean CCI 6), 64% were assessed to have mild cognitive impairment and 62% were classified as frail. Also, 28% did not know the indication for their medication and 30% reported missing medications. The calculated CrCl ranged from 19–99ml/min, with the majority of patients falling between the range of 30–60ml/min (mean 49ml/min). On average, each patient was taking 1 medication that is ≥50% renally excreted unchanged (or their active metabolites), 1 medication that requires dose reduction when CrCl is 30–60ml/min, 2 medications that require dose reduction when CrCl is 10–30ml/min and 1 medication infrequently or commonly classified as nephrotoxic. The average total number of medications did not change significantly with decrease in CrCl, however, there was a non-significant increase in potentially nephrotoxic medication use. Patients experienced a similar anticholinergic or sedative load (as measured by the drug burden index) regardless of CrCl.

**Conclusion:** A substantial burden of medications was found in individuals of advanced age (≥80years) with renal impairment. The risk of medication-related harm may be further compounded by age-related barriers and challenges to managing multi-drug regimens. Regular medication reviews are essential for this vulnerable patient group.
#5534
HIF-PH INHIBITORS AND ESA IN NDD-CKD PATIENTS WITH ANEMIA COMPARING THEIR SAFETY AND EFFICACY
Sandesh Warudkar, Amit B Jain, Jay Sharma, Nilanj Dave and Alok Chaturvedi
Intas Pharmaceuticals Ltd, Medical Affairs, Ahmedabad, India

Background and Aims: Hypoxia-inducible factor prolyl hydroxylase inhibitors (HIF-PHIs) are a new class of oral medicines for the management of anemia in CKD patients. These agents are found to be efficacious in the management of renal anemia, however safety is still under scrutiny. While, ESAs (Erythropoietin stimulating agents) are available since long with a well-established clinical profile. This network meta-analysis aimed to compare the safety and efficacy of HIF-PHI vs ESA in CKD patients with anemia not undergoing dialysis.

Method: An electronic database search was carried out in EBM (Evidence Based Medicine) Reviews, Cochrane Library and PubMed from inception to July 2022 for phase III clinical trials comparing six different HIF-PHIs and ESA for treating anemia in non-dialysis-dependent (NDD) CKD patients. The outcomes included the serious adverse events (SAEs) and change in hemoglobin (Hb) levels.

Results: Total 163 records were identified out of which 6 studies involving a total of 6847 patients were eligible for analysis. Compared to ESA, all HIF-PHIs increased risk for SAEs (daprodustat of RR, 1.21[95% CI, 0.825–1.77]; desidustat, 1.38[95% CI, 0.695–2.76]; enarodustat, 1.29[95% CI, 0.568–3.02]; molidustat, 1.02[95% CI, 0.585–1.74]; roxadustat, 1.29[95% CI, 0.674–2.57] and vadadustat, 1.01[95% CI, 0.693–1.47]) although these differences were statistically non-significant. When change in Hb was analyzed, there was no statistically significant difference between the two groups. The mean difference in change in HB with various HIFs as compared to ESA were: daprodustat (MD: 0.0796, 95% CI –0.676–0.838), desidustat (MD: 0.120, 95% CI: −0.626–0.883), enarodustat (MD: -0.309, 95% CI: −1.36–0.753), molidustat (MD: 0.0402, 95% CI: −0.802–0.720).

Conclusion: In terms of safety, HIF PHIs were associated with more SAEs compared to ESA although these differences are not statistically significant. Comparing efficacy, HIF-PHIs and ESA both effectively increase Hb level in NDD-CKD patients without any significant difference. Results of our network meta-analysis suggest the need for larger and long-term studies comparing HIF-PHIs with ESAs to have better understanding of their comparative efficacy and safety profiles.

Figure 1:
THE ASSOCIATION OF FIBROBLAST GROWTH FACTOR-23 AND CARDIORENAL SYNDROME IN PATIENTS WITH DIABETES MELLITUS

Volha Vasilkova1, Ivan Pchelin2 and Tatiana Mokhort2

1Gomel State Medical University, Endocrinology, Belarus; 2Saint Petersburg State University, Faculty Therapy; Russia and 1Belarusian State Medical University, Belarus

Background and Aims: Previous studies suggest that interactions between the heart and the kidney can contribute to the progressive dysfunction of both organs. Recently, there has been an increase in the prevalence of cardiovascular disease (CVD) and chronic kidney disease (CKD) due to increasing diabetes mellitus rate. It is known that fibroblast growth factor-23 (FGF-23) has been found to be related to kidney metabolism especially as a biomarker and a key factor for remodeling in the kidney field. The aim of our study was to assess potential therapeutic approaches of the use of FGF-23 in clinical settings as a potential circulating biomarker for CVD and CKD.

Method: A total of 155 patients with DT2, aged 34 to 84 years (60 [60;72]), were examined. Control group included 94 healthy people the same age. All patients underwent standard clinical and laboratory examination, with an assessment of the levels of FGF-23 in baseline plasma samples. Renal function was assessed based on the levels of serum creatinine, cystatin C, eGFR, which was calculated according to the CKD-EPI formula, and albuminuria, which was assessed as albumin/creatinine ratio (A/C). An echocardiographic examination was conducted according to the standard protocol with the calculation of dimensional, volume and speed characteristics.

Results: The levels of FGF-23 were significantly higher in DT2 patients with CKD 5 in comparison with stages 1–4. There were positive strong significant association between FGF-23 and creatinine (r = 0.71, p < 0.001).

In both unadjusted and adjusted analyses, probability of decreased eGFR was associated strongly with FGF-23 (COR: 95% CI 1.890; 1.362-2.622, p < 0.001). When evaluating the dependence of the probability of decreased eGFR on the FGF-23 using the ROC analysis, the cut-off value of FGF-23 was 0.9 pmol/l. The sensitivity and specificity of the method were 75.3% and 74.5%, respectively (AUC 0.832 [0.035 with 95% CI: 0.764-0.901, p < 0.001).

Conclusion: Our study identifies FGF-23 as a promising target of novel therapeutic interventions in cardiorenal syndrome, which should be investigated in future clinical studies.

HYPERBARIC OXYGEN TREATMENT IN CALCIFIC UREMIC ARTERIOLOPATHY PATIENTS IN ADDITION TO CONVENTIONAL MULTIDISCIPLINARY CARE

Espen Nordheim1, Ine Roed2, Fredrik Barth Brekke3, Helga Gudmundsdottir1, Martin Rygh Braathen1 and Nanna Von der Lippe1

1Oslo University Hospital, Ullvål, Department of Nephrology, Oslo, Norway and 2Oslo University Hospital, Ullvål, Department of Anesthesiology, Oslo, Norway

Background and Aims: Calcific uremic arteriopathy (CUA), also referred to as calciphylaxis, is a rare and serious complication in patients with advanced kidney disease. CUA has limited treatment options and poor prognosis, with 1-year survival often reported to be below 50% after diagnosis [1,2]. Hyperbaric oxygen therapy (HBOT) may improve wound healing by increasing tissue oxygenation, and has been suggested as adjuvant treatment for CUA patients [3]. We added HBOT to our conventional multidisciplinary care of CUA patients in 2012 and this study aims to evaluate long-term outcomes of CUA patients after this.

Method: Data from all CUA patients treated at our institution from 2012 to 2022 were retrospectively retrieved from hospital records. This is a single-centre study, but patients from different Norwegian hospitals were referred for treatment at our centre. Conventional multidisciplinary care of CUA in our centre included sodium-thiosulphate, dialysis if indicated medical optimization of calcium- phosphate homeostasis, substitution of vitamin K2, withdrawal of warfarin and iron and vitamin D if used, minimization of systemic steroids, in addition to optimization of weight- and nutritional status. Our centre is restrictive with surgical revisions to CUA patients.

Results: 25 CUA patients received a total number of 1493 HBOT treatments in addition to conventional CUA multidisciplinary care in the study period. Median HBOT per patient was 45 (range 1–267). One year after CUA diagnosis, 20 out of 25 patients were alive (80%). Fifteen out of the 20 patients, who were alive at one year after CUA diagnosis, had completely resolved CUA lesions (75%). Five patients died within the first year after CUA diagnosis, due to acute cardiovascular disease (n = 3) and infection (n = 2). Our impression is that HBOT is well-tolerated and associated with less wound-associated pain.

Conclusion: Our results suggest that HBOT is well-tolerated in CUA patients. After we included HBOT in our multidisciplinary care of CUA patients, 80% of the patients were alive one year after CUA diagnosis.

INFLUENCE OF REDUCTION IN THE MASS OF ACTIVE NEPHERONS ON THE EXPRESSION OF MiRNA AND NfκB IN THE MYOCARDIA AND AORT OF WKY RATS

Olga Beresneva, Marina Parastaeva, Galina Ivanova, Mikhail Zaraiski, Mokhamad Khasun, Anatoly Kucher and Aleksander Rumyatsev

Pavlov First Saint Petersburg State Medical University, Department of Propadeutics of Internal Disease, Saint-Petersburg, Russia

Background and Aims: At present, there is no doubt about the relationship between the state of the kidneys and the cardiovascular system, which is reflected in the concept of the cardiorenal continuum. The emerging data suggest that miRNAs may be one of the links connecting the kidneys and the cardiovascular system. However, information about the role of epigenomic changes in the development of damage to the heart and blood vessels in chronic kidney disease remains not fully understood.

Target. The aim of the work was to evaluate changes in the expression levels of miRNA-21, 133, 203, as well as the nuclear transcription factor B (NfκB) in the tissues of the myocardium and aorta in the development of remodeling of the heart and blood vessels with a chronic reduction in the mass of active nephrons in the experiment.

Method: Systolic blood pressure (BP, mm Hg), myocardial mass index (MMI, mg/g), relative expression levels of miRNA-21, -133, -203 and NfκB in myocardium and aorta were analyzed in rats Wistar-Kyoto (WKY) with 5/6 nephrectomy (Nx) and duration of experimental exposure 2 mo (n = 9). Controls were sham operated (SO) animals (n = 9). The reverse transcription reaction for 'complementary' DNA (cDNA) preparation was carried out under the StemLoop-technology separately for the studied miRNA. The following primers were used in PCR: microRNA-21–5' GCCCGGTCGTTATCAGACGTG-3', microRNA-133–5' GCCGGTCGTTAATGGAAC-3', microRNA-203–5' GCCGGTGAATTTGAGGACG-3', and U6–5' GCCGGTCTGGAAGCTTC-3', and common reverse 5' GTGGAGGAGTCGAGG-3'. The semi-qualitative evaluation of the miRNA expression level (in relative units, RU) under the (ΔΔCt) protocol at the laboratory referent (0.09) was used in calculations. NfκB expression was quantified using a StemLoop technology and RealTimePCR compared to the expression of the reference-gene GAPDH. Data were analyzed using Student’s t-test and the Mann–Whitney, a P < 0.05 was considered statistically significant.

Results: In rats WKY with an experimental decrease of the nephron mass in comparison to control, significantly higher levels (median [interquartile range]) of blood pressure (145.5 [135.0; 155.0] vs 117.9 [110.0; 120.0] mm Hg; P < 0.001) and NfκB expression in the myocardium (1.25 [0.87; 1.87] vs 0.89 [0.31; 1.15] relative units; P < 0.001) and aorta (0.87 [0.57; 1.63] vs 0.35 [0.22; 0.87] relative units; P < 0.05). The expression level of miRNA-21 in the myocardium increased in rats with NE (1.40 [0.54; 3.73] vs 0.37 [0.06; 1.62] relative units;
P < 0.01) relative to the SO group, but did not change significantly in the aorta (p > 0.05). Relative expression levels of microRNA-133 and -203 both in the myocardium and in the aorta of WKY rats with NE were more than 10 times lower compared to those of the SO group (p < 0.001). BMI in rats 2 months after NE increased relative to the SO group (p < 0.05).

**Conclusion:** An experimental decrease in the number of functioning nephrons not only leads to an increase in blood pressure and myocardial mass in WKY rats, but also causes epigenomic changes in the myocardium and blood vessels, in particular, activation of signaling pathways associated with NFκB in the myocardium and aorta of rats. Possibly, it is accompanied by growth in expression of NFXB-associated proliferative, proinflammatory and profibrotic cytokines. It is possible that microRNA-21 is also involved in the formation of fibrosis and myocardial remodeling. However, specific mechanisms of miRNA involvement in the pathogenesis of heart and vascular remodeling require further study.

**FRAX® ASSOCIATION, BONE DENSITOMETRY, BIOCHEMICAL PARAMETERS OF BONE MINERAL METABOLISM AND ADVANCED CHRONIC KIDNEY DISEASE**

Cristina Andrades Gómez, Gema Montilla Cosano, Francisco Roca Oporto, Alba Temprado Collado, Marisa Vidal Blandino and Francisco Javier Toro Prieto

Hospital Universitario Virgen del Rocio, Nephrologist, Seville, Spain

**Background and Aims:** Currently, there are calculation tools that predict the risk of fractures (fx), one of which is the Fracture Risk Assessment Tool (FRAX®). Patients with advanced chronic kidney disease (CKD) have a higher risk of fx than the general population and it is an independent factor for fx. However, this tool does not consider the presence or absence of CKD, where alterations in bone mineral metabolism have important clinical consequences and their prevention should be the objective of CKD control. The aim of our study is to evaluate the FRAX® tool in patients with advanced CKD and to analyze possible relationships with parameters of bone mineral metabolism.

**Method:** Observational, descriptive, retrospective study of a series of cases of patients with advanced chronic kidney disease in our center, where demographic data, FRAX® calculation, personal history of Diabetes Mellitus, etiology of CKD, personal history of fx, measurement of bone mineral densitometry by dual energy X-ray absorptiometry (DXA), estimated glomerular filtration rate (CKD-EPI), levels of serum calcium and phosphorus, vitamin D1, 25 levels, Parathyroid hormone (PTH), fibroblast growth factor 23 (FGF-23), use of phosphorus chelating treatment and vitamin D were collected. Descriptive results of continuous variables are expressed as mean and standard deviation or median and interquartile range (IQR) according to their distribution. For categorical data, frequency and percentage are reported. To analyze the impact of the variables on the event to be studied, a univariate and multivariate Cox regression model was used.

**Results:** 59 patients with advanced CKD with DXA performed within one year of the FRAX® analysis were analyzed. The median age was 66 years (IQR 22), 59.3% were male, 55.6% had a personal history of diabetes mellitus. The most frequent etiology of CKD was unknown etiology (41.4%), followed by vascular (16.9%). History of some type of fx (13.6%) or personal history of Diabetes Mellitus, etiology of CKD, personal history of fx, measurement of bone mineral densitometry by dual energy X-ray absorptiometry (DXA), estimated glomerular filtration rate (CKD-EPI), levels of serum calcium and phosphorus, vitamin D1, 25 levels, Parathyroid hormone (PTH), fibroblast growth factor 23 (FGF-23), use of phosphorus chelating treatment and vitamin D were collected. Descriptive results of continuous variables are expressed as mean and standard deviation or median and interquartile range (IQR) according to their distribution. For categorical data, frequency and percentage are reported. To analyze the impact of the variables on the event to be studied, a univariate and multivariate Cox regression model was used.

**Conclusion:** In patients with advanced CKD, FRAX® index identifies patients at high fracture risk for whom active treatment for osteoporosis should be instituted. In patients with advanced chronic kidney disease, FRAX® underestimates those patients with decreased bone mass and elevated risk of osteoporosis. We did not find any association with biochemical parameters of bone mineral metabolism which could guide us in anticipating the treatment of osteoporosis. The loss of renal function accelerates the loss of bone mass, so we believe that the introduction of this variable is necessary in the equation, especially in this profile of patients.

![Figure 1: Fracture risk according to FRAX® and bone densitometry. N: number of patients. FRAX®: Fracture Risk Assessment Tool. DXA: bone mineral densitometry by dual energy X-ray absorptiometry.](image1)

**SERUM IRON AND NUTRITIONAL STATUS ARE ASSOCIATED IN PATIENTS WITH CHRONIC KIDNEY DISEASE**

Ting-Yun Lin and Szu-Chun Hung

Taipei Tzu Chi Hospital, New Taipei City, Taiwan, Rep. of China

**Background and Aims:** Both anemia and malnutrition are highly prevalent in patients with chronic kidney disease (CKD). Iron deficiency plays a significant role in anemia of CKD. However, whether iron deficiency contributes to malnutrition in CKD is unclear.

**Method:** We examined the association of iron status with nutritional status among patients with CKD stages 3–5 not yet on dialysis. The iron indices for assessing iron status included serum iron, serum ferritin, and transferrin saturation. Nutritional status was determined using body composition assessed by anthropometric measures and multi-frequency bioelectrical impedance, serum albumin, handgrip strength, Malnutrition Inflammation Score (MIS), and dietary protein and energy intake. We performed linear regression analyses to explore the cross-sectional association between iron status and different nutritional assessment tools.

**Results:** A total of 157 patients (age 64 ± 12 years; 93 men and 64 women; diabetes 39%) with CKD [estimated glomerular filtration rate (eGFR) 24.4 ± 13.4 ml/min/1.73 m²] were included. Patients were stratified as low (<70 μg/dL) or high (≥70 μg/dL) serum iron. Compared with patients with high serum iron (n = 104), patients with low serum iron (n = 53) were more likely to be female and had a significantly lower eGFR, hemoglobin, lean tissue index, serum albumin, handgrip strength, and dietary protein intake but a significantly higher MIS. In adjusted linear regression analyses, there was a significant association of serum iron with serum albumin, handgrip strength, and MIS (all adjusted P < 0.05). Serum ferritin was not associated with nutritional status, while the association between transferrin saturation and handgrip strength was only marginal (adjusted P = 0.044).

**Conclusion:** Higher serum iron is associated with better nutritional status in patients with CKD. Serum iron may be considered a complementary tool to assess nutritional status in CKD.

MALNUTRITION DIAGNOSIS IN CKD PATIENTS
Olga Vetchinnikova, Maria Ivanova, Andrey Vatazin and Aleksei Zulkarnaev
Moscow Regional Research and Clinical Institute, Russia

**Background and Aims:** Malnutrition is a prevalent condition in patients with chronic kidney disease (CKD) receiving replacement therapy by peritoneal dialysis (PD). Geriatric nutritional risk index (GNRI) is an effective tool for screening nutritional status in maintenance hemodialysis patients. The purpose of this study was to determine the information content of GNRI for the diagnosis of protein-energy malnutrition in patients with CKD receiving replacement therapy with PD when compared to malnutrition inflammation score (MIS) and 7-point subjective global assessment (7p-SGA).

**Method:** A prospective cohort study included 222 adults PD-patients (man 100, female 112, age 44±14). All patients received continuous ambulatory peritoneal dialysis. Median duration PD before inclusion in the study was 12 months, the observation period of patients was 36 months. Nutritional status assessment included anthropometric (body mass index, triceps skinfold thickness, midupper arm muscular area) and biochemical (albumin, C-reactive protein, total iron-binding capacity, total cholesterol, hemoglobin and others) examinations as well as bioelectrical impedance analysis (BIA – fat mass). GNRI calculated according to the formula GNRI = \(1.489 \times \text{albumin (g/dL)} + [41.7 \times (\text{body wt/ideal body wt})]\), where the ideal body weight for women is: height (cm) - 100 - [(height - 152) \times 0.2], ideal body weight for men is equal to: height (cm) - 100 - [(height - 152) \times 0.4]. We used MIS and 7p-SGA as a reference standard, a score ≥ 6 and ≤ 5, respectively, defined malnutrition. The cutoff of GNRI the diagnosis of malnutrition were derived from these ROC-analysis.

**Results:** Most of the individual nutritional indexes, including the anthropometric, biochemical and BIA indexes, were significantly (P < 0.001) lower in the patients with MIS score ≥ 6 and 7p-SGA score ≤ 5, thus both nutritional screening tools were considered reasonable as a reference standard to determine the information content GNRI in PD-patients. The GNRI fluctuated in the range 66–126 (median 99), MIS score – 2–24 (median 7) and 7p-SGA score – 2–7 (median 5). The GNRI showed a significantly negative correlation with MIS (r = -0.708, p < 0.0001) and a significantly positive correlation with 7p-SGA (r = 0.636, p < 0.0001) (Fig. 1). The most accurate GNRI cutoff to identify a malnourished patient according to the MIS was ≤ 99 (Fig. 2). The frequency of malnutrition among the observed patients was 52.3% when using GNRI<99, 55.9% when using MIS≥6 and 51.4% when using 7p-SGA≤5 (n.s.). The values for sensitivity and specificity with a GNRI of ≤ 99 in predicting malnutrition based on the MIS were 77.4% (95%CI...
Background and Aims: Many chronic kidney disease (CKD) patients suffer from mineral and bone disorders like osteoporosis, which also affects a huge part of the general population, predominantly postmenopausal women. For the treatment of osteoporosis, several drug types with different mechanisms of action are available, such as bisphosphonates, PTH analogs, RANKL inhibitors and sclerostin inhibitors (some of which are contraindicated for CKD patients beyond CKD stage 3). Different drugs can be given individually or combined in various ways, simultaneously or sequentially, resulting in a huge number of theoretically possible drug combinations that are practically impossible to study in clinical studies. We aimed to study using simulations whether there are combination therapies that would work considerably better than those tested and employed in clinical practice. If so, this could be beneficial for the treatment of a large number of osteoporosis patients by leading to a higher increase in bone strength and a higher reduction in bone fracture risk than standard therapies.

Method: We developed a physiology-based mathematical model that simulates the process of bone renewal in the human body and can predict how different osteoporosis drugs (including bisphosphonates, PTH analogs, RANKL inhibitors, and sclerostin inhibitors) affect this process, alone and in combination [1].

Results: The model was validated on over 30 clinical osteoporosis studies with about 90 study arms. It predicted the time courses of bone mineral density and bone turnover markers with a high degree of accuracy based on the knowledge of the used drugs and dosing schemes alone. We used the model to study how treatment results changed when merely reshuffling the order in which different drugs were given. For example, for 3-year drug therapies involving alendronate, denosumab and romosozumab (1 year each), our simulations showed that the order in which these drugs were given can have a considerable effect on short- and long-term therapy success [1]. This is due to different drugs favorably interacting when applied in the right sequence.

Conclusion: Our findings indicate that some osteoporosis drug administration schemes are superior to others while relying on the exact same types and amounts of drugs. Therefore, there is a large potential to improve pharmacologic therapies of osteoporosis using physiological simulations. For renal patients beyond CKD stage 3, a restricted set of drug types may be considered to account for contraindications related to impaired renal clearance. If translated into clinical practice, findings obtained using our model could give rise to novel treatments using combinations of existing drugs for osteoporosis that lead to a lower bone fracture risk than standard treatments. Moreover, our model could serve as a basis for personalizing osteoporosis therapy to individual patients.

Background and Aims: CKD is associated with alterations in body composition, such as reduced muscle mass, increased amount of fat or both simultaneously. Furthermore, both sarcopenia and sarcopenic obesity are associated with worse physical functioning, poor quality of life, increased morbidity and mortality in CKD. Magnetic resonance imaging (MRI) is considered an accurate method for the study of body composition. A water/fat separated MRI scan with automated image analysis can quantify the skeletal muscle volume and allows a quantitative measure of muscle quality by assessing muscle fat infiltration. The combined observation of low muscle volume and high muscle fat infiltration, i.e. adverse muscle composition (AMC), has been shown to be linked to poor function and metabolic comorbidities within subjects with non-alcoholic fatty liver disease. The aim of this study was to investigate the prevalence of AMC and its association with poorer muscle function and metabolic comorbidity within CKD in the large UK Biobank imaging study.

Method: This is a cross-sectional and prospective study including a total of 647 UK Biobank participants with eGFR cystatin C < 60 ml/min/1.73 m². A control group was created by selecting participants (matched on sex, age, and BMI) with an eGFR cystatin ≥ 60 ml/min/1.73 m². Fat-tissue free muscle volume and muscle fat infiltration (MFI) were quantified using a rapid whole-body water and fat separated MRI protocol and automated image analysis (AMRA® Researcher). For each participant, a personalized muscle volume z-score (sex- and body size-specific) was calculated and combined with muscle fat infiltration for AMC detection. AMC was defined as having low muscle volume in combination with high muscle fat infiltration. Sarcopenia was calculated according to the last published recommendation by the European Working Group on Sarcopenia in Older People. Data describing muscle function (hand strength, walking test, stair climbing and number of falls) and metabolic comorbidity (coronary heart disease (CHD) and type 2 diabetes (T2D)) have been included and obtained from the study database linked to the study participants' electronic health records. A Cox proportional hazards ratio model, corrected for age, sex, BMI, low hand grip strength, T2D, smoking, and alcohol consumption, was used to assess the association between AMC and CHD incidence.

Results: The prevalence of AMC was 1.4x higher in CKD participants compared with the control group without CKD (27.7% vs 20.4%, p < 0.001). CKD participants had significantly higher prevalence of sarcopenia (7.2% vs 4.4%, p = 0.004), low hand grip strength (16.0% vs 11.8%, p = 0.006), slow walking pace (17.3% vs 9.9%, p < 0.001), CHD (17.4% vs 8.9%, p < 0.001) and T2D (13.7% vs 9.2%, p = 0.001) compared with the control group without CKD (Fig. 1). CKD participants with AMC (179 out of 647) had a significantly higher prevalence of sarcopenia (17.3% vs 3.5%, p < 0.001), low hand grip strength (22.8% vs 13.4%, p = 0.006), slow walking pace (27.0% vs 13.6%, p < 0.001), as well as prevalence of CHD (23.6% vs 15.0%, p = 0.014) and T2D (18.6% vs 11.8%, p = 0.033) compared with CKD participants without AMC (Fig. 2). CKD participants with prevalent CHD at the study had higher prevalence of AMC (37.5% vs 25.5%, p = 0.014) compared to CKD participants without CHD. AMC was associated with 1.9x higher incidence of CHD (95% confidence interval 1.15-3.15, p = 0.012) compared to those without AMC.

Conclusion: AMC, as determined by MRI with automated image segmentation, is highly prevalent within CKD and associates with poor function, high prevalence of metabolic comorbidities and an increased risk for CHD. CKD patients with poor muscle health is a highly vulnerable group and this technique enables them to be targeted for accurate interventions in order to improve outcomes.

CARDIOVASCULAR RISK AND THE RISK OF KIDNEY DAMAGE IN PATIENTS WITH HYPERTENSION

Akselnder Kulikov, Olga Beresneva, Galina Ivanova, Marina Parastaeva, Anatoly Kucher, Mohkadam Khasan and Sergey Orlov

Pavlov First Saint Petersburg State Medical University, Department of Propaedeutics of Internal Disease, Saint-Petersburg, Russia

Background and Aims: A high salt content in the diet is one of the reasons for the increase in blood pressure (BP) and the development of cardiovascular disorders. However, high intake of sodium chloride does not always lead to an increase in blood pressure, but causes endothelial dysfunction and cardiac remodeling. It has been established that the introduction of soy products into the diet can have a nephro- and cardioprotective effect in chronic kidney disease. At the same time, it is not clear whether the damaging effect of a high-salt diet on the cardiovascular system can be offset by other dietary interventions, in particular, soy proteins. In this regard, the aim of the study was to study the effect of long-term use of diets with different content of sodium chloride and soy protein on myocardial remodeling in cynomolgus monkeys.

Method: A total of 18 cynomolgus male monkeys with age 6–8 years were studied. The animals were divided into three groups (six in each group). The first (control) group received the standard diet. The second group received the diet rich in common salt (8 g of NaCl/kg), and the third, the high salt diet in combination with soy protein SUPRO 760 (200 g/kg; Protein Technology International, USA). Systolic (BP) and diastolic (BPd) blood pressure (BP) in monkeys was recorded by oscillometric method on a veterinary tonometer ML-410 VET (Microlux, Russia) under anesthesia. After registration of blood pressure, an echocardiographic study (EchoCG) was performed with a sector scanner with a frequency of 3-5 MHz on an ultrasound system Chison Sonic Touch 60 (China). Echocardiography was performed in B-mode (two-dimensional scanning), M-mode (one-dimensional scanning), as well as in pulsed and tissue Doppler modes. Echocardiography and blood pressure measurements were performed at baseline, after 4 and 12 months of follow-up.

Results: BP values (group 1 - BPs: 109±10.09, BPd: 60±7.42; group 2 - BPs: 109±25.14, BPd: 57±11.86; group 3 - BPs: 101±8.59, BPd: 57±6.92 mm Hg; all p > 0.05) and heart rate (group 1 - 77±12.61, group 2 - 81±18.07, group 3-80±19.9 beats/min, all p > 0.05) in macaques did not undergo significant changes over 12 months of the study in any of the groups. In group 1, there were also no significant changes in echocardiographic parameters. Group 2 monkeys showed no early changes in LV shortening fraction (FU) and ejection fraction (EF). However, after 12 months, FU decreased by an average of 26.6%, and EF by 12.8% compared with the indicator for a period of 4 months. In addition, the speed of the transmitral flow in early diastole (E) decreased by 19.1% compared with the baseline. Long-term intake of soy proteins prevented a decrease in LV FU in macaques on a high-salt diet. Its value was 25.1% greater than in group 2. In group 3 monkeys, after 12 months, the magnitude of systolic excursion of the mitral annulus plane and the maximum rate of excursion of the fibrous ring of the mitral valve in early diastole (E') increased, the thickness of the interventricular septum in diastole decreased, and E/e' ratio. In group 3, the thickness of the posterior wall of the left ventricle decreased in systole (0.57±0.056 mm), the mass of the LV myocardium (14.9±2.94 g/m2), the average diameter of the base of the right ventricle (1.20±0.115 mm) compared with group 2 (0.69±0.040 mm), 19.6±2.83 g/m2, 1.40±0.111 mm, respectively; all p < 0.05.

Conclusion: The obtained results can be considered as confirmation of the hypothesis that high consumption of sodium chloride leads to adverse structural and functional changes in the heart and blood vessels, not associated with an increase in blood pressure. The inclusion of isolated soy proteins in the diet is likely to reduce the effects of this negative impact. The specific mechanisms of this cardioprotective effect remain to be explored.

Statistical analysis used: One-way analysis of variance for unrelated samples when comparing the data of 3 studied groups and one-way analysis of variance for related samples when studying the dynamics of the indicator in each of the groups during 12 months of observation. Results are presented as mean ± standard deviation (M ± SD). Differences were considered significant at p < 0.05.

DIAGNOSTIC ACCURACY OF BONE TURNOVER MARKERS IN PATIENTS WITH VARIOUS DEGREES OF KIDNEY DYSFUNCTION AND PRIMARY OSTEOPOROSIS

Mohamed Abdalbarry

1 Mansoura University, Mansoura Nephrology and Dialysis Unit, Mansoura, Egypt and 2 University of Kentucky, Division of Nephrology & Bone and Mineral Metabolism, Lexington, United States of America

Background and Aims: There are limited data available on the validity of bone turnover markers (BTMs) to predict bone turnover in patients with kidney dysfunction and primary osteoporosis. Method: This is a cross-sectional retrospective study of patients with primary osteoporosis and eGFR <90 ml/min/1.73 m² who had bone biopsy for clinical purposes for a time period of 8 years. CKD-EPI equation 2021 was used to calculate eGFR based on the mean serum creatinine readings. Bone biopsy samples were evaluated qualitatively using KDIGO TMV classification.
Routine laboratory data were collected in addition to alkaline phosphatase, iPTH, cyclase activating (CAP) PTH, osteocalcin, bone specific alkaline phosphatase (BSAP), and N-telopeptide collagen (NTX).

**Results:** Study included 156 patients with mean age of 64.7 years. The majority of patients were females (93.6%). The mean BMI was 26.2 kg/m². The mean eGFR was 70 ml/min with 78% of patients had eGFR from 60-90 ml/min/1.73 m². CKD stage III was found in 19%, and 3% of patients had CKD stage IV. HTN was found in 47%, history of kidney stones in 9%, and fragility fractures in 77%. Bisphosphonates were the most used pre-biopsy bone specific medication (66%). Teriparatide was used in 10.9% and SERM was used in 7.7% of patients, while 31.4% of patients did not receive any bone anti-resorptive or anabolic medication "treatment naïve". Bone cortical thickness and cancellous volume were low in 94.2%, while high bone turnover (HBT) was found in 42.9% and low bone turnover (LBT) in 57.1%. Mineralization was defective only in 9.6%, while osteoid thickness was increased in 5.8%. Figure 1 shows the distribution of bone turnover among study group. Baseline characteristics and routine laboratory data were not different between HBT and LBT. PTH, especially PTH CAP, and alkaline phosphatase tended to be higher in HBT but did not reach statistical significance. While BTMs (osteocalcin, BSAP and NTX) were significantly higher in HBT (Table 1). Using ROC curve analysis, the area under the curve (AUC) for BSAP, NTX and osteocalcin were 0.605, 0.660, 0.642, respectively. Combining the NTX with either BSAP or osteocalcin did not result in increasing the AUC. This was also the same when the three of them were combined. BTMs were able to discriminate bone turnover status only among patients with eGFR≥60 ml/min/1.73 m² (Table 2).

**Conclusion:** Low bone turnover was found in 43% in treatment naïve patients with primary osteoporosis, with a higher prevalence among patients with eGFR≥60. In the study group, PTH and total alkaline phosphatase were not able to discriminate LBT from HBT, while BTMs showed a modest ability to discriminate the turnover status only among patients with eGFR≥60.
Elevated phosphate concentrations are associated with a significantly increased risk of cardiovascular disease and overall mortality in patients with chronic kidney disease. Current Kidney Disease: Improving Global Outcomes (KDIGO) guidelines recommend lowering elevated serum phosphorus concentrations toward the normal range in patients with end-stage kidney disease on dialysis through restriction of dietary phosphorus intake, increase in clearance by dialysis, and the use of phosphate binders. However, ~75% of dialysis patients are not achieving normal phosphate concentrations, potentially due to low adherence and/or binders’ insufficient phosphate binding capacity. Therefore in patients with chronic kidney disease (CKD) death. On the other hand, elevated cardiac Troponin T (cTnT) levels are associated with cardiovascular events and mortality. Several studies have established an inverse association between CKD and cTnT, and knowledge of this association in diabetic patients would benefit their management. The objective of this study was to analyze the relationship between cTnT levels, renal function and echocardiographic parameters in diabetic patients with advanced chronic kidney disease (ACKD).

Method: A prospective study was carried out during one year of 180 patients attending for the first time for ACKD consultations, with an estimated glomerular filtration rate (eGFR) < 30 ml/min/1.72 m². The following data were analyzed: age, sex, diabetes, HBP, BMI, smoking, peripheral artery disease, coronary artery disease, non-age-adjusted Charlson index (non-age-CCI), eGFR by CKD EPI, ultrasensitive cTnT, C-reactive protein (CRP), ferritin, hemoglobin (Hb), ejection fraction (EF) and left ventricular hypertrophy (LVH), interventricular septum thickness (IVST) and left ventricular wall thickness (LVWT).

Results: Baseline characteristics are summarized in Table 1. In the group of patients, when analyzing the presence or absence of diabetes, diabetic patients were significantly older, had higher troponin levels, a higher percentage of smoking, coronary artery disease, peripheral artery disease, non-age-CCI, IVST and LVH than non-diabetic patients. In diabetic patients, troponin levels correlated significantly with eGFR (0.03) and ACR (0.09), with ACR remaining as a predictive variable (0.003). It did not correlate with echocardiographic data. In non-diabetics, the correlation was significant with age and IVST and LVH (Table 2, Figure 1). In the multivariate analysis in diabetic patients, only the association remained with ACR (0.026) and in non-diabetics with eGFR (0.038) and IVST (0.004).

Conclusion: The cTnT levels are found to be higher in diabetic patients and with higher ACR, considering it as a therapeutic target to reduce cardiovascular risk since echocardiographic data would not discriminate this risk in this profile of patients.

**EPICARDIAL ADIPOSE TISSUE AND REVERSE EPIDEMIOLOGY IN DIALYSIS PATIENTS**

**Luis D’marco¹, Ana Checa-Ros¹, Cristina Karohl², Carlos Soto³, Valmore Bermudez⁴ and Paolo Raggi⁵**

¹CEU Cardinal Herrera University, Facultad de Ciencias de la Salud, Valencia, Spain, ²Hospital de Clínicas de Porto Alegre, Brazil, ³Hospital Sant Antoni Abat, Vilanova i la Geltrú, Spain, ⁴Simon Bolivar University, Barranquilla, Colombia and ⁵University of Alberta, Medicine, Edmonton, Canada

**Background and Aims:** Conventional risk factors of cardiovascular disease and mortality in the general population such as body mass is relate to adverse outcome in dialysis patients, but often in an opposite direction (reverse epidemiology). On the contrary, epicardial adipose tissue (EAT) has reported to have a local inflammatory and proatherogenic effect. Thus, the association of EAT as direct measures of region specific adipose tissue in chronic kidney disease (CKD) has been studied.

**Method:** The study evaluated 37 CKD-5 patients in hemodialysis (mean dialysis duration 26±30 months, 70% males, 57% African-American, 48% diabetic) that underwent MSCT to measure EAT and coronary artery calcium (CAC) score. CAC distribution in quartiles of EAT was assessed. Finally, we measured patients’ body mass index (BMI) and categorized them as normal (BMI 18.5-25 kg/m²) and abnormal BMI (BMI >25 kg/m²).

**Results:** The mean BMI was 28.6±5.7 kg/m², and the mean EAT volume was 66±29 ml and 102±69 ml for normal and abnormal BMI groups. There was a direct correlation between dialysis vintage and EAT while BMI showed an inverse relationship with dialysis vintage (p = 0.05). In this small sample size, the association of CAC and EAT was only marginally significant (p = 0.7). EAT was significantly correlated with age (p = 0.02), history of cardiovascular disease (p = 0.03) and diabetes (p = 0.001).

**Conclusion:** The direct association of EAT with dialysis vintage in the face of an inverse association of BMI with dialysis duration appear to support the notion that chronic hemodialysis is a state of chronic inflammation and malnutrition.
INSULIN RESISTANCE IN PEDIATRIC CKD PATIENTS  
Dina E. Sallam  
Faculty of Medicine, Ain Shams University, Pediatric Nephology, Cairo, Egypt

**Background and Aims:** Pediatric chronic kidney disease (CKD) is associated with disturbance of glucose metabolism & insulin receptor sensitivity leading to impaired glucose tolerance & insulin resistance (IR), which are potential risk factors for cardiovascular disease (CVD). Hyperinsulinemia and IR are not extensively investigated in children with CKD, especially in different stages of CKD. The aim of our study was to detect hyperinsulinemia & IR in pediatric CKD patients.

**Method:** A total of 87 children and adolescents; 58 with chronic kidney disease (CKD); (29 CKD stage 2-4, pre-dialysis group & 29 CKD stage 5 on regular hemodialysis, CKD5d group) & 29 age & gender matched controls were enrolled in the current cross-sectional study. Homeostasis model assessment of insulin resistance (HOMA-IR) using fasting insulin & glucose, where IR was considered if HOMA-IR was 4.39.

**Results:** Fasting insulin & glucose hadn't significantly changed between CKD patients & controls (p = 0.7, 0.3 respectively), while IR represented by HOMA-IR was found in a total of 11 (12.6%) CKD patients (6, 6.89% CKD5d & 5, 5.74% CKD 2-4) with no significant difference between pre-dialysis & dialysis groups (p > 0.05), while it was significant with controls (p = 0.039), meanwhile, the total means of HOMA-IR between were no statistically significant between all CKD patients & (p = 0.64). HOMA-IR correlated positively to dialysis durations (p < 0.001, < 0.001 respectively), but hadn’t changed with BMI.

**Conclusion:** Pre-dialysis & dialysis CKD pediatric patients are at a high risk of IR & hence CVD. CKD & dialysis durations are independent risk factors for IR.

QUALITY OF LIFE, PRURITUS BURDEN, AND TREATMENT SATISFACTION IN CHRONIC KIDNEY DISEASE PATIENTS IN GERMANY

Dmitry Zavlin1, Thomas Weinreich2, Kai van Bentum3, Berno Müller1 and Martin Koczor4

1CSI, Vifor, Medical Affairs, Munich, Germany, 2Nephrologisches Zentrum Villingen-Schwenningen, Villingen-Schwenningen, Germany, 3MVZ Saarpfalz GmbH, Heimdialyse Saar, Homburg, Germany and 4Bundesverband Niere eV, Mainz, Germany

Background and Aims: Chronic kidney disease (CKD) and its related symptoms significantly impact patients’ health-related quality of life (HRQoL). CKD-associated pruritus (CKD-aP) often affects patients with advanced CKD, particularly those on renal replacement therapy, and remains mostly underrecognized by both patients and medical providers. To explore the current patients’ impairment of HRQoL due to CKD-aP, we conducted a quantitative survey amongst members of a CKD patient association in Germany.

Methods: Our questionnaire was distributed via the channels of the German National Kidney Patients Association (Bundesverband Niere e.V.) from mid-June to mid-September 2022. Responses of 569 CKD-patients of a total of roughly 16,000 members were analysed regarding their general health, HRQoL, and general treatment satisfaction using multiple choice questions. Pruritus burden was assessed with a 0-10 numeric rating scale.

Results: The demographic details are displayed in Figure 1. Among the surveyed CKD patients, 33% were transplanted, 39% on hemodialysis, and 7% on peritoneal dialysis. We could confirm that most CKD patients (92%) suffered from comorbidities. Initially, 12% reported dermatological comorbidities but when asked specifically about pruritus, 62% reported this symptom which was also associated with worse HRQoL. (Figure 2). However, only one third was receiving antipruritic treatment by a physician. Furthermore, patients who were able to fully or at least partially participate in their medical decisions showed higher satisfaction and higher HRQoL (86% vs. 65% vs. 43% satisfaction, depending on full/partial/no participation, respectively) yet the patients did not always perceive that shared-decision-making was possible. Patients also showed high interest in topics outside of their primary CKD treatment, such as overall symptom control and additional psychological measures. They reported higher HRQoL when these areas were addressed by the medical team (87% vs. 55% satisfaction).

Conclusions: Our survey results emphasize the persisting need for shared or co-creative exchange between patient and physician. Improving patient education and the caregiver’s awareness of the burden of pruritus – one of the many CKD-related symptoms – could be a first step towards higher patient satisfaction and HRQoL and higher treatment rates. CKD-aP appears underreported by patients via unprovoked questioning and should be screened frequently.

Figure 1:
IN CHRONIC KIDNEY DISEASE, IRON DEFICIENCY-INDUCED ANEMIA IS ASSOCIATED WITH HIGHER LEVELS OF FGF23 THAT ARE NOT REDUCED BY IRON ADMINISTRATION

Karen Valdés-Díaz, Rodrigo Lopez-Baltanas, Ana Torralbo Romero, Cristina Membrives, Julio Manuel Martínez Moreno, Casimiro Valle Dominguez, Mariano Rodríguez, Maria Sagarro Soriano Cabrera, Juan R Muñoz-Castañeda, Maria Encarnacion Rodriguez Ortiz and Alejandro Martin-Malo

Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC). Nephrology Service, Reina Sofia University Hospital. University of Córdoba (Spain), Córdoba, Spain

Background and Aims: Iron (Fe) deficiency significantly contributes to anemia in chronic kidney disease (CKD). High FGF23 levels, commonly found in CKD, are related to adverse outcomes in patients. In the normal setting, an association between Fe deficiency and FGF23 has been observed. However, it is unknown whether Fe deficiency-induced anemia might contribute to the excessive FGF23 levels in CKD. Thus, this study was intended to evaluate the interplay between Fe deficiency, CKD, and FGF23.

Method: Male Wistar rats with normal renal function received either standard (40 ppm Fe) or Fe-deficient (4 ppm Fe) diets for 6 weeks to induce anemia. Then, several normal and all the anemic rats were switched to an adenine-enriched (0.6%) diet to induce renal damage. Groups of anemic-uremic animals were treated with oral (ferric citrate, FC and ferrous sulfate, FS) or intravenous (ferric carboxymaltose, FCx) Fe at a dose of 9 mg/kg for 5 weeks. Hematological and mineral metabolism parameters were determined at sacrifice. All experimental protocols were approved by the Ethics Committee for Animal Research of the University of Córdoba.

Results: Plasma and serum biochemistries are shown in Table 1. CKD per se was associated with derangements in hematological parameters. The presence of Fe deficiency-induced anemia further decreased these parameters, being statistically significant in the case of serum Fe (P = 0.003). Iron therapy improved hematocrit, hemoglobin, and Fe levels, although statistical significance for all of them was only reached when FC was administered (P = 0.012, P = 0.038, and P = 0.002, respectively). As expected, CKD rats exhibited disturbances in mineral metabolism. Interestingly, anemic and anemic rats showed higher intact (P = 0.039) and c-terminal (P = 0.048) FGF23 levels when compared with CKD group. Despite normalization of serum Fe, intact FGF23 further increased following administration of FS (P = 0.022), and same trend was observed with all the compounds. However, cFGF23 levels remained unchanged in all the Fe-treated groups.

Conclusion: The presence of Fe-induced anemia in an experimental model of CKD is associated with further increases in the levels of both intact and c-terminal FGF23. Thus, other factors distinct than serum Fe might influence FGF23 levels. Our results support the need for investigating the precise mechanisms underlying the relationship between Fe and FGF23 to optimize the clinical management of anemia, particularly in the context of renal dysfunction.

Audiological assessment in pediatric CKD patients

Dina E. Sallam

Faculty of Medicine, Ain Shams University, Pediatric Nephrology, Cairo, Egypt

Background and Aims: Many similarities exist between the nephron & ear infrastructures, making them vulnerable to same risk factors. Idiopathic sensory neural hearing loss is frequent in pediatric patients with chronic kidney disease (CKD). Our aims were to determine the prevalence, type, & degree of hearing impairment in pediatric CKD patients.

Method: This cross-sectional study was carried out at pediatric dialysis & nephrology unit at Children's hospital & Audiology unit, Faculty of Medicine Ain Shams University, included 45 CKD patients’ stage 2-4, 45 CKD patients’ stage 5 on hemodialysis, & 90 children as controls. Detailed history, physical, otological examinations & audiological assessment by standard pure tone audiometry, speech audiometry & tympanometry, IQ test, in addition to some laboratory investigations were done for all our studied patients.

Results: The mean IQ was significantly lower in CKD patients than the controls, however, it was significantly higher in dialysis than non-dialysis groups (P = 0.05). Pure tone audiometry showed 16.6% of out CKD patients had hearing loss, which was mainly sensory neural (SNHL); (53.3%), that was significantly higher compared to the control group (P < 0.001). A mild degree of high-frequency hearing loss was frequently reported. These findings weren’t significantly different between dialysis & non-dialysis patients, but were significant compared to control group (P < 0.001). Regarding speech discrimination scores, controls had a higher significant change compared to CKD patients. Regarding Tympanometry test results, most of CKD patients & the controls had normal middle ear pressure. The most determining factor affecting the hearing loss in our patients was the IQ.

Conclusion: High-frequency SNHL is not uncommon in CKD pediatric patients, in addition to low IQ. It’s recommended to do a routine audiological evaluation & follow up for early diagnosis & intervention.

Method: We performed control cross-sectional study in single center in Turkey between 2019, and 2022. We evaluated two groups aged 18-50 years. Patients groups; consisted of patients with stage 4 - 5 chronic kidney disease, and control healthy groups; consisted of healthy participants. The bone status of thirty-three participants was evaluated using both cQCT and DXA. Diagnostic discordance was assessed between the lumbar spine and femoral neck from DXA and cQCT.

Results: Thirty-eight participants were included in the study and BMD of 33 was evaluated with DXA and cQCT. The median age was 44 years (range 22-50) in the patient’s group (33% female), and 42 years (range 27-48) in controls (55% female). Baseline variables were outlined in Table 1. Using the DXA T score and cQCT; the incidence of osteopenia or osteoporosis was not statistically different in the patient and control groups (for DXA; spine and femoral neck, p: 0.62 and 0.61 respectively, for cQCT; spine and femoral neck, p:0.8 and 0.73 respectively). Regarding the lumbar spine, DXA diagnosed osteopenia or osteoporosis more frequently compared to QCT in the patient’s group [6 (40%) vs 3 (20%), p = 0.01]. Three of 6 patients (50%) diagnosed with osteopenia or osteoporosis by DXA were evaluated as having normal bone status by QCT. There was no statistical difference between the two methods in the control group. The results of bone status in lumbar spine and femoral neck in the whole cohort were summarized in Table 2.

Conclusion: According to our result, in young or middle-aged patients with stage 4-5 CKD, DEXA might overdiagnosis osteopenia or osteoporosis compared to QCT.

PEAK SYSTOLIC VELOCITY IN THE KIDNEY INTERLOBAR ARTERIES AS A POSSIBLE SCREENING MARKER OF CKD IN PREGNANT WOMEN
Tatyana Maryanova1, Marina Chechneva 1, Elena Prokopenko1,2, Tatiana Chumarnaya3 and Aleksei Zulkarnaev2
1Moscow Regional Research Institute of Obstetrics and Gynecology, Moscow, Russia, 2Moscow Regional Research Clinical Institute, Moscow, Russia and 3Ural Federal University, Ekaterinburg, Russia

Background and Aims: Currently, pregnancy is increasingly occurring in patients with CKD including patients with chronic renal failure (CRF) - CKD grade 3-5. Physiological renal hyperperfusion and glomerular hyperfiltration in pregnant women leads to a temporary decrease in serum creatinine values even in patients with CRF. Consequently, the CKD diagnosis during pregnancy may be difficult in women without a history of kidney disease, and the degree of kidney damage may be underestimated [1]. The aim of our study was to

estimate Doppler sonography of the renal arteries as a possible CKD screening method in pregnant women.

**Method:** The study included 283 pregnant women (Table 1). Doppler sonography was performed in the main renal, segmental, interlobar and interlobular arteries in left and right kidney at the first, second and third trimesters of pregnancy. Peak systolic velocity (PSV), end-diastolic velocity, pulse index, resistive index and systolic-diastolic ratio were analyzed.

**Results:** PSV in the renal arteries was significantly lower in pregnant women with CKD 3-5 compared with healthy control group since 22 weeks of pregnancy. However, PSV in the interlobar arteries had a higher diagnostic value. The values of this parameter were significantly lower in pregnant women with all stages CKD compared with healthy control group. We found cut-off points of right and left interlobar arteries PSV linear combination at the second and third trimesters of pregnancy. Peak systolic velocity (PSV), end-diastolic velocity, pulse index, resistive index and systolic-diastolic ratio were analyzed.

**Conclusion:** In pregnant women, interlobar renal arteries PSV can be used as screening marker of CKD. Additionally, it allows to identify pregnant women with advanced stages of CKD. The linear combination of right and left interlobar arteries PSV has the greatest diagnostic value.

### Table 2: Cut-off points of interlobar arteries PSV (cm/sec) and linear combination of right and left interlobar arteries PSV (cm/sec) for CKD and CRF diagnosing in pregnant women; sensitivity (Se) and specificity (Sp) of method.

THE PERSISTENT UNDERREPRESENTATION OF PEOPLE WITH CHRONIC KIDNEY DISEASE IN CARDIOVASCULAR TRIALS: A SYSTEMATIC REVIEW AND EVIDENCE MAP

Julia M't Colombijn 1,2, Demy Idema 3, Sanne van Beem 1, Anna Marthe Blokland 1, Kim van der Braak 1, M Louis Handoko 1, Linde Huis 1, In’t Veld 1, Tabea Kaul 1, Nurda Kolagasi-Sakdemir 2, Mike Pt Kusters 3, Sabine Meijvis 1, Ilse J Oosting 1, Rene Spijker 1,2, Michel Bots 1, Lotty Hooft 1, Marianne Verhaar 1 and Robin Vernooij 1,3

1UMC Utrecht, Department of Nephrology and hypertension, Utrecht, Netherlands, 2UMC Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 3Cochrane Netherlands, Julius Centre for Health Sciences and Primary Care, UMC Utrecht, Utrecht, Netherlands, 4Amsterdam UMC, Vrije Universiteit Amsterdam, Amsterdam Cardiovascular Sciences, Amsterdam, Department of Cardiology, Amsterdam, Netherlands and 5Amsterdam UMC, University of Amsterdam, Amsterdam Public Health, Medical library, Amsterdam, Netherlands

**Background and Aims:** People with chronic kidney disease (CKD) have a markedly higher risk for cardiovascular disease. Systematic underrepresentation of people with CKD in cardiovascular randomised controlled trials (RCTs) limits evidence to guide cardiovascular risk management (CVRM). In this systematic review we aimed to identify evidence gaps regarding CVRM medication for people with CKD and evaluated the prevalence of exclusion of people with CKD from cardiovascular RCTs.

**Method:** We searched Clinicaltrials.gov through the Cochrane Central Register of Controlled Trials from inception until October 2021. Eligible studies were randomised controlled trials (RCTs) that investigate the efficacy of guideline-recommended CVRM medications on (cardiovascular) mortality, cardiovascular morbidity, and end-stage kidney disease in adults with a history of cardiovascular disease or one or more major risk factors for cardiovascular disease. Two reviewers independently determined the eligibility of references and extracted data. Outcomes were an overview of studies that report results for people with CKD, evidence gaps in results, and the rate of exclusion of people with CKD.

**Results:** We included 2794 eligible RCTs involving 2,158,869 participants (mean age 63±6 years, 36% female). Overall, 841 (71%) RCTs excluded (subgroups of) people with CKD based on heterogenous exclusion criteria. Since 2000, this prevalence has increased from 70% to 73%. Of included RCTs, only 157 (13%) reported results for people with CKD (again in heterogenous subgroups). The prevalence of RCTs with results for people with CKD has increased since 2000 to 10% to 23%. Nevertheless, significant evidence gaps remain for most CVRM interventions, particularly for those with an eGFR <30 ml/min/1.73m² (22 RCTs), and people who are treated with dialysis (14 RCTs) or received a kidney transplant (1 RCTs).

**Conclusion:** The majority of cardiovascular RCTs continues to exclude (subgroups of) people with CKD and this has only increased over the years. Although more RCTs report results for people with CKD, evidence gaps for the efficacy most CVRM medications persist, particularly for those with severe CKD.

ESTIMATED PROXIMAL TUBULE FLUID PHOSPHATE CONCENTRATION AS AN ELEMENT OF DECREASED RENAL FUNCTION IN PATIENTS UNDERGOING UNILATERAL NEPHRECTOMY

Lida Tartaglione, Silverio Rotondi, Francesca Franco, Marzia Pasquali, Francesca Tinti and Sandro Mazzaferro

Sapienza University of Rome, Roma, Italy

Background and Aims: Patients with chronic renal failure (CRF) develop early alterations in mineral metabolism called Chronic Kidney Disease Mineral Bone Disorders (CKD-MBD), detectable with the available markers (PTH, Ca, P) only in the most advanced stages of disease. Recent evidence suggests that the early development of CKD-MBD is related to the nutritional phosphorus intake and the reduction of the number of nephrons (renal functional reserve). In fact, with the reduction in the nephrons number, compensation systems must be activated for the maintenance of the phosphoric balance with an increase in urinary phosphate and in the concentration of phosphorus in the single nephron (ePTFp). Therefore, the measurement of ePTFp has been proposed as a new early marker of CKD-MBD and effective renal functional reserve. Threshold values of ePTFp (2.2 mg/dl) have been identified to indicate patients with reduced renal functional reserve and therefore at increased risk of progression of renal damage. The measurement of residual renal function with ePTFp may be a useful parameter to be evaluated in patients who undergo unilateral nephrectomy due to renal neoplasia. In fact, post-nephrectomy some patients have a high reduction of the renal function not identified by preoperative GFR assessment or other risk factors. In these patients, ePTFp could represent a measure of pre nephrectomy kidney functional reserve and thus indicate the risk of reduce renal function after nephrectomy. The aim of the study was to evaluate the relationship between pre-operative ePTFp and renal function after nephrectomy.

Methods: This is a transversal monocentric observational study. From January 2022 to November 2022, we enrolled patients diagnosed with renal cell carcinoma for which has been indicated unilateral nephrectomy surgery. In all patients we evaluated pre nephrectomy and three months after surgery, renal function, and ePTFp with the formula \[ ePTFp = \frac{\text{Phosphaturia}}{\text{creatininuria}} \times \text{ creatininemia} \times 3.33 \]. 30 subjects with normal renal function (eGFR 100 ± 10 ml/min, no proteinuria) were evaluated for the ePTFp preference values.

Results: We evaluated 13 patients: age 57.5 ± 13.6; Cr 1.48 ± 0.7 mg/dl; eGFR 58.5 ± 23.3, ml/min; Pi, mg/dl 3.2 ± 0.6; Ca 9.9 ± 0.6 mg/dl; PTH 38.8 ± 41 pg/ml FA 176.7 ± 108 IU/L, proteinuría 500 ± 150 mg. Compared to the control population (GFR 100 ml/min) the 24-hour phosphaturia was no different while ePTFp was increased 2.1 ± 0.9 vs 1.2 ± 0.2 mg/dl; p: 0.05. In the post-nephrectomy assessment, creatinine and GFR were stable (Cr 1.48±0.7 vs 1.5 ± 0.7 mg/dl; p: n.s; eGFR 58.5 ± 23.3, vs 56.5 ± 22.3, ml/min; p: n.s), while ePTFp was increased (ePTFp pre 2.1 ± 0.9 vs ePTFp post 3.3 ± 2.7; p<0.01). Patients with pre-nephrectomy ePTFp ≥ 2.2 mg/dl (n. 6, eGFR 56.5 ± 20.3, proteinuría 500±100 mg/24h) had a greater renal function reduction post nephrectomy (mean GFR delta -9.5±2 ml/min) respect to patients with pre-nephrectomy ePTFp <2.2 mg/dl (n. 7, eGFR 59.7 ± 24.3, proteinuría 500±200 mg/24h; mean GFR delta -0.5±2 ml/min; p: 0.05). In all the population there was direct correlation between ePTFp and the reduction of GFR post nephrectomy (r: 0.667; p: 0.05).
Conclusion: In our patients ePTFp was higher than the control group and correlate with the entity of the GFR reduction post nephrectomy. The group with a preoperative ePTFp ≥ 2.2 mg/dl had a higher post nephrectomy GFR reduction. These results suggest that ePTFp identify the pre nephrectomy kidney functional reserve. In particular and ePTFp higher than limits highlighted in the literature (2.2 mg/dl) pre nephrectomy identify a greater risk of kidney function reduction post nephrectomy. ePTFp may be proposed as a parameter to identify patients with higher risk of decreased renal function post nephrectomy.

ASSOCIATION BETWEEN FIBROBLAST GROWTH FACTOR 23 AND TRABECULAR BONE SCORE IN EARLY STAGES OF CKD

Zuzana Kužmová1, Martin Kužma2, Andrea Gazova3, Zdenko Killinger4, Peter Jackuliak2, Ján Kyselovič2 and Juraj Payer2

1Comenius University Faculty of Medicine, University Hospital Bratislava, 5th department of Internal Medicine, Bratislava, Slovakia and 2Comenius University Faculty of Medicine, University Hospital Bratislava, 5th department of Internal Medicine, Bratislava, Slovakia

Background and Aims: Newer markers of kidney damage and mineral and bone changes in chronic kidney disease (CKD) are needed. The fracture risk increases with worsening of CKD with highest incidence in later stages. Thus methods for early bone status assessment and laboratory marker of kidney function is needed. Aim of the study was to evaluate bone mineral density (BMD) and trabecular bone scores (TBS) – a novel surrogate of trabecular bone microstructure, in relationship with newer laboratory markers of CKD, such as fibroblast growth factor 23 (FGF23) and klotho.

Method: A cross-sectional study during July 2018-July 2019 was conducted. Plasma levels of soluble klotho and FGF23 were determined by ELISA (enzyme-linked immuno - assay). All patients underwent bone mineral density (BMD) and trabecular bone scores (TBS) measurement. Patients were divided into 2 groups as follows: A - patients in stages G1 - G3; B - patients in stages G4 – 5 according to KDIGO.

Results: A total of 74 CKD patients (42 males and 32 females; mean age 68.8 years) were included in the study. Greater FGF23 levels in group B(N = 15) in comparison to group A (N = 59)(p = 0.01) were observed. FGF23 was associated with glomerular filtration (GF)(R = -0.43; p = 0.003), with greater levels of FGF23 at GF less than 0.8 ml/s. Significant difference in TBS within first 3 CKD stages (mean TBS in G1 = 1.374 vs. G2 = 1.304 vs. G3a = 1.24; p = 0.03) and negative correlation of FGF23 and TBS (R = -0.33; p = 0.05) and a positive correlation between klotho and TBS (R = 0.419; p = 0.04) was observed.

Conclusion: This study confirmed that FGF23 is associated with TBS. However, TBS reflects kidney function decline only in first 3 stages of CKD. Thus, FGF23 together with TBS are promising markers of early trabecular bone impairment in CKD.

EFFECT OF DAPAGLIFLOZIN IN PATIENTS WITH CKD ACROSS THE SPECTRUM OF AGE AND BY SEX

Margaret Yu1, Priya Vart2, Hiddo Lambers Heerspink3,4, Niels Jong1, Ricardo Correa-Rotter4, John McMurray5, Peter Rossing6,7, Anna Maria Langkilde8, Robert Toto9, David C. Wheeler10 and Glenn Chertow11

Background and Aims: The SGLT2 inhibitor dapagliflozin reduces the risk of progressive kidney disease and cardiovascular events in patients with and without type 2 diabetes. Among patients with CKD, baseline risks of cardiovascular disease and CKD progression vary based on age and sex. Whether the effects of dapagliflozin are uniform among patients across the spectrum of age and among men and women is unknown. Therefore, we performed a pre-specified analysis from the DAPA-CKD trial to evaluate efficacy and safety of dapagliflozin according to baseline age and sex.

Method: We randomized 4304 adults with baseline estimated glomerular filtration rate (eGFR) 25–75 ml/min/1.73m² and urinary albumin-to-creatinine ratio 200–5000 mg/g to dapagliflozin 10 mg or placebo once daily. The primary endpoint was a composite of ≥50% eGFR decline, end-stage kidney disease, and kidney or cardiovascular death. Secondary endpoints included a kidney composite endpoint (primary composite endpoint without cardiovascular death), a cardiovascular composite endpoint (hospitalized heart failure or cardiovascular death), and all-cause mortality. Study participants were categorized based on decades of age (<50, 50-59, 60-69, 70-79, ≥80 years). Sex was based on self-report. We conducted time-to-event analyses using a proportional hazards (Cox) regression stratified by randomization factors (diabetes status and UACR), adjusting for baseline eGFR, and analyzed the effects of dapagliflozin on total and chronic eGFR slopes using a mixed effects linear spline model.

Results: Median follow-up was 2.4 years. 671 (15.6%), 935 (21.7%), 1501 (34.9%), 999 (23.2%), and 198 (4.6%) participants were <50, 50-59, 60-69, 70-79, and ≥80 years of age, respectively; 1425 (33.1%) were women and 2879 (66.9%) were men. Racial composition varied by age and sex; older patients were more likely to be white, younger patients were more likely to be Asian, and a higher proportion of women were black. As expected, absolute risks of the cardiovascular composite endpoint and all-cause mortality were higher in older patients; absolute risks of the kidney composite endpoint were highest in patients <50 (10.7 and 6.2 per 100 patient-years in the placebo and dapagliflozin groups, respectively) and lowest in patients ≥80 years (3.0 and 1.2 per 100 patient-years in the placebo and dapagliflozin groups, respectively). There was no evidence of heterogeneity of the relative effects of dapagliflozin on the primary composite or secondary endpoints based on age or sex. Neither age nor sex modified the effects of dapagliflozin on total or chronic eGFR slope (Figure 1).

Conclusion: Benefits of dapagliflozin were evident across the spectrum of age and among women and men. Although younger trial participants with CKD and albuminuria were more likely to experience CKD progression, dapagliflozin reduced the risks of mortality, cardiovascular events, and CKD progression in older patients, including in more than 25% septuagenarians and octogenarians. Ageism and/or therapeutic nihilism should not diminish the use of dapagliflozin in older patients who are likely to experience considerable benefit.
THE SYSTEMIC AND RENAL HAEMODYNAMIC EFFECTS OF APELIN IN HEALTH AND CHRONIC KIDNEY DISEASE

Fiona Chapman1, Vanessa Melville3, Lorraine Bruce3, Janet Maguire3, Anthony Davenport4, David Newby1 and Neeraj Dhaun1

1University of Edinburgh, Centre for Cardiovascular Science, Queen’s Medical Research Institute, Edinburgh, United Kingdom, 2University of Edinburgh, Clinical Research Centre, Edinburgh, United Kingdom, 3Queen’s College, Cambridge, United Kingdom and 4University of Cambridge, Experimental Medicine & Immunotherapeutics, Cambridge, United Kingdom

Background and Aims: Chronic kidney disease (CKD) is a leading cause of global morbidity and mortality and is independently associated with cardiovascular disease. Indeed, patients with CKD are more likely to die of cardiovascular disease than they are to progress to kidney failure. Despite current standard of care, outcomes remain poor and newer therapies are needed. Apelin, an endothelium-dependent vasodilator and potent inotrope, is a potential novel treatment for CKD. There are no clinical studies of the renal actions of apelin, but pre-clinical data show that it regulates glomerular haemodynamics and promotes aquaresis. We investigated the cardiovascular and renal actions of apelin in healthy volunteers and in patients with CKD.

Method: Patients with stable, non-diabetic CKD and age- and sex-matched healthy volunteers were recruited to a prospective, randomised, double-blind and placebo-controlled study. Subjects received either pyroglutamated apelin-13 (Pyr1-apelin-13, 1 nmol/min and 30 nmol/min) or placebo on two separate visits. Cardiovascular assessments included blood pressure, impedance cardiology and pulse wave velocity; iohexol and para-aminohippurate clearance were used to assess glomerular filtration rate (GFR) and renal blood flow, respectively. Tubular function was examined via urinary sodium, potassium and free water excretion.

Results: Twelve patients with CKD and 12 healthy volunteers were recruited and completed both phases of the study protocol. Baseline characteristics are shown in Table 1. Whilst infusion of 1 nmol/min [Pyr1]apelin-13 did not affect systemic haemodynamics, 30 nmol/min [Pyr1]apelin-13 led to significant changes. Compared to placebo, mean arterial pressure fell by 3 mmHg and 4 mmHg in health and CKD, respectively (p<0.05 for both groups), and systemic vascular resistance index fell by 309 dynes*s*cm⁻⁵ m² and 407 dynes*s*cm⁻⁵ m², respectively (p<0.01 for both groups). Cardiac index increased by 0.3 L/min/m² and 0.2 L/min/m², respectively (p<0.05 for both groups compared to placebo). In contrast, both 1 nmol/min and 30 nmol/min [Pyr1]apelin-13 had similar effects on renal haemodynamics. Effective renal blood flow increased by ~15% in health and CKD (p<0.01 compared to placebo for both groups). GFR fell by ~4 mL/min compared to placebo in patients with CKD (p<0.01) but we observed no change in healthy volunteers. As a result of these changes in effective renal blood flow and GFR, filtration fraction fell by ~3% in CKD, reflected by a fall in proteinuria of ~25% (p<0.001 compared to placebo for both). Both low and high doses of [Pyr1]apelin-13 promoted natriuresis and free water clearance in health and CKD. In comparison to placebo, sodium excretion increased by ~30% and free water clearance by ~15% in both groups (p<0.05 for all comparisons). Overall, the effects of apelin were prolonged in CKD.

Conclusion: Apelin offers systemic and renal haemodynamic benefits to patients with CKD. If these effects were maintained longer-term they would translate to improved cardiovascular and renal outcomes in this at-risk patient group. Clinical trials of long-acting, oral apelin analogues are now justified in CKD and other conditions with impaired salt and water balance.

# APABETALONE REDUCES CARDIAC EVENTS IN CKD PATIENTS BY DOWNREGULATING FIBROTIC AND INFLAMMATORY PROCESSES

Dean Gilham 1, Sylwia Wasial 1, Brooke Rakai 1, LI Fu 1, Laura Tsujikawa 1, Christopher Sarsons 1, Jan Johansson 2, Michael Sweeney 2, Kamyar Kalantar-Zadeh 1 and Ewelina Kulikowski 1

1 Resverlogix Corp., Calgary, Canada, 2 Resverlogix Inc., San Francisco, United States of America, 1 Harbor-UCLA Medical Center, Torrance, United States of America and 1 Resverlogix Corp., Calgary, Canada

**Background and Aims:** Major adverse cardiac events (MACE) are a leading cause of mortality in patients with chronic kidney disease (CKD). Apabetalone is an orally available inhibitor of bromodomain & extraterminal (BET) proteins – epigenetic readers that modulate gene expression involved in fibrosis & inflammation. In the phase 3 BETonMACE trial in patients with CVD & diabetes mellitus (NCT02586155), apabetalone reduced MACE by 50% in the population with CKD (eGFR < 60 mL/min/1.73 m²). HR 0.50 95% CI 0.26,0.96 p = 0.04 indicating favorable response along the kidney-heart axis. This study examines effects of apabetalone in human renal mesangial cells (HRMCs) on fibrotic & inflammatory pathways. In the clinic, we assess plasma levels of fibrotic factors in CKD patients & matched controls after receiving apabetalone.

**Method:** TGF-β1 is a pro-fibrotic cytokine that activates HRMCs to over-produce extracellular matrix (ECM). HRMCs were stimulated with TGF-β1 or LPS ±1-25 μM apabetalone 0.15-0.5 μM JQ1 or 0.1 μM MZI - BET inhibitors (BETi) with chemical scaffolds different than apabetalone. Gene expression was measured by RNA-seq & real-time PCR. RNA-seq was evaluated by Gene Ontology (GO) & Ingenuity Pathway Analysis (IPA). Proteins were measured by immunofluorescence microscopy or ELISA. Collagen gel contraction was assessed in 3D culture. In human subjects, proteomic analysis of plasma was performed via SOMAscan 1.3k 12 hours after 100 mg of apabetalone in CKD patients (n = 8 eGFR < 30 stage 4 or 5) and matched controls (n = 8 eGFR > 60).

**Results:** GO analysis of RNA-seq from TGF-β1 stimulated HRMCs showed multiple gene sets associated with ECM production & remodeling in the top 20 affected by BETi. IPA predicted NRκ-B-RelA and NRκB (complex) were inhibited by apabetalone, consistent with suppressed inflammation. IPA also predicted apabetalone activated pathways of glucose utilization & tolerance of ROS production, including Oxidative Phosphorylation (z-score 5.7, p = 2.95 × 10⁻³ at 25 μM) & NRF2-Mediated Oxidative Stress Response (z score 2.3, p = 7.9 × 10⁻¹² at 25 μM; z-score 1.6, p = 1.5 × 10⁻³ at 5 μM). Predicted changes may allow tolerance of elevated glucose. Mechanically, apabetalone suppressed TGF-β1 induced α-smooth muscle actin (α-SMA) gene expression, a marker of activation, up to 89% (p = 2.8 × 10⁻⁸ at 25 μM), and abolished α-SMA filament formation. Consequently, apabetalone opposed TGF-β1 induced collagen gel contraction up to 24% (p = 0.031 at 25 μM). Further, apabetalone countered TGF-β1 induced expression & protein production of key drivers of fibrosis including (a) thrombospondin, an activator of latent TGF-β1 (b) fibronectin, a key ECM component (c) peristin, a promoter of ECM production (d) osteonectin, a regulator of TGF-β1 expression and (e) IL6, a pro-inflammatory cytokine (Table 1). In addition, apabetalone dose dependently opposed LPS stimulated expression of inflammatory genes: IL6 up to 94%, IL1B up to 95% and PTGS2 up to 94% (p<0.001 for each). In all studies, JQ1 or MZI had similar activity as apabetalone, confirming on-target BETi effects. In humans, plasma levels of probiotic and inflammatory markers were reduced 12 hours after receiving apabetalone specifically in those with CKD. Only peristin was reduced in subjects without renal impairment (Table 1).

**Conclusion:** Through epigenetic regulation of transcription in HRMCs, apabetalone reduces production of fibrotic & inflammatory factors known to signal along the kidney-heart axis & exacerbate kidney dysfunction. Predicted changes in energy metabolism suggest apabetalone facilitates adaptation to high glucose in kidneys. In a clinical trial, plasma levels of fibrotic & inflammatory factors were reduced specifically in CKD patients receiving apabetalone. Our results provide mechanistic insights into reduced MACE in CKD patients receiving apabetalone in the phase 3 BETonMACE trial & will be further evaluated in an upcoming Phase 3 trial.

# RENAL TOLERABILITY OF SGLT-2 INHIBITORS COMBINING WITH RENIN-ANGIOTENSIN SYSTEM BLOCKERS AND MINERALOCORTICOID RECEPTOR ANTAGONISTS IN CKD

Saul Pampa Saico, Simona Alexandru, Aida Frias, M. Soledad Pizarro-Sánchez, Elena Burgos, María López-Picasso and Laura García Puente-Suárez

Spain

**Background and aims:** Recently the sodium glucose cotransporter-2 (SGLT-2) inhibitors combining with angiotensin-converting enzyme (ACE) inhibitor or angiotensin-receptor II blocker (ARBs) or angiotensin-receptor neprilysin inhibitor (ARNI)) and mineralocorticoid receptor antagonist (MRA) (triple therapy (TT)), would help prevent further progression of renal and cardiovascular (CV) endpoints including progression of end-stage kidney disease (ESKD). The degree to which data on TT initiation and discontinuation in chronic kidney disease (CKD) patients can be generalized to patients in real-world practice is unclear.

**Aims:** to evaluate renal tolerability to the TT at target doses as well as clinical incidents and dosage adjustments. To analyze the risk factors for TT discontinuation.

**Method:** A retrospective cohort study was carried out in patients ≥18 years old with chronic kidney disease (CKD) treated with TT in Rey Juan Carlos Hospital between January 2019 to December 2022. The collected clinical data included age, gender, associated morbidities, serum creatinine (Scr), estimated
glomerular filtration rate (eGFR), potassium, sodium levels, dose adjustments before administration of TT and in the first year of follow up. Multivariate logistic models were performed to evaluate the risk factors to dosage adjusted and discontinuation of TT.

Results: Among 104 patients treated with TT were included. Medium age was 69 years old (range, 37-91). Most of them were men, 78% (81). The main cause to initiate TT was cardiorenal syndrome 59% (61). Before to initiate TT, in 35% patients the treatment was adjusted. The main modification was reduced or discontinuation of diuretics (loop or thiazide) therapy 23% (24/104). In the first year of follow up, in 69 patients (66%) it was necessary dosage adjustments, being the reduced of MRA (spironolactone and eplerenone) the main modification treatment 38% (26/69). The major cause of dose adjustment was developed of acute kidney injury (AKI) in 43 patients (41%). According to KDIGO criteria, 38 patients (88%) reached stage 1; 4 patients (9%) stage 2 and 1 case (2%) stage 3. The independent risk factor associated with dosage adjustment were AKI development (OR: 28.57; 95% CI 6.04-134.4; P = 0.0001) adjusted by sex and age. Despite the dosage adjustment and titers, in 29 patients (28%) TT was discontinued in a median time of 4 months (IQR 2–11) after its initiation. The risk factor associated with TT discontinuation were AKI developed (P = 0.003) and eGFR at the 12 months of follow up (P = 0.01). There were no significant excess risks of symptomatic hypotension, volume depletion, and hyperkalemia after a year of follow up.

Conclusions: The renal tolerability of use to triple therapy in chronic kidney disease appears to be low. The AKI development was the main risk factor of dosage adjustment and discontinuation of TT. Its necessary to clarify which is the best way to maximizing renal tolerability in this complex groups of patients. The use of early combination therapy requires careful assessment. Its important to find strategies to guide clinicians about the steps and challenges to improving overall use of triple therapy tolerability and dosage adjustment.

#4483
THE 2021 KDIGO BLOOD PRESSURE TARGET AND THE PROGRESSION OF CHRONIC KIDNEY DISEASE: FINDINGS FROM THE KNOW-CKD
Hyun Jung Lee1, Cheol Ho Park1, Hyung Woo Kim1, Jung Tak Park1, Tae Ik Chang1, Tae-Hyun Yoo1, Shin-Wook Kang1 and Seung Hyoek Han1
1Department of Internal Medicine, College of Medicine, Institute of Kidney Disease Research, Yonsei University, Seoul, Rep. of South Korea and 2Department of Internal Medicine, National Health Insurance Service Medical Center, Ilsan Hospital, Goyang, Rep. of South Korea

Background and Aims: The 2021 Kidney Disease: Improving Global Outcomes (KDIGO) clinical practice guideline for management of blood pressure (BP) in chronic kidney disease (CKD) recommends a target systolic BP of <120 mmHg because this lower target can provide cardiovascular benefits. However, whether implementing the new BP target could improve kidney outcome remains unknown.

Method: We examined the association of the 2021 KDIGO BP target with CKD progression compared with the 2012 KDIGO BP target among 1724 participants from the Korean Cohort Study for Outcomes in Patients With CKD. The main exposure was BP status categorized according to the 2012 or 2021 KDIGO guideline: 1) controlled within 2021 target; 2) controlled within 2012 target only; and 3) above both targets. The primary outcome was a composite kidney outcome of ≥50% decline in estimated glomerular filtration rate from baseline measurement or the initiation of kidney replacement therapy during the follow-up.

Results: During 8,078 person-years of follow-up (median, 4.9 years), the composite kidney outcome occurred in 650 (37.7%) participants. The incidence rates of this outcome were 55, 66.5, and 116.4 per 1,000 person-years in BP controlled within the 2012 and 2012 KDIGO targets, and BP above both targets, respectively. In the multivariable cause-specific hazard model, hazard ratios for the composite outcome were 0.76 (95% confidence interval, 0.60-0.95) for BP controlled within the 2021 target and 1.36 (95% confidence interval, 1.13-1.64) for BP above both targets, compared with BP controlled within 2012 target only.

Conclusion: The newly lowered BP target by the 2021 KDIGO guideline was associated with improved kidney outcome compared with BP target by the 2012 KDIGO guideline.

EFFICACY AND SAFETY OF PATIROMER IN THE TREATMENT OF CHRONIC HYPERKALEMIA IN ASTURIAS: THE K-ASTUR STUDY
Jose Emilio Sanchez-Alvarez1, Maria del Carmen Merino Bueno1, Anna Gallardo Perez1, Cristina Sango1, Carlos Ruiz Zorrilla1 and Catalina Ulloa2
1Hospital de Cabueñes, Nephrology, Gijón, Spain and 2Fundacion Hospital Jove: Gynecology and Obstetrics, Nephrology, Gijón, Spain

Background and Aims: Hyperkalemia is a frequent problem in patients with chronic kidney disease (CKD), especially in those on hemodialysis (HD) and confers increased morbidity and mortality. It is common to carry out urgent HD sessions or increase the number of weekly sessions due to toxic hyperkalemia. Hyperkalemia also prevents the administration or adequate titration of drugs such as renin-angiotensin-aldosterone system (RAAS) inhibitors despite the evidence of their cardiovascular benefits and on the progression of CKD. New drugs have recently entered the market that can help treat chronic hyperkalemia. The aim of the present study was to analyse the efficacy and safety of Patiromer in patients with CKD.

Method: Multicenter, prospective, clinical practice study in patients with CKD stages 3-5. Patiromer was administered with the indication of chronic hyperkalemia. Epidemiological and clinical data were analyzed; the evolution of serum potassium and elements involved in bone and mineral metabolism were taken into account.

Results: Finally, 52 patients (71±12 years old, 75% male, 63% diabetic, 54% with heart failure, and 42% receiving RAAS inhibitors) were included in the study. Regarding CKD, 17% were in stage 3b, 31% in stage 4, 38% in stage 5 (not on dialysis) and 13% were on HD. Of the 52 patients included, 46 reached 6 months of follow-up, 2 died, 2 underwent a kidney transplant and 2 were transferred to another center. The initial dose of Patiromer was in all cases 8.4 g administered orally in a single dose. Only one patient required doubling the dose because the therapeutic objectives were not achieved. Taking Patiromer was associated with a decrease in the levels of serum potassium of 27% (5.9 vs 4.6 mEq/L; P<0.001), a decrease that was more pronounced in the first month of treatment. There were no changes in the concentration of serum calcium and magnesium. We did find a decrease of 18% in serum phosphorus (5.1 vs 4.2 mg/dl; P 0.022), with no changes in diet or phosphate binders. Patiromer was well tolerated and only 2 patients reported mild constipation; none discontinued the medication due to adverse effects.

Conclusion: Patiromer is effective and safe in reducing serum potassium concentrations. Due to its calcium content, it is possible that it favors the reduction in phosphoremia due to a decrease in the intestinal absorption of phosphorus. The use of this drug can help us control potassium levels in patients with CKD, properly titrate the use of ISRAAs, and even reduce the number of HD sessions or dialysis emergencies in some patients.

THE NUTRITIONAL AND NEPHROLOGICAL IMPACT OF A LOW-NORMAL PROTEIN HIGH CALORIE DIET ON THE ONCOLOGICAL SOLITARY KIDNEY: TIME FOR A NEW PERSPECTIVE?
Francesco Trevisiani1, Matteo Paccagnella2, Francesco Fiorio3, Fabiana Laurenti1, Riccardo Vago1, Federico Di Marco1, Matteo Floris4, Umberto Capitanio1, Michele Ghidini5, Andrea Salonia1, Francesco Montorsi1 and Arianna Bettiga4
1IRCCS San Raffaele Scientific Institute, Department of Urology and Division of Experimental Oncology, Milan, Italy, 2Carle Hospital, Laboratory of Oncology Translation, Cuneo, Italy, 3University of Aquila, Department of Clinical Medicine, Public Health, Science of ambiental and life (MeSVA), Aquila, Italy, 4San Michele Hospital, ARNAS G. Brotzu, Department of Medical Science and Public Health, Cagliari, Italy and 5Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Medical Oncology Unit, Milan, Italy

Background and Aims: Nutritional therapy (NT) based on controlled protein intake represents a cornerstone in the management of chronic kidney disease (CKD). However the international guidelines do not precisely define an adequate protein intake for nephrological patients affected by cancer, the onco-nephrological ones. Among them, there is a precise asset where a personalized nutritional strategy can make the difference; the oncological patients who...
Method: A consecutive cohort of 44 pts was enrolled in the Urological Department at San Raffaele Scientific Institute between 2018-2021. Inclusion criteria were: Age (>18 years old), eGFR (<60 ml/min/1.73 m²), Malnutritional Screening Tool (MST<2), Solitary kidney for radical nephrectomy for renal cancer, informed consent (signed). Each patient underwent an initial nephrological and nutritional evaluation and was subsequently subjected to a conventional CKD LNPHC diet integrated with aprotic foods (0.7-1 g/kg/die: calories: 30-35 kcal per kg body weight/die) for a period of 6 months (+/- 2 moths). The diet was based on the estimated Glomerular Filtration Rate (CKD-EPI 2021 Creatinin formula), comorbidities and nutritional status. MST, Body Mass Index (BMI), Phase Angle (PA), Fat Mass percentage (FM%), Fat-Free Mass Index (FFMI), body cell mass index (BCM1), extracellular/intracellular water ratio (ECW/ICW), waist/hip circumference ratio (WHC), lab test exams and clinical variables were examined at baseline and after 6 months. Statistical analysis: Kruskal-Wallis rank sum test; Data analysis: R programming language and RStudio integrated development environment.

Results: Descriptive analysis is showed in Table 1. Our results clearly highlighted that LNPHC was able to generate a significant improvement in all the investigated nutritional parameters (Table 2 and 3) avoiding malnutrition or catabolism. Moreover, regarding the nephrological asset, LNPHC was responsible for a significant decrease of urea, the most important parameter influencing general status. The non-significant increase of serum creatinine and therefore decrease of eGFR was related to the augmented muscle mass (Table 4).

Conclusion: LNPHC represents a new important therapeutic strategy to apply in the onco-nephrological patients with solitary kidney due to renal cancer.

ASSOCIATION OF PLANT PROTEIN INTAKE AND RISK OF INCIDENT CHRONIC KIDNEY DISEASE: THE UK BIOBANK STUDY

Ga Young Heo 1, Hee Byung Koh 1, Hye Jeong Kim 1, Kyung Won Kim 1, Chan-Young Jung 1, Hyung Woo Kim 1, Jung Tak Park 1, Tae Ik Chang 1, Tae Hyun Yoo 1, Shin-Wook Kang 1 and Seung Hyeok Han 1

1Yonsei University College of Medicine, Seoul, Rep. of South Korea and 2NHIS Ilsan Hospital, Department of Internal Medicine, Goyang-si, Rep. of South Korea

Background and Aims: Dietary intake from various protein sources can affect health differently. However, the association between plant protein intake and incident chronic kidney disease (CKD) is uncertain.

Method: Using the UK Biobank prospective cohort, we included 117,809 participants who completed more than one dietary questionnaire and had an estimated glomerular filtration rate (eGFR) ≥60 ml/min/1.73 m², urinary albumin-to-creatinine ratio (UACR) <30 mg/g, and no prior history of CKD. The main predictor was the daily plant protein intake, assessed with a web-based 24-hour recall questionnaire. The primary outcome was incident CKD, based on the International Classification of Diseases, 10th Revision (ICD-10) or Office of Population Censuses and Surveys Classification of Interventions and Procedures, version 4 (OPCS-4) codes. We additionally analyzed this association in 37,955 participants with primary care-linked data for eGFR and UACR. We used strictly defined CKD based on ICD-10 and OPCS-4 codes or two consecutive measures of eGFR <60 ml/min/1.73 m² or UACR >30 mg/g.

Results: During the median follow-up of 9.9 years, incident CKD occurred in 3745 (3.2%) participants (incidence rate, 3.2 per 1,000 person-years). In a multivariable cause-specific model, the adjusted hazard ratios (aHRs; 95% confidence intervals [CIs]) for the second, third, and highest quartiles were 0.91 (0.83-0.99), 0.79 (0.71-0.87), and 0.75 (0.64-0.85), respectively, compared with the lowest quartile. In a continuous model, the aHR (95% CIs) per 0.1 g/kg/day increase in plant protein intake was 0.91 (0.88-0.94). This beneficial association was also consistent in the secondary analysis with strictly defined CKD and various sensitivity analyses.

Conclusion: This large prospective cohort study showed that increased dietary plant protein intake was associated with a lower risk of CKD.

Background and Aims: Chronic kidney disease (CKD) is often underrecognised until later stages when most of the kidney function is lost and the therapeutic window for disease-modifying therapy is narrow [1]. We previously developed a lab-based risk prediction model to accurately predict CKD progression in adults at all stages of CKD [2]. Here, we describe a validation of our model in the clinical trial population of FIDELITY, a prespecified post hoc analysis of the phase III FIDELIO-DKD (NCT02545049) and FIGARO-DKD (NCT02545409) trials for the nonsteroidal mineralocorticoid receptor antagonist finerenone [3].

Method: We performed a post hoc analysis of all participants from the FIDELITY database, irrespective of estimated glomerular filtration rate (eGFR) or albuminuria stage. Baseline values for the underlying laboratory tests required for the model, Klinrisk, were extracted from the complete blood count, comprehensive metabolic panel and urine albumin-to-creatinine ratio (UACR). The predicted outcome was a ≥40% decline in eGFR or kidney failure. We calculated discrimination ability of the model and calibration using area under the curve (AUC), Brier scores and calibration plots in the overall population, and stratified by treatment assignment. Sensitivity analyses examined the accuracy of the models in predicting CKD failure. We calculated discrimination ability of the model and calibration (UACR). The predicted outcome was a ≥57% decline in eGFR, as well as the change in risk score over time. Kidney Disease: Improving Global Outcomes (KDIGO) heat map categories were used as the reference standard.

Results: We included 13,026 participants with a mean age of 64.8 ± 9.5 years, mean eGFR of 57.6 ± 21.7 ml/min/1.73 m², and median UACR of 58.2 mg/mmol (interquartile range 22.4–129.6). At time horizons of 2 and 4 years,
894 and 1795 patients experienced a primary outcome event, respectively. The Klinrisk risk model accurately predicted progression in all four randomized groups (AUC of 0.81 [95% CI: 0.76–0.85] at 3 years), which is characterized by poor renal outcomes and mortality in patients with DKD. However, an effective, well-tolerated treatment of progressive renal disease driven by inflammation has remained elusive.

Inhibition of IL-33 may provide a novel opportunity to improve glomerular endothelial health as indicated by decreased cellular inflammation and reduced release of pro-inflammatory cytokines such as IL-1β, IL-6, IL-8, TNFR-1, and CCL2.

**Conclusion:** Taken together, inhibition of IL-33 may be beneficial in patients with DKD on standard of care, who have elevated biomarkers of inflammation such as TNFR-1 and/or CCL2. This hypothesis is currently being tested in the FRONTIER-1 phase 2b clinical study. To identify the patients most likely to benefit from immunomodulatory treatment with tozorakimab, the study will consist of a retrospective analysis of albuminuria and other biomarkers. The primary analysis of the study is planned for the second half of 2023.

**Background and Aims:** Several biomarkers of inflammation have been correlated with poor renal outcomes and mortality in DKD. However, an effective, well-tolerated treatment of progressive renal disease driven by inflammation has remained elusive. Inhibition of IL-33 may provide a novel opportunity to address this unmet medical need in high-risk patients. Here, we: 1) show that tozorakimab, a high-affinity IL-33-neutralizing mAb, promotes glomerular health in inflammation; 2) describe the clinical study to test tozorakimab in patients with DKD; and 3) present participant baseline characteristics, safety and efficacy, and biomarker response to independent reference cohorts (N = 775). The inflammatory state of participants at baseline was assessed in preclinical models of DKD and demonstrated with improved glomerular endothelial health as indicated by decreased cellular inflammation and reduced release of pro-inflammatory cytokines such as IL-1β, IL-6, IL-8, TNFR-1, and CCL2.

**Method:** FRONTIER-1 (NCT04170543) is a phase 2b, randomized, double-blind, placebo-controlled, multicenter study designed to evaluate the efficacy, safety, pharmacokinetics (PK), and immunogenicity of tozorakimab in patients with DKD; defined as T2DM with an eGFR of 25-75 mL/min/1.73 m² and a UACR in the range of 100-3000 mg/g. All participants are expected to receive an ACEI/ARB for > 6 weeks before the treatment period. Approximately 556 patients from multiple countries will be randomized to four dose levels of tozorakimab, or volume-matched placebo dosed subcutaneously every 28 days over a 4-week treatment period. All participants will receive 10 mg dapagliflozin Day 85-168. The primary objective of the study is to evaluate the safety and tolerability of tozorakimab and with and without SGLT2i, evaluate the effect of tozorakimab in combination with ACEI or ARB with and without SGLT2i on albuminuria, and describe the PK and immunogenicity of tozorakimab.

**Key exploratory objective is to assess baseline and treatment-response for urine albumin and circulating biomarkers of inflammation, including hsCRP, IL-33/sIL1RL1, CCL2, and TNFR-1/2. Biomarker response was, furthermore, evaluated in pre-clinical models of DKD, and respective distributions and risk were assessed in four independent DKD cohorts (N > 200).**

**Results:** Transcriptomic profiling of kidney biopsies from patients with DKD indicated a significant glomerular up-regulation of IL-33. Inhibition of IL-33 signalling reduced glomerular damage and albuminuria in the urine/macromolecules-dib/db model associated with improved glomerular endothelial health as indicated by decreased cellular inflammation and reduced release of pro-inflammatory cytokines such as IL-1β, IL-6, IL-8, TNFR-1, and CCL2. Hence, FRONTIER-1 was started in 2019. So far, all trial groups are well-balanced and in line with our expectations for this patient population (N = 574). At baseline, > 95% were receiving ACEI/ARBs and approximately 25% were receiving SGLT2i. The mean eGFR was 47.8 mL/min/1.73 m² (± 14.7) and mean UACR was 765 mg/g (± 775). The inflammatory state of participants at baseline was assessed in urine and urine by hsCRP, TNFR-1 and CCL2 and showed that 6-week treatment of dapagliflozin did not alter these biomarkers significantly.

**Conclusion:** Taken together, inhibition of IL-33 may be beneficial in patients with DKD on standard of care, who have elevated biomarkers of inflammation such as TNFR-1 and/or CCL2. This hypothesis is currently being tested in the FRONTIER-1 phase 2b clinical study. To identify the patients most likely to benefit from immunomodulatory treatment with tozorakimab, the study will consist of a retrospective analysis of albuminuria and other biomarkers. The primary analysis of the study is planned for the second half of 2023.

**Background and Aims:** The 1-year, randomized, placebo-controlled phase (Phase A) of a 2-part trial of tolvaptan in children/adolescents with ADPKD (NCT02964273) demonstrated acceptable safety/tolerability and evidence of vasopressin type 2 receptor antagonism. A 2-year, open-label extension (Phase B) evaluated longer-term outcomes.

**Method:** By entry criteria, participants at Phase A baseline were aged 4-17 years, had a diagnosis of ADPKD, estimated glomerular filtration rate (eGFR) ≥60 mL/min/1.73 m², and body weight ≥20 kg. Participants in the tolvaptan and placebo arms who completed Phase A could enter Phase B to receive open-label tolvaptan for 24 months. Dosing was based on body weight and tolerability, with tolvaptan re-initiated in participants who had received tolvaptan in Phase A to preserve the blind until Phase A completion. Phase B post-baseline study visits occurred at Week 1, Months 1, 6, 12, 18, and 24. Laboratory safety assessments were performed monthly, with more frequent liver function testing if any indication of liver injury was detected. eGFR and height-adjusted total kidney volume (htTKV) were calculated using the mixed model repeated measures method with model terms treatment, visit, treatment by visit, and baseline by visit interaction. To exclude the acute hemodynamic effect of tolvaptan, change in eGFR after week 1 of treatment is shown.
Results: Of 83 Phase A completers, 81 (42 prior tolvaptan, 39 prior placebo) enrolled in Phase B; 33/42 (78.6%) prior tolvaptan and 30/39 (76.9%) prior placebo participants completed the Phase B Month 24 visit on tolvaptan. The average daily tolvaptan dose was 41.1 mg in the prior tolvaptan group (mean [SD] age 14.3 [3.2] years) and 38.0 mg in the prior placebo group (13.9 [2.9] years). Adherence determined by returned drug was ≥90% in 32/42 (76.2%) participants in the prior tolvaptan group and 28/39 (71.8%) in prior placebo. In Phase A, eGFR increased in the tolvaptan group and decreased in the placebo group (significant difference at Month 6), with significant benefit maintained at most assessment visits in Phase B for the prior tolvaptan group compared to the prior placebo group (Figure 1A). Growth in htTKV on MRI (participants ages 12-17) was slowest during the first year of tolvaptan treatment, as shown by the slope of htTKV during Phase A in the tolvaptan group and during year 1 of Phase B in the prior placebo group (Figure 1B), with growth rates higher thereafter, although sample sizes did not permit meaningful statistical comparison of the changes. Scores on pediatric health-related quality of life assessment instruments, including the PedsQL Generic Core Scale and the PedsQL Multidimensional Fatigue Scale, remained stable during both phases and indicated low health-related quality of life burden and high functioning. The most common adverse events in Phase B (>15% participants overall: prior tolvaptan and prior placebo, respectively) were headache (36%, 44%), nasopharyngitis (26%, 33%), rhinitis (26%, 10%), oropharyngeal pain (21%, 18%), pyrexia (19%, 18%), cough (17%, 21%), abdominal pain (12%, 31%), polyuria (5%, 33%). Eleven participants overall experienced elevated liver enzymes by investigator report (no prespecified enzyme levels were required to report an event): 6 recovered without intervention, treatment was interrupted in 4, and in 1 tolvaptan was withdrawn for a reason other than the hepatic event. No participant met predefined laboratory criteria for serious drug-induced liver injury in either phase. There were no notable differences between prior tolvaptan and prior placebo in Tanner staging progression or change from baseline in growth percentile in Phase B.

Conclusion: Consistent with adult data in the TEMPO 3:4 and TEMPO 4:4 trials, children and adolescents who received tolvaptan during a randomized trial exhibited eGFR benefit relative to those who received placebo, a difference that was preserved during a 2-year, open-label extension. As in adults, kidney volume growth was higher after 1 year of treatment. Tolvaptan exhibited...
acceptable safety and good tolerability, with few discontinuations and a low quality of life burden.

THE EFFECT OF DAPRODUSTAT ON INTRAVENOUS IRON USE IN PATIENTS WITH CKD-RELATED ANAEMIA ON DIALYSIS IN THE ASCEND TRIALS

Pablo Pergola1, Tomas Ganz2, Elizabeta Nemeth3, Christine K. Bailey4, Purav Bhatt5, Amy Meadowcroft5, Jennifer B Shannon5 and Lucia Del Vecchio6

1Renal Associates, PA, San Antonio, TX, United States of America, 2Center for Iron Disorders, David Geffen School of Medicine, UCLA, Los Angeles, CA, United States of America, 3Center for Iron Disorders, David Geffen School of Medicine, UCLA, Los Angeles, CA, United States of America, 4GSK, Collegeville, PA, United States of America, 5GSK, Durham, NC, United States of America and 6Department of Nephrology and Dialysis, Sant’Anna Hospital, ASST Lariana, Como, Italy

Background and Aims: Intravenous (IV) iron is frequently needed in patients with chronic kidney disease (CKD) to ensure sufficient iron is available for erythropoiesis. However, high doses of IV iron and erythropoiesis stimulating agents (ESAs) may be associated with risks in these patients [1]. The hypoxia-inducible factor-prolyl hydroxylase domain inhibitor daprodustat was non-inferior to comparator ESAs for the primary endpoint of efficacy (change-in-Hb) in the multicentre, randomised, Phase 3 trials ASCEND-D (NCT02879305) [2] and ASCEND-TD (NCT03400033) [3], also for the safety (major adverse cardiovascular [CV] events) coprimary endpoint in ASCEND-D [2]. This analysis of ASCEND-D and ASCEND-TD compared daprodustat to active ESAs on measures of IV iron use in dialysis patients.

Method: Daprodustat and ESAs were compared in patients with CKD anaemia on haemodialysis/peritoneal dialysis (ASCEND-D); haemodialysis (ASCEND-TD). ASCEND-D (N = 2,964) was an open-label CV outcome study using daprodustat once daily, while ASCEND-TD (N = 407) was a double-blind, double-dummy, 52-week study investigating three times weekly dosing of daprodustat. In both studies, following randomisation, treatment dosage was titrated to achieve the Hb target range of 10.0–11.0 g/dL, with Hb efficacy assessed during the evaluation period (EP), Weeks 28–52. All patients were required to have ferritin > 100 ng/mL and/or transferrin saturation (TSAT) > 20% at baseline for inclusion. Throughout the study, iron therapy was administered if ferritin was ≤ 100 ng/mL and/or TSAT was ≤ 20% so patients would remain iron replete throughout the study. Investigators chose the route and dose of iron administration per patient iron status and clinical judgement. Stopping threshold criteria of 800 ng/mL ferritin + TSAT > 20%, or TSAT > 40% were implemented to avoid iron overload, but investigators could stop administration of iron at levels below the protocol-defined stopping thresholds. The average monthly IV iron dose (mg/patient to Week 52 was a principal secondary endpoint, while the proportion of patients who met iron management criteria with a decrease in monthly IV iron dose during the EP relative to baseline and until patients received first transfusion were exploratory endpoints. The baseline monthly IV iron dose was defined as the average monthly IV iron (mg) over the 16 weeks prior to randomisation for ASCEND-D and over the 12 weeks prior to randomisation for ASCEND-TD.

Results: The proportion of patients with IV iron use at baseline was similar in patients with chronic kidney disease (CKD) to ensure sufficient iron is available for erythropoiesis. However, high doses of IV iron and erythropoiesis stimulating agents (ESAs) may be associated with risks in these patients [1]. The hypoxia-inducible factor-prolyl hydroxylase domain inhibitor daprodustat was non-inferior to comparator ESAs for the primary endpoint of efficacy (change-in-Hb) in the multicentre, randomised, Phase 3 trials ASCEND-D (NCT02879305) [2] and ASCEND-TD (NCT03400033) [3], also for the safety (major adverse cardiovascular [CV] events) coprimary endpoint in ASCEND-D [2]. This analysis of ASCEND-D and ASCEND-TD compared daprodustat to active ESAs on measures of IV iron use in dialysis patients.

Method: Daprodustat and ESAs were compared in patients with CKD anaemia on haemodialysis/peritoneal dialysis (ASCEND-D); haemodialysis (ASCEND-TD). ASCEND-D (N = 2,964) was an open-label CV outcome study using daprodustat once daily, while ASCEND-TD (N = 407) was a double-blind, double-dummy, 52-week study investigating three times weekly dosing of daprodustat. In both studies, following randomisation, treatment dosage was titrated to achieve the Hb target range of 10.0–11.0 g/dL, with Hb efficacy assessed during the evaluation period (EP), Weeks 28–52. All patients were required to have ferritin > 100 ng/mL and/or transferrin saturation (TSAT) > 20% at baseline for inclusion. Throughout the study, iron therapy was administered if ferritin was ≤ 100 ng/mL and/or TSAT was ≤ 20% so patients would remain iron replete throughout the study. Investigators chose the route and dose of iron administration per patient iron status and clinical judgement. Stopping threshold criteria of 800 ng/mL ferritin + TSAT > 20%, or TSAT > 40% were implemented to avoid iron overload, but investigators could stop administration of iron at levels below the protocol-defined stopping thresholds. The average monthly IV iron dose (mg/patient to Week 52 was a principal secondary endpoint, while the proportion of patients who met iron management criteria with a decrease in monthly IV iron dose during the EP relative to baseline and until patients received first transfusion were exploratory endpoints. The baseline monthly IV iron dose was defined as the average monthly IV iron (mg) over the 16 weeks prior to randomisation for ASCEND-D and over the 12 weeks prior to randomisation for ASCEND-TD.

Results: The proportion of patients with IV iron use at baseline was similar in both treatment arms for ASCEND-D (64%) but lower in the daprodustat group in ASCEND-TD (63% vs 72% in the ESA group). In both studies the proportion of patients receiving IV iron during the EP decreased (ASCEND-
Daprodustat 49%, ESA 52%; ASCEND-TD: daprodustat 38%, ESA 40%). The average monthly IV iron dose during the EP and from Day 1 to Week 52 was lower than monthly IV iron dose at baseline, however daprodustat was not associated with a statistically significant reduction in monthly IV iron per patient to Week 52 vs ESA comparator (Table 1). After a period of IV iron requirements decreasing, based on adjustment to protocol-specified levels, IV iron dosage remained relatively stable for daprodustat and ESA (Figure 1). In ASCEND-D, 3 of 23 pre-defined subgroups (prior ESA dose group, ESA hyporesponder group, history of myocardial infarction) showed a trend towards heterogeneity (interaction p-value < 0.1), with differences in monthly IV iron use in the prior ESA dose group receiving ≥ 7000 U/week (-21.2 mg/month) and in the ESA hyporesponder group (-31.7 mg/month) in favour of daprodustat. Fewer patients met the criteria for stopping iron while on daprodustat vs ESA, whereas the converse was observed in ASCEND-TD (Table 1).

Conclusion: In ASCEND-D and -TD, no clinically or statistically significant reduction in monthly IV iron use was seen with daprodustat vs ESA comparators, although there was a numerical decrease in the proportion of patients receiving IV iron during the EP for the daprodustat group in both studies.

ASSESSING ACCURACY OF POINT-OF-CARE CREATININE AND POTASSIUM TESTING IN A MULTI-ETHNIC SOUTH LONDON POPULATION

Ciaran Twomey Brenner1, Kate Bramham1,2,3, Emmanuel Mangahis1, Vera Mireku1, Sheyenne Oliveros1, Rachelle Villarhermosa1 and Rouvick Gama*

1King’s College Hospital NHS Foundation Trust, King’s Kidney Care, London, United Kingdom, 2King’s College London, Centre for Nephrology, Urology and Transplantation, London, United Kingdom and 3King’s College London, Department of Women and Children’s Health, London, United Kingdom

Background and Aims: Point-of-care (POC) testing allows rapid analysis of blood samples without delay of laboratory testing. For patients with chronic kidney disease (CKD), this allows for instant identification of changes in kidney function, such as acute kidney injury or hyperkalaemia, and assists in timely decision-making in outpatient or community settings (e.g. commencing or up-titrating medications dependent on renal function). It also provides an opportunity for early recognition of CKD in high-risk populations by providing screening in more convenient and trusted settings. To achieve these aims, it is essential to confirm that POC systems can produce accurate results in real world settings with diverse patient populations. This pilot validation study assessed accuracy of the Siemens Epoc Blood Analysis System venous creatinine and potassium compared with laboratory assays in a diverse UK renal patient population.

Method: Venous blood samples from 57 patients, aged ≥ 18 years old and receiving care at a London teaching hospital, were analysed using the Siemens Epoc Blood Analysis System. POC-Creatinine (POC-Cr) and Potassium (POC-K) measurements were compared with laboratory (IDMS-traceable Siemens enzymatic and Roche) assays. Demographics (age, ethnicity and sex) were recorded for each patient. Passing-Bablock regression analysis were used to compare the results using both methods. Comparison between testing
methods was assessed using a Bland-Altman plot. Limits of agreement were compared with CLIA criteria for acceptable performance for creatinine and potassium.

**Results:** The mean age was 55.6 ± 15.3 years old and 64.9% were male (n = 37). The majority of patients were of White (N = 23; 40.4%), Black (N = 21; 36.8%) or South Asian (N = 9; 15.8%) ethnicity respectively. Median POC-Cr was 216 μmol/L (interquartile range (IQR) 111, 396 μmol/L) versus median venous creatinine 212 μmol/L (IQR 114, 380 μmol/L). The median bias for creatinine was +1.0 (IQR -3.0, +8.0). Limits of agreement on Bland-Altman plot were +36.5 μmol/L and –34.4 μmol/L (Figure 1). Overall, there remained a strong positive correlation between POC-Cr and IDMS-traceable enzymatic creatinine assays (R = 0.997; P < 0.0001) (Figure 2). Median POC-K was 4.3 mmol/L, IQR 4.0, 4.8 mmol/L versus median venous potassium 5.0, IQR 4.3, 5.3 mmol/L. The median bias for potassium was +0.4 (IQR +0.2, +0.5). Limits of agreement on Bland-Altman plot were +0.16 mmol/L and –0.91 mmol/L (Figure 3). A strong positive correlation between POC-K and laboratory potassium assays was also confirmed (R = 0.937; P < 0.0001) (Figure 4).

**Conclusion:** There was strong positive correlation between POC and laboratory analysis of venous creatinine, comparable to product literature (R = 0.997 vs 0.998). Limits of agreement were outside the CLIA criteria for acceptable performance (+/- 27 μmol/L). POC and laboratory potassium levels were also strongly correlated and comparable to product literature (R = 0.937 vs 0.997). Limits of agreement were outside the CLIA criteria for acceptable performance (+/- 0.5 mmol/L). This discrepancy is likely due to haemolysis in some blood samples and small sample size. Overall, this pilot study demonstrated a strong correlation between POC and laboratory testing. Larger scale evaluation is still required in a multi-ethnic population, prior to assessing feasibility in community-led protocolized pathways.
Background and Aims: Well-based therapies may repair diseased nephrons and stabilize and enhance kidney function to delay the onset of end-stage kidney disease and improve co-morbidities. REACT™ is a novel product formed of cryopreserved autologous homologous selected renal cells, undergoing phase III clinical trials for diabetic kidney disease (DKD). We describe an open label phase II study to evaluate how patients respond to
REACT™ injections in both kidneys and a redosing trigger, as being evaluated in a Phase III blinded data trial (proact 1 & 2 trials).

Method: REGEN 007 is a multi-center Phase II, open label 1:1 randomized controlled trial enrolling up to 50 patients ages 30-80 years with DKD, who have an eGFR of 20 - 50 mL/min/1.73 m². Each patient undergoes a percutaneous kidney biopsy and ex vivo culture expansion of their selected renal cells. Patients are then randomized to an arm where they receive two REACT™ injections, one in each kidney, three months apart if they meet inclusion criteria, or an arm with an initial single REACT™ dose in one kidney and a 2nd REACT™ dose in the contralateral kidney > 90 days apart, based on a sustained eGFR decline of ≥ 20%, and/or an increase in the urine albumin to creatinine ratio (UACR) from baseline of ≥ 30% and ≥ 30 mg/g. CT-guided bilateral percutaneous renal cortex injections of REACT™ are performed under conscious sedation. Trial design, inclusion and exclusion criteria can be found at the National Clinical Trial Registry (Trial number 05018416).

Results: Thirty-one of the targeted 30 participants have been enrolled with the following characteristics at screening: 64.0% males, 97.0% Non-Hispanic/Latino. Mean age 62.9 years, serum creatinine (sCr) 2.0 mg/dL ±0.50, Cystatin C 2.0 mg/L ±0.40, eGFR (sCr + Cystatin C) 31.2 mL/min/1.72m² ±7.88, HgbA1C 7.4% ± 1.14, Hgb 12.9 g/dL ± 1.78, K⁺ 4.6 mEq/L ± 0.44, Bicarbonate 20.3 mEq/L ± 3.0, and a median UACR 662 mg/g [SD 705.8]. Percent baseline medications are: Angiotensin Converting Enzyme inhibitors 25.8, Angiotensin Converting Enzyme receptor Blockers 48.4, beta blockers 64.5, diuretics 64.4, glucose lowering agents 100, Sodium glucose Cotransporter 2 inhibitors 32.3, and platelet inhibitors 67.7. Efficacy endpoint is an eGFR slope improvement from first injection to 18 months after last injection. REACT™ and procedure related serious adverse events are expected to be commensurate with ongoing trials and standard of care.

Conclusion: REACT™ cell-based therapy has the potential to effect nephron structure and function by stabilizing or improving DKD progression and its comorbidities. Current phase II and III trials are underway to determine structure and function by stabilizing or improving DKD progression and its comorbidities. Current phase II and III trials are underway to determine.

KIDNEY FUNCTION ESTIMATORS FOR DRUG DOSE ADJUSTMENT OF DIRECT ORAL ANTICOAGULANTS IN OLDER ADULTS WITH ATRIAL FIBRILLATION

Cédric Villain1,2, Natalie Ebert1, Tim Bothe1, Muhammad Barghouth1, Anne-Katrin Fietz3,4, Antonios Douros4,5, Nina Mielke1 and Elke Schaeffner1

1Charité – Universitätsmedizin Berlin, Institute for Public Health, Berlin, Germany, 2Normandie Univ UNICAEN, INSERM U1073 COMETE, Department of Geriatrics, CHU de Caen, Caen, France, 3Charité - Universitätsmedizin Berlin, Institute of Biometry and Clinical Epidemiology, Berlin, Germany, 4McGill University, Departments of Medicine and of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada and 5Charité - Universitätsmedizin Berlin, Institute of Clinical Pharmacology and Toxicology, Berlin, Germany

Background and Aims: The Food and Drug Administration and the European Medicines Agency (EMA) recommend using the Cockcroft-Gault equation (CG) for drug dose adjustment of direct oral anticoagulant drugs (DOACs) in non-valvular atrial fibrillation (NVAF), whereas Cardiology guidelines recommend using estimated glomerular filtration rate (eGFR). This issue is of great importance in older adults, which are more prone to adverse drug reactions and have higher prevalence of atrial fibrillation as compared to younger adults, and in whom CG has worse diagnostic performance than most eGFR equations. We aimed to assess if prognosis was similar according to drug dose status using different kidney function estimators based on creatinine and/or cystatin C in older adults with NVAF.

Method: We used data from the Berlin Initiative Study (BIS): a population-based prospective cohort study initiated in 2009, with five biennial study visits. Participants with a history of NVAF (based on ICD-10 codes) and a dispensed prescription of DOAC four months prior to baseline or a follow-up visit according to claims data were included. Drug dose status was defined according to the EMA guidelines. CG and/ or cystatin C (xg) and/or cystatin C-based (CGstation) and deindexed (in ml/min) creatinine and/or cystatin C-based (BIS 2 (creatinine- and cystatin C-based) equations were included. Associations between dosing status and mortality, stroke or systemic embolism, and bleeding events were assessed using marginal structural Cox models with time-advancing variables and taking account of various confounders. Subgroup analyses were performed in rivaroxaban and apixaban users, but not in dabigatran and edoxaban users because of too small sample sizes.

Results: Two hundred forty four patients treated with DOACs were included in this analysis (median age 87 years, median eGFR (EPA) 56 ml/min/1.73m², median follow-up length 40 months for the mortality analysis). Of those, 99 (44%) were taking rivaroxaban, 86 (38%) apixaban, 21 (9%) edoxaban, and 18 (8%) dabigatran. Using CG, 154 (69%) had appropriate DOAC dose at baseline, 52 (23%) were underdosed, and 18 (8%) were overdosed. Discrepancies were found by comparing dosing status according to CG and eGFR equations (Figure 1). During the follow-up period, 109 (14.9/100 person-years) participants died, 25 (3.6/100 person-years) experienced a stroke or systemic embolism, and 60 (9/100 person-years) experienced a bleeding event. Drug dose status was not significantly associated with mortality and the occurrence of stroke or systemic embolism, whatever equation was used. Underdose status was associated with a significantly lower risk of bleeding events with all the equations but overdose status was not associated with a higher risk of bleeding events (Figure 2). In subgroup analyses, drug dose status was not associated with mortality and bleeding event in apixaban users, whatever equation was used. In rivaroxaban users, underdose status was associated with a significant higher risk of death by using CG, eGFR (EPA), and BIS 2, and a lower risk of bleeding event by using eGFR (EPA). Conclusion: In this population of very old adults with NVAF, drug dose status of DOAC was not associated with mortality or the occurrence of stroke or systemic embolism for any of the studied equations. However, underdose status was associated with bleeding events occurrence regardless of the equation used.

Figure 1: Dosing status of direct oral anticoagulants at baseline according to kidney function estimators in older adults with non-valvular atrial fibrillation (percentages).
These associations differed according to the used drug, but this should be interpreted with caution due to small sample sizes. Our results do not allow us to provide any guidance which equation to use in this context. A study including a larger group of patients with discrepancy in dose status according to the used equations would be of great interest.

LESSONS LEARNT FROM VIRTUAL RECRUITMENT TO A MULTICENTRE RANDOMISED CONTROLLED TRIAL EVALUATING A DIGITAL HEALTH INTERVENTION FOR CKD
Gurneet K Sohanso1,2, Noemi Vadaszy1,2, Thomas Wilkinson1,3, Courtney J Lightfoot1,2 and Alice Smith1,2
1Leicester Kidney Lifestyle Team, Department of Population Health Sciences, University of Leicester, Leicester, United Kingdom, 2Leicester NIHR Biomedical Research Centre, Leicester, United Kingdom and 3NIHR Applied Research Collaboration East Midlands, Leicester Diabetes Centre, Leicester, United Kingdom

Background and Aims: The post-COVID era has seen an escalation in the use of digital health interventions (DHIs), which have the potential to provide a widely accessible and cost-efficient approach to aspects of health service delivery such as patient education. Robust effectiveness evaluation is essential for all novel interventions to enable appropriate and sustained implementation. We have developed an education/self-management DHI named “My Kidneys & Me” (MK&M) for chronic kidney disease (CKD). A multi-centre randomised controlled trial (RCT) (SMILE-K) with virtual study processes allowing for minimal face-to-face participant contact was conducted to pragmatically deliver and evaluate MK&M. Here we report the recruitment metrics of SMILE-K to inform and improve future design of virtual trials and delivery of DHIs.

Method: The SMILE-K virtual study design involved outcome measures collected via an online survey, and 2:1 randomisation to intervention or control group. The recruitment process is summarised in Figure 1. Briefly, eligible adult CKD patients were identified by their clinical teams and given or sent a study invitation. If interested, patients emailed the study team, who then sent sequential emailed links to: 1) the information sheet and consent form; 2) the baseline outcome measure survey; and 3) (if randomised to intervention), MK&M.

Results: 26 hospital sites in England recruited to SMILE-K between May 2021 and December 2022. 6693 invitations were issued: 4942 (74%) by mail, 883 (13%) in-person, 616 (9%) by mail following remote consultation; and 252 (4%) by email. 13% (875/6693 invited) invitees expressed interest, of which 60% (533/875) consented. Of the 533 consented, 5% (265/4942) had been invited via mail, 14% (120/883) in-person, 17% (103/616) via mail following remote appointment, and 2% (5/252) via email. Of those consented, 80% (424/533) completed the baseline survey and were subsequently randomised. The mean age of recruited participants was 74 years (±9.0; range: 20-88) and 94% were White British. The median time from expression of interest to consent was 1 day (IQR:0-5), and consent to randomisation was 6 days (IQR:2.5-11).

Conclusion: Our experience shows that a virtual strategy for DHI RCT recruitment provides the opportunity to reach a high number of eligible participants. However, only 13% of invited patients expressed interest, and just 7% were recruited into the study. Most invitations were sent via mail with no prior approach or explanation. This method resulted in a markedly lower response rate than invitations issued after discussion with a healthcare professional, either remotely or in-person, underlining the importance of personal contact. Substantial attrition occurred at the consent stage, indicating that reading the information sheet and completing the online consent form unassisted was a barrier. Despite the need for internet access and digital skills, there was a wide participant age range, including those in their 80s. However, we noted a disproportionate representation of White ethnicity. This highlights the need to embed specific strategies to engage minority ethnic communities and other disadvantaged groups in the design of DHIs and future virtual trials to maximise reach and access to their potential benefits.

PHASE II DOSE-SELECTION, RANDOMISED DOUBLE-BLIND TRIAL OF THE ASI, BI 690517, ALONE AND IN COMBINATION WITH EMPA IN PEOPLE WITH CKD

Katherine Tuttle1, Peter Rossing2,3, Lisa Cronin4, Sibylle Hauske5,6, Joanna Hussain7, Dick de Zeeuw8 and Hiddo Lambers Heerspink4

1Providence Inland Northwest Health, University of Washington, Spokane, United States of America, 2Steno Diabetes Center, Copenhagen, Herlev, Denmark, 3Copenhagen University, Copenhagen, Denmark, 4Boehringer Ingelheim USA, Ridgefield, United States of America, 5Boehringer Ingelheim, Geleen, The Netherlands, 6Medical Center Groningen, Groningen, Netherlands

Background and Aims: Elevated aldosterone levels are associated with chronic kidney disease (CKD) progression and adverse kidney and cardiovascular disease outcomes. Therapy with an angiotensin-converting enzyme inhibitor (ACEi) or angiotensin receptor blocker (ARB) improves clinical outcomes, yet elevated aldosterone levels often persist. BI 690517 is a first-in-class, selective aldosterone synthase inhibitor (ASI) that may reduce deleterious mineralocorticoid receptor-dependent and -independent actions of aldosterone. Co-administration of BI 690517 with a sodium–glucose cotransporter-2 inhibitor could mitigate the risk of hyperkalaemia. This study is investigating the efficacy and safety of three doses of BI 690517, alone and in combination with empagliflozin (EMPA), on top of an ACEi or ARB, for treatment of CKD with or without type 2 diabetes.

Method: A randomised, double-blind, placebo-controlled, parallel-dose Phase II trial (NCT05182840) in adults with or without type 2 diabetes who had an estimated glomerular filtration rate (eGFR) ≥30 and <90 mL/min/1.73 m², urine albumin:creatinine ratio (UACR) ≥200 and <5000 mg/g, and serum potassium ≤4.8 mmol/L on stable background therapy with an ACEi or ARB. After an 8-week run-in period to assigned background therapy (EMPA 10 mg or matched placebo randomised 1:1), participants were randomised 1:1:1:1 to BI 690517 (low, medium or high dose) or matched placebo for 14 weeks. Primary outcome was the change in UACR measured in a first morning void (UACR_{1MV}) from baseline to Week 14. Secondary outcomes were the proportion of participants with ≥15 and 30% decreases in UACR_{1MV}. Safety outcomes and changes in eGFR and serum potassium were also evaluated.

Results: Recruitment is complete, with 1719 participants from 168 sites in 29 countries screened. In total, 714 were randomised and entered the run-in period (last randomisation on 30 December 2022). The trial is currently ongoing; data on baseline characteristics will become available and shared.

Conclusion: This study will provide key data on the potential synergistic kidney-protective effects and safety of combination therapy with BI 690517 plus EMPA, as well as data on monotherapy, for CKD with or without type 2 diabetes. Findings will inform BI 690517 dose selection for further clinical trial development.

QUANTIFICATION OF URINE PROTEINS FOR DISCOVERY OF BIOMARKERS FOR KIDNEY INJURIES BY DIA-PROTEOMICS

Keiko Yamamoto1 and Tadashi Yamamoto2

1Niigata University, Biofluid Biomarker Center, Niigata, Japan and 2Niigata University, Biofluid Biomarker Center, Tokamachi, Japan

Background and Aims: Recent advances in proteomics have enabled to quantify proteins comprehensively. We aimed to establish a platform of urine quantitative proteomics for selection of the biomarkers and assessment of health conditions. Since plasma proteins of varying amounts of were present in urine especially from proteinuric patients, we subtracted the plasma protein contents from total urine proteomes after the quantitative proteomics for discovery of biomarkers for kidney injuries. On the other hand, urine proteins excreted from plasma may be indicators of pathophysiological conditions in the body, suggesting that the urine proteome profiles figure out health conditions and early discovery of any diseases in the future.

Method: More than 120,000 urine samples (∼10 ml each) have been collected from ∼15,000 patients with various diseases and healthy volunteers (HV) and stored in -20°C freezers. In this study, urine samples were selected from HV, diabetic patients (DM) with or without microalbuminuria and other CKD patients. Proteins were precipitated by a methanol/chloroform precipitation method from 1 ml urine. The protein fractions were digested with trypsin and the tryptic peptides were purified by C18 column chromatography. The tryptic peptides of 200 ng each were analyzed by LC-MS (tims-TOFPro, Bruker) by quantitative Data-independent acquisition (DIA) proteomics and proteins were quantified by the DIA method. Major top 30 plasma proteins were removed from the quantitative proteomics data and kidney- and other urinary tract organ-derived proteins were normalized to compare their proportions in urine.

Results: Approximately 2,500 proteins were quantified by the DIA analysis. In urine from HV, proportions of plasma proteins were small, however, in urine from DM patients with microalbuminuria or CKD patients, the plasma protein contents were increased, resulting in relative decreases of urine proportions of other proteins derived from the kidney or other urinary tract organs. By subtraction of the plasma proteins from total urine proteins, protein proportions were comparable to select candidates of biomarkers for kidney injuries. Comparison of total urine protein profiles between HV and DM elucidated their differences, which might indicate changes of pathophysiological conditions.

Conclusion: By recent quantitative proteomics urine proteins were quantified comprehensively, facilitating discovery of biomarkers for kidney injuries and also evaluation of health conditions in the body.

PULSE WAVE VELOCITY AND AMBULATORY BLOOD PRESSURE IN PATIENTS WITH RENAL HYPERFILTRATION

Nil Kodal1, Ilhan Kurultak2, Ferdi Karagoz2 and Sedat Üstündağ2

1Trakya University, Faculty of Medicine, Internal Medicine, Edirne, Turkey and 2Trakya University, Faculty of Medicine, Nephrology, Edirne, Turkey

Background and Aims: Recent studies have been implicated that abnormally increased glomerular filtration rate, defined as renal hyperfiltration, may be a risk factor for the development of renal damage and cardiovascular disease. Herein, we aimed to investigate the possible relationship between renal hyperfiltration (RHf) and pulse wave velocity, ambulatory blood pressure measurements and clinical parameters.

Method: All individuals included the study were between 18 and 65 years old. The eGFR (CKD-EPI) values of above 140 ml/min/1.73 m² were defined as RHf. Nineteen individuals in the renal hyperfiltration group and 20 in the control group were included. Blood and urine samples of the cases were examined. The individuals with diabetes, obesity, pregnancy, hypertension, cardiovascular disease, peripheral artery disease, cerebrovascular disease, chronic rheumatological disease, and thyroid dysfunction were excluded from the study. The parameters related arterial stiffness and ambulatory blood pressure measurements were obtained in all cases. The results were analyzed statistically.

Results: The two groups were similar in terms of gender, age, BMI and smoking. In RHf group, total cholesterol, 24-hour urine proteinuria and albuminuria, SBP, DBP, MAP and PP values were found higher than control group. Interestingly, the differences of “night time” measurements of all these hemodynamic parameters were more pronounced in RHf group. The trend of “non-dipper” pattern was to be higher in the hyperfiltration group. In arterial stiffness parameters the augmentation pressure (AP), central systolic pressure and pulse wave amplification (PPA) were found significantly different. Pearson’s correlation analysis revealed that AP, CSP, CBP was the positively; Pearson’s correlation analysis.

Conclusion: We found that augmentation pressure is the most important independent parameter correlated with RHf among arterial stiffness measurements. The vascular risk may be increased in this population.

Brozut, Cagliari, Italy, 6DKD Helios Klinik Wiesbaden, KfH and Kidney Center-Rheumatology, Wiesbaden, Germany, 7GSK, TBC, Switzerland, 8GSK, Durham, United States of America and 9University of Würzburg, Würzburg, Germany

Background and Aims: Daprodustat (GSK1278863) is a hypoxia-inducible factor prolyl hydroxylase inhibitor under investigation for the treatment of anaemia of chronic kidney disease. Phase 3 studies in dialysis (ASCEND-D) and non-dialysis (ASCEND-ND) patients demonstrated the non-inferiority of daprodustat vs recombinant human erythropoietin (rhEPO) control (in ASCEND-D) or darbepoetin alfa (ASCEND-ND) control in terms of the mean change in haemoglobin levels between Weeks 28 and 52 versus baseline and the first occurrence of a composite major adverse cardiovascular (CV) event (MACE) [1, 2]. Post-hoc analyses were conducted to evaluate prespecified CV endpoints for patients enrolled in these studies from participating countries in Europe (EU patients) versus elsewhere (non-EU patients).

Table 1: Laboratory, hemodynamic and arterial stiffness parameters found to be different statistically in both groups.

Pearson’s correlation analysis. p < 0.05 was considered significant.
Method: Post-hoc time to the first adjudicated MACE (death from any cause, non-fatal myocardial infarction or non-fatal stroke), time to the first adjudicated MACE or thromboembolic event (TEE; deep vein thrombosis, pulmonary embolism or vascular access thrombosis), and time to the first adjudicated MACE or hospitalisation for heart failure (HHF) were analysed for EU (enrolled from Austria, Belgium, Bulgaria, Czech Republic, Denmark, Estonia, France, Germany, Greece, Hungary, Italy, the Netherlands, Norway, Poland, Portugal, Romania, Spain, Sweden and the UK; not all countries participated in both studies) and non-EU (all other participating countries) patients. Hazard ratios (HRs) and associated 95% confidence intervals were calculated to evaluate the likelihood of CV events with daprodustat versus alternative therapy in both studies. HRs for EU and non-EU patients were compared for each endpoint in each study and p-values were calculated to assess the statistical significance of observed differences. Significance was defined at the 10% level (interaction p-value <0.1).

Results: ASCEND-D included 415 EU patients and 1072 non-EU patients randomised to daprodustat, and 440 EU and 1037 non-EU patients randomised to rhEPO. ASCEND-Nd included 410 EU patients and 1527 non-EU patients randomised to daprodustat, and 407 EU and 1037 non-EU patients randomised to rhEPO. No significant heterogeneity was observed between EU and non-EU patients in terms of the prespecified CV endpoints (p=0.1979). In ASCEND-D and ASCEND-Nd, the results for MACE, MACE+TEE and MACE+HHF for the EU subgroup were consistent with the non-EU subgroup (Table, as well as with the co-primary analysis [1, 2]. Efficacy and additional safety data for EU versus non-EU patients are being explored and will be included in the subsequent presentation.

Conclusion: Non-inferiority in terms of the first occurrence of MACE was demonstrated for daprodustat versus rhEPO in ASCEND-D and versus darbeepoetin alfa in ASCEND-Nd.1,2 Results for EU and non-EU patients in the current analysis were consistent with the global outcomes from both studies.

THE PROACT 2 PHASE 3 STUDY DESIGN: A RANDOMIZED CONTROLLED STUDY OF REACT IN PARTICIPANTS WITH TYPE 2 DIABETES AND CHRONIC KIDNEY DISEASE
Hiddo Lambers Heerspink1, Adrian Liew2, Kerry Cooper3, Joseph Stavas4, Tim Bertram3, Ashley Johns1, Roberto Pecóits-Filho5 and Katherine Tuttle6,8

1University Medical Center Groningen, Groningen, Netherlands, 2Mount Elizabeth Novena Hospital, Singapore, Singapore, 3ProKidney, Raleigh, United States of America, 4Arbor Research Collaborative for Health, Ann Arbor, United States of America, 5Providence Health, Spokane, United States of America and 6University of Washington, Seattle, United States of America

Background and Aims: The global burden of chronic kidney disease (CKD) is estimated at 850 million people worldwide, with diabetic kidney disease (DKD) being the main cause. Existing medical therapies may delay the deterioration of kidney function; however, many patients continue to progress to kidney failure. REACT (Renal Autologous Cell Therapy), a cell-based advanced therapy, is being developed to decrease the risk of CKD progression. REACT is composed of selected renal cells (SRC), isolated from a patient’s own kidney, which are involved in the process of kidney repair and regeneration. Preclinical studies in multiple animal models of DKD have demonstrated that SRC injected directly into the kidney cortex produced a regenerative response improving overall kidney function and histology. Encouraging early clinical results from phase 2 studies with REACT resulted in RMAT (Regenerative Medicine Advanced Therapy) designation by the Food and Drug Administration in the USA.

Method: Description of therapy - REACT is derived from the participant’s own kidney tissue obtained by percutaneous biopsy in an outpatient setting. Renal cells are culture expanded ex vivo, and SRC are isolated. SRC are cryopreserved at a concentration of 100 × 10^6 cells/mL and shipped to the clinical site approximately 12 weeks after the biopsy. REACT will be percutaneously re injected by specially trained interventional proceduralists utilizing CT guidance and a non-cutting 25-gauge needle inserted into the kidney cortex. A single REACT dose will be injected into each kidney, approximately 3 months apart. Participants - The study will enroll 600 participants from approximately 250 global sites (including 38 sites in the EU) with up to 60 months of follow-up. Patients aged 30-80 years with type 2 diabetes who have an estimated glomerular filtration rate (eGFR) of 20-50 mL/min/1.73 m^2, and urine albumin-to-creatinine ratio (UACR) 300-5000 mg/g will be eligible. Participants will be randomized 1:1 to REACT or sham biopsy/injection in a single blind manner. Standard-of-care therapies including renin angiotensin system inhibitors and sodium glucose cotransporter inhibitors may be given as per local guidance.

Results: Study Endpoints - The primary endpoint for proact 2 is the time from first injection to the earliest of ≥40% eGFR decline, eGFR < 15 mL/min/1.73m^2 sustained for 30 days, initiation of chronic dialysis or kidney transplantation, or cardiovascular or renal death. proact 2 is an endpoint driven trial with 80% power to detect a hazard ratio of 0.6 for the primary outcome. Key secondary outcomes will include time to these individual components as well as annualized change in eGFR and change from baseline in UACR.

Conclusion: proact 2 is a global Phase 3 randomized controlled trial that will evaluate the safety and efficacy of REACT on major kidney disease endpoints, among participants with type 2 diabetes and moderate-severe CKD. This trial is part of a comprehensive phase 3 development program with an estimated start date of June 2023. REACT, a novel autologous cell therapy composed of SRC, has the potential to directly improve kidney function with a goal to prevent kidney failure.

INCREASE IN HOSPITALIZED DAYS AFTER HYPERKALEMIA-RELATED REDUCTION IN RAASI USE: AN OBSERVATIONAL STUDY ON CARDIORENAL PATIENTS IN SWEDEN AND JAPAN
Maria Eriksson Svensson1, Toyoaki Murohara2, Johan Sundström3,4, Eva Lesén5, Matthew Arnold5, Thomas Cars6, Krister Järbrink7, Gengshi Chen8, Naru Morita9, Sudhir Venkatesan10 and Eiichiro Kanda11

1Uppsala University, Department of Medical Sciences, Renal Medicine, Uppsala, Sweden, 2Nagoya University Graduate School of Medicine, Division of Cardiology, Department of Internal Medicine, Nagoya, Japan, 3Uppsala
Background and Aims: Guidelines recommend renin-angiotensin-aldosterone system inhibitor (RAASI) therapy at the maximum tolerated dose to achieve optimal treatment benefits in chronic kidney disease (CKD) and heart failure (HF). However, hyperkalaemia (HK) is a barrier to achieving guideline-directed target dosing, with RAASI treatment often down-titrated or discontinued in patients who experience HK. Current international guidelines recommend novel oral anti-HK treatments to manage HK and facilitate maintenance of RAASI therapy. The aim of this study was to describe the extent of RAASI reduction (down-titration or discontinuation) following an HK episode, and the associated change in inpatient days, in patients with cardio renal disease in Sweden and Japan.

Methods: This observational study used data from health registers and hospital records in Sweden (national registers linked with health records from two large regions) and Japan (Medical Data Vision). Patients with an index HK episode, defined as ICD-10 code E87.5 (Japan and Sweden) or potassium >5.0 mmol/L (Sweden only), during March 2018 to July 2020 (Sweden) or May 2020 to February 2022 (Japan), with a prior diagnosis of CKD and/or HF, and RAASI use at index were included. RAASI classes included angiotensin-converting enzyme inhibitors (ACEI), angiotensin receptor blockers (ARB), mineralocorticoid receptor antagonists (MRA), and an angiotensin receptor-neprilysin inhibitor (ARNI). Patients were defined as having reduced or maintained their pre-HK RAASI treatment based on filled prescriptions, or lack thereof, within 90 (Japan) or 120 (Sweden) days before versus after the index HK episode. Propensity score matching (1:1) was applied to balance lack thereof, within 90 (Japan) or 120 (Sweden) days before versus after the index HK episode. The change in number of all-cause, CKD-, and HF-related inpatient days (per person-years of follow-up) was described from 6 months before to 6 months after the index HK episode.

Results: In total, 20,824 patients from Sweden and 7789 from Japan were included. The mean age was 76 (Sweden) and 74 (Japan) years, 57% and 65%, respectively, were male. In Sweden, 86% had CKD and 57% had HF; in Japan, 49% had CKD and 75% had HF. The most common RAASI classes in Sweden were ACEi (used by 49%), ARB (44%), and MRA (30%). In Japan, ARB was the most common class (73%), followed by MRA (28%), and ACEi (17%). Overall, 42% (n = 8716) of patients in Sweden and 38% (n = 2976) in Japan reduced their RAASI treatment after the HK episode. In the propensity score matched cohorts, the increase in number of all-cause inpatient days following an HK episode in those with reduced RAASI treatment was 18.2 days in Sweden (n = 6998) and 17.9 days in Japan (n = 2092) (Figure 1A and B). For reference, the increase in those who maintained their RAASI treatment was 9.4 and 8.5 days in Sweden and Japan, respectively. Similar patterns were observed for CKD- and HF-related inpatient days.

Conclusion: In clinical practice, an episode of hyperkalaemia was often followed by reduced RAASI treatment. Reduced RAASI treatment was associated with a greater increase in the number of inpatient days, compared with maintained RAASI treatment. A better understanding of how guideline adherence can be increased to maintain RAASI treatment in patients experiencing HK is needed to achieve optimal treatment benefits in chronic kidney disease (CKD) and heart failure (HF).
THE VALUE OF MANAGING DIABETIC KIDNEY DISEASE: CONTRASTING FINDINGS FROM THE INDIVIDUAL PATIENT AND POPULATION LEVEL PERSPECTIVES

Phil McEwan1 and Marc Evans2

1Health Economics & Outcomes Research Ltd, Cardiff, United Kingdom and 2University Hospital Llandough, Diabetes Centre, Cardiff, United Kingdom

Background and Aims: The management of diabetic kidney disease (DKD) is associated with considerable resource utilisation. Within the context of the broader healthcare system, understanding the health economic implications of adopting strategies to ameliorate the progression of DKD is imperative for fully informed decision-making. The objective of this study was to estimate the UK whole healthcare system economic value, from the individual patient and population perspectives, associated with modifying the progression of DKD through attenuating the decline in eGFR by values consistent with those observed in recent randomised clinical outcome trials.

Method: Since type 2 diabetes (T2D) is the commonest single cause of chronic kidney disease (CKD), we developed a deterministic model utilising published estimates of disease progression stratified by stages: stage 1/2, stage 3a, stage 3b and stage 4/5. Patient characteristics and mean annual decline in eGFR were aligned to the placebo arm of DECLARE-TIMI 58 (-2.44 ml/min/1.732). We explored scenarios where a sustained attenuation in the rate of eGFR decline by 1 and 2ml/min/1.732 per year was realised. T2D specific and all-cause mortality were captured using UKPDS risk equations. CKD stage specific costs and changes in health utility were drawn from NICE guidelines (NG203). Per-patient and population level costs (indexed to 2022) and quality adjusted life years (QALYs) were estimated, and both discounted at 3.5%.

Results: We estimated there were 3.2M, 0.6M, 0.2M and 0.04M DKD patients in stages 1/2, 3a, 3b and 4/5 respectively. Declining kidney function was associated with increasing per-patient lifetime costs and decreasing QALYs: stage 1/2 £36,714, 8.1 QALYs; stage 3a £90,666, 6.5 QALYs; stage 3b £126,931, 5.2 QALYs; stage 4/5 £168,604, 3.7 QALYs. A sustained attenuation in the rate of eGFR decline by 1 and 2ml/min/1.732 per year had the greatest impact in those in stage 3b: with cost savings of £23,690 and £47,463 and gains in QALYs of 0.68 and 1.46 for 1 and 2ml/min/1.732 respectively. At the population level, however, total lifetime cost for DKD was greatest in those in stage 1/2 £30.3Bn; followed by stage 3a, £19.2Bn; stage 3b £9.5Bn; stage 4/5 £146M. A sustained attenuation in eGFR resulted in the largest cost savings in those in stage 1/2: £16.9 Bn and £22.3 Bn for 1 and 2ml/min/1.732 respectively, and the greatest gains in QALYs of 0.8M and 1.1M for 1 and 2ml/min/1.732 respectively. In contrast, population level stage 4 cost savings and QALY gains were modest at £70.7M and £281.6M and 0.02M and 0.4M for 1 and 2ml/min/1.732 respectively.

Conclusion: The notion of value in healthcare is influenced by stakeholder perspective. From the clinician’s and patient’s perspective the greatest value in attenuating the progression of DKD is in those with more advanced disease. However, from the health care provider perspective, at the population level, modest cost-savings and QALY gains are realised in such patients. By contrast, those at an earlier disease stage deliver much greater population level return on investment consequent upon larger numbers of such individuals. This study illustrates that attenuating DKD progression provides value at both the individual and public health levels, irrespective of disease stage.

EFFECTS OF SODIUM-GLUCOSE CO-TRANSPORTER 2 INHIBITORS ON HEART FAILURE IN CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Maria Eleni Alexandrou1, Alexandros Tsiourtidis1, Marieta Theodorakopoulou1, Vasilios Kamperidis2, Eva Pellia, Erasmia Sampani3, Andrew Xanthopoulos4, Aikaterini Papagianni1 and Pantelis Sarafidis1

1Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece, 2Aristotle University of Thessaloniki, First Department of Cardiology, AHEPA Hospital, Thessaloniki, Greece and 3University of Thessaly, Department of Cardiology, Larissa, Greece

Background and Aims: Sodium-glucose co-transporter 2 (SGLT-2) inhibitors significantly reduce the risk for hospitalizations for heart failure (HF) in patients with diabetes, and HF; findings in patients with chronic kidney disease (CKD) are not uniform. Objectives: We aimed to perform a meta-analysis exploring the effect of SGLT-2 inhibitors on HF events in patients with CKD and across subgroups defined by baseline kidney function.

Method: A systematic search in major electronic databases was performed. Randomized controlled trials providing data on the effect of SGLT-2 inhibitors on the primary outcome, time to hospitalization or urgent visit for worsening HF in patients with prevalent CKD at baseline or across subgroups stratified by baseline estimated glomerular-filtration-rate (eGFR) were included.

Results: Twelve studies (n = 89,191 participants) were included in the meta-analysis. In patients with CKD, treatment with SGLT-2 inhibitors reduced the risk for HF events by 32% compared to placebo (hazard ratio [HR] 0.68, 95% CI 0.63-0.73). Reduction in HF events with SGLT-2 inhibitors was more prominent in patients with eGFR < 60 ml/min/1.732 (HR 0.68; 95%CI 0.63-0.74) than in those with eGFR > = 60 ml/min/1.732 (HR 0.76; 95%CI 0.69-0.83). Subgroup analysis according to type of SGLT-2 inhibitor showed a consistent treatment effect across all studied agents (p subgroup-activity analysis = 0.44). Sensitivity analysis including data from studies including only diabetic patients showed an even more pronounced effect in eGFR subgroup <60ml/min/1.732 (HR 0.62; 95%CI 0.54-0.70).

Conclusion: Treatment with SGLT-2 inhibitors led to a significant reduction in HF events in patients with CKD. These findings may change the landscape of HF treatment in patients with advanced CKD.
the present study was to examine the long-term health effects of a dietary intervention with NNRD in patients with CKD stage 3-4 [2].

Method: A 26-week randomized, controlled, non-blinded trial comparing the effect of NNRD vs. non-restricted habitual diet. Patients in the NNRD group received weekly home delivery of fresh food items (free of charge) and recipes for five days of the week, and on the remaining two days they were instructed to prepare meals according to the NNRD food principles. The study was designed with seven follow-up visits in the outpatient clinic where fasting blood samples and 24-hour urine collection were delivered. Linear mixed-effects models were used to assess the effects of the intervention, time, and the potential interaction between intervention and time. The primary endpoint was the difference in 24-hour urine phosphorus excretion between the two study groups. Secondary endpoints included fractional phosphorus excretion and plasma fibroblast growth factor 23 (p-FGF23).

Results: Sixty patients (mean age 54 years, 31 women) with mean eGFR of 34 ml/min/1.73 m² were included. Two patients were withdrawn due to dialysis initiation. In the NNRD-group (n = 29), mean 24-hour urine phosphorus excretion during the intervention period was 651 mg (SD, 35 mg) vs. 930 mg (SD, 84 mg) in the control group (n = 29), between-group difference 279 mg (95% CI; -372, -91; P < 0.001) (Figure 1). Mean fractional phosphorus excretion was 11% (SD, 5%) in the NNRD-group and 14% (SD, 7%) in the control group, between-group difference 3% (95% CI; -6.4, -0.8; P = 0.01). Mean p-FGF23 was 162 pg/ml (SD, 130 pg/ml) in the NNRD-group and 215 pg/ml (SD, 230 pg/ml) in the control group, between-group difference 52 pg/ml (95% CI; -5.3, -0.2, P = 0.03) and 24-h urine bicarbonate excretion was 4.1 mmol higher in the NNRD group (95% CI; 0.7, 7.5, P = 0.01). There was no difference between study groups in p-calcium, p-creatinine, p-potassium, p-calcium, p-lipids, or proteinuria.

Conclusion: NNRD intervention in the context of fresh food delivery and recipes was feasible and had a major beneficial effect on phosphorus parameters in patients with CKD 3-4.

#3804 ASSOCIATION BETWEEN PLASMA XOR AND OUTCOMES IN CKD PATIENTS
Shuzo Makino1, Hiroki Okushima2, Nao Kani1, Nobuhiro Hashimoto1, Rei Iio1, Yoshiyasu Ueda1 and Terumasa Hayashi1
1Osaka General Medical Center, Osaka, Japan and 2Osaka University Graduate School of Medicine, Osaka, Japan

Background and Aims: Plasma xanthine oxidoreductase (pXOR) is an enzyme plays a key role in uric acid (UA) production and produces reactive oxygen species (ROS), and it has been reported that pXOR activity is related with cardiovascular events in the general population. However, the relationship between pXOR activity and prognosis in patients with chronic kidney disease (CKD) remains unclear.

Method: We measured pXOR activity by Liquid chromatography tandem quadruple mass spectrometer (LC-TQMS method) in 415 outpatients with CKD, and compared demographic and laboratory data between two groups based on the median pXOR activity. Furthermore, we examined the association between pXOR activity and outcomes; renal replacement therapy (RRT), major adverse cardiovascular events (MACE), and all-cause mortality, using multivariate Cox proportional hazards model.

Results: Median age and eGFR were 71 years old and 21.6 ml/min/1.73 m², respectively. Median pXOR activity is 3.33 pmol/h/ml and 26.3 pmol/h/ml in the lower and higher pXOR activity groups, respectively. eGFR was significantly lower and UA was significantly higher in the lower pXOR activity group compared with the higher pXOR group (eGFR, 18.9 vs 27.4, P < 0.001; UA, 5.7 vs 6.1, P < 0.001). During the follow-up period of 38 months, the incidence of each outcome including RRT, MACE, or all-cause mortality were significantly higher in the lower pXOR group (log rank test, P < 0.001). Multivariate Cox proportional hazards analysis including eGFR and UA levels showed that lower pXOR activity was significantly associated with poor renal outcome (HR, 1.4; 95% CI, 1.0–2.1; P = 0.038). Furthermore, in subgroup analysis with or without antihyperuricemic use, univariate Cox analysis showed similar association between pXOR and each outcome.

Conclusion: In patients with CKD, lower pXOR activity has a significantly higher risk of all outcome (RRT, MACE, and all-cause mortality).

#4878 STUDYING THE EFFECTIVENESS OF PRASUGREL AND CLOPIDOGEL IN PATIENTS WITH CHRONIC LOWER LIMB ISCHEMIA WITH STAGE 2 CKD
Yorkin Rasulev1 and Durdona Adylova2
1Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan and 2Tashkent Pediatric Medical Institute, Internal medicine, nephrology and hemodialysis, Uzbekistan
Background and Aims: To compare the clinical and rheological efficacy of prasugrel and clopidogrel in patients with chronic lower limb ischemia with stage 2 chronic kidney disease. According to statistics, in Europe, peripheral arterial disease is common in more than 40 million Europeans. According to the developed tactics, not only stroke should be recognized as a serious, life-threatening condition, but other peripheral vascular diseases can lead to disability and death.

Methods: The study included 101 patients with critical lower limb ischemia of atherosclerotic origin. The mean age of the patients was 51.51±8.33 years. As a control group, 20 healthy volunteers (mean age 53.90 ± 9.05 years) were examined without signs of pathology of the cardiovascular system, including those of a vegetative nature. All patients included in the study were hospitalized in the Department of Interventional Cardiology of the Republican Specialized Scientific and Practical Center for Therapy and Medical Rehabilitation, Tashkent city.

Results: In 94 patients (93.07%), CLCI was accompanied by hemodynamically significant multifocal atherosclerotic lesions. The first place in frequency of combined lesions was occupied by the coronary vessels, the second place - by the arteries of the brachiocephalic basin. 82 patients (81.19%) had previously suffered arterial occlusion, also most often in the form of acute myocardial infarction, somewhat less often - acute cerebrovascular accident. 47 patients (46.53%) underwent revascularization earlier, mainly coronary artery stenting, coronary artery bypass grafting, carotid endarterectomy. 8 patients (7.92%) underwent revascularization of the contralateral leg. The study studied spontaneous (SAT) and ADP-induced platelet aggregation. In the CG, SAT was noted only in 50% of cases and in all patients of the CLCI group. After comparing the results in the groups of patients with CLCI and representatives of the CG, in whom SAT was noted, it was found that both the rate and degree of SAT in the group of patients were significantly higher than in healthy individuals (2.95±0.59% versus 0.55±0.21% and 6.05±1.54% versus 1.24±0.21%, respectively, p<0.001 significance of the intergroup difference of both parameters). All patients due to CINC underwent endovascular revascularization of the affected leg. After the procedure, patients were prescribed an antiplatelet agent at a maintenance dose (prasugrel 10 mg/day, clopidogrel 75 mg/day). After 3 months, a control examination was carried out, during which the dynamics of platelet aggregation activity was studied. It was found that the indicators of CAT and ADP induced aggregation decreased by 22-37%. During the test, patients with resistance to antiplatelet agents were identified - in whom the decrease in the degree of ADP5 induced aggregation was less than 20%. Such resistance was found in 19 patients: 1 patient in the prasugrel group (1.69%) and 18 patients in the clopidogrel group (42.86%, chi square = 27.00, p<0.001). Isolation of patients with normal and reduced response to the loading dose of clopidogrel revealed some differences (Table 3.3). So, already initially in this group of patients, the degree of ADP5-induced aggregation was lower than in the group of patients with an antiplatelet response of more than 20%. After the application of a loading dose of clopidogrel, differences in relative dynamics were noted only in terms of the degree of ADP%-induced aggregation (p<0.001).

Conclusions: Thus, the present study revealed that in patients with CLCI, there is a significant activation of CAT and an increase in the aggregation response to the introduction of high doses of the inducer of ADP5 aggregation. The loading dose of antiplatelet agents contributed to a significant decrease in platelet aggregation activity after 2 hours with a large effect of prasugrel. Chronic antiplatelet therapy led to a decrease in the rate and degree of aggregation, both spontaneous and ADP-induced, a decrease in the endogenous ADP release response, also with a great effect in patients taking prasugrel.

THE INFLUENCE OF ANTIRETROVIRAL DRUGS AND HIV RESISTANCE MUTATIONS ON THE SHEDDING OF HIV-1 INTO PERITONEAL DIALYSIS EFFLUENT

Teboho Mooko1, Busiswa Bisiwe2, Perpetual Chikobvu3, Daniel Morobadi4, Martin Nyaga5, Phillip Bester6, Gabre Kemp7, Dominique Goedhals8, Thabiso Mofokeng9 and Kwazi Ndlovu10

1University of the Free State, Department of Internal Medicine and Next Generation Sequencing Unit, Bloemfontein, South Africa, 2University of the Free State, Department of Internal Medicine and Division of Nephrology, Bloemfontein, South Africa, 3Department of Health of the Free State, Bloemfontein, South Africa, 4University of the Free State, Division of Virology, Bloemfontein, South Africa, 5University of the Free State, Next Generation Sequencing Unit and Division of Virology, Bloemfontein, South Africa, 6University of the Free State, Division of Virology and National Health Laboratory Service, Bloemfontein, South Africa, 7University of the Free State, Department of Microbiology and Biochemistry, Bloemfontein, South Africa, 8University of the Free State, Division of Virology and PathCare Vermaak, Bloemfontein, South Africa, 9University of the Free State, Department of Internal Medicine and Department of Health of the Free State, Bloemfontein, South Africa and 10University of Cape Town, Kidney and Hypertension Research Unit and Division of Nephrology and Hypertension, Cape Town, South Africa

Background and Aims: Antiretroviral therapy (ART) is effective HIV management even in HIV-positive patients with end-stage kidney failure (ESKF). However, drug resistance mutations are important determinants of therapeutic effects. The study aimed to determine the prevalence of HIV resistance mutations and ART drug penetration in the peritoneal compartment and their effect on the shedding of HIV-1 into continuous ambulatory peritoneal dialysis (CAPD) effluents.

Method: This prospective cross-sectional study of HIV-positive ESKF patients managed with ART and CAPD at Universitas Academic Hospital collected enrolled patients’ background information and clinical and laboratory data. HIV-1 was detected using quantitative polymerase chain reaction (qPCR) and sequenced by the Sanger method, while ART levels were quantified using LC-MS/MS.

Results: There were 38 patients recruited with a median age of 41.8 (IQR, 36.15–48.0) years and were predominantly on abacavir (89.5%), lamivudine (100%) and efavirenz (76.3%) for a median duration of 8 (IQR, 6–11) years. Among participants with detectable HIV in CAPD effluents, the prevalence of ARV-drug resistance mutations was 71.4% (5/7) compared to 12.9% (4/31) among those with undetectable HIV-1 (p = 0.004) with NNRTI resistance mutations predominating. Participants with detectable HIV-1 had lower abacavir (0.0182 vs 5.68 ng/μl; p = 0.021), lamivudine (0.0152 vs 1.09 ng/μl; p = 0.001) and efavirenz (3,605 vs. 57.8 ng/μl; p = 0.004) plasma levels compared to those with undetectable HIV-1. Measured lamivudine (0.455 vs 0.342 ng/μl; p = 0.007) and efavirenz (46.5 vs 2.34 ng/μl; p < 0.001) drug levels are significantly higher in plasma than CAPD effluents.

Conclusion: ART resistance mutations, lower drug levels and poor compartment penetration are suggested significant factors for HIV-1 shedding into CAPD effluents.
Figure 1: A representation of factors hypothesized to be contributing to HIV-1 shedding into peritoneal dialysis (PD) effluents. Figure 1: Shows the association of environmental, underlying diseases (communicable and non-communicable) (A) and genetic factors (B) associated with HIV-1 particle-induced kidney failure (D) and shedding of the particles into PD waste (F). Virological failure due to HIV-1 mutations on Gag, Pol and Env segments (C, C1 and D) and altered anti-retroviral therapy (ART) pharmacodynamics (D2) in individuals who are carriers or non-carriers of either homozygous or heterozygous pair of renal risk alleles (B1). Moreover, single nucleotide polymorphisms and frame-shift deletion mutations on G1 and G2, respectively, induces a nonsynonymous substitution and Insertion that alters SRA binding domain of apolipoprotein 1 (B2). This in synergy with continuous viral replication alters the behaviour and function of tubular and podocyte cells (D3), thus impairing the renal tubule and glomerulus capacity to filter out nitrogenous waste from the blood (D4 - D5) and possibly leads to acute and chronic kidney failure which may be reversible until stage 3B (E1). Progression to stage 4 and 5 may imply a complete loss of kidney function in terms of the glomerular filtration which is usually managed by dialysis, either haemodialysis or PD (E2). The shedding of HIV-1 particles has been observed mainly in peritoneal effluent in a setting of HIV positive patients complying to their respective renal friendly ART, most likely due to lowered ART dosage regimen and modified ART pharmacokinetics as well as HIV-1 mutations and other factors (F1), Figure created with Biorender.com.

RELEVANCE OF REPEATED ALBUMINURIA AND GLOMERULAR FILTRATION RATE IN A LARGE COHORT OF SICKLE CELL ANEMIA CHILDREN LIVING IN A RESOURCE-LIMITED AREA

Agathe Nkoy1, Floreen Mumaka1, Ange Ngonde3, Robert Kitenge3, Leon Tshilolo4, Lambertus P. Van den Heuvel2, Veerle Labarque1, Pepe Ekulu4 and Elena Levchenko1

1University Hospital of Kinshasa, Department of Pediatrics, Kinshasa, Democratic Republic of the Congo (formally known as Zaire), 2REZODREPANO SS, Democratic Republic of the Congo (formally known as Zaire), 3Centre de Formation et d’Appui Sanitaire (CEFA)/Monkole, Democratic Republic of the Congo (formally known as Zaire), 4KULeuven, Department of Development and Regeneration, Belgium and 5KULeuven, Department of Paediatric Haematology, Belgium

Background and Aims: Chronic kidney disease (CKD) is associated with significant morbidity and mortality among patients with sickle cell anemia (SCA). Glomerular hyperfiltration (GHF) and albuminuria are known as early manifestations of kidney disease occurring in early childhood and can predict the progression to CKD in these patients. Studies reported the prevalence of these kidney abnormalities in SCA children using a single measure and their association with genetic risk factors, especially the co-inheritance of APOL1 risk variants (RVs). However, data on the prevalence of persistent kidney abnormalities (based on the KDIGO CKD definition) and their association with APOL1 RVs are limited in SCA children, particularly those living in sub-Saharan Africa. This study aimed: (i) to determine the prevalence of persistent kidney abnormalities (albuminuria and/or GHF) in SCA children living in the Democratic Republic of Congo (DRC); and (ii) to assess the association between persistent kidney abnormalities with clinical and genetic risk factors.

Method: From March 2021 to December 2022, we prospectively enrolled 585 steady state SCA children aged 2 to 18 years (male gender 278/585; 47.5%). The SCA status was confirmed through the molecular sequencing of beta-globin gene. Clinical and biological parameters were obtained. All participants were genotyped for apolipoprotein-L1 (APOL1) G1 (rs73885319, rs60910145) and G2 (rs71785313) variants. APOL1 high-risk genotype (HRG) was defined by the presence of 2 risk variants (G1/G1, G2/G2, and G1/G2), and low-risk genotype (LRG) by the presence of 0 or 1 risk variant. Albuminuria was defined as urinary albumin-to-creatinine ratio (ACR) ≥ 30mg/g. The estimated glomerular filtration rate (eGFRcr) was calculated using the original Schwartz formula and GHF was defined as eGFRcr ≥ 180 ml/min/1.73 m² for...
children between 2-10 years of age and > 140 ml/min/1.73 m² for children more than 10 years of age. All measurements were repeated at least three months later in participants who presented with kidney abnormalities at the first screening. The main outcome parameter was persistent albuminuria or persistent GHF for more than three months.

Results: At enrollment, 234/585 (40.0%) participants presented with kidney abnormalities, among which 80/585 (13.7%) with albuminuria and 171/585 (29.2%) with hyperfiltration. From participants found with kidney abnormalities at the first screening, 176/234 (75.2%) were available for repeated screening: 56/176 (31.8%) presented with persistent kidney abnormalities and 120/176 (68.2%) had a regression of kidney abnormalities without any treatment. Out of 176 participants who benefited from repeated screening, 57 had baseline albuminuria and 130 had baseline GHF. Persistent albuminuria and persistent GHF were found in 38.6% (22/57) and 28.5% (37/130), respectively. Multivariate logistic regression revealed that APOL1 HRG was significantly associated with persistent albuminuria (OR 3.4, 95CI 1.1-10.7, p = 0.037), while male gender was significantly associated with persistent GHF (OR 2.1, 95CI 1.0-4.2, p = 0.042).

Conclusion: A significant proportion (almost 70.0%) of SCA children who had kidney abnormalities at the first measure, presented regression of these abnormalities without any reno-protective drugs. This result emphasizes the importance of repeating screening at least three months later to confirm CKD, as recommended by the KDIGO Guidelines. This strategy will reduce the need for unnecessary treatment, which represents a high financial burden in a resource-limited area.

USING REDUCED RANK REGRESSION TO INVESTIGATE THE RELATIONSHIP BETWEEN DIETARY PATTERNS AND ADULT KIDNEY FUNCTION IN THE GENERAL POPULATION

Giulia Barbieri1,2, Vanessa Garcia Larsen3, Rebecca Lundin1, Ryosuke Fujii1,4, Roberto Melotti1, Lucia Cazzoletti2, Pramstaller Peter1, Maria Elisabetta Zanolin2, Cristian Pattaro1 and Essi Marjatta Hantikainen1

1Eurac Research, Institute for Biomedicine, Bolzano, Italy, 2University of Verona, Unit of Epidemiology and Medical Statistics, Department of Diagnostics and Public Health, Verona, Italy, 3The Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States of America and 4Fujita Health University School of Medical Sciences, Department of Preventive Medicine, Toyoake, Japan

Background and Aims: Chronic kidney disease (CKD) is a severe public health burden, characterized by a gradual loss of kidney function over time. Diet is a modifiable lifestyle-related risk factor for CKD. However, there is uncertainty about which specific dietary patterns (DPs) are more beneficial or detrimental in CKD prevention. We aimed at deriving DPs using an hybrid approach that combines a priori knowledge and data-driven methods to identify dietary factors that may affect kidney function in healthy and diseased subjects.

Method: We analysed data of 8686 adults participating in the population-based Cooperative Health Research In South Tyrol (CHRIS) study. Kidney function was multiply assessed by the estimated glomerular filtration rate (eGFR), based on serum creatinine, using the 2021 CKD-EPI equation, the urinary albumin-to-creatinine ratio (UACR), and a kidney disease questionnaire. Participants were split between those free of diagnosed kidney disease, hypertension or diabetes (Group1, n = 6133) and those diagnosed with any of the three conditions (Group2, n = 2553). Diet was assessed through the self-administered and validated GA2LEN food frequency questionnaire (FFQ). The individual consumption of each food group was converted into portions per week and adjusted for total energy intake. DPs were estimated using reduced rank regression (RRR), based on four FFQ-derived nutrient mediators (total daily dietary protein; potassium; sodium; and phosphorus intake) selected based on known effects on kidney health. Generalized cross-validation identified an optimal number of 3 DPs. Factor Loading (FL)-based scores, either as continuous or stratified into sex-stratified tertiles (T1-T2-T3), were included in multiple-adjusted linear regression models for eGFR and log(UACR).

Results: Group1 participants (53.4% females) were younger and presented better kidney health (median, Mdn age 39.7 years; Mdn eGFR 101.8 ml/min/1.73m², interquartile range, IQR 91.5-112.1; Mdn UACR 5.2 mg/g, IQR 3.5-8.8) than Group2 participants (Mdn age 57.2 years; Mdn eGFR 90.8 ml/min/1.73 m², IQR 80.4-100.3; Mdn UACR 6.5 mg/g, IQR 4.1-12). The identified DPs were (Figure 1): DP1, reflecting greater consumption of all nutrients; DP2, reflecting increased potassium and phosphorus intake and lower sodium and protein intake; and DP3, reflecting increased intake of protein and phosphorus and lower intake of potassium and sodium. The 3 DPs presented stable FLs across groups. In Group1, DP1 was negatively associated with eGFR (larger effect size in males) both as linear score and in the 3rd tertile (Figure 2); DP2 was positively associated with eGFR in males and with UACR both at low and high levels of the score, with heterogeneous effects between males and females; DP3 was positively associated with UACR overall in the 3rd tertile. In Group 2, we observed protective effects of diet on eGFR, especially at lower DP1 and DP3 levels, and at high levels of DP2 (Figure 2). Similar to Group1, also in Group2 DP2 was positively associated with UACR both at low and high level of the score, but not in males. In its 3rd tertile, DP3 was negatively associated with UACR in females.

Conclusion: Using RRR proved to be a valid approach to integrate a priori knowledge about nutrients in the estimation of kidney function-oriented DPs. Our results showed heterogeneous effects of the DPs across kidney outcomes, possibly reflecting specificity to kidney function or damage. In individuals affected by any kidney disease, hypertension or diabetes, the effects of DPs

Figure 1: DPs in Group1 (blue) and Group2 (orange), described by Factor Loadings (FLs) of the most characterizing food groups.

Abstracts

1660
on eGFR reflected possible benefits of specific diets, suggesting that disease-specific dietary interventions can be a fundamental and effective approach for disease control.

THE IMPACT OF CHRONIC KIDNEY DISEASE-ASSOCIATED PRURITUS RELIEF ON SKINDEX-10 DISEASE AND SOCIAL FUNCTIONING DOMAINS
Sonja Ständer1, Thilo Schaufler2, Despina Ruessmann3, Isabelle Morin3, Frederique Menzaghi3, Warren Wen4 and Kieran McCafferty4
1University of Münster, Center for Chronic Pruritus, Münster, Germany, 2CSL Vifor, Switzerland, 3Cara Therapeutics, Stamford and 4Barts Health NHS Trust, London, United Kingdom

Background and Aims: Chronic kidney disease-associated pruritus (CKD-aP) is a serious condition that greatly impacts patients’ quality of life (QoL). Moderate-severe pruritus affects up to 47% of patients undergoing haemodialysis (HD) [1]. The aim of this analysis was to assess the impact of itch relief on the disease and social functioning domains of the Skindex-10 questionnaire in a post hoc analysis of the difelikefalin (DFK) Phase 3 studies in patients with CKD-aP undergoing HD.

Method: Patients with moderate-to-severe CKD-aP (mean Worst Itch Numerical Rating Scale [WI-NRS] score ≥4 [KALM-1] or ≥5 [Study 3105 and KALM-2]) undergoing HD were enrolled and randomised 1:1 to receive intravenous DFK 0.5 μg/kg or placebo (KALM-1 and -2) or open-label DFK (Study 3105) 3 times/week for 12 weeks. Data from all patients who completed the studies were included in the present analysis irrespective of study drug exposure; data were pooled for patients receiving DFK and placebo from the KALM studies. The 12-week change from baseline in the Skindex-10 questionnaire subdomains were assessed for disease (Q1–3) and social functioning (Q7–10). Change from baseline in the mood/emotional distress domain has previously been reported (Q4–6) [2].

Results: Skindex-10 scores were available for 914 patients (KALM studies: n = 720; Study 3105: n = 194). At Week 12, patients with a clinically relevant (WI-NRS ≥3-point) change (decrease) in itch (KALM: n = 305; 3105: n = 143) reported a relative mean (± standard error) corresponding improvement of 59.7% ± 2.0 (KALM) and 65.9% ± 2.6 (3105) from baseline in the disease domain of Skindex-10, compared with 18.4% ± 2.3 and 30.7% ± 4.4 of patients with <3-point WI-NRS improvement (KALM: n = 415; Figure A; 3105: n = 51; Figure B). In addition, a much greater improvement in QoL was reported for the social functioning domain for patients with ≥3-point WI-NRS improvement, compared with patients with <3-point improvement (66.2% ± 3.5 vs 11% ± 7.6 in the KALM studies; 75.5% ± 4.0 vs 49.4% ± 8.5 in Study 3105). Overall, the patients with ≥3-point WI-NRS change reported relative mean improvement from baseline ranging from 64% ± 2.3 to 70.2% ± 2.6 across the total Skindex-10 scale compared with 15.1% ± 4.8 to 35.4% ± 5.3 of patients with <3-point improvement at Week 12 across all studies.

Conclusion: In this post hoc analysis, patients with CKD-aP undergoing HD who reported a clinically meaningful reduction in itch intensity also achieved a substantially greater improvement in both the disease and social functioning domains of Skindex-10, as well as overall itch-related QoL.

Abstracts
Figure 1: The relative mean (standard error) percentage change from baseline to Week 12 in Skindex-10 questionnaire scores for patients reporting ≥3-point vs <3-point improvement in in disease and social functioning domains in KALM studies (A) and Study 3105 (B).

EARLY REFERRAL TO PRE-DIALYSIS NEPHROLOGICAL CARE ASSOCIATES WITH LOWER COVID-19 INCIDENCE IN PREVALENT DIALYSIS PATIENTS

Mathias Haarhaus1,2, Lavinia Bratescu3, Nicholae Pana3, Gemene Emanuela Marta4, Olvera Stojceva-Taneva5, Eliana Silva1, Carla Santos1 and Fernando Macário1

1Diaverum, Malmö, Sweden, 2Karolinska Institutet, Department of Renal Medicine, Stockholm, Sweden, 3Diaverum Romania, Bucarest, Romania, 4Diaverum Romania, Bucarest, Romania and 5Diaverum, Skopje, Republic Of North Macedonia

Background and Aims: Early referral to nephrological care associates with improved long-term survival and lower hospitalization rates after dialysis initiation. Despite the strong evidence for this beneficial effect of early referral to pre-dialysis nephrological care in dialysis patients, the effect on COVID-19 incidence and outcome has not yet been investigated.

Method: Patients in the current study were recruited from a cohort of 349 consecutive patients who initiated dialysis between 2015 and 2018 at a dialysis network in Romania. All patients alive at the start of the pandemic (March 2020 = baseline) were included in this retrospective cohort study. Follow-up ended July 2021. At each visit, patients were screened for 2019 Coronavirus Disease (COVID-19) symptoms and symptomatic patients underwent PCR testing. We studied the effect of pre-dialysis nephrological care in COVID-19 incidence, and outcome has not yet been investigated.

Results: In total, 224 patients were included. Of these, 89 were early referral patients. At dialysis initiation, they had higher hemoglobin (median (25-75%), 10.0 (9.4-10.8) g/dL vs. 8.5 (7.6-9.4) g/dL, p < 0.001), transferrin saturation (21.5 (16.8-25.3)% vs. 18.1 (13.4-23.5)%), p = 0.01), calcium (8.8 (8.3-9.1) mg/dL vs. 8.3 (7.8-8.8) mg/dL, p < 0.001), phosphate (5.9 (5.0-6.8) mg/dL vs. 4.8 (3.9-5.8) mg/dL, p < 0.001), and albumin (3.5 (3.2-4.2) g/dL vs. 3.5 (3.2-3.8) g/dL, p = 0.04), lower PTH (220 (136-357) pg/mL vs. 289 (148-510) pg/mL, p = 0.03), and initiated dialysis less often via a central dialysis catheter (40 (44.9%) vs. 132 (97.8%), p < 0.001). Age, sex, diabetes, and Charlson Comorbidity Index did not differ between groups. During the 16 months of follow-up, 82 patients (36.6%) developed COVID-19. Incidence of COVID-19 was higher in patients with diabetes (32 (46.4%) vs. 50 (32.4%), p = 0.04), while early referral was weakly associated with a lower COVID-19 incidence (26 (29.2%) vs. 56 (41.5%), p = 0.06). Logistic regression, correcting for differences between early and late referral and differences between patients with and without COVID-19, identified a lower risk for COVID-19 among early referral patients (Table 1). No difference in mortality was detected between patients with and without COVID-19 during follow-up (19 (23.2%) vs. 36 (25.4%), p = 0.7).

Conclusion: Among prevalent dialysis patients, early referral to nephrological care before dialysis initiation was an independent predictor of lower COVID-19 incidence during a follow-up period of 16 month from the beginning of the pandemic.

#6431
THE DEVELOPMENT OF AN INTEGRATED COMMUNITY, CONSERVATIVE KIDNEY CARE AND PALLIATIVE-RENAL CARE SERVICE
Jawad Ahmed1, Lucia Birch 2, Matthew Dodd3, Donna Roberts3, Simon Harlin4 and Huda Mahmoud4
1Walsall Manor Hospital, Medicine, Walsall, United Kingdom, 2Walsall Together, Palliative Care, Walsall, United Kingdom, 3Walsall Together, Community Services, Walsall, United Kingdom and 4Walsall Manor Hospital, Nephrology Department, Walsall, United Kingdom

Background and Aims: Conservative kidney care is the chosen therapeutic strategy for approximately 6% of renal patients. It is estimated that a third of renal patients in the United Kingdom have a dedicated conservative kidney care service. Equally, other units manage this cohort of patients in general nephrology/low-clearance clinics or alternatively, discharge to community services. Walsall Together, is a collaborative initiative between community and speciality services, driven to provide multi-agency, patient-focused care. By combining specialist input and community resources, we aimed to optimally manage individuals on the conservative kidney care and palliative-renal pathways at home.

Method: Community, nephrology and palliative care teams devised a service for those individuals identified for conservative kidney care or individuals with renal disease requiring palliative care management. Two separate, yet linked services; the community, conservative care pathway feeding into the community, palliative renal pathway. Individuals suitable for community conservative care pathway were identified from routine nephrology inpatient and outpatient workstreams. Prior to a telephone consultation with a nephrologist, phlebotomy for routine bloods were performed at the GP surgery or at the patients home by the community phlebotomy service. Any alterations to medications would be performed directly by the community pharmacist. Symptoms were assessed using the integrated palliative outcome score (IPOS)-renal survey. The IPOS renal-survey asks individuals to rate symptom burden as the three most common symptoms that generated discomfort in the three days prior to taking the IPOS-renal survey. On detailed assessment; significant symptom burden was attributed to reduced mobility (82% scoring slightly to overwhelmingly), pain (65% scoring slightly to overwhelmingly) and bowel concerns (65% scoring slightly to overwhelmingly). Ictching affected a third of the cohort, scoring moderately to overwhelmingly. Importantly, as a result of the service, patients reported that either all or most renal-related problems were addressed. To date all patients who died while under the renal-palliative care service, died in their chosen place of death, and not in hospital.

Conclusion: The Walsall Together initiative has demonstrated that utilising conservative care and renal-palliative care pathway. 94% of patients felt that the community approach did not waste time waiting for appointments/treatments. 87% of patients felt that the community approach provided them with sufficient information to understand their healthcare condition and relevant management strategies. Patients reported pain, nausea and reduced appetite as the three most common symptoms that generated discomfort in the three days prior to taking the IPOS-renal survey. On detailed assessment; significant symptom burden was attributed to reduced mobility (82% scoring slightly to overwhelmingly), pain (65% scoring slightly to overwhelmingly) and bowel concerns (65% scoring slightly to overwhelmingly). Ictching affected a third of the cohort, scoring moderately to overwhelmingly. Importantly, as a result of the service, patients reported that either all or most renal-related problems were addressed. To date all patients who died while under the renal-palliative care service, died in their chosen place of death, and not in hospital.

Conclusion: The Walsall Together initiative has demonstrated that utilising a collaborative approach to managing complications of advanced kidney disease can result in the reduction of hospital admissions, face-to-face hospital outpatient appointments and time wasted attending healthcare appointments. Furthermore, the cooperative multi-speciality approach, has led to improve patient satisfaction and the attainment of patient healthcare goals.

EFFECTS OF LIPID-LOWERING DRUGS ON IMPROVING KIDNEY FUNCTION: A DRUG TARGET MENDELIAN RANDOMIZATION STUDY
Schyler Bennett1, Venexia Walker2,3, Jie Zheng1, Ben Brumpton1, Kristian Hveem1, Anna Köttgen1,5, Bjorn Åsvold6,9, Tom Gaunt2,7 and Humaira Rasheed1,2
1Norwegian University of Science and Technology (NTNU), K.G. Jebsen Center for Genetic Epidemiology, Trondheim, Norway, 2University of Bristol, Medical Research Council Integrative Epidemiology Unit, Bristol, United Kingdom, 3Perelman School of Medicine at the University of Pennsylvania, Department of Surgery, Philadelphia, United States of America, 4Institute of Genetic Epidemiology, University of Freiburg, Department of Biometry, Epidemiology and Medical Bioinformatics, Freiburg, Germany, 5Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States of America, 6St. Olav’s University Hospital, Department of Endocrinology, Trondheim, Norway and 7University of Bristol, NIHR Biomedical Research Centre, Bristol, United Kingdom

Background and Aims: Chronic kidney disease (CKD) affects one in ten adults worldwide. CKD frequently co-occurs with cardiovascular diseases, hypertension, and diabetes. Despite this high prevalence, few specific therapies exist. Thus, using drug-target Mendelian randomization (MR), we investigated the existing treatments for cardiovascular diseases, hypertension, and diabetes as potential treatment options for improving kidney function.

Methods: We identified SNPs as genetic proxies for the effects of targets of statins, ezetimibe, and alirocumab/evolocumab (as hypercholesterolemia drugs); angiotensin-converting enzyme (ACE) inhibitors, β-blockers (BB), and calcium channel blockers (CCB: as antihypertensive drugs); and metformin (as an antidiabetic drug) on kidney function. Effects of these SNPs on exposures, including low-density lipoprotein cholesterol (LDL-C) for hypercholesterolemia drugs, systolic blood pressure (SBP) for antihypertensive drugs, and Hba1c for antidiabetic drug, were obtained from published genome wide association studies (GWASs) summary statistics. Similarly, SNP-outcome data for kidney related markers, including serum creatinine and serum cystatin C based estimated glomerular filtration rate (eGFRcrea and eGFRcys, respectively) and blood urea nitrogen (BUN), were obtained using the largest GWAS for these phenotypes. Two-sample MR analysis using the inverse variance weighted (IVW) method and additional sensitivity analyses including weighted median, weighted mode, and MR-Egger methods were carried out in R (version 4.2.1). The results are presented as standard deviation (SD) change in outcome per 1 SD change in exposure caused by the drug.

Results: Each 1 SD lowering in LDL-C caused by HMGGCR variants, proxying the effect of statins, was associated with higher serum creatinine and cystatin-C based eGFR of approximately 0.01 SD (eGFRcrea β = 0.012, 95% CI = 0.007-0.018, p = 0.00032; eGFRcys β = 0.012, 95% CI = 0.002-0.022, p = 0.017), and lower BUN of 0.010 SD (β = -0.010, 95% CI = -0.020-0.00020, p = 0.050) (Figure 1), with consistent findings from sensitivity methods and no bias due to pleiotropy (Pegger = 0.22-0.70). Findings for other lipid-lowering drugs including NPC1L1 (target of ezetimibe) and PCSK9 (target of alirocumab/evolocumab) remained inconclusive. Similarly, we found limited evidence for the causal role of genetically proxied antihypertensive or antidiabetic drugs in improving kidney function, though beta values were close to null (Figure 1).

Conclusion: The genetically proxied LDL-C lowering effect of HMGGCR variants is associated with improved kidney function, which is consistent with the reported causal association of LDL-C with kidney function in a previous trans-ethnic MR study (1). Limited evidence was found for antihypertensive and antidiabetic drugs. These results provide insights into potential drug target candidates for future trials to address the treatment of CKD and comorbidities.

RENAL SAFETY OF FLOT REGIMEN FOR GASTROESOPHAGEAL CANCER

Francesco Trevisani1, Matteo Floris2, Andrea Angioi2, Nicole Liscia3, Alessandra Cinque4, Antonello Pani2, Marco Puzzoni2, Mario Scartozi3, Manuela Dettori6, Elena Mazza3 and Stefano Cascini4

1San Raffaele Scientific Institute, Urology, Milano, Italy; 2G. Brotzu Hospital, Nephrology, Cagliari, Italy; 3San Raffaele Scientific Institute, Oncology, Milano, Italy; 4San Raffaele Scientific Institute, Biorek, Milano, Italy; 5Policlinico Universitario, Oncology, Monserrato, Italy and 6G. Brotzu Hospital, Nephrology, Cagliari, Italy

Background and Aims: Currently, peri-operative docetaxel, oxaliplatin, leucovorin, and 5-fluorouracil (FLOT) chemotherapy is the gold standard treatment for patients with locally advanced gastric cancer (LAGC), who undergo peri-operative chemotherapy and surgery. The known nephrotoxicity of both docetaxel and oxaliplatin compounds may limit its application in CKD population. Nevertheless, limited evidence is available regarding the effects of FLOT regimen on renal function. In our analysis we evaluated the renal safety of FLOT regimen in LAGC population.

Method: Retrospective data on patient with resectable gastric cancer in four tertiary referral hospital between January 2018 to January 2022 have been analyzed. Patient have been treated with docetaxel (60 mg/m2), oxaliplatin (85 mg/m2), leucovorin (200 mg/m2), and 5-fluorouracil (2,600 mg/m2 as a 24 hr infusion), all given on day 1 and administered every 2 weeks in 4 administrations before surgery. Serum creatinine, hemoglobin, lymphocytes and CKD-EPI eGFR were detected at baseline and before each cycle. AKI and CKD onset/prevalence were determined according to K-DIGO criteria.

Results: A consecutive cohort of 90 patients was enrolled. At baseline CKD was present in 16 pts (21.9%). Median eGFR was 84.9 ml/min. In terms of eGFR decay and CKD onset during the treatment cycle, the result of ANOVA indicated no significant differences or relationship with FLOT; Wilks’ Lambda = 0.94, p = 0.354 (Table 1 and Figure 1). AKI incidence was very low with one episode of stage 2 AKI (0.7%) between the 2nd and the 4th treatment cycle. New onset anemia between the 1st and the 2nd cycle was the only significant adverse event observed (p = 0.003).

Conclusion: According to our results, the pre-operative FLOT regimen seems to have a negligible impact on renal function with very low rate of renal toxicity suggesting the possibility to extend its use even in patient with advanced CKD.

Efficacy and Safety of Sacubitril/Valsartan in Patients with Stage 3B-5 CKD and Hypertension

Qin Zhou, Wenjuan Yu, Xiaofei Shao, Qin Liu, Honglei Wang, Junzhe Chen and Ying Tang

The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, P.R. China

Background and Aims: Sacubitril/valsartan (SV) plays a key role in improving left ventricular remodeling and prognosis in patients with heart failure. However, its effects on kidney function in people with moderate to severe chronic kidney disease (CKD3b-5) are unknown. The present study was designed to assess the efficacy and safety of sacubitril-valsartan in patients with stage 3b-5 CKD and hypertension.

Method: In this randomized, double-blind, 3-month trial, patients with stage 3b-5 CKD and hypertension were randomly assigned to sacubitril/valsartan treatment group (n = 44, the doses of SV were up-titrated to sacubitril/valsartan 400 mg), and conventional antihypertensive treatment group (n = 40). The primary outcome was reduction in GFR from baseline at week 12.

Results: In total, 44 participants were assigned to sacubitril/valsartan group and 40 to control group (conventional antihypertensive group). Baseline measured GFR was 29.94±11.83, 27.86±10.14 mL/min/1.73 m², respectively. There was no difference in measured GFR (P = 0.064). At week 12, there was a reduction in measured GFR in control group: 27.86±9.15 versus 22.03±11.41, but there was no significant difference (P = 0.155). Sacubitril/valsartan could improve eGFR: 29.94±11.83 versus 32.05±14.57 (P = 0.018). We also observed that, compared with control group, sacubitril/valsartan decreased albuminuria: reductions in urinary albumin:creatinine ratio (ACR) in sacubitril/valsartan group was 89.5mg/g and reductions in urinary ACR in control group was -44.55mg/g. At week 12, Sacubitril/valsartan provided a significantly greater reduction in office mean sitting (ms) systolic BP (msSBP) than control group (20.75mmHg vs 12.88mmHg, P = 0.046). There was no serious adverse events in both groups. The incidence of hyperkalemia (potassium ≥ 5.5 mmol/L) was 4.5% in SV group and 7.5% in control group.

Conclusion: The present data suggested that, in patients with stage 3b-5 CKD and hypertension, Sacubitril-valsartan could improve kidney function and decrease albuminuria, and was generally safe and well tolerated.

EFFECTS OF SODIUM-GLUCOSE CO-TRANSPORTER 2 INHIBITORS ON CARDIOVASCULAR MORTALITY IN CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Maria Eleni Alexandrou1, Eva Pella1, Alexandros Tsaitouridis1, Marieta Theodorakopoulou1, Erasmia Sampani1, Areti Georgiou1, Vasileios Kamperidis2, Aiakterini Papagianni1 and Pantelis Sarafidis1

1Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece and 2Aristotle University of Thessaloniki, First Department of Cardiology, AHEPA Hospital, Greece

Background and Aims: In studies of patients with chronic kidney disease (CKD), recommended nephroprotective therapy with ACE-inhibitors or ARBs has not been shown to reduce cardiovascular (CV) events or mortality. Sodium-glucose co-transporter 2 (SGLT-2) inhibitors reduce cardiovascular events and death in patients with diabetes and established CV disease; evidence from studies in populations with CKD has been inconsistent. The aim of this meta-analysis was to evaluate the effect of SGLT-2 inhibitors on cardiovascular (CV) mortality in patients with CKD.

Method: Studies were identified by search in major electronic databases (PubMed/MEDLINE, Scopus, Cochrane Library and Web of Science) (PROSPERO ID: CRD42022382863). We included randomized controlled trials assessing the effect of SGLT-2 inhibitors on the primary outcome, time to cardiovascular death, in patients with CKD at baseline. Secondary outcomes included all-cause mortality and major adverse cardiac events (MACE).

Results: Eleven studies with 83,203 participants with CKD were eligible for inclusion in the meta-analysis. Treatment with SGLT-2 inhibitors, compared to placebo, reduced the risk of CV death by 14% (hazard ratio [HR] 0.86; 95%CI 0.79-0.94), of all-cause death by 15% (HR 0.85; 95%CI 0.79-0.91) and of MACE by 13% (HR 0.87; 95%CI 0.81-0.93). A consistent treatment effect on the primary outcome was observed with all SGLT-2 inhibitors (canagliflozin: HR 0.84; 95%CI 0.69-1.02, dapagliflozin: HR 0.89; 95%CI 0.78-1.01, empagliflozin: HR 0.82; 95%CI 0.69-0.97, tofagliflozin: HR 0.90; 95%CI 0.73-1.12) studied (p-subgroup differences = 0.85). Sensitivity analysis pooling data from studies including only diabetic patients with CKD yielded similar results (HR 0.86; 95%CI 0.77-0.97).

Conclusion: Treatment with SGLT-2 inhibitors led to a significant reduction in the risk for CV and all-cause mortality in CKD patients. These findings support the use of these agents also for protection against cardiovascular events and death in CKD.

POTASSIUM LEVELS AND EGFR DO NOT PREDICT SEVERE HYPERKALEMIA FOLLOWING SPIRONOLACTONE INTRODUCTION IN PATIENTS WITH CKD AT HIGH RISK OF HYPERKALEMIA

Frederik Husum Mårup1,2, Christian Peters2, Steffen Nielsen3,4, Bo Madsen5, Louis Nøgaard Pedersen5, Frank Mose3,4 and Henrik Birn2,6

1Aarhus University, Dept. of Biomedicine, Aarhus C, Denmark, 2Aarhus University Hospital, Dept. of Renal Medicine, Aarhus N, Denmark, 3Godstrup Hospital, University Clinic in Nephrology and Hypertension, Herning, Denmark, 4Aarhus University, Dept. of Clinical Medicine, Herning, Denmark, 5Aalborg University Hospital, Dept. of Nephrology, Aalborg, Denmark and 6Aarhus University, Dept. of Clinical Medicine, Aarhus N, Denmark

Background and Aims: Mineralocorticoid receptor antagonists (MRA) reduce blood pressure, albuminuria and the rate of disease progression in patients with chronic kidney disease (CKD) and albuminuria. Despite these apparent benefits, only a very small fraction of patients with CKD are treated with an MRA. This may in part be due to the fear of hyperkalemia (HK), which in the most severe cases can cause life-threatening arrhythmias. Indeed, international guidelines and previous studies have excluded patients believed to be at high risk of severe HK from treatment with MRA including patients with pre-existing high serum potassium. To examine if the risk of HK can in fact be predicted by baseline potassium levels or eGFR, we performed a clinical study testing the effect of introducing spironolactone on plasma potassium (P-K) levels in closely monitored, high-risk patients excluded from other studies. Secondly, we analyzed the effect of spironolactone on eGFR and albuminuria.

Method: We included patients with eGFR 25-60 ml/min/1.73 m² on maximal tolerated RAAS-blockade (ACEi or ARB) and a history of at least two HK-episodes (P-K > 4.5 mmol/l) within 24 months prior to inclusion. Following dietary counselling on avoidance of potassium-rich foods, spironolactone was initiated at 25 mg daily. If tolerated as defined by a decline in eGFR < 30%, a P-K ≤ 5.5 mmol/l and the absence of severe hypotension, the dose was increased to 50 mg after two weeks. Total follow-up was four weeks measuring P-K, eGFR, blood pressure and spot urine albumin creatinine ratio. Results from maximal tolerated dose were compared to baseline using paired t-test. In a post-hoc analysis, patients were grouped based on the occurrence of severe HK (P-K > 5.5 mmol/l) or not, and baseline characteristics and the change from baseline to maximal dose were compared using unpaired t-test. Linear regression model was used to test the association between baseline P-K vs. P-K at maximal dose of spironolactone and the change in P-K from baseline to maximal dose of spironolactone vs. baseline eGFR.

Results: Fifty-eight patients were included with a mean age of 65 years. Forty-seven were males and 23 had diabetes. Forty-eight patients reached a spironolactone dose of 50 mg. Following spironolactone introduction, mean eGFR declined from 39 at baseline to 34 ml/min/1.73 m² (p < 0.001) and albuminuria was reduced from a median of 1276 mg/g to 654 mg/g (49%; 95% CI: 44 – 54%) with no significant change in blood pressure. Mean P-K increased 0.5 mmol/l (95% CI 0.3 – 0.7 mmol/l) from 4.70 vs 4.67 mmol/L (p = 0.83 and 36.2 vs. 40.1 ml/min/1.73 m², p = 0.13). Furthermore, baseline P-K did not correlate with P-K at maximum spironolactone dose (Figure 1) and the change in P-K did not significantly correlate with baseline eGFR (Figure 2).

Conclusion: Short-term treatment with spironolactone in patients with CKD at high risk of HK leads to similar reductions in albuminuria and eGFR when compared with low-risk cohorts. With dietary counseling, 30% of patients will develop severe HK within 4 weeks. Importantly and contrary to common belief, neither baseline P-K levels nor baseline eGFR were associated with the development of severe HK. Thus, excluding patients from MRA treatment based solely on eGFR and P-K levels is not appropriate. Instead, we believe an empirical approach based on dietary counseling and close monitoring of P-K should be used.
Figure 1: Scatterplot of P-K at maximal dose of spironolactone vs. baseline. Best fitted line is plotted. $R^2$ and $P$-values are from linear regression model.

Figure 2: Scatterplot of the change in P-K from baseline to maximal dose of spironolactone vs. baseline eGFR. Best fitted line is plotted. $R^2$ and $P$-values are from linear regression model.
PATIENT ACTIVATION STATUS AND PATIENT PERCEIVED FUNCTION IMPAIRMENT IN CKD: A ROUTE TO OPTIMISING LIFE PARTICIPATION THROUGH ENHANCED SELF-MANAGEMENT?

Courtney J Lightfoot1,2, Thomas Wilkinson1,3 and Alice Smith1,2

1University of Leicester, Department of Population Health Sciences, United Kingdom, 2Leicester NIHR Biomedical Research Centre, United Kingdom and 3NIHR Applied Research Collaboration East Midlands, Leicester Diabetes Centre, United Kingdom

Background and Aims: Chronic kidney disease (CKD), even at earlier stages where kidney replacement therapy is not required, is associated with significant health and symptom burdens which negatively impact on an individual’s functional status and ability to fully engage with work, leisure, and social activities. Life participation can be maximized with optimal day-to-day management of CKD. A strong partnership between the healthcare team and patient is required to support effective self-management. Central to this partnership is patient activation, defined as the knowledge, skills, and confidence to manage one’s own health. Individuals who are highly activated take an active role in their health, whilst those with low activated have a more passive role. Higher activation is associated with better clinical outcomes. As part of a wider survey in people living with non-dialysis CKD (ND-CKD), we explored the relationship between patient activation and perceived functional impairment as a result of CKD.

Method: 14 hospital sites across England invited patients with ND-CKD to complete a survey on health and lifestyle factors including demographic and clinical information, the SF-12 health-related quality of life (QoL) questionnaire, Chalder Fatigue Scale, Patient Activation Measure (PAM-13), and Work and Social Adjustment Scale (WSAS). Participants were classified as having ‘low’ or ‘high’ activation based on their PAM-13 level (Levels 1&2 ‘low’; 3&4 ‘high’). Higher WSAS scores indicated greater perceived functional impairment due to CKD. To compare perceived impairment in WSAS domains between low and high activated participants, Mann-Whitney tests was conducted. To determine the relationship between participant characteristics (i.e., age, gender, ethnicity, eGFR, patient activation, fatigue, physical and mental QoL) and WSAS score, linear regression was performed.

Results: 828 ND-CKD patients completed the survey [mean age 67.9 (±13.8) years, 60% (n = 501) male, 92% White British (n = 771), eGFR 33.1 (±19.7) ml/min/1.73m², total number of additional comorbidities 2.0 (±1.5)], 64% (n = 529) of participants were classified as having ‘low’ activation. The mean WSAS score was 7.8 (±9.9) indicating mild functional impairment. Both high and low PAM groups perceived social and leisure activities (with other people e.g., outings/dating/parties) to be their most impaired functional activities, and close relationships with others as least impaired. Low activated participants perceived greater impairment on work (P = 0.035), home management (P <0.001), other social activities (P =0.001), leisure activities (P =0.001) and close relationships (P = <0.001) as a result of their CKD compared to those with higher activation. Individuals who perceived greater functional impairments were younger (P <0.001), had lower levels of activation (P = 0.036), poorer physical (P <0.001) and mental (P = 0.043) QoL, and greater levels of fatigue (P = 0.001).

Conclusion: People with lower patient activation perceived greater functional impairment to work, leisure, and social activities as a result of their CKD. Younger people may have greater expectations as to what they can functionally achieve and the marked impact in comparison to their peers without CKD may be greater and more prominent. Conversely, older individuals may be more likely to attribute functional impairments to other age-associated comorbidities or to the effects of aging itself than to CKD. Interventions designed to increase patient activation and improve psychosocial adjustment have the potential to help individuals manage their CKD and reduce the perceived impairment on life participation.

USE OF SUPERVISED DEEP LEARNING ALGORITHM TO PREDICT RISK OF RENAL REPLACEMENT THERAPY (RRT) IN PATIENTS WITH CHRONIC KIDNEY DISEASE (CKD)

Ka Chun Leung1, Wing-Sze Ng2, Yui-Pong Siu1, Kai-Ching Hau1 and Hoi-Kan Lee3

1Tuen Mun Hospital, Department of Medicine and Geriatrics, Hong Kong, P.R. China and 2Queen Mary Hospital, Adult Intensive Care Unit, Hong Kong, P.R. China

Background and Aims: Chronic kidney disease (CKD) is one of the most common causes of mortality, affecting around 10% adults worldwide [1]. Although statistical models for predicting risk of renal replacement therapy (RRT) have been developed for a decade [2], referral of patients with CKD to nephrology service is often based on clinical experience of primary care physicians. The use of deep learning algorithms (DLAs) allow clinicians to capture complex, multidimensional, non-linear relationships instead of relying on linear relationships between independent variables and outcome. Our study aims to develop a DLA that has at least non-inferior performance compared to the Kidney Failure Risk Equation (KFRE), which is a well-established and validated risk prediction tool [3].

Method: This is a retrospective cohort study carried out in 3 acute hospitals in Hong Kong providing a total of 3000 beds from Jan 1, 2009 to Mar 31, 2022. All patients aged > 18 with an estimated glomerular filtration rate (eGFR) <30 ml/min/1.73 m² according to the CKD-EPI formula, who attended follow-up for at least 3 months in nephrology clinic of the 3 hospitals, were recruited. Those who were on chronic RRT, received renal transplantation or had an eGFR<15 ml/min/1.73 m² before referral were excluded. Supervised DLAs of different structures and their combinations were created and trained. Data in the test set were fed into models to predict the risk of requiring RRT in 2 years and 5 years. Predictive performance of these models were compared with that of KFRE [3].

Results: 4992 patients were recruited in the study. Data of 499 patients were isolated as test set and were not used for model training. 1576 patients progressed to stage 5 CKD during their follow-up, and 989 patients required initiation of RRT during the study timeframe. When compared with KFRE (4-variable: ROC-AUC = 0.84, 95%CI:0.835-0.852; 8-variable: ROC-AUC = 0.84, 95%CI:0.830-0.847), almost all DLAs showed statistically significant superior robustness in predicting the risk of requiring RRT (Figure 1). No significant difference was found between performance of DLAs combining different neural network layers and those with single structures (CNN+LSTM+ANN layers ROC-AUC = 0.90, 95%CI:0.896-0.902; CNN ROC-AUC = 0.91, 95%CI:0.907-0.914) (Table 1).

Conclusion: The use of DLAs provided better prediction in the risk of requiring RRT when compared with KFRE.

KIDNEY FAILURE MANAGEMENT IN THE ELDERLY: A PRELIMINARY SURVIVAL ANALYSIS
Fiammetta Zanetti1,2, Giulia Fanton1,2, Francesca Martin0, Sabrina Milan Manani1,2, Michele Baretta1,2, Cataldo Abaterusso0, Maurizio Nordio0, Claudio Ronco0 and Monica Zanella1,2
1San Bortolo Hospital, AULSS 8 Berica, UOC Nephrology, Vicenza, Italy,
2International Renal Research Institute of Vicenza (IRRIV), Vicenza, Italy,
3University of Padova, UOC Nephrology, Dialysis and Renal Transplantation Unit, Padova, Italy,
4Civil Hospital of Castelfranco Veneto, Nephrology and Dialysis Unit, Castelfranco Veneto, Italy and
5Treviso Hospital, Nephrology Dialysis and Renal Transplantation Unit, Treviso, Italy

Background and Aims: Dialysis treatment (DT) is the most common approach for patients with kidney failure. However, this may not be optimal for geriatric individuals, as more than half of elderly patients who initiate DT die within the first year. As a result, current guidelines advocate for presenting comprehensive conservative management (CM) as an alternative option for vulnerable patients and their families. A recent meta-analysis (2022) revealed that DT had a median survival time of 20-67 months, compared to 6-31
months for CM, indicating that individuals who opt for DT may have higher survival benefits. This distinction, however, disappears in +80 y/o patients, suggesting that both therapies may yield similar outcomes in this population.

The efficacy of CM, however, remains poorly recognized due to the difficulty in comparing the treatments and the heterogeneous nature of the studies conducted. Therefore, our study aimed to investigate and compare the survival of the elderly who elected to undergo either conservative therapy or dialysis.

**Method:** We present a preliminary analysis of a prospective observational study conducted across 3 Nephrology Units (Veneto, Italy). We enrolled 117 patients in the pre-dialysis or CM clinics, meeting the eligibility criteria: ≥75 y/o, eGFR >15 ml/min/1.73 m² (CKD-EPI formula), and had not already undergone DT or CM (personalized pharmacological therapy combined with a low-protein diet). At baseline, socio-demographic information, patient comorbidities, and blood and urine tests were collected through medical records and interviews. Additionally, the SF-36 questionnaire, the Barthel questionnaire, and the Mini-Mental State Examination assessed the quality of life, functional status, and global cognitive functioning.

Survival was evaluated at 3 and 9 months after follow-up initiation, defined as the date of the first dialysis session or when the eGFR dropped below 15 ml/min/1.73 m² (CKD-EPI formula), and had not already undergone DT or CM (personalized pharmacological therapy combined with a low-protein diet). At baseline, socio-demographic information, patient comorbidities, and blood and urine tests were collected through medical records and interviews. Additionally, the SF-36 questionnaire, the Barthel questionnaire, and the Mini-Mental State Examination assessed the quality of life, functional status, and global cognitive functioning. Survival was evaluated at 3 and 9 months after follow-up initiation, defined as the date of the first dialysis session or when the eGFR dropped below 10 ml/min/1.73 m² in CM patients. The follow-up ended when patients reached the 9th month, died from any cause, switched treatments, discontinued medical follow-up, dropped out of the study voluntarily, or at the end of the project. To determine if any across-group differences existed at the baseline, non-parametric tests were used for continuous variables and the chi-square test for categorical variables. Kaplan-Meier curve, Log Rank Test and Cox regression were performed for survival analysis.

**Results:** Of the 117 enrolled patients, 64 initiated the follow-up, 47 (59.6% M) in CM, and 17 (64.7% M) in DT. The patients in CM were older than those in DT (p = 0.028), with a median age of 82.5 (75.4-91.7) compared to 78.9 (75.6-87.9). At baseline, there were other statistically significant differences (p < 0.05) in median levels of BUN, creatinine, PTH, haemoglobin, and total cholesterol.

Comorbidities were similar in both groups. During the follow-up, 11 patients died (17.2%), 10 in CM (21.3%) and 1 in DT (5.9%). One patient in CM had an unavailable death date and was, therefore, excluded from further analysis. Kaplan-Meier curves and Log Rank Test revealed no significant difference in survival (p = 0.25). The median survival time was undefined, as over 50% of subjects in both groups did not experience the event during follow-up. In CM, unadjusted survival rates at 3 and 9 months were 91.3% and 78.2%, respectively. The effect of the therapies resulted in not significant after adjusting for important prognostic covariates.

**Conclusion:** In this study, we found that middle-term survival in the elderly is comparable to DT and CM. Despite limitations, these results provide valuable information for clinical decision-making. Our results suggest that well-organized CM can be a reasonable option for elderly patients with kidney failure.

**APELIN INCREASES FOREARM BLOOD FLOW IN CHRONIC KIDNEY DISEASE**

Fiona Chapman¹, Vanessa Melville², Lorraine Bruce¹, Janet Maguire³, Anthony Davenport¹, David Newby² and Neeraj Dhaun³

¹University of Edinburgh, Centre for Cardiovascular Science, Queen’s Medical Research Institute, Edinburgh, United Kingdom, ²University of Edinburgh, Clinical Research Centre, Edinburgh, United Kingdom and ³University of Cambridge, Experimental Medicine & Immunotherapeutics, United Kingdom

**Background and Aims:** Chronic kidney disease (CKD) affects 1 in 10 people and cardiovascular disease is its commonest complication. Despite current standard of care, many patients continue to progress to kidney failure and/or die of cardiovascular disease. Thus, there is an urgent unmet need for new treatments that slow kidney function decline and offer broad cardiovascular protection. The apelin system, comprising the apelin receptor and its two endogenous ligands apelin and elabela, is an attractive therapeutic target for CKD. Apelin is an endothelium-dependent vasodilator and a potent inotrope. Clinical studies show that apelin improves endothelial function in health and heart failure, and pre-clinical studies in models of kidney disease find apelin offers renoprotection. At present, apelin has not been studied in patients with CKD. The aims of this study were to examine the local vascular actions of apelin in CKD.

**Method:** Participants with stable, non-diabetic CKD and age- and sex-matched healthy volunteers were recruited to a prospective, randomised, placebo-controlled study. Blood pressure and arterial stiffness (measured using pulse wave velocity) were assessed at baseline. Endothelial function was examined using gold-standard venous occlusion plethysmography. Forearm vasodilation was measured in response to incremental intra-arterial doses of acetylcholine (7.5, 15 and 30 μg/min, used to assess endothelium-dependent vasodilatation), sodium nitroprusside (1, 2 and 4 μg/min, used to assess endothelium-independent vasodilatation), and pyroglutamated apelin-13 ([Pyr¹]apelin-13; 0.3, 1, 3, 10, 30 and 100 nmol/min). Circulating tissue plasmogen activator (tPA) and plasmogen activator inhibitor-1 (PAI-1) were assessed as measures of endogenous fibrinolysis.

**Results:** Fifteen patients with CKD (mean age 55±4 years; 53% male) and 15 healthy volunteers (mean age 51±3 years; 67% male) completed the study. In comparison to healthy volunteers, patients with CKD had a higher blood pressure (mean arterial pressure: 102 mmHg versus 93 mmHg, p < 0.05) and increased pulse wave velocity (7.5±2.2 m/s versus 6.0±0.9 m/s, p < 0.01). Similar dose-dependent vasodilatation to acetylcholine and sodium nitroprusside was seen in both groups. [Pyr¹]apelin-13 increased forearm blood flow by a maximum of ~30% in both health and CKD (p < 0.01 compared to baseline for both) (Figure 1). This response appeared to be dose-dependent. Net tPA antigen release increased 20-70 fold in response to [Pyr¹]apelin-13 in both health and CKD, with a trend to a greater release in CKD. There

**Figure 1:** Kaplan-Meier curve showing the estimated survival probability of patients following DT and CM during the 9-month follow-up.
was no change in PAI-1. No relationship was seen between the response to [Pyr1]apelin-13 and kidney function.

**Conclusion:** Apelin promotes vasodilatation in optimally managed patients with CKD and may regulate endogenous fibrinolysis. If this effect were maintained in the long-term with systemic apelin treatment, it would be expected to reduce cardiovascular risk. Systemic studies are now justified to investigate the haemodynamic and renal effects of apelin in these patients.

**BENEFICIAL EFFECTS OF CHRONIC INTRADIALYTIC EXERCISE TRAINING ON HEMODIALYSIS-INDUCED-MYOCARDIAL STUNNING**

Matthieu Josse1, Laure Patrier2,3, Myriam Isnard4, Cécile Turc-Baron1,5, Antoine Grandperrin1, Stéphane Nottin4, Stéphane Mandigout4, Jean-Paul Cristol2,5, Claire Maufrais4 and Philippe Obert5

1 Avignon University, UPR4278, Laboratoire de physiologie expérimentale cardiovasculaire, Avignon, France, 2 Fondation Charles Mion – AIDER Santé, France, 3 Grabels, France, 4 CHU Nîmes, France, Nîmes, France, 5 ATIR Avignon, France, Avignon, France, 6 CHRU Montpellier, Montpellier, France and 7 University of Limoges, Laboratory HAVAEEA-6310, Limoges, France

**Background and Aims:** Hemodialysis (HD) induces left ventricular (LV) segmental regional wall motion abnormalities (RWMAs) due to hypoperfusion, leading to acute LV transient dysfunction, well known as myocardial stunning. Repeated episodes of HD-related myocardial stunning contribute directly to the development of heart failure and increased mortality in patients receiving HD (Burton et al., 2009). Exercise training exert pleiotropic favorable effects on the cardiovascular system. No study has however investigated its impact on the kinetics of regional myocardial function during HD. This study aims to evaluate the effect of intradialytic exercise (IDE) on RWMAs compared with standard care.

**Method:** This was a prospective, open-label, two-center trial (clinicaltrials.gov NCT04697459) with two parallel groups: 31 patients (ENT) undergoing a 4-month IDE program (30min of cycling + 30min of resistance training starting 30 min after HD onset) and 21 patients continuing usual care (CTRL). Untrained adults, aged 20-79 years, undertaking maintenance HD for >3 months were eligible to participate. Exclusion criteria were poor echogenicity, contraindication to exercise, orthopedic complications, severe heart (ischemic, valvular, ...), vascular or respiratory diseases, ejection fraction <45% and body mass index >35. Longitudinal strain (LS) using speckle-tracking echocardiography were measured during a standard HD session, just before HD onset (HD_{T0}) and at peak stress of HD (30 min before HD-ending, HD_{Peak}). The same procedure was used before and after 4-months of IDE or usual care. LS from a 18 LV segment model were used to assess the presence of HD-induced RWMAs, defined as ≥20% reduction in LS at peak stress compared to baseline. A generalized linear mixed model (Poisson model) was used to analyze the effect of IDE on RWMAs.

**Results:** After 4 months of IDE, we observed a significant reduction of RWMAs at HD_{Peak} (mean before: 6.09±3.16; point estimate: -0.05, 95% CI: -1.45/-1.54, p = 0.06). There was also evidence that IDE program significantly attenuated the decline of global LS observed during HD (mean before: 20.21±3.19 vs after: 4.55±2.26; point estimate: -1.48, 95% confident interval CI: -0.39/-2.57, p = 0.03), whereas its occurrence remained unchanged in CTRL (mean before: 6.14±3.51 vs after: 6.09±3.16; point estimate: -0.05, 95% CI: 1.45/-1.54, p = 0.96). There was also evidence that IDE program significantly attenuated the decline of global LS observed during HD (mean before: 2.11±2.39% vs after: 1.10±1.95%; point estimate: -1.01%, 95% CI: -1.86/-0.13, p = 0.02) compared to the similar impairment in CTRL (before: 1.60±2.30% vs after: 1.79±2.08%; point estimate: +0.18%, 95% CI: +1.20/-0.85 p = 0.72).

**Conclusion:** There is clear evidence that chronic IDE is cardioprotective. Identifying the underlying mechanisms responsible for exercise-induced cardioprotection was beyond the scope of our study, but we can reasonably assume that structural and/or functional changes in the coronary arteries, especially in microcirculatory territories (i.e. increased collateral circulation due to angiogenesis/arteriogenesis, improved endothelial function, reduced blood viscosity) and/or intrinsic changes in the cardiac myocyte (reduced fibrosis, enhanced calcium handling/sensitivity, altered mitochondrial turnover and phenotype), related among others to reduced oxidative stress and/or inflammation, might play a role (Powers et al 2014). Whether our results translate to longer-term reduction in clinical outcomes and cardiovascular mortality in end-stage renal disease patients require further studies.
SCREENING AND DIAGNOSIS STRATEGY FOR FABRY DISEASE IN TAIWANESE PATIENTS WITH CHRONIC KIDNEY DISEASE

Ming-Ju Wu¹, Chih-Jen Wu², Cheng-Jui Lin³, Feng-Jung Yang⁴ and Mai-Szu Wu⁴

¹Taichung Veterans General Hospital, Division of Nephrology, Department of Internal Medicine, Taichung, Taiwan, Rep. of China, ²Mackay Memorial Hospital, Division of Nephrology, Department of Internal Medicine, Taipei, Taiwan, Rep. of China, ³National Taiwan University Hospital Yun-Lin Branch, Hu-Wei Region, Division of Nephrology, Department of Internal Medicine, Yun-Lin, Taiwan, Rep. of China and ⁴Taipei Medical University, Department of Internal Medicine, School of Medicine, College of Medicine, Taipei, Taiwan, Rep. of China

Background and Aims: Fabry disease (FD) is not uncommon in patients with chronic kidney disease (CKD) who are on dialysis or have stroke at a young age, left ventricular hypertrophy (LVH) or hypertrophic obstructive cardiomyopathy (HOCM). However, FD is easily overlooked by physicians due to the heterogeneity of clinical manifestations. Therefore, an expert consensus meeting was held to establish a screening algorithm for FD in patients with CKD.

Method: The first meeting was held in Taiwan in August 2022. The screening criteria for FD with respect to age, sex, family history, cardiac involvement and signs and symptoms were discussed. The findings of meeting and the consensus opinion of the expert group were summarized.

Results: The screening algorithm was shown in Figure 1. It is recommended to screen for FD regardless of age. Screening for FD is recommended for CKD patients with family history of FD, stroke at young age (<55 years) or typical signs and symptoms including angiokeratoma, hypohidrosis, neuropathic pain, heat/cold and exercise intolerance, hearing loss and cornea verticillata. If CKD patients have one of the cardiac symptoms including dyspnea, palpitation and chest pain, it is recommended to check the cardiac-related red flags including LVH and HOCM using echocardiogram, short PQ interval, atrioventricular block and prolonged QRS interval using electrocardiogram, and low native T1 and posterolateral late gadolinium enhancement using magnetic resonance imaging. If cardiac-related red flags are present, screening for FD is recommended. Screening can also be performed in patients with CKD who do not have any typical symptoms but have a high suspicion of FD. In males, screening can be performed by measuring α-galactosidase A enzyme activity. If the enzyme activity is reduced or absent, assessment of globotriaosylsphingosine (lyso-Gb3) levels in plasma and genetic analysis are recommended. In female, assessment of lyso-Gb3 levels in plasma and genetic analysis are recommended.

Conclusion: FD is an underrecognized and not so rare disease. Physicians should maintain a skeptical attitude in clinical practice in order to make diagnosis in time and help patients and their entire families avoid life-threatening diseases at a young age. There are still more issues to be addressed, including whether to inform patients of the screening results, how to interact and communicate with patients, etc.

Figure 1: Proposed flowchart for diagnosis of Fabry disease in patients with chronic kidney disease. HOCM, hypertrophic obstructive cardiomyopathy; lyso-Gb3, globotriaosylsphingosine; LVH, left ventricular hypertrophy.
C3 GLOMERULOPATHY CURRENT THERAPY AND REAL-WORLD MANAGEMENT - INTERIM RESULTS FROM A MULTI-COUNTRY STUDY

Clare Proudfoot1, Katharina Pannagl2, Briana Ndife3, Andrea King1, Kathleen Murphy3, Susanna Libby4 and Richard Lafayette5

1Novartis Pharma AG, Basel, Switzerland, 2Novartis Pharmaceuticals UK Limited, London, United Kingdom, 3Novartis Pharmaceuticals Corp., East Hanover, United States of America, 4Adelphi Real World, Bollington, United Kingdom and 5Stanford University Medical Center, Stanford, United States of America

Background and Aims: C3 glomerulopathy (C3G) is a rare form of glomerulonephritis, with an estimated incidence of 1–2 per million per year. C3G is associated with a high risk of disease progression with approximately 50% of patients reaching kidney failure within 10 years of diagnosis. No treatments have been proven effective through randomized controlled trials. KDIGO glomerular disease guidelines recommend treating with renin-angiotensin-aldosterone system inhibitors (RAASi) to reduce blood pressure and proteinuria, and, in select patients, utilization of immunosuppressants such as mycophenolate mofetil and corticosteroids. Newer agents, such as eculizumab, are also sometimes used off-label. The aim of this analysis was to better understand the current management of C3G in the US, Europe, and Asia.

Method: An analysis was conducted using interim data from the Adelphi C3G Disease Specific Programme (DSP), a cross-sectional survey of C3G-treated nephrologists in US, EU5 (France, Germany, Italy, Spain, UK), China and Japan (study ongoing since August 2022; interim analysis based on data until November). Nephrologists completed structured forms administered via online links for consecutive patients presenting with C3G. Forms included information on current and most recent therapy.

Results: In this interim analysis, 88 nephrologists had completed records for 277 patients, including 95 in US, 120 in EU5, 39 in China and 23 in Japan. Median patient age at time of the survey was 44, and 60% were male. 80% had C3 glomerulonephritis (C3GN) and 19% had dense deposit disease (DDD). At the time of the survey, 82% out of 277 patients were receiving treatment. The majority (69%) of 228 treated patients were receiving RAASi, 27% were receiving mycophenolate mofetil/mycophenolate sodium, 48% corticosteroids, and biologics were used in almost a third of patients. At the time of the survey, mean proteinuria was 2.1 g/day, with 60% of patients having proteinuria ≥ 1 g/day (Table 1).

Conclusion: C3G is a rapidly progressing glomerulonephritis for which there is no approved therapy. Most patients in this real-world study were receiving treatment, with both conventional immunosuppressants and biologics frequently added to RAASi. Despite this, proteinuria remained high, with the majority of patients having proteinuria ≥ 1 g/day. This highlights the need for novel therapies to actively treat C3G.

Table 1: Current therapy and proteinuria levels by region.

REAL WORLD EVALUATION OF SGLT2 INHIBITORS IN PATIENTS WITH DIABETIC NEPHROPATHY AND HEART FAILURE: THE EFFECT ON THE DIASTOLIC DYSFUNCTION

Dimitris Xydakis, Ergini Antonaki, Eleni Tsali, Fanouria Liaka, Christina Petra, Konstantinos Kostakis and Eleftheria Vardaki

Venizeleio Hospital, Nephrology Department, Greece

Background and Aims: In patients with diabetes mellitus and diabetic nephropathy, a high incidence of left ventricular diastolic dysfunction has been reported by various studies. The objective of this study was to the real world evaluation of the impact of sodium glucose cotransporter type 2 (SGLT2) inhibitors on left ventricular (LV) diastolic function of type 2 diabetes mellitus (T2DM) patients with diabetic nephropathy and heart failure (HF).

Method: We studied patients with Diabetes Mellitus type 2, diabetic nephropathy (eGFR > 30 ml/min/1.73 m²) and stable (at least for 3 months) Heart Failure with reduced ejection fraction. We excluded patients treated with SGLT2 before the study initiation. Laboratory and Echocardiographic studies (Left Ventricular Ejection Fraction LVEF%, the ratio (E/A), Early diastolic velocity (Em), LV mass index (LVMI)), were performed in all patients at baseline and after 12 months of treatment with dapagliflozin 10 mg/day.

Results: 67 patients were included (38/29 M/F, age 68 ± 14.2 years), with eGFR 72.5 ± 9.2 ml/min/1.72 m²) at baseline. Mean duration of diabetes was 14.2 ± 7.9 years, and mean HbA1c was 7.9 ± 1.1%. There was a significant increase of LVEF (38.5 ± 8.1% to 43.7 ± 7.4%; p = 0.02). LV Mass Index was decreased from 78 g/m² to 67 g/m² (p = 0.01) and there was a significant decrease in E/e′ (11.8 to 9.6 cm/s (p = 0.01). Urinary albumin excretion rate at baseline was 526 ± 233 mg/24H and there was a reduction of 32% at the end of the follow up. Multiple regression analysis showed that reduction in albuminuria was an independent predictive factor for E/e′ changes.

Conclusion: Data from this study showed LV diastolic function as assessed in terms of E/e′ and LVMI had significantly improved 12 months after the initiation of dapagliflozin. Reduction of albuminuria by SGLT2i, is an independent predictive factor for improvement of LV function.

A NETWORK META-ANALYSIS COMPARING INTENSIVE GLYCEMIC CONTROL AND SGLT-2 INHIBITORS IN PREVENTING RENAL OUTCOMES

Samit Ghosal

Nightengale Hospital, Endocrinology, Kolkata, India

Background and Aims: Type 2 diabetes (T2D) is one of the prominent causes for chronic kidney disease (CKD) leading to end-stage renal failure. Traditionally, prevention and retardation of CKD was attempted with effective glycemic and blood pressure control. In recent times sodium glucose co-transporter 2 inhibitors (SGLT-2is), glucagon-like peptide 1 receptor agonists (GLP1-RA), and non-steroidal mineralocorticoid receptor (MRA) inhibitors have proved to be excellent agents in preventing cardio-renal outcomes in patients with T2D, independent of baseline glucose control. SGLT-2is rank the highest in recent network meta-analysis-based scoring. We conducted this network meta-analysis to explore the ranking of intensive glucose therapy in comparison to SGLT-2is, to better understand the present position of the traditional approach and its relevance.

Method: A database search was conducted using the Cochrane library to identify relevant citations. Analysis was conducted using RStudio (2022.07.1, Build 554). Using progression of macroalbuminuria and end-stage kidney disease (ESKD) as the outcomes of interest, scoring was performed comparing intensive glycemic control (IGC) and SGLT-2is. Using a frequentist approach P-score was conducted and corroborated using the Surface Under the Cumulative Ranking (SUCRA) using Bayesian network meta-analysis.

Results: A pooled population of 62,742 patients from twelve citations were included for analysis. The Cochrane risk of bias was used to assess quality of the studies. IGC scored higher than SGLT-2ias as far as retardation of progression of macroalbuminuria was concerned while using both the P-score (0.99 Vs 0.50) as well as the SUCRA (0.97 Vs 0.52). A similar trend was also observed with ESRD as the end point with both the P-score (0.84 Vs 0.65) and the SUCRA (0.81 Vs 0.68) rankings favoring IGC (Fig. 1).

Conclusion: The importance of achieving glycemic targets should be emphasized in recommendations in the same footing as the choice of individual reno-protective agents.
Background and Aims: ADPKD is the most prevalent genetic kidney disease. Tolvaptan is the first proven disease-modifying therapy, but is associated with aquaretic side effects, frequently leading to treatment discontinuation. Therefore, identifying factors, which can ameliorate the aquaretic side effects and facilitate therapy is crucial. Previous data reported 24-h-osmolar excretion in urine or GFR as the main determinants of urine volume on tolvaptan but included only few patients. This study’s objective was to prospectively examine the 24-hour urine volume and urine osmolality during the up-dosing phase of tolvaptan in a cohort with a moderate sample size and different subgroups in order to identify modifiable and non-modifiable factors for urine volume increase. Finally, quality of life (QoL) during tolvaptan treatment was investigated in relation to urine volume since these data are scarce thus far and provide crucial insights into the therapy burden.

Method: Analysis of 24-h urine collection at baseline and at least once on tolvaptan was carried out for 75 patients (complete cohort). For 35 patients (longitudinal cohort) urine collections were available for baseline and all three tolvaptan doses (45/15 mg, 60/30 mg and 90/30 mg). All patients are participants of the German AD(H)PKD registry. Sodium, protein and potassium intake were calculated from excretion in 24h-urine and QoL was assessed by the Short Form-12 (SF-12) questionnaire. Statistical analyses were computed using R statistical software. A p-value of ≤ 0.05 was regarded as significant.

Results: The mean age of the patients in the complete cohort was 41.3 ± 10.7 (range 18-64 years) with a mean eGFR of 67.3 ± 27.2 ml/min/1.73m² and was similar to the longitudinal cohort with a mean age of 41.8 ± 10.1 (23-64 years) and eGFR of 69.4 ± 27.5ml/min/1.73m². A significant increase (p< 0.0001) in 24-hour urine volume (138%) occurred only immediately after therapy initiation with no further significant increase during up-dosing in the complete and longitudinal cohort. In line with this 24-hour osmolality decreased (57%) significantly (p< 0.0001) only after beginning of treatment and remained almost unchanged after up-dosing. Total solutes, protein and sodium intake showed non-significant changes across all doses. There were no significant differences in urine volume between gender, age classes (<45 vs. >45 years), or Mayo class when examining the various subgroups. Considering modifiable factors, 24-hour urine volume was positively correlated with eGFR on tolvaptan reaching significance on 45/15 mg (p = 0.013) and 90/30 mg (p = 0.027). Patients <45 years and patients with an eGFR ≥ 60 ml/min/1.73m² experienced a significantly higher relative urine volume increase at the beginning (p = 0.0332 vs. ≥45 years and p = 0.0097 vs eGFR < 60 ml/min/1.73m²) in the complete cohort. In multivariable linear regression analyses containing modifiable and non-modifiable covariates only sodium intake had a significant impact in tolvaptan-naive patients (p = 0.0064), while on tolvaptan age (p = 0.008) and weight (p = 0.0190) became significant together with sodium intake (p = 0.008) and potassium intake (p = 0.0040). Across the three tolvaptan doses no significant differences between the number of patients reaching pre-defined osmolality goals (< 250 mosmol/kg for spontaneous urine and < 150 mosmol/kg for 24-hour) could be detected. Before and after tolvaptan treatment, neither the mental nor physical QoL changed significantly.

Conclusion: Our study showed that the significant rise in urine volume occurs immediately after therapy initiation with only minor and non-significant increases upon further up-dosing. Urine osmolality decreases significantly directly after start of tolvaptan and remains constant with most patients achieving adequate suppression of urine osmolality. Patient counseling should consider that younger patients and patients with better eGFR might experience stronger urine volume increase at the beginning and advising to reduce salt and potassium intake can ameliorate aquaretic side effects. Tolvaptan treatment showed no negative impact on QoL but further investigations in larger cohorts are needed.
MAINTAINING PHYSICAL ACTIVITY IN PATIENTS THROUGH INTRADIALYTIC VIRTUAL REALITY EXERCISE INTERVENTION: THE REVID STUDY

Marina Toquero1, Vicente Benavent Caballero1, Francisco José Martínez-Olmo1, Noemi Valtueña-Gimeno1, Alicia García-Testa2, Alicia Cana-Poyatos2, Inmaculada Rico-Salvador2, Verónica Vercher Narbona2, José Antonio Gil-Gómez3 and Eva Segura4

1CEU Cardinal Herrera University, Alfara del Patriarca, Spain, 2Manises Hospital, Manises, Spain and 3Valencia Polytechnic University, Valencia, Spain

Background and Aims: People suffering from Chronic kidney disease (CKD) have lower levels of physical activity than their healthy counterparts. The lower level of physical activity is associated with impaired physical function in people undertaking hemodialysis. The COVID-19 pandemic has worsened the physical activity level of this cohort. Intradialysis exercise programs have a positive impact on many functional variables, but despite these proven benefits exercise interventions are scarce in clinical practice. Our group is implementing strategies to increase clinical applicability of exercise programs. Virtual reality (VR) intradialysis programs improve function of patients. The main aim of this study was to analyze the impact of an intradialytic non-immersive VR exercise program on physical activity level of people undertaking hemodialysis treatment.

Methods: A randomized trial (the REVID study) included two groups of patients, exercising at different times during the dialysis session for up to 12 months. The present study includes participants from the REVID study who, once the study finished, continued exercising at their preferred time during the hemodialysis treatment, with the only support of the health professionals at the HD unit. Adherence to the exercise program was measured as a percentage (number of sessions attended divided by the number of sessions offered). The physical activity level was evaluated using the Human Activity Profile (HAP) questionnaire. The HAP scale is self-administered and is a list of 94 daily activities; the maximal activity score (MAS) and adjusted activity score (AAS) were calculated in this evaluation. Depending on the outcome of the HAP, patients were classified as having physical activity levels that were “impaired” (<53 points), “moderately active” (33–74 points), or “active” (>74 points). These patients had been exercising The intradialytic exercise consisted of a non-immersive VR game called ‘Treasure Hunt’ in which the participant try to catch targets and avoid obstacles by moving their lower limbs (hip flexion, abduction and adduction, and knee flexion and extension). The difficulty level of the game was graduated according to the characteristics of each player and the participants were allowed to change their legs during the game at their convenience. The impact of the program on physical activity level was analyzed with a non-parametric test for paired samples (p < 0.05).

Results: This study included 11 participants, mean age 71.6 (13.9) years, 9 males, median dialysis vintage 18 months (10 to 50 interquartile range), and Charlson index 6.3 (2.2). The AAS at the baseline of the REVID study was 58.7 (58–72 interquartile range). The median time that participants exercised in the REVID study was 12 months (6 to 18 months interquartile range). After 3 months of the present study, when they exercised at any time during dialysis, they maintained their physical activity level, from a median AAS of 69 (interquartile range 52–71), to a Median of 70 (interquartile range 41–74). The changes were non-significant. The main adherence to the exercise sessions was 54.6 (11.7%).

Conclusion: This study suggests that an intradialysis virtual reality exercise program maintains the physical activity level of elderly patients undertaking HD. Most of the participants in this long-term intervention were male and moderately active. Future interventions should include an ‘exercise champion’ professionals in the units to recruit women and less conditioned participants, and to achieve higher adherence rates.

EFFECT OF BROCCOLI SPROUT EXTRACT IN PATIENTS WITH TYPE 2 DIABETES AND CHRONIC KIDNEY DISEASE (INITIATE) - DESIGN AND BASELINE DATA

Carla Maria Avesani1, Oskar Swartling2, Maria Eriksson Svensson3, Olof Heinberger4, Sigrid Lundberg4, Gregor Guron4, P. Andreas Jonsson4, Marten Segelmark4, Marie Evans3 and Peter Stenvinkel4

1Karolinska Institutet, Department of Clinical Science, Technology and Intervention, Stockholm, Sweden, 2Karolinska Institutet, Clinical Epidemiology Department, Stockholm, Sweden, 3Uppsala University, Department of Medical Sciences, Renal Medicine, Uppsala, Sweden, 4Danderyds Hospital, Danderyd, Sweden, 5Sahlgrenska Academy at the University of Gothenburg, Department of Molecular and Clinical Medicine/Nephrology, Institute of Medicine, Gothenburg, Sweden, 6Umeå University, Department of Public Health and Clinical Medicine, Umeå, Sweden and 7Lund University, Department of Clinical Sciences, Lund, Sweden

Background and Aims: In advanced stages of chronic kidney disease (CKD) some glucose-lowering agents, such as metformin, cannot be prescribed to patients with type 2 diabetes (T2D) due to the risk of accumulation and adverse events. Foods with bioactive components, “functional food”, can be an alternative to mitigate the metabolic disturbances in these patients. Previous research on experimental animals and patients with T2D has shown that sulforaphane, present in broccoli sprouts, improves insulin sensitivity and glucose control. We hypothesize that sulforaphane ingested as a broccoli sprout extract (BSE) can improve glucose control in patients with T2D and CKD.

Method: This is an ongoing multicentre randomized double-blinded controlled trial with glucose control as the primary outcome. Glucose control is evaluated by fasting serum glucose, serum insulin in all patients, and oral glucose tolerance test (OGTT) in patients not on insulin treatment. Moreover, as a secondary aim, we investigate the role of BSE in improving other signs of metabolic alterations, including oxidative stress, proteinuria, inflammation and production of uremic toxins from the gut microbiota.

Patients: Adult patients with T2D and CKD (eGFR 15–45 ml/min/1.73m²) are included and randomized 1:1 to receive BSE or placebo. Both groups are followed for 20 weeks. The first 12 weeks, patients receive BSE or placebo and are then followed for 8 weeks. Patients randomized to BSE receive an increasing dose of sulforaphane administered as BSE (Lamtämnes®) starting with 50 μmmol/day in week 0–4; 100 μmmol/day in week 5–8 and 150 μmmol/day in week 9–12. The placebo consists of maltodextrin sprayed with copper-chlorophyllin. Blood and urine laboratory measurements and OGTT is performed at week 0, 12 and 20. Randomization is done using a computer-based block randomization algorithm. The protocol is registered at clinicaltrials.gov (NCT049858854).

Results: 98 patients with T2D and CKD from 12 centers in Sweden were included and the recruiting phase has now been finalized but the follow up phase is still ongoing. We here present baseline characteristics of all study participants (Table 1). Median age is 75 years and a minority are women. Mean eGFR corresponds to CKD stage 4 and there are large variations in albumin/creatinine ratios. Most participants are on a combination of oral glucose-lowering agents and insulin. A history of cardiovascular disease is common, and 21% had a previously had myocardial infarction.

Conclusion: We are currently conducting a randomized clinical trial testing if BSE can be used as an alternative or add-on to improve glucose control in patients with T2D and CKD stages 3–4 type and to see if this ‘high risk’ patient group could benefit from treatment with BSE.

Table 1: Baseline characteristics of patients with type 2 diabetes and chronic kidney disease in the INITIATE trial (n = 98).

| Overall | Age, years, median (IQR) | 75 (70–78) |
| Sex, % (women) | 30 (31%) |

CLINICALLY MEANINGFUL IMPROVEMENT IN QUALITY OF LIFE ACCOMPANIES ITCH RELIEF IN PATIENTS WITH CHRONIC KIDNEY DISEASE ASSOCIATED PRURITUS

Leonie Kraft1, Thilo Schaufler2, Despina Ruessmann2, Isabelle Morin3, Frederique Menzaghi3, Warren Wen1 and Thilo Krüger4

1Robert-Bosch-Krankenhaus, Stuttgart, Germany, 2CSL Vifor, Zurich, Switzerland, 3Cara Therapeutics, United States of America and 4University Clinic of the RWTH Aachen, Division of Nephrology and Rheumatology, Germany

Background and Aims: The impairing effect of chronic kidney disease-associated pruritus (CKD-aP) on the quality of life (QoL) of patients undergoing haemodialysis (HD) is well-established. The aim of this post-hoc analysis was to assess the impact of itch relief on QoL, as measured by the 5-Ditchscale,inpatientswithCKD-aPenrolledinthePhase3KALM-1and-2 clinicaltrials.Thisstudyalsoaimedtoconfirmtheuseof ≥5-pointreductionin 5-D itch scale total score as a threshold for clinically meaningful improvement in itch-related QoL, by comparing to notable improvement on the Patients’ Global Impression of Change (PGI-C) scale.

Method: Data were pooled from 851 patients with moderate-to-severe CKD-aP undergoing HD in the KALM-1 and -2 trials testing difelikefalin vs placebo. Sustained responders were defined as patients who achieved a ≥3-point improvement in the weekly mean 24-hour Worst Itching Intensity Numerical Rating Scale [WI-NRS] score at Week 12 of the study, whereas non-sustained responders were defined as patients that reported a ≥3-point improvement in any week of the study but not at Week 12. Improvements in QoL, as measured by the mean change in 5-D itch scale total score from baseline to Week 12, were compared in sustained responders vs non-sustained responders. Data were analysed by ANCOVA multiple imputation, with a missing-at-random assumption. The mean change in 5-D itch scale total score was analysed in relation to patients’ reporting on the five categories of the PGI-C scale.

Results: In pooled analysis, 305 patients undergoing HD with CKD-aP qualified as sustained responders, whereas 128 patients were non-responders. Reduction in 5-D itch scale total score over 12 weeks was significantly higher in sustained responders compared with non-sustained responders (least squares [LS] mean ±standard error; –7.1±0.2 vs –4.0±0.3, LS mean difference –3.0±0.3, p<0.001) (Figure 1). Greater reductions in 5-D itch scale total score were observed in patients reporting more substantial improvements in PGI-C. Specifically, patients reporting much, or very much, improvement in PGI-C score ≥5-point reduction on the 5-D itch scale (mean ±standard error; –5.3±0.2 and –8.2±0.3, respectively) (Figure 2).

Conclusion: This study observed a greater improvement in QoL, as measured by the 5-D itch scale total score, in patients with CKD-aP who reported a clinically meaningful reduction in itch, as measured by WI-NRS, at Week 12. These results also support the use of ≥5-point reduction in the 5-D itch scale total score as a threshold for clinically meaningful improvement in the QoL of patients with CKD-aP. As only sustained responders exceeded this threshold, these data suggest that continued treatment of itch may be necessary to maximally improve QoL in these patients.

Figure 1: Change from baseline to Week 12 in 5-D itch scale total score in sustained responders and non-sustained responders. ANCOVA analysis multiple imputation, with missing-at-random assumption. Responders were defined as patients who reported a ≥3-point improvement in WI-NRS score at the 12-week time point. Non-responders were defined as patients who no longer achieved ≥3-point improvement in WI-NRS score at the 12-week time point, despite achieving at least one weekly ≥3-point improvement in WI-NRS score earlier in the study period. LS, least squares; SE, standard error; WI-NRS, Worst Itch Numerical Rating Scale.
HEALTHY PLANT-BASED DIET IN CHRONIC KIDNEY DISEASE THROUGH USE OF SODIUM ZIRCONIUM CYCLOSILICATE (HELPFUL TRIAL): RESULTS OF DIETARY INTAKE

Torsten Sallstrom1, Olof Heimbürger 2, Charlotta Rubin3, Awa Danielsson4, Gerd Faxen Irving5, Bengt Lindholm6, Peter Stenvinkel6 and Carla Maria Avesani6

1Nyköping Hospital, Department of Dietetics, Nyköping, Sweden, 2Karolinska Institutet, Department of Clinical Science Intervention and Technology, Stockholm, Sweden, 3Karolinska University Hospital, Medical Unit Clinical Nutrition, Stockholm, Sweden, 4Karolinska University Hospital, Medical Unit Nephrology, Stockholm, Sweden, 5Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Stockholm, Sweden and 6Karolinska Institutet, Department of Clinical Science, Technology and Intervention, Stockholm, Sweden

Background and Aims: The dietary restriction of healthy food sources of potassium (K) counselled to patients with chronic kidney disease (CKD) and hyperkalemia (HK) contributes to a diet with poor dietary quality. The K lowering medication sodium zirconium cyclosilicate (SZC) has the potential to treat HK, thereby allowing a healthy plant-based diet (PBD). We designed a clinical trial to explore the safety and feasibility of prescribing a healthy PBD to CKD patients with HK with the concomitant use of SZC.

Method: The HELPFUL trial is an ongoing single-arm study with CKD stage 4-5 patients not on dialysis and with plasma K (pK) between 5.1-6.5 mmol/L at inclusion. Patients are followed for six weeks. In the first three weeks, SZC is prescribed to normalize pK while patients ingest a low protein diet with low K content. In the subsequent three weeks, a healthy PBD with a target K intake of 3700mg/day is prescribed while maintaining the use of SZC. A food basket with PBD is delivered to participants weekly. A weekly monitoring of pK and titration of SZC to keep normokalemia is performed. Two dietary quality scores were calculated using the 24-hour food record (24h-FR) at baseline, week three and six. The first index is the Swedish version of Nutrient rich food index (S-NRF11.3) that measures the density of 11 beneficial nutrients (fiber, folate, iron, calcium, potassium, protein and vitamins A, C, D and E) and three non-beneficial nutrients (saturated fat, sodium and added sugars). The second index is the mean adequacy ratio (MAR) with the average intake of the same 11 beneficial nutrients as a proportion of the recommended daily intake (RDI). Data was analyzed by repeated measures-ANOVA or by Friedman test for related samples, as appropriate. Registered at www.clinicaltrials.gov (identifier NCT04207203).

Results: 22 patients were included; 59±13 years; 13 men, eGFR 18±4 mL/min/1.73m² (Table 1). The total intake of energy, fibre, folate and K increased significantly in week 6. Nutrient density did not change, but the MAR-score increased significantly. The intake of servings of fruits, vegetables and nuts increased significantly throughout the PBD. Regarding animal protein, there was a tendency to decrease the intake of servings of red meat and a significant increase in poultry and fish. The mean pK normalized in week three and six. After the start of PBD, three patients (13.6%) had pK between 5.1-5.3 mmol/L.

Conclusion: The strategy of PBD food baskets with concomitant use of SZC improved the dietary quality and increased the intake of servings of healthy foods. The K intake increased but not to target value. The pK was kept within normal values for most patients.

Background and Aims: CEUS is a reliable method to diagnose ischemic renal pathologies such as infarction, identify renal abscesses, discriminate between renal tumors and anatomical variants, describe complex cyst lesions, and monitor non-surgical renal lesions. Few studies explore the relationship between CEUS and the diagnosis or progression of CKD. The aim of this study was to evaluate the relationship between contrast-enhanced ultrasonography with arrival time parametric imaging (CEUS-PAT) and CKD.

Method: We prospectively evaluated 64 subjects (37 liver cirrhosis patients and 27 healthy volunteers) using CEUS-PAT to detect if the presence of CKD influences the arrival time of the contrast in the kidney. CKD was defined according to KDIGO 2021 guidelines. Ultrasonography was performed using the LOGIQ E9 (GE Healthcare, Chalfont St.Giles-UK) system, probe C1-6. CEUS was performed on each subject using SonoVue (Bracco SpA, Milan, Italy) as a contrast agent (1/2 of a vial). A 2.5 mL contrast substance followed by a 5 mL normal saline solution was infused in the cubital vein. A ratio between the arrival time of the substance in the kidney and liver was calculated. Subjects were in fasting conditions for at least 12 h. Laboratory data were extracted from the patient’s GP file. The study was conducted between January - December 2018. All patients provided their informed consent for the procedures.

Results: The study included 64 subjects, mean age of 58.98 ± 8.90 years, predominantly male gender (56.3%). Of the 64 patients, 13 (20.3%) had chronic kidney disease. All patients with chronic kidney disease had liver cirrhosis. When comparing the two groups, with and without CKD, there was a significant difference between the ratio of the arrival time of the contrast agent into the kidney and liver, 0.85 ± 0.09 vs 0.65 ± 0.19, p = 0.0005. The factors associated with kidney disease were liver steatosis (p<0.0001), age over 60 years (p = 0.01) and low albumin (p<0.0001).

Conclusion: Our study indicated that the presence of CKD influences the contrast agent arrival time in the kidney. Further studies are needed to establish the predictive significance of CEUS-PAT data in CKD patients.

THE EFFECTS AND MECHANISM OF BRAIN-TARGETING DRUG-LOADED EXOSOMES ON ADRIAMYCIN NEPHROPATHY MODEL

Lishan Tan1,2, Guang Yang1,2, Zheng Fengping2, Zhiwei Lai1,2,3, Sanmu Li2 and Zibo Xiong3

1 P.R. China, 2 Peking University Shenzhen Hospital, Nephrology, Shenzhen, P.R. China and 3 Nephrology, Shenzhen, P.R. China

Background and Aims: Chronic kidney disease (CKD) is a common clinical syndrome, and the current clinical efficacy is still limited. Our previous study confirmed that a small amount of losartan injected into the central lateral ventricle can effectively protect the kidneys, but the route of administration limits its clinical application. As a drug carrier, exosomes have several advantages and are expected to support drug delivery. Therefore, this study aims to develop a brain-targeting exosome complex to provide a new idea for the treatment of CKD.

Method: In this study, the brain-targeting exosome complex (ExoACP) was synthesized by co-cultivation. The markers of ExoACP were detected by immunoblotting. The structure and particle size distribution were observed by TEM and NTA. Angiotensin II receptor antagonist losartan (ExoACP@Los) was loaded on ExoACP by electroporation. The mice of Adriamycin (ADR)-induced nephropathy were divided into 5 groups: Control, ADR, ADR + Los (IG), ADR + ExoACP (lv.), ADR + ExoACP@Los (lv.). Corresponding treatment was given every other day from the 3rd week after modeling, and all mice were sacrificed at the 5th week, serum and renal tissue was collected for the following experiments.

Results: This study found that the exosome markers of ExoACP were highly expressed. The Exo and Ang-CP06-Exo were disc-like structures, and the size of the latter was larger than that of the former, suggesting that ExoACP was successfully modified on the surface of Exo. The modification efficiency of ExoACP on Exo was as high as 96.1%. Compared with free Exo, the distribution of ExoACP in brain was increased. Blood biochemical results showed that ExoACP and ExoACP@Los had no apparent side-effects on mice (Figure 1).

In-vivo, ExoACP@Los treatment significantly improved the levels of kidney function in mice with ADR nephropathy. ExoACP@Los could significantly reduce renal tubular damage, interstitial fibrosis area and degree of glomerulosclerosis, suggesting that ExoACP@Los could improve the injury of renal tissue (Figure 2).

Conclusion: This study synthesized a drug-loaded exosome complex with brain targeting and good biocompatibility, and significantly improved renal function, renal tissue damage and collagen fiber deposition in the ADR model.
SGLT-2 INHIBITORS DELAY KIDNEY FAILURE PROGRESSION AND REDUCE NEED OF DIALYSIS IN CHRONIC KIDNEY DISEASE PATIENTS: A META-ANALYSIS

Aditya Indra Mahendra1, Nur Samsu2, Atma Gunawan3 and Achmad Rifai2

1Faculty of Medicine, Brawijaya University, Department of Internal Medicine, Malang, Indonesia and 2Faculty of Medicine, Brawijaya University, Nephrology Division, Department of Internal Medicine, Indonesia

Background and Aims: chronic kidney disease (CKD) is the main complication of type 2 diabetes mellitus (type 2 DM) with up to 7 million cases requiring dialysis therapy. The newest type 2 DM therapy, sodium-glucose co-transporter-2 inhibitor (SGLT-2 inhibitor), has developed into an attractive option for patients with comorbid CKD because of its effect on blood pressure and albuminuria, in addition to its effect on lowering blood sugar. Therefore, we conducted a systematic review and meta-analysis aimed at assessing the effect of SGLT-2 inhibitors in preventing the progression of renal failure and the need for dialysis in CKD patients with and without type 2 DM.

Method: We performed an analysis of randomized controlled trials of SGLT-2 inhibitors reporting renal outcomes in patients with and without type 2 DM. We searched the PUBMED, MEDLINE, and CENTRAL databases from baseline to August 2022 to identify suitable studies. The major outcome evaluated was the combination of a persistent increase in serum creatinine two times from baseline and the need for dialysis.

Results: Of the 2890 identified articles, ten studies were included in the inclusion criteria assessing the effect of using SGLT-2 inhibitors. Out of 76,312 participants, 1716 participants experienced a 2-fold increase in serum creatinine and 647 participants required dialysis. The use of SGLT-2 inhibitors significantly reduced progressive renal failure and the need for dialysis in both patients with type 2 DM (RR: 0.65, 95% CI 0.60-0.71, p = 0.000) and patients without type 2 DM (RR: 0.59, 95% CI 0.46-0.77, p = 0.000). Subgroup analysis also showed that SGLT-2 inhibitors showed a significant effect in the group with eGFR > 60 ml/min (RR: 0.53, 95% CI 0.45-0.62, p = 0.000) and the group with eGFR 30-60 ml/min (RR: 0.66, 95% CI 0.57-0.75, p = 0.000).

Conclusion: SGLT-2 inhibitors can significantly inhibit the progression of CKD and reduce the risk of needing dialysis in patients with and without type 2 DM. These effects were shown consistently across groups with varying baseline eGFR values.

REDUCING FRAILTY IN HEMODIALYSIS PATIENTS THROUGH INTRADIALYTIC VIRTUAL REALITY EXERCISE INTERVENTION: THE REVID STUDY

Vicente BenavenCaballer1, Francisco José Martínez-Olmos1, Noemí Valtuena-Gímino1, Marina Toquero1, Alicia García-Testal2, Alicia Cana-Poyatos2, Rafael García-Maset2, Pilar Royo-Maicas2, José Antonio Gil-Gómez1 and Eva Segura1

1CEU Cardinal Herrera University, Physiotherapy and Nursery, Alfar del Patriarca, Spain, 2Manises Hospital, Nephrology, Manises, Spain and 3Instituto Universitario de Automática e Informática Industrial, Instituto Universitario de Automática e Informática Industrial, Valencia, Spain

Background and Aims: People in hemodialysis experience fatigue, weakness, weight loss, exhaustion, and low physical activity - all criteria of the frail phenotype. Frailty is a critical issue in the hemodialysis population due to its link to negative health outcomes, but few studies have focused on frailty in this population, despite the knowledge that frailty can be reversed with continued exercising at their preferred time during the hemodialysis treatment. Our group has previously shown that non-immersive virtual reality exercise during hemodialysis is a safe method to mitigate and manage frailty in the hemodialysis population.

Method: A randomized trial (the REVID study) included two groups of participants, exercising at different times during the dialysis session. The present study includes participants from REVID study who, once the study finished, continued exercising at their preferred time during the hemodialysis treatment. All participants were evaluated using the five Fried frailty phenotype criteria: unintentional weight loss of more than 4.5 kg in the past year, exhaustion was assessed using two questions from the Center for Epidemiological Studies Depression (CES-D) scale, weakness was measured using a handgrip dynamometer, walking speed was assessed by timing the 4.6m distance covered at the participant's normal pace, and physical activity was measured using the short version of the Minnesota Leisure Time Physical Activity questionnaire. Each of the five criteria was scored as 0 (not frail-related) or 1 (frail-related). Participants were then stratified into three groups: a score of 0/5 for robust or not frail, a score of 1-2/5 for pre-frail, and a score of 3-5/5 for frail. After the frailty phenotype assessment, all participants performed an intradialytic exercise program consisting of a non-immersive virtual reality game (Treasure Hunting) adapted to the dialysis session. The game consists of catching treasures and avoiding bombs by moving the lower extremities, with a progressive duration of 15 to 45 minutes. Adherence to the exercise program was measured as a percentage (number of sessions attended divided by the number of sessions offered). All assessments and interventions were conducted at Hospital de Manises in Valencia, Spain from September to December 2022.

Results: The study included 12 subjects with a mean age of 71.8 (13.9) years, 9 of whom were male, median time in Hemodialysis 20 (11.3 - 56 interquartile range) months. Out of the 12 participants, 2 were classified as robust, 5 as pre-frail, and 5 as frail. A chi-square test showed a significant change in the frailty phenotype of the participants after the exercise intervention (15.400; P = 0.003). At the end of the program, 3 participants were classified as frail, 7 as pre-frail, and 2 as robust. 2 participants improved from being frail to pre-frail. Furthermore, five participants (four frail and one pre-frail) reduced the number of criteria associated with the frail phenotype. No worsening in the frailty phenotype was reported among the participants. The average adherence to the exercise program throughout the study was 54.4 (11.2) %.

Conclusion: This study suggests that an intradialytic exercise program consisting of a non-immersive virtual reality can be useful in mitigating and managing frailty in the hemodialysis population.

Method: We selected 214 variants of pharmacogenetics relevance, based on evidence and frequency criteria. We evaluated their depth of coverage on 300 patients randomly selected in our CKD cohort.

Results: Eleven of those 214 variants were not covered by ES. Three of 11 variants were in UGT1A1 and were excluded from analysis since this information is only relevant for Irinotecan treatment. The remaining 8 variants fall in CYP2C19, CYP3A5, CYP3A4, CYP2D6, HLA B (B15:02), HLA A (A31:01), IFN3, VORCR1 genes: we completed exome data by targeted sanger sequencing for these variants. One challenging region is CYP2D6 given high sequence homology with CYP2D7 and CYP2D8: to assess if we could reliably call variants in this region, we used 7 additional Coriell samples, as 8 others were also assessed with an orthogonal technique. We were able to properly detect variants in these complex regions in all cases, including hybrid genes.

Conclusion: Our preliminary data show that exome sequencing, initially ordered for CKD, could also be used to deliver pharmacogenetic meaningful information, by adding a few targeted genotyping assays. We currently evaluate the clinical utility and impact of pharmacogenetics in our CKD cohort prospectively.

#3303
SUBOPTIMAL EXTENT OF RAAS RE-INITIATION AFTER DISCONTINUATION FOLLOWING HYPERKALEMIA: AN OBSERVATIONAL STUDY OF CARDIORENAL PATIENTS IN THE US AND JAPAN

Eiichiro Kanda1, Charles Pollack Jr2, Anjay Rastogi3, Eva Lesén4, Abiy Agiro5, Matthew Arnold6, Gengshi Chen7, Naru Morita8, Krister Järbrink4 and Toyoaki Murohara9

1Kawasaki Medical School, Department of Medical Science, Okayama, Japan, 2University of Mississippi School of Medicine, Department of Emergency Medicine, Jackson, United States of America, 3David Geffen School of Medicine at the University of California Los Angeles, Department of Medicine, Los Angeles, United States of America, 4AstraZeneca, CVRM Evidence, Gothenburg, Sweden, 5AstraZeneca, Renal Payer Evidence, Wilmington, United States of America, 6AstraZeneca, Real World Science and Digital, Cambridge, United Kingdom, 7AstraZeneca, Health Economics & Payer Evidence, Cambridge, United Kingdom, 8AstraZeneca, CVRM Medical Affairs, Osaka, Japan and 9Nagoya University Graduate School of Medicine, Department of Cardiology, Nagoya, Japan

Background and Aims: Guidelines recommend renin-angiotensin-aldosterone system inhibitor (RAASI) therapy at the maximal tolerated dose to achieve optimal treatment benefits in chronic kidney disease (CKD) and heart failure (HF). However, hyperkalemia (HK) is a barrier to achieving guideline-directed target dosing and RAASI treatment is often compromised in patients who experience HK. Current international guidelines recommend novel oral anti-HK treatments to manage HK and facilitate RAASI therapy. This study assessed the extent of both temporary and longer-term discontinuation of RAASI following an HK episode, and the magnitude of RAASI re-initiation, in cardiorenal patients in the US and Japan.

Method: This observational study used data from hospital records and claims from the US (Optum’s de-identified Market Clarity Data) and Japan (Medical Data Vision). Patients with an index HK event (ICD-10 code E87.5) during July 2019–September 2021 (US) or May 2020–February 2022 (Japan) with a prior diagnosis of CKD and/or HF and use of RAASI in the preceding 6 months were included. RAASI classes included angiotensin-converting enzyme inhibitors (ACEI), angiotensin-receptor blockers (ARB), mineralocorticoid receptor antagonists (MRA), and angiotensin receptor neprilysin inhibitors (ARNi). In patients who discontinued RAASI treatment following their index HK episode, duration of discontinuation was described within a time frame of 6 months from the date of discontinuation (those with <6 months follow-up time were excluded). The RAASI dose prior to discontinuation versus at re-initiation was also assessed.

Results: In total, 25,963 patients from the US and 8,722 from Japan were included. The mean age was 68.3 (US) and 74.8 (Japan) years; 53% and 65% were male; and 30% and 12% of patients had a recorded history of HK prior to their index event. In the US, 85% filled a RAASI prescription in the 3 months prior to HK episode; the most common RAASI classes were ACEI (used by 46% of the overall cohort), ARB (27%), and MRA (19%). In Japan, 91% filled a RAASI prescription in the 3 months prior to HK episode; ARB was the most common (67%), followed by MRA (25%), and ACEI (16%). ARNI was used by <5% of patients in the US and <2% in Japan; it was not assessed further due to low patient numbers. Following the HK episode, ACEI/ARB were discontinued in 23–26% of patients, while MRA was discontinued in 33–46% (Table 1). In those who discontinued, re-initiation within 6 months occurred among 10–15% of patients in the US and among 6–8% of patients in Japan. In those who re-initiated, 17–37% of patients in the US and Japan had their dose reduced by >25%.

Conclusion: In clinical practice, HK leads to discontinuation of RAASI treatment despite guidelines recommending maintained treatment. Re-challenge of RAASI treatment is uncommon and, when re-introduced, the dose is commonly reduced. These findings emphasize the need for improved guideline adherence in managing HK to facilitate continued RAASI therapy.

#3015
EFFECT OF DAPAGLIFLOZIN ON ALBUMINURIA IN PATIENTS WITH TYPE 2 DIABETES AND CKD

Sherzod Abdullaev1 and Olimkhon Sharapov2

1Republican Scientific and Practical Medical Center of Nephrology and Kidney Transplantation, Immunogenetics, Tashkent, Uzbekistan and 2Republican Scientific and Practical Medical Center of Nephrology and Kidney Transplantation, Adult and Pediatric Nephrology, Tashkent, Uzbekistan

Background and Aims: Albuminuria in patients with diabetes presents a higher risk for adverse renal and cardiovascular (CV) outcomes. Sodium-glucose co-transporter 2 (SGLT2) inhibitors demonstrate improved albuminuria and reduces the risk of end-stage renal disease in patients with

chronic kidney disease. The study aim was the impact of the SGLT2 inhibitor dapagliflozin on urine albumin-to-creatinine ratio (UACR) and GFR decline.

**Method:** In the single center trial, total 132 participants with CKD and type 2 diabetes (T2D) were randomly assigned to dapagliflozin (n = 78) 10 mg once daily or placebo (n = 54). Kidney inclusion criteria were eGFR 30-60ml/min/1.73 m² and any UACR. The primary end point was a composite of sustained decline in eGFR ≥50%, end-stage renal disease, or kidney or cardiovascular death. Percentage treatment difference was estimated by geometric mean ratio for the overall cohort and by eGFR and UACR subgroups. Progression/regression of UACR were assessed. Hazard ratios, 95% confidence intervals (CI), and p-values were estimated by Cox proportional hazards model.

**Results:** Median baseline eGFR was 42.3ml/min/1.73 m², with 5% at <30ml/min/1.73 m². At baseline, median UACR was 103 mg/g, and 1/4 of patients had normal albuminuria, 2/4 had micro, and 1/4 had macroalbuminuria. Median follow up was 18 months. The UACR difference for dapagliflozin vs placebo was -25.1% (95% CI -27.5, -23.2; p < 0.001). Reductions were similar across eGFRs. In UACR 30-299mg/g and ≥300mg/g, reductions were significant in dapagliflozin (p < 0.001). Progression risk was lower and regression risk higher in dapagliflozin vs placebo (p < 0.001).

**Conclusion:** Dapagliflozin significantly slowed long-term eGFR decline in patients with CKD with T2D compared with placebo, and significantly reduced UACR and had favorable effects on UACR progression and regression.

**3204 CASE-BASED ONLINE MEDICAL EDUCATION ENHANCES PHYSICIANS' KNOWLEDGE AND COMPETENCE IN THE MANAGEMENT OF PATIENTS WITH DIABETES WITH CARDIORENOLOGICAL DISEASE**

**Joachim Trier1, Per-Henrik Groop2 and Rita Moreira Da Silva1**

1WebMD Global LLC, Medscape Education, New York, United States of America and 2Helsinki University Hospital, Department of Nephrology, Helsinki, Finland

**Background and Aims:** Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) have a substantially impaired cardio-renal health prognosis and a reduced life expectancy highlighting the urgent need for early detection and comprehensive vascular risk control. The goal of this activity for primary care physicians (PCP) and diabetologists/endocrinologists (D/E) was to improve their understanding of and competence in managing patients with diabetes with cardiorerenal disease in clinical practice.

**Method:** An interactive educational program including one detailed patient case challenges clinicians to apply most recent evidence-based guideline recommendations. Detailed scenarios prompt learners to determine the correct treatment and follow-up for the patient with expert commentaries providing in-depth advice at each stage and a conclusion at the end of the program. Educational effect was assessed using a repeated-pair design with pre-/post-assessment. 3 multiple choice questions assessed knowledge/competence, 1 question rated on a Likert-type scale assessed confidence. A paired samples t-test was conducted on overall average number of correct responses and for confidence rating, a McNemar's test was conducted at the question level (5% significance level). Cohen's d with correction for paired sample estimates the effect size of the education on number of correct responses. Data collection from 5/25/22 to 9/13/22.

**Results:** 74% of PCP (n = 74) improved their knowledge regarding the need for comprehensive vascular risk control in patients with T2D and CKD and their competence related to the practical implementation of the latest diabetes guidelines for the individualized management of these patients (p < 0.001; d = 0.56)

- 56% of D/E (n = 32) advanced their knowledge regarding the need for comprehensive vascular risk control in patients with T2D and CKD (P < 0.01, d = 0.35)
- 39% of PCP and 41% of D/E increased their confidence (p < 0.001 and p < 0.01 respectively) in proactively monitoring their patients with T2D for kidney disease

**Conclusion:** Participation of PCP and D/E in an interactive online case-based education program improved their understanding of the need for comprehensive vascular risk control and the competence of PCPs in managing patients with T2D and cardiorenal disease in clinical practice.

THE ROLE OF RENAL DYSFUNCTION DURING ANTICOAGULANT USE IN COPD PATIENTS WITH ATRIAL FIBRILLATION
Guzaq Karimdjanova

Tashkent Pediatric Medical Institute, Internal Disease, Nephrology and Haemodialysis, Tashkent, Uzbekistan

Background and Aims: Renal dysfunction is known to be the most important predictor of outcome in patients with atrial fibrillation (AF). Purpose of the study was to evaluate the prognostic role of kidney dysfunction in terms of possible cardiovascular events and bleeding in patients with COPD and AF treated with oral anticoagulants.

Method: We examined 56 COPD patients with CHF and AF who received oral anticoagulants. Renal function (creatinine level and estimated glomerular filtration rate - eGFR) was assessed at baseline and on follow-up. The functional state of the kidneys was calculated using the CKD-EPI-2011 formula. Initially, the risk of bleeding was assessed using the HAS-BLED score. The deterioration of the functional state of the kidneys was noted with an increase in the level of creatinine or a decrease in eGFR by at least 20%.

Results: In addition to the standard treatment for COPD in the presence of AF, patients received oral anticoagulants during a six-month follow-up. The deterioration of the functional state of the kidneys was observed in 18.3% of patients. In patients with kidney dysfunction, the frequency of episodes of CHF decompensation and non-massive bleeding (MB) was significantly higher. When reduced glomerular filtration rate did not affect the frequency of bleeding and stroke. The oral anticoagulants used did not significantly affect the observed renal dysfunction and did not affect the occurrence of new cardiovascular events in patients with COPD. It turned out that the predictors of renal dysfunction in patients with COPD are age, female gender, and low hemoglobin levels. In multivariate analysis, renal dysfunction was identified as an independent predictor of non-massive bleeding (OR 2.04, 95% CI, p<0.05).

Conclusion: In patients with COPD and atrial fibrillation, the presence of kidney dysfunction was an additional aggravating factor associated with adverse cardiovascular prognosis in the medium term and the risk of bleeding. However, oral anticoagulants did not affect the degree of deterioration in renal function or the incidence of cardiovascular events.

RELATIONSHIP BETWEEN INITIAL EGFR DIP AND CHANGES IN LABORATORY PARAMETERS WITH DAPAGLIFLOZIN TREATMENT IN NON-DIABETIC CKD PATIENTS
Maiko Kokubu, Go Okanishi, Kusuke Tansho and Masaru Matsu

Nara prefecture General Medical Center, Department of Nephrology, Nara, Japan

Background and Aims: Treatment with sodium-glucose co-transporter-2 inhibitors (SGLT2i) induces an initial decline in estimated glomerular filtration rate, also termed the 'eGFR dip' and remains beneficial effects for cardiovascular and kidney outcomes, even after modified by eGFR dip in diabetic CKD. However, the difference of eGFR dip after SGLT2i between diabetic and non-diabetic CKD patients and the effects of eGFR dip on changes of laboratory parameters is not fully understood. In this study, we aimed to investigate the eGFR dip after Dapagliflozin in terms of changes of laboratory parameters and its relationship with clinical and laboratory data in non-diabetic CKD patients.

Method: We conducted a cohort study on 127 non-diabetic CKD patients receiving Dapagliflozin in whom at least two measurements of eGFR levels at three months were confirmed. eGFR dip was defined by percent eGFR change from baseline. eGFR was calculated using Japanese equation. Correlation analysis between initial eGFR dip and clinical value were conducted using the Pearson correlation coefficient.

Results: The mean age of study participants was 60±13 years and 69 (54%) were male. The underlying kidney diseases included glomerulonephritis in 59 (46%) patients and hypertensive nephrosclerosis in 57 (45%). The mean levels of baseline eGFR were 43±13 ml/min/1.73 m² and the mean proteinuria was 0.58±0.83 g/gCRE. The mean eGFR change from baseline was −0.33±4.3 ml/min/1.73 m² with eGFR dip of 0.8±9.4%. Factors including age, sex, body mass index, baseline eGFR and urinary protein were not significantly associated with the eGFR dip. Dapagliflozin increased hemoglobin levels by 0.5g/dl and decreased uric acid levels by 0.9 mg/dl. We found indirect and direct correlation of the eGFR dip with changes in proteinuria (r = 0.30, p = 0.001) and uric acid levels (r = 0.21, p = 0.015) after Dapagliflozin, respectively.

Conclusion: Our results suggest that the eGFR dip following SGLT2i initiation may be associated with the changes of proteinuria and uric acid levels in non-diabetic CKD patients.
EFFICACY OF MRNA VACCINE BNT162B2 AGAINST NOVEL SARS-COV-2 VIRUS IN END-STAGE KIDNEY DISEASE

Gai Milo1,2, Haneen Daoud-Asfour1, Marian Karram1, Marina Tchirkov1, Ben Cohen2, Tehila Azoulay3, Nelly Zaltzman Bershady3, Ilana Slouzkey3, Moran Szwarcwort1 and Suheir Assady1,2

1Rambam Health Care Campus, Department of Nephrology and Hypertension, Haifa, Israel, 2Technion-Israel Institute of Technology, The Ruth & Bruce Rappaport Faculty of Medicine, Haifa, Israel and 3Rambam Health Care Campus, Laboratory Services Division, Haifa, Israel

**Background and Aims:** Covid-19 pandemic affected more than 600 million people worldwide. Chronic kidney disease was shown to be a significant risk factor for disease severity. The introduction of the novel mRNA vaccines against SARS-CoV-2 prompted studies to evaluate their efficacy and safety. This study aims to assess the humoral response to the BNT162b2 vaccine, its durability, the booster effect, and breakthrough infections among end-stage renal disease patients (ESRD).

**Methods:** A one-year, single center, observational prospective study was conducted between 2021 and 2022. The cohort included adult dialysis patients (n = 143), kidney transplant recipients (11), and healthy controls (n = 75). Demographic and clinical data were retrieved from electronic medical records. All participants received 30 μg/dose of BNT162b2 mRNA vaccine, at 0 and 3 weeks. A third vaccine (booster) was administered at least 6 months after the first dose. SARS-CoV-2 infection was diagnosed based on PCR test of nasal and oropharyngeal swabs. Infections that occurred from January 2022 were attributed to omicron variant. Longitudinal blood samples were collected as indicated in Figure after the first vaccine dose (V1) and after the booster dose (V3). Humoral immune response was assessed by measuring serum IgG antibodies against the receptor-binding domain of the SARS-CoV-2 S1 subunit, using the ABBOTT kit. The study protocol was approved by the Institutional Review Board and was conducted in adherence to the Declaration of Helsinki.

**Results:** Twenty-eight weeks after two doses of vaccine, the median antibody levels were significantly lower in dialysis and transplant patients compared with healthy controls (122 AU/mL (2–4,557) and 6 AU/mL (1–217) vs 831 AU/mL (117–40,000), respectively). Furthermore, only 75% of dialysis patients developed positive antibody response (>50 AU/mL) as compared to 100% in controls (see Figure 1). A significant waning of immunity was seen over time in both dialysis and healthy participants (p < .0001). Four weeks after a booster...
dose, antibody levels surged and did not differ between dialysis and healthy participants $13,840 \pm 15,126$ AU/mL vs $18,080 \pm 13,354$ AU/mL, respectively ($p = .283$). Non-responder rate among dialysis patients dropped from 21% after a 2-dose vaccination to 7% after a booster dose. Lower antibody levels measured at 28-week after the first vaccination were associated with higher risk for Covid-19 infection ($p = .021$). Of note, all infection cases occurred in subjects with antibody levels below $1050$ AU/mL. However, no association was found between antibody levels and Covid-19-omicron variant infection rate among dialysis patients and healthy controls ($p = 0.650$).

**Conclusions:** Dialysis patients had a blunted humoral immune response after two doses of BNT162b2 vaccine compared with healthy controls, which improved after a booster dose. Based on the observed omicron variant breakthrough infections, further studies are needed to improve the vaccines’ efficacy against the evolving SARS-CoV-2 variants.

**ANALYSIS OF SARS-COV2 INFECTION AND COVID-19 VACCINATION IN TWO DIAVERUM CLINICS IN NORTH MACEDONIA**

Kristina Petrova1, Ditka Ivanovska2, Nadica Misovska3, Eleonora Grozdanova4, Mence Nedelkoska3, Marija Krzovska4, Zorica Medarova-Stojkovska1, Maja Kjulibrk-Nedelkovska1, Stefan Ilievski2 and Boris Roglev6

1Diaverum, Center for Hemodialysis, Kochani, Republic of North Macedonia, 2Diaverum, Center for Hemodialysis, Strumica, Republic of North Macedonia, 3Diaverum, Center for Hemodialysis, Skopje, Republic of North Macedonia, 4Diaverum, Center for Hemodialysis, Stip, Republic of North Macedonia, 5Diaverum, Center for Hemodialysis, Kumanovo, Republic of North Macedonia and 6Diaverum, Center for Hemodialysis, Gevgelija, Republic of North Macedonia

**Background and Aims:** Hemodialysis patients as a separate group of immunosuppressive patients are at highest risk of severe clinical complications and death caused by infection with SARS-CoV-2 virus. With the introduction of COVID-19 vaccination in hemodialysis patients, the situation has changed significantly. The aim of the study was to analyze the difference in morbidity and mortality between two groups of hemodialysis patients, vaccinated and unvaccinated for Covid-19 in two Diaverum Clinics.

**Method:** The study is based on analysis of the data of hemodialysis patients in two Diaverum clinics during the period from April 2020, when the first case of SARS-CoV-2 virus was detected in Diaverum Kochani Clinic, to August 2022, when the last case of SARS-CoV-2 virus was detected in both clinics. Analytical data are taken from IRIMS database used only by Diaverum Clinics worldwide.

**Results:** During the period of observation, a total number of 214 hemodialysis patients were treated in both Diaverum Clinics. Regarding gender distribution 63% are males and 37% are females. From the total number of patients in both clinics, 67% (143) were vaccinated with two or three doses of the COVID 19 vaccines, while the remaining 33% (71) patients were COVID-19 unvaccinated. The majority of the patients (67%) were vaccinated with Chinese vaccine Sinopharm; 19% with Sinovac; 7% with Astra Zeneca; 7% with Pfizer BioNTech (the vaccines that were available in that period in our country). In 2020 a total of 28 COVID infection occurred in both clinics, all of them were unvaccinated patients; 16 of them were hospitalized and 9 of them died. Hospitalization rate was 57% and mortality rate 32% among the positive patients. In 2021 a total of 35 COVID infections were registered, 18 were hospitalized (unvaccinated 61% vs 39% vaccinated), 26% (9) of the positive patients died, 6 were unvaccinated and 3 were vaccinated with 2 doses. Hospitalization rate was 51% and mortality rate 26%. In 2022 a total of 43 COVID infections occurred, only 4 were hospitalized and only 1 patient died; hospitalization rate 9%; mortality rate 2.3%. When the whole study period was analyzed, the infection rate between the vaccinated and unvaccinated patients in both clinics was statistically not significant, 51% vs 46.5%, $p = 0.5634$ (Fisher exact two-tailed test). But, when the hospitalization rate was compared between vaccinated and unvaccinated patients, 12.3% vs 84.8%, the difference was highly statistically significant ($p = 0.0001$). When death rate was compared between the two groups, the difference was also highly statistically significant, 5.5% vs 45.4% in the unvaccinated group ($p = 0.0001$).

**Conclusion:** The results of our study showed no difference in the infection rate between vaccinated and unvaccinated patients, but they confirmed high level of protection from hospitalization and mortality in vaccinated patients.

**PRIORITY OUTCOMES FOR EDUCATION AND SELF-MANAGEMENT IN NON-DIALYSIS CHRONIC KIDNEY DISEASE: A PATIENT AND PROFESSIONAL DELPHI SURVEY**

Naema A Patel1,2, Courtney J Lightfoot1,2 and Alice Smith1,2

1University of Leicester, Leicester Kidney Lifestyle Team, Department of Population Health Sciences, Leicester, United Kingdom and 2Leicester NIHR Biomedical Research Centre, Leicester, United Kingdom

**Background and Aims:** It is important for people living with Chronic Kidney Disease (CKD) to develop the knowledge, skills, and confidence (patient activation) to effectively self-manage their health in partnership with their healthcare team. Resources intended to educate and support self-management should be subject to robust evaluation to provide the evidence base for clinical implementation. Trials in both research and clinical practice settings should...
include outcomes which are meaningful and valued by all users, but these are not known for CKD education and self-management interventions. We carried out a Delphi survey to identify the priorities valued by both CKD patients and healthcare professionals (HCPs) in the UK.

Method: Kidney patients and multidisciplinary kidney HCPs based in the UK were invited to complete two sequential rounds of an online Delphi survey. People with CKD and their significant others (SOs) were invited via social media, and HCPs via direct email. For Round One, participants were asked to identify in their own words the 3 potential benefits (outcomes) for CKD self-management that they personally considered to be most important. These free-text responses were collated and analysed inductively using conventional content analysis to identify dominant themes and constituent items. In Round Two, participants were asked to rate each of these items on a 9-point Likert scale from 1 (least important) to 9 (most important), and overall median ratings were calculated for each theme.

Results: 135 participants contributed to Round One: 47% (64) CKD patients/SOs; 51% (69) kidney HCPs; 2 individuals identified in both groups. 58% of HCPs who were invited by email agreed to take part. Round One analysis identified 28 outcome items which fell into 5 main themes: clinical; knowledge, skills, and confidence to manage own health; behaviour and self-care; psychological and social factors; healthcare usage. 69% (44) of invited CKD patients/SOs and 77% (53) HCPs took part in Round Two. Table 1 shows the median ratings for each theme. The highest-ranked overall and for both groups was “clinical”, while “healthcare usage” was ranked the lowest.

Conclusion: Our UK Delphi survey has identified a range of potential benefits for successful self-management in non-dialysis CKD, which were categorised into 5 main themes. Clinical outcomes such as improving blood pressure management or avoiding progression to end stage kidney disease were the top priority for both CKD patient/SO and HCP participants. Aspects of patient activation (knowledge, skills, and confidence to manage health) were also rated as important by both groups. This Delphi survey identified which benefits kidney patients and HCPs value most from effective CKD education and self-management. It is important that the views of intended users of new interventions are consulted throughout the development process to ensure that the product meets their needs and expectations. The information we present here is vital for the successful design, evaluation and implementation of interventions and support tools to educate people with CKD and enable them to improve self-management behaviours.

#3439 EXERCISE, METABOLIC SYNDROME AND CHRONIC KIDNEY DISEASE (CKD): THE EX-RED STUDY
Raúl Morales Felles1, Amelia González Martín1, Daniel Sánchez Baez2, Patricia Isabel Delgado Mallén3, Rosa Miquel3, Sara Estupiñán Torres3, María Angeles Cobo Caso1, Coriolano Cruz Perea4, Laura Díaz Martín3, Sergio Luis-Lima5, Federico González Ronne6 and Esteban Porrini6

1 University of La Laguna, Faculty of medicine, Spain; 2 University of La Laguna, Faculty of Medicine, San Cristóbal de La Laguna, Spain; 3 University hospital of Canary island, Nephrology, San Cristóbal de La Laguna, Spain; 4 University hospital of Canary island, Nephrology, Spain and 5 University hospital of Canary island, Nephrology, San Cristóbal de La Laguna, Spain

Background and aims: Obesity and metabolic syndrome (MS) are risk factors for renal disease progression in patients with established chronic kidney disease (CKD). Although therapeutic exercise has a potential role to treat or ameliorate chronic diseases, the effect of this intervention on obesity/MS and major renal outcomes: proteinuria and/or glomerular filtration rate (GFR) in patients with CKD is scarcely known. In particular, the effect of exercise in short term changes in renal outcomes are unknown. So, the aim of the study is to evaluate the effect of therapeutic exercise on: (a) the amelioration of MS traits and (b) renal parameters, GFR and proteinuria, in patients with CKD and MS.

Method: This is a 6-month exploratory study that included clinically stable patients with CKD of different causes and MS with measured GFR of 30-90 ml/min/kg. Patients were treated with an incremental protocol of exercise which was prescribed by a physiotherapist. Baseline treatment and increments in prescription were based on physical status and individual response on follow-up, treatment involved both aerobic and strength exercise. All patients start with aerobic exercise training 30-60 minutes and 5 times per week. Strength exercise was individualized and consisted of free weight exercises. The prescription was increased every month. The following outcomes were considered: changes in GFR i.e., ≥7%, which is twice the variability of the method in our laboratory (https://lfrc.echucan.es), and weight loss ≥5%, a change associated to lower cardiovascular risk. In parallel with exercise training, we designed a plan to evaluate and promote adherence using regular telephone calls, an activity tracker, and visits to the hospital. Measured glomerular filtration rate (iohexol-DBS), urine samples (albuminuria/proteinuria), anthropometric parameters and analytics were collected at baseline, 3 and 6 months. There is no evidence in the field to evaluate the sample size of the study. Then, we designed and explorative study including 40 cases.

Results: This is a preliminary analysis of 25 cases: 3 were lost of follow-up at 3 months, and so, we show data of 22 patients that finished the study. Mean age was 58 ± 12 and 70% (N = 17) were male. All patients were obese or overweight and 17 (70%) were diabetic. The most frequent kidney diseases were glomerulonephritis (40%) and diabetic nephropathy (30%). Most patients were on ACE inhibitors/ARB (46%) and lipid-lowering agents (52%). At 6 months, 5 (22%) patients did not have major changes in weight, which was attributed to low adherence to treatment, and so, were not considered for further analyses. Of the remaining cases (N = 17, 78%), all showed a reduction in weight: from 97 ± 18 to 87 ± 18, p = 0.01. These patients were then classified in 3 groups based on GFR changes: (A) decreased GFR (N = 6, 35%), with GFR changing from 54 ml/min ± 3 ± 14 ± 14, p = 0.001; BMI decreasing from 33 kg/m2 ± 3 to 30 ± 5, p = 0.003 and TG from 211 mg/dl ± 98 to 127 ± 59, p = 0.026; (B) stable GFR (N = 7, 41%), GFR from 47 ml/min ± 22 ± 26 ± 41 p = 0.2; BMI decreasing from 35 kg/m² ± 3 ± 31 ± 3, p = 0.002 and TG from 160 mg/dl ± 57 to 105 ± 29, p = 0.02; (C) increased GFR (N = 4, 24%), GFR increasing from 39 ml/min ± 16 ± 66 ± 18, p = 0.015 and BMI decreasing from 39 kg/m² ± 3 ± 36 ± 2, p = 0.015. No significant changes were observed in albuminuria and other MS traits in the subgroups analyzed. No adverse events were found during follow-up.

Conclusion: exercise is an effective and safe intervention method to lose weight and improve dyslipidaemia in patients with MS and CKD. The effect of weight reduction on GFR is not universal. Some patients showed a reduction of GFR in line with the reduction of weight, which may reflect the correction of hyperfiltration related to obesity and MS. On the other hand, in some patients GFR remained stable or even increased after weight loss. The pathogenesis behind this aspect is clearly unexpected and unknown. The impact of GFR changes associated with weight and MS changes in CKD deserve detailed attention in ad hoc designed studies.

#6018 SODIUM-GLUCOSE CO-TRANSPORTER-2 INHIBITOR USE IN THE MANAGEMENT OF PATIENTS WITH CHRONIC KIDNEY DISEASE AND TYPE 2 DIABETES MELLITUS
Sarah Alzetani1 and Vijayan Suresh2

1 University of Birmingham, Medical School, United Kingdom and 2 Birmingham Heartlands Hospital, United Kingdom

Background and Aims: Sodium-glucose co-transporter-2 (SGLT-2) inhibitors were initially developed for the management of type 2 diabetes mellitus (T2DM). Results from large placebo-controlled clinical outcome trials have now highlighted efficacy of SGLT-2 inhibitors in reducing the risk of CKD progression [1,2]. NICE CKD guidelines now recommend use of SGLT-2 inhibitors alongside standard of care in those patients with T2DM [3]. This has subsequently extended SGLT-2 inhibitor licensing highlighting the importance of wider multi-disciplinary team practise awareness. The aim of this audit was to assess the level of implementation of updated NICE guidelines in patients under a specialist CKD clinic in Birmingham.
Method: A database of renal diabetics under a specialist CKD clinic in May 2022 was generated via a trust electronic patient record system. Patients with a recorded diagnosis of T2DM and estimated glomerular filtration rate (eGFR) >25 ml/min (current UK regulatory licensing for SGLT-2 inhibitor use) were included. Parameters of renal function (urine albumin: creatinine ratio (uACR) and eGFR) as well as medication histories were retrospectively collected for 158 patients and analysed using descriptive statistics.

Results: Results demonstrated 19% (n = 43) of 143 patients with an accessible drug history were prescribed an SGLT-2 inhibitor. Less than half (44%) of those prescribed standard of care (ACEI/ARB) with a uACR > 30 mg/mmol (n = 34) were prescribed an SGLT-2 inhibitor as per NICE recommendations. The prescribing of SGLT-2 inhibitors in patients at different stages of CKD was noted except in those with eGFR < 30 ml/min.

Conclusion: Results suggest a number of patients with T2DM are not prescribed an SGLT-2 inhibitor as per NICE recommendations for CKD management. Whilst considering sample size limitation as well as possible contraindications relevant to SGLT-2 inhibitor treatment, these findings may reflect the recent update to NICE guidelines and delayed dissemination of information between multi-disciplinary teams around extended SGLT-2 inhibitor licensing. Glycaemic control is less effective in later stages of CKD however, trials have demonstrated the independent role of SGLT-2 inhibitors in reducing the risk of CKD progression irrespective of their attenuated ability to lower glucose in reduced kidney function [1, 2]. It is imperative patients not currently prescribed an SGLT-2 inhibitor are reviewed for treatment eligibility and any contraindications. Results of this study were fed back to the local renal and diabetes team with the recommendation for development of clear guidelines for use of SGLT-2 inhibitors in all eligible patients in order to achieve maximum healthcare benefits. In addition, there are ongoing discussions with primary care regarding review of their use of SGLT-2 inhibitors.

THE IMPACT OF CKD STATUS BEFORE KIDNEY TRANSPLANTATION ON ALPHATORQUEVIRUS DNA LEVELS
Claudia Vuste Lozano1, Celia González-García1, Paula Jara Caro Espada1, Paul Hernandez-Velasco1, Lucia Rodriguez Gayo1, Natalia Inmaculada Polanco Fernandez1, Amado Andrés Belmonte1, Enrique Morales1 and Mario Fernandez1,2
1University Hospital October 12, Nephrology, Madrid, Spain and 2University Hospital October 12, Unit of infectious diseases, Madrid, Spain

Background and Aims: Torque teno virus (TTV) is a non-pathogenic anellovirus whose replication kinetics reflects the overall state of immuno-suppression. Although chronic kidney disease (CKD) induces a well-stabilised dysfunction of the immune system, long-term use of renal replacement therapies (RRT) itself could also modify the immune response.

Method: We analyzed TTV DNA loads at baseline (in the pre-transplant assessment), day 7 and months 1, 3, 6 and 12 after kidney transplantation (KT). Recipients were categorized according to their RRT status: pre-emptive KT (pre-KT), hemodialysis (HD) and peritoneal dialysis (PD). TTV DNA load was measured by real-time polymerase chain reaction.

Results: A total of 221 CKD patients were analyzed. The mean age was 53.9 ± 15.7 years. 72.4% were males, and hypertension (85.1%) and diabetes (30.1%) were the most common comorbidities. According to the pre-transplant TTR status, 159 (72.0%) were on HD, 35 (15.8%) on PD and 27 (12.2%) received pre-KT. There were no differences in baseline comorbidities or age between patients according to their RRT status, except for residual diuresis (P < 0.01). PD patients had higher serum albumin levels than patients receiving pre-KT or HD (4.4 ± 0.5 vs. 4.1 ± 0.6 vs. 3.9 ± 0.4 g/dL, respectively, P < 0.01). PD patients exhibited higher TTV DNA load (3.4 ± 1.2 log10 copies/mL) than HD (2.8 ± 1.6 log10 copies/mL) or pre-KT patients (2.4 ± 2.1 log10 copies/mL), although the differences were not statistically significant. PD patients had lower time on dialysis than HD patients (18.4 ± 16.2 vs. 37.5 ± 33.6 months, respectively; P = 0.038). Although PD patients had higher TTV DNA load during the post-transplant follow-up than HD and pre-KT patients, viral kinetics were comparable across these three groups by month 12 after transplantation. Time on dialysis was not associated with TTV DNA load (P = 0.18). RRT status was not associated with the incidence of post-transplant infection or a composite of opportunistic infection and/or de novo malignancy.

Conclusion: TTV DNA load could be useful identifying KT recipients at high risk of immunosuppression-related complications. Although PD patients presented a non-significant higher TTV DNA load, we did not find differences according to the modality of prior RRT or the time on dialysis.

#2808
REMDESIVIR FOR MODERATE-TO-SEVERE COVID-19 PNEUMONIA IN MAINTENANCE DIALYSIS PATIENTS: A RETROSPECTIVE COHORT STUDY
Stephanie Gutierrez
National Kidney and Transplant Institute, Adult Nephrology, Quezon City, The Philippines

Background and Aims: Remdesivir has shown better patient outcomes and shorter time to recovery among hospitalized patients with moderate to severe COVID-19 pneumonia. However, data on its safety and efficacy in dialysis patients is lacking.

Method: Dialysis patients with moderate to severe COVID-19 pneumonia who were given remdesivir were matched 1:2 to those who received standard-of-care (SOC) based on age, sex, COVID-19 severity and CKD etiology.

Results: The final cohort comprised 201 patients and 67 were given remdesivir. Median age was 52 years, majority were male (51.7%), 94% were on hemodialysis (94%) and 48% had diabetic nephropathy. The 28-day probability of survival among moderate COVID-19 cases was 100% for both remdesivir and SOC group. In severe cases, the survival probability for remdesivir recipients was lower compared to SOC (67.63% vs 87.72%), but this was not statistically significant. Overall, median length of stay (LOS) was significantly shorter by 17 days (QR: 11-24) in the remdesivir group, compared to 21 days (QR: 16-24) in the SOC group (p = 0.0485). Median LOS in the remdesivir group was only significantly shorter in those with moderate COVID-19 pneumonia but not in severe cases. Early administration of remdesivir resulted in a significantly shorter LOS with a median of 10 days (QR: 7-15) compared to 18 days (QR: 13-25) in the SOC group (p = 0.0240). When stratified by severity, there was no significant difference whether remdesivir was given early or late.

Conclusion: Remdesivir administration within 48 hours of admission in maintenance dialysis patients with moderate COVID-19 pneumonia resulted in a significantly shorter LOS. However, there was no significant difference in 28-day mortality in early or late administration of remdesivir in both moderate and severe COVID-19 pneumonia among HD patients. Thus, survival was similar to SOC. Our study showed that it is safe to use in dialysis patients.

NEPHROPROTECTION IN BOYS WITH X-LINKED ALPORT SYNDROME: THE SOONER THE BETTER

Marina Aksenova, Ozana Piruzeva, Natalia Zaikova, Tatjana Lepaeva, Tatjana Nikishina, Varvara Obuhova and Natalia Konkova

Yeltsichev Research and Clinical Institute for Pediatrics and Pediatric Surgery at N.Pirogov Russian National Research Medical University, Nephrology Department, Moscow, Russia

Background and Aims: Proteinuric (Pr) is a marker of glomerular diseases progression. The aim of study was to define the efficiency of angiotensin-converting enzyme inhibitors (ACEi) treatment in prevention of Pr development in boys with X-linked Alport’s syndrome (XLAS).

Method: Single center observation study included boys with confirmed XLAS (n = 87). Twenty-nine pts (1gr) started ACEi (enalapril 4.2–4.4 mg/m²/day) in non-proteinuric stage of disease (Pr<100 mg/m²/day); mean age 6.2±3.9 yrs. eGFR Schwartz 118±15.2 ml/min/1.73 m², Pr 67±23 mg/m²/day. Fifty eight pts (2gr) without preemptive ACEi treatment were observed from mean age 6.8±4.9 yrs, eGFR 119±17.3 ml/min/1.73 m², Pr 87±43 mg/m²/day. Follow up was 6.2±5.9 yrs, mean age at the last observation was 11.7±3.9 yrs vs 14.2±4.6 yrs (p = 0.67) in 1gr and 2gr, respectively. The occurrence of Pr (Pr>100 mg/m²/day) was defined as primary end point of the study.

Results: The pts of 1gr had lower rate (0.48 vs 0.94, p =0.001) and higher age (10.2±3.9 vs 4.9±3.4 yrs, p = 0.3) of Pr occurrence than in 2gr. ACEi treatment reduced risk of Pr onset (OR = 0.059%CI 0.013-0.23) with absolute risk reduction of Pr by 47% (RD = 0.47) and number of treated pts to prevent Pr development (NNT) 2.14. No difference was revealed between 1gr pts with and without Pr development in age of therapy start (7.1±3.3 vs 6.3±2.8 yrs). ACEi dose (2.3±0.8 vs 2.1±0.6 mg/m²/day) and COL4A5 gene mutation type (missense variants 0.72 vs 0.86). Arterial hypertension was a risk factor of Pr occurrence in 1gr (x² = 4.42, p = 0.04); children with Pr development was older at the last observation: 13.5±3.2 vs 9.9±3.8 yrs, p = 0.47. No side effects of treatment were observed.

Conclusion: The early ACEi therapy halved the risk of Pr development in boys with XLAS and may prevent the disease progression in these patients.

THE IMMUNE EFFECTS OF SARS-COV-2 INFECTION AND BNT162B2 VACCINATION IN CKD PATIENTS AND TRANSPLANT RECIPIENTS

Paulina Nazarak1, Ignacy Tkaczyk2, Anna Jedrzejczak1, Natalia Krata1, Leszek Paczek1, Bartosz Foroncewicz1 and Krzysztof Mucha1

1Medical University of Warsaw, Department of Immunology, Transplantology and Internal Diseases, Warsaw, Poland and 2Medical University of Warsaw, Warsaw, Poland

Background and Aims: The use of vaccination against severe acute respiratory syndrome coronavirus (SARS-CoV-2) significantly limited the spread of the coronavirus disease 2019 (COVID-19) pandemic. However, it was reported that after 6 months of vaccination (including the BNT162b2 vaccine) immunity decreases in general population. The results for chronic kidney disease (CKD) patients and solid-organ transplant (SOT) recipients appeared similar. Therefore, it was proposed to use an immune booster with the next, third immunization scheme.

Methods: We retrospectively analyzed the data of randomly selected 40 patients (37 CKD and 4 livers) who received two or three 30 μg doses of BNT162b2 vaccine. The follow up was performed in five time points (TP1-5): 4–6 weeks after the 1st dose (TP1), 4–8 weeks after 2nd dose (TP2), 9–20 weeks after 2nd dose (TP3), 21–32 weeks after 2nd dose and 1–12 weeks after 3rd dose (TP4), 33–48 weeks after 2nd dose, at the same time 4–20 weeks after 3rd dose (TP5). We assessed the anti-SARS-CoV-2 spike 1 protein IgG antibody (anti-S1 Ab) titer as well as graft function, COVID-19 history and patients’ clinical condition.

Results: We found Ab titer in IgG group higher than in SOT patients (p = 0.05). LTRs achieved higher values than KTRs. 55 patients received 3 doses of vaccination. The protective level after the 3rd dose was not observed only in 8.4% at TP4 and 5% at TP5. We demonstrated the advantage in Ab levels of a 2 doses vaccination scheme with and without COVID-19 history over a 3 doses in a group of patients with no COVID-19 history in TP 1-4 (p =<0.001 – 0.005, respectively, Table1). Subjects in 2 doses schedule had a longer time to infection from the last dose compared to the 3 doses schedule (31.5-39 vs. 9 weeks, MD). No deterioration of renal or graft function was noted and no rejection episodes were diagnosed.

Conclusion: Immunocompromised patients are non-homogeneous with respect to the vaccine response immunity. Therefore, the approach to the vaccination schedule should be individualized based on measurements of vaccination response and medical history including COVID-19 history. Combined post-infectious and post-vaccination immunization appears to be the most effective in producing anti-SARS-CoV-2 responses.

REAL WORLD CHARACTERISTICS, SYMPTOM BURDEN AND TREATMENT PATTERNS OF ANAEMIA OF CKD IN EGYPT, SAUDI ARABIA, SOUTH AFRICA, AND TURKEY

Alain Assounga1, Saeed Al-Ghamdi2, Mustafa Arici3, Ahmed El Keraie2, Martin Blagg4, Lucia Camidge5, Elvira Zenaida Lansang6, Daniel Ng7 and Budwani Sumarsono1

1University of KwaZulu-Natal, Berea, South Africa, 2King Abdulaziz University and King Faisal Specialist Hospital & Research Center, Jeddah, Saudi Arabia, 3Hacettepe Universitesi, Turkey, 4Alexandra Faculty of Medicine, Alexandria University, Egypt, 5Astellas Pharma Europe Ltd., United Kingdom, 6Adelphi Real World, Bollington, United Kingdom and 7Astellas Pharma Singapore Pte Ltd, Singapore, Singapore

Background and aims: Patients with chronic kidney disease (CKD) often have comorbid anaemia [1]. Real-world data on patient characteristics, disease burden, and treatment management for people with anaemia of CKD in the Middle East and Africa are limited.

Methods: SATISFY (Survey on treatment patterns in Anemia of CKD, patient Treatment satisfaction and perspectives as reported by patients with pSySc1ans) was a real-world survey conducted between 01 June to 01 September 2022 in Egypt, Saudi Arabia, South Africa, and Turkey. Physician and patient perceptions of treatment were captured via cross-sectional surveys;
patients’ clinical characteristics were recorded by physicians in electronic case report forms via retrospective review of medical records. Eligible physicians were nephrologists with ≥1 years’ experience who managed ≥12 patients with anaemia of CKD per month and with drug management experience for anaemia of CKD. Physicians collected data on the first 7–10 patients seen in routine clinical practice during the study period. Eligible patients were ≥18 years with CKD stage 3b, 4, or 5 at the time of anaemia of CKD diagnosis and with ≥2 years’ follow-up data from diagnosis to time of survey. Patients with functioning kidney transplants or acute kidney injury were excluded. Primary outcomes were to describe clinical and demographic characteristics, monitoring test results, treatment patterns of patients with anaemia of CKD, physicians’ reasons for not treating anaemia of CKD, and physicians’ and patients’ reasons for therapy choice. Data were analysed descriptively.

Results: A total of 1788 patients and 217 physicians were included; 1138 patients (64%) were non-dialysis dependent (NDD) and 611 (34%) were dialysis dependent (DD) at the time of data extraction (n = 39 [2%] data missing). Mean (standard deviation [SD]) age was 46 (14) years, mean (SD) body mass index was 24.1 (3.1) kg/m², 56% (n = 1004) were male, and median (interquartile range [IQR]) follow-up from diagnosis of anaemia of CKD was 2.6 (2.5–3.2) years. The most common comorbidities were hypertension (n = 858, 48%) and diabetes (n = 324, 18%). Symptom burden was high, with lack of energy and fatigue among the most commonly reported symptoms by physicians and patients across both NDD and DD groups (Figure 1). Differences were seen between physician and patient symptom reporting and between NDD and DD groups. Patients’ self-reported symptom burden was greater than that reported by physicians, particularly for NDD patients. The median (IQR) times per year physicians reported testing CKD patients for anaemia was 4 (4–6) for NDD patients and 12 (10–12) for DD patients. Median test levels for haemoglobin at which patients were diagnosed were lower than those reported by physicians as being used for diagnosis; similar results were seen for thresholds used to initiate treatment (Table 1). Median (IQR) days from diagnosis to first treatment was 61 (0–419). Of those who received treatment, the most common first treatment option was erythropoietin-stimulating agents + intravenous iron for both patients with NDD and DD anaemia of CKD at diagnosis (NDD n = 291/736, 40%; DD n = 170/316, 54%). A large proportion of patients never received treatment for anaemia of CKD (n = 701, 39%). The most important reasons to not initiate treatment from a physician perspective were patient refusal (n = 172, 79%) and risk of adverse reactions (n = 168, 77%); for patients, top reasons were that their symptoms were not severe (n = 168, 22%) and their physicians’ concerns about adherence (n = 116, 15%). Similar reasons were seen for both the Middle East and Africa regions.

Conclusion: Symptom burden is high in patients with anaemia of CKD in the Middle East and Africa, particularly lack of energy and fatigue. Differences were seen between physician and patient perceptions of symptom burden and between NDD and DD groups. Substantial treatment inertia exists. Physicians rated patient refusal and risk of adverse reactions as main reasons for not treating patients, while patients attributed this to a belief that their symptoms were not severe.

REFERENCE
THE IMPACT OF MOBILE HEALTH ON HOME BLOOD PRESSURE AND HEALTH LITERACY IN CHRONIC KIDNEY DISEASE

Pei-Yu Wu1,2,3, Yi-Chun Tsai2,3 and Yi Wen Chiu2,4

1 Kaohsiung Municipal Siaogang Hospital, Kaohsiung Medical University Hospital, Kaohsiung Medical University, Department of Internal Medicine, Kaohsiung, Taiwan, Rep. of China, 2 Kaohsiung Medical University Hospital, Kaohsiung Medical University, Division of Nephrology, Department of Internal Medicine, Kaohsiung, Taiwan, Rep. of China, 3 Kaohsiung Medical University, Faculty of Medicine, College of Medicine, Kaohsiung, Taiwan, Rep. of China and 4 Kaohsiung Medical University, Faculty of Medicine, College of Medicine, Kaohsiung, Taiwan, Rep. of China

Background and Aims: Mobile health (mHealth) management is an emerging therapeutic strategy for chronic diseases. mHealth has been considered to improve self-care management and assist in detecting a worsening health status early. However, the effect of mHealth management on the blood pressure (BP) of patients with chronic kidney disease (CKD) has not been well-studied. This study aimed to access the association between mHealth management and BP control in CKD. We also investigated the association between mHealth and health literacy (HL) in CKD.

Method: Kaohsiung Medical University Hospital designed and developed a new healthcare mobile application called iCKD. The application has several major features, including BP monitoring, alarms, and a warning system. We randomly assigned 122 CKD patients stages 1-5 to utilize iCKD or paper records (control group) for BP management. The primary outcome was the portion of reaching the target goal, defined as office BP less than 130/80 mmHg, during the 6-month study. Trained nurses interviewed CKD patients using structured questionnaires to evaluate HL.

Results: Baseline kidney function and BP were not significantly different between iCKD and control groups. During the study period, 11 participants had withdrawal. 42.3% of the iCKD group (22/52) had the BP control reaching the target goal, while only 22.4% (11/49) in the control group (p = 0.03). Regarding HL, CKD patients with BP reaching the target goal had higher total scores than those without. The score for iCKD group, ranging from 29.29 to 32.85, were higher than the control group, ranging from 28.94 to 31.03. (p = 0.01).

Conclusion: The iCKD group had a higher proportion of reaching the BP target goal and better HL score than the control group. This study demonstrates that mHealth can improve the CKD population’s health literacy and BP management.

DIALYSIS

D1 - EXTRACORPOREAL TECHNIQUES & ADEQUACY

TOWARDS SUSTAINABLE HEMODIALYSIS: FIRST STEPS TO CHANGE THE PARADIGM

Marta Arias Guillen, Marta Quintela, Miquel Gomez, Nuria Clemente and Francisco Maduell

Nephrology Department, Hospital Clinic, Barcelona, Spain

Background and Aims: In the field of nephrology, environmental awareness is booming and we claim that it is responsible for our impact. Hemodialysis treatment generates an excessive burden owing to the high consumption of water and energy, as well as the production of a large amount of waste. On the part of the European Kidney Health Alliance (EKHA), several proactive suggestions have been proposed worldwide. To this regard, we implemented different improvements in our dialysis unit, including the reverse osmosis (RO) treatment plant automation upgrade. However, to change the paradigm, it was still necessary to first know the reality from which we start to identify opportunities for improvement. The objective of our study was to determine the environmental impact of care activities in our hemodialysis center over the last 5 years.

Method: A retrospective analysis of key environmental indicators derived from hemodialysis treatments, from January 2018 to December 2022 was performed. Energy consumption (KWh/dialysis), water expenditure (L/dialysis), technical operator (TO) required time as well as the generation of sanitary waste (SW, Kg/dialysis) derived from the activity were monitored according to their classification: GI (unspecific non-hazardous waste), GII (patient care non-hazardous waste such as disposable items, used empty bloodlines and hemodialyzers) and GIII (sharp material, needles or anatomical waste). All of these data were compared with the treatment sessions carried out during the analyzed period, and the costs of the environmental impact were calculated.

</tbody>
</table>

† excluding transmission and distribution losses.
‡ assuming supply and treatment factors combined.
+++ assuming a 3Km trip in a fueled medium sized-car for every 2 activity hours.

Results: Table 1 summarizes the average generated waste, energy and water expenditure as well as TO required working time at the beginning and at the end of the study period. Additionally, an estimated Co₂ footprint of each activity is calculated. The increase in SW was associated with a change in format of presentation of certain materials by the producer, which allowed the reduction of the hazardous GIII amount of waste as was reassigned to non-hazardous GI or GII group. Regarding the upgrade in the RO plant, a slight increase in energy consumption due to the implementation of improved sensors allowed a substantial reduction of water required (with a high 75% efficiency) and a prominent reduction of TO time needed and traveled distance, which severely reduced the environmental impact. In addition, the remotely monitored RO reduced TO costs by 7101 €/year and material resources by 2892 €/year.

Conclusion: The first step in achieving 'green' dialysis should be to measure key indicators that determine the environmental impact of our activity, establishing our standards to easily analyze the possible deviation factors. Technological improvements and the remotely monitoring in our water treatment plant have made water consumption more efficient and overall reduced the environmental impact. To address the viability of hemodialysis, we need to raise awareness among professionals to minimize the carbon footprint derived from our care activities, designing action plans to reduce the environmental impact such as:

1. Use of moderated dialyzer flows (<600 mL/min).
2. Post-treatment bloodline and hemodialyzer drainage to reduce waste weight.
3. Initiate both awareness campaigns and specific training on the correct management of waste, and assess the costs of waste management before the acquisition of new materials.
4. Potentiate home based treatments whenever possible.

CHARACTERISTICS OF PROTEIN LOSS WITH MEDIUM CUT-OFF MEMBRANES COMPARED TO HIGH FLUX MEMBRANES

Xiaoling Wang1, Nadja Grobe1, Colleen Fisher2, Kylie Colvin2, Chih-Hu Ho2 and Peter Kotanko1,3

1 Renal Research Institute, New York, United States of America, 2 Fresenius Medical Care, Ogden, United States of America and 3 Icahn School of Medicine at Mount Sinai, New York, United States of America

Background and Aims: Medium cut-off membranes (MCO) have been introduced with the claim that larger pores enhance the removal of middle-sized uremic toxins. To date, no adequately powered randomized controlled trial has demonstrated that this membrane characteristic translates into improved mortality. A well-described consequence of larger pore sizes is a higher dialytic albumin loss [1]. In addition, other proteins could also be lost with MCO, including ones that are beneficial or even essential, e.g., to patients’ nutritional status. To better understand the spectrum of proteins cleared with MCO, we set up an ex vivo HD simulation system and compared protein loss characteristics between MCO and high-flux (HF) dialyzers.

Method: Over the course of an hour, a single reservoir of 2.5 liters EDTA human plasma was ultrafiltered using two Fresenius 2008T machines. One machine served the MCO dialyzer (Theranova 400), the other the HF dialyzer (Fresenius Optilux F180NR). Ultrafiltrate (UF) was returned to the plasma reservoir (Figure 1A). Blood flow was 400ml/min, dialysate flow was zero, ultrafiltration rate was 13ml/min. UF samples were taken at ~10 min intervals. Upon experiment completion, residual filtrate was collected from the dialysate compartment. Samples were stored at ~80°C until analysis with Bradford protein assay, silver-stained SDS-Page, and Olink Proteomics (Watertown, MA). Selected samples underwent 3K MWCO protein concentration.

Results: Figure 1B shows the UF protein concentration at several time points. Total protein loss (in mg) during the one-hour simulation was 18 (HF) and 239 (MCO) in the UF, and 10 and 359 in the residual filtrate, respectively. SDS-PAGE protein gel revealed that HF filtrate contained less amount of protein than MCO filtrate when equal filtrate volumes were loaded (Figure 1C, lane 3 vs 2, lane 6 vs 5). All 10 proteins were above the limit of detection (LOD; Table 1). The MCO-to-HF protein concentration ratio in equal filtrate volumes ranged from 1.7 to 13.1.

Conclusion: Our results show a higher amount of protein loss with MCO compared to HF. The HF filtrate protein distribution is skewed towards lower molecular weights compared to MCO filtrate. All 10 proteins identified were more abundant in MCO filtrate compared to HF filtrate. Further identification and quantification of protein loss during hemodialysis

Figure 1: Protein analysis in the filtrate. A) Ex vivo hemodialysis simulation setup to compare synchronously protein loss with MCO and HF (red, arterial line; blue, venous line; gray, UF line). Multiple UF samples were collected during the simulation. Residual filtrate was collected after the simulation from the dialysate outlet of the dialyzer. B) Trend of UF protein concentration over time. C) SDS-PAGE gel analysis of protein distribution in plasma, UF, and residual filtrate.

CONDUCTIVITY AND PLASMA SODIUM DURING HEMODIALYSIS MONITORS SWITCHING-INDUCED VARIATIONS IN

#6844

MONITOR SWITCHING-INDUCED VARIATIONS IN CONDUCTIVITY AND PLASMA SODIUM DURING HEMODIALYSIS SESSIONS

Jose Jesus Broseta Monzo, Diana Rodríguez, Elena Cuadrado, Joaquim Casals, Lida Rodas, Néstor Fontserè Baldellou, Marta Arias Guillen, Manel Vera, Miquel Gomez and Francisco Maduell

Hospital Clinic de Barcelona, Barcelona, Spain

Background and Aims: Until the advent of the new monitors with sodium modules, the differences between prescribed and actual sodium have been little studied. And most dialysis centers have a fixed sodium prescription. However, the sodium gradient during sessions is one of the key factors in its balance in hemodialysis patients. Predialysis plasma sodium has an important interindividual but not intraindividual variability, which supports the hypothesis of reference sodium (setpoint). This work aimed to compare the impact of switching from the 5008 Cordiax monitor to the new 6008 Cordiax monitor on the actually measured conductivity and initial and final plasma sodium.

Method: A total of 106 hemodialysis patients were included. Each patient received two dialysis sessions in which only the monitor was varied. The variables collected were: concentrate, prescribed sodium and bicarbonate, real conductivity, initial and final plasma sodium measured by ionic dialysance, and the change in plasma sodium concentration during treatment (ΔPNa), which has been related to mortality when it exceeds 4 mmol/L, was calculated. The clinical research ethics committee of Hospital Clinic de Barcelona approved the present study.

Results: The change of dialysis monitor showed small, although significant, differences in initial (138.14 mmol/L with 5008 vs. 138.81 mmol/L with 6008) and final plasma sodium (139.58 mmol/L vs. 140.97 mmol/L), as well as in the actual conductivity obtained (13.97 vs. 14.1 mS/cm). The ΔPNa also increased significantly, with the percentage of patients with a ΔPNa greater than 4 mmol/L going from 6 to 22% with the monitor change. All these differences were statistically significant regardless of the concentrate used. All sessions were performed without notable clinical incidents, hypotension, cramps or thirst episodes.

Conclusion: The ultimate goal of hemodialysis should be to achieve isonatremia that allows complete elimination of interdialytic sodium gain and avoid intradialytic sodium loading. The change from 5008 to 6008 monitor is associated with an increase in conductivity, higher plasma sodium, and an increase in ΔPNa. Knowing and confirming this change will allow us to individualize the sodium prescription to find adequate isonatremic dialysis and, thus, avoid possible adverse effects.

INTERACTIVE-HD 2.0 PROJECT – PRELIMINARY RESULTS OF LUGANO DATABASE

Carlo Balsamello1, Silvio Pianca2, Antonio Bellosta1, Davide Giunzioni2, Pietro Cippà2, Giustina Casagrande1 and Maria Laura Costantini1

1 Politecnico di Milano, Department of Chemistry, Materials and Chemical Engineering “Giulio Natta”, Milan, Italy and 2 Ente Ospedaliero Cantonale, Ospedale Regionale di Lugano, Nephrology Unit, Lugano, Switzerland

Background and Aims: Computational models can be used in nephrology and dialysis divisions in order to predict the intradialytic trends of the main electrolytes, breakdown products, and body fluids volumes. However, predictive models need to be trained with consistent clinical data for a certain amount of HD sessions: if successfully trained, these models can be a useful support tool for a therapy customization, mainly needed for ESRD patients characterized by multiple comorbidities. Strength and limits of similar approaches have to be evaluated before their daily clinical use.

Methods: The multi-compartmental, multi-solute model optimized during the INTERACTIVE-HD 2.0 study needs to be trained with one week’s HD sessions, during which data machine and hourly blood compositions are given in input to the model itself. After the training, this model allows an accurate prediction of the patient’s response using only the clinical data recorded at the beginning of the therapy, not only in the same sessions used for the model training (ID mode) but also in independent sessions (PRED mode). The preliminary results refer only to the center of Lugano, in which 25 patients were enrolled and whose sessions were monitored in consecutive phases over a 7-month span (for a total of n = 292 sessions); model performance (stratified by age, presence of diabetes and heart disease or hypertension) has been evaluated in terms of normalized Root Mean Squared Error defined as follow:

\[
\text{nRMSE} = \sqrt{\frac{1}{N} \sum_{i=1}^{N} \left( \frac{y_{\text{cl},i} - y_{\text{mod},i}}{y_{\text{ref},i}} \right)^2}
\]

where the subscript \(i\) stands for the \(i\)th of \(N\) intradialytic acquisition time-points, while \(y_{\text{cl},i}\) and \(y_{\text{mod},i}\) refer to the clinically measured data of interest and to the model simulated ones, respectively; \(y_{\text{ref},i}\) is the variable of interest, i.e., electrolytes’ hematic concentrations. Inter-stratification variability in terms of model performance has been analysed via a Kruskal-Wallis test.

Results: From the results’ stratification, it can be observed a good ability of the model to describe all variables, with bias with respect to pathologies in the short term. From 2 months onwards, the presence of hypertension, alone (n = 23), or the presence of cardiovascular diseases, alone (n = 38), leads to an increase in the error. Error that is instead very limited in the main group of patients (n = 229). Regarding age groups’ stratification, all variables are well simulated in the short term; however, already at 2 months, it is highlighted an increase in the error only for patients under 70 years of age (n = 87). On the other hand, for patients older than 70 years (n = 203), the stratification shows more stability. Finally, regarding the stratification based on the presence of diabetes, it can be observed that glycaemia is no longer simulated well only in insulin-dependent patients (n = 75) compared to non-insulin-dependent patients (n = 89) around 5 months; in the case of insulin-dependent patients, for K+ and urea the model is not able to avoid some other phenomenon to be modelled as they are tracked with lower precision already in the short term.

Conclusions: The stratification highlighted that hypertensive patients should be reevaluated more often, preferably two months after the first training of the model. Moreover, it was observed that the most sensitive group is the
one with patients under 70 years of age, thus requiring re-evaluation, already at 2 months; on the other hand, for patients older than 70 years, in the absence of other pathologies, this re-evaluation can be postponed at least 7 months. Finally, the ability to simulate blood glucose is always acceptable in the 7 months, except for insulin-dependent patients in whom a re-evaluation between 2 and 5 months is necessary. Either way, given the general results and what the stratifications have evidenced, we claim the clinical effort is worth it and the model can represent an important support for clinical decisions.

**DOES STARTING RENAL REPLACEMENT THERAPY WITH INCREMENTAL HAEMODIALYSIS WORSEN OUTCOMES?**

Javier Deira Lorenzo 1, André Rocha Rodrigues 1, Elena Jiménez Mayor 1, José Carlos Aguilar Aguilar 1, María Elena Davín Carrero 1, José María Sánchez Montalban 1, Silvia Gonz-Lez Sanchidrián 1, Miguel Angel Suárez Santisteban 2, Vanesa García-Bernal Funes 2 and Francesco Casino 3

1 Hospital San Pedro de Alcántara, Nephrology, Cáceres, Spain, 2 Hospital Virgen del Puerto Plasencia, Nephrology, Plasencia, Spain and 3 Regional General Hospital F. Miulli, Nephrology, Acquaviva delle Fonti, Italy

**Background and Aims:** Most patients start maintenance haemodialysis (HD) with a fixed dose of 3 HD sessions per week (3HD/Wk), regardless of their residual kidney function (RKF). This intense schedule is considered the “standard” or “conventional” modality (cHD). It is widely accepted, and no randomised controlled trial (RCT) has examined whether other less frequent schedules are inappropriate or harmful. Thus, the optimal modality for incident patients is currently unknown. Incremental HD (iHD), on the other hand, adjusts the frequency of sessions to the RKF, increasing their number to compensate for any subsequent reduction in RKF. While iHD approaches precision medicine by customising the number of sessions, it raises concerns about long intersession periods and the risk of under-dialysis. Pending ongoing RCTs [1], our aim is to analyse the efficacy and safety of iHD in our incident patients.

**Method:** The policy of our Centre is to try to start with iHD in incident patients who are clinically stable and with RKF. We start with 1 session (1HD/Wk) if the RKF is above 4 ml/min/1.73 m2 and with 2 sessions (2HD/Wk) if the RKF is between 2.5 and 4 ml/min/1.73 m2. We progress from 1HD/Wk to 2HD/Wk and from 2 to 3HD/Wk depending on the RKF and ultrafiltration rates required, which are assessed at least monthly. Since 2012, we have treated 186 incident patients with iHD, of whom 168 had a follow up ≥ 90 days. 72% (128 patients) started with 1HD/Wk and the remaining 28% (40 patients) with 2HD/Wk. We compared the results with 410 incident patients who from baseline receive 3 sessions/Wk (cHD) and with 80 incident patients on Peritoneal Dialysis (PD). We also analysed 27 iHD patients who after 60 days were already dialysed with 3 sessions (3HD/Wk/60d group). We calculated the mortality rate (deaths/365 days in %) in each group and survival in the iHD technique (sessions not performed).

**Results:** The mean age in the iHD group was higher than in cHD or PD (Table 1). Mortality in iHD patients was similar to cHD patients, although the latter were younger. Patients who stayed less time in iHD (3HD/Wk/60d group) had the highest mortality rate (Table 1). Survival in technique (time in which 50% of patients remain on iHD) was 12 months, avoiding 86 sessions/patient. The cost reduction was €17,200/patient (session + transport = €200).

**Conclusion:** iHD is efficient, as it considerably reduces the number of sessions performed and thus costs, thereby improving quality of life. It is safe, as it has a similar mortality rate to cHD. Being on iHD for more than 60 days does not worsen the results. On the contrary, requiring 3 weekly sessions at the beginning of HD treatment may be associated with a poor prognosis.

NOVEL REAL-TIME PREDICTION SYSTEM FOR HYPOTENSION IN DIALYSIS COMBINING RISK INCIDENCE AND NUMERICAL PREDICTION MODEL

Jennie Ting Hsuan Chu, Hsiang Wei Hu, Hsuanning Lin,
Kuanyu Chen, Chi Him Un, Jian-An Wang and Chih-Hao Liu

1University of California Riverside, Master of Engineering Specialization in Data Science, United States of America, 2International Academy of Biomedical Innovation Technology, Department of Artificial Intelligence in Healthcare, United States of America, 3An Nan Hospital, China Medical University, Tainan, Taiwan, Rep. of China and 4Acusense Biomedical Healthcare, United States of America

Abstract: Although there have been many studies on the machine learning prediction model of intradialytic hypotension, the high prediction accuracy in the academic field needs to be transferred to the clinical environment to aid in medical professionals’ decision-making process. Before this clinical trial, our team built a data storage, edge computing, and decision support system. However, to achieve real-time decision support, real-time data transmission is also needed along with the system to achieve clinical decision needs. Therefore, this study aims to integrate the AI predictive model with edge computing to build an overall decision support system for intradialytic hypotension in the real-world clinical environment; we have developed a system architecture to deploy the system.

Method: Development of the IDH decision support system: We developed a complete IDH prediction system to be implemented in dialysis centers and hospitals, which incorporates patient data retrieval to AI prediction models to the web application and monitoring dashboard for medical professionals. The system architecture includes a bridge service used to retrieve the HIS database (patient history), DIS database (dialysis information), and NIS database (nursing care). The data is stored in a data warehouse and then converted into a structured format for AI model training and prediction. Furthermore, an API Server, a communication service for the database and front-end web, is used to present the warning signals in real-time. Lastly, there is a multi-bed monitoring dashboard presenting personalized patient information, the incidence rate of hypotension, and numerical prediction of the actual blood pressure value.

Design and validation of the online AI prediction model: The real-time AI prediction model is built through automatic machine-learning training, which retrains the model every week, utilizing the data of the past 180 days. The features of the input data include biochemistry lab data, nursing records, demographical characteristics, hemodialysis machine parameters and vital signs; it then uses the SMOTE method to fill in missing values and via RFECV to do feature extraction and selection. Lastly, the model is trained through improved RNN models of LSTM (Long short-term memory) and GRU (Gated Recurrent Unit) integrated with machine learning models of XGboost and LightGBM algorithms to generate a combination of binary classification and numerical prediction. Hypotension’s output label is defined when systolic blood pressure drops below 90 mmHg. Finally, the validation of the AI machine learning models for binary classification used accuracy score, specificity, and sensitivity, whereas the numerical prediction model used RMSE and MAE.

Results: With the implementation of the edge computing and decision support system, clinical and dialysis data of the patients upload directly to the data warehouse in real-time, and it presents the hypotension prediction information to the medical professional’s computer. As a result, the online real-time AI prediction system for the binary classification model yielded an accuracy score, specificity and sensitivity of 0.95, 0.99 and 0.86, respectively, and the RMSE and MAE yielded 17.5 and 11.6, respectively. Furthermore, the model predicted within 15 seconds to ensure a real-time and automatic parameters update.

Conclusion: Introducing and implementing this integrated intelligence AI prediction system reduces the occurrence of hypotension in dialysis, improves patient safety and satisfaction of patients, and enhances the work environment of medical professionals. Furthermore, this framework and validation can also be provided to home dialysis patients to improve their quality of care. In addition, this system architecture can also be extended to other medical conditions in developing intelligent decision support systems for practical clinical applications.

#3472 PRELIMINARY DATA FROM MOTHER HDx STUDY: A MULTICENTRE OPEN-LABEL RCT STUDY TO EXPLORE THE MORBIMORTALITY WITH THE THERANOVA HDx VS OL-HDF

Patricia De Sequera Ortiz, Rafael Pérez García, Almudena Vega and Francisco Maduell

1Hospital Universitario Infantia Leonor, Nephrology, Madrid, Spain, 2Hospital General Universitario Gregorio Maranon, Nephrology, Madrid, Spain and 3Hospital Clinic, Nephrology, Barcelona, Spain

Background and Aims: Dialysis patients have a high rate of cardiovascular morbidity and mortality. For this reason, new technical advances are necessary to be introduced in clinical practice. Medium cut-off (MCO) membranes are a new generation of membranes that allow the removal of a greater number of medium-sized molecules compared to high-flux hemodialysis (HF-HD) but retaining albumin. Theranova, a MCO membrane has an increased permeability and also produces high convective volume in the form of internal filtration. For these special properties, MCO generated a new concept of therapy called expanded HD (HDx). Until now, online hemodiafiltration (OL-HDF) has demonstrated its superiority, in terms of survival, compared to HF-HD. But the comparison between OL-HDF and HDx is a question not solved.

Method: The MOTHéR HDx study trial (NCTO3714386) is an open-label, multicentric, prospective, 1:1 randomized, parallel-group trial designed to evaluate the efficacy and safety of HDx compared to OL-HDF in incident HD patients in Spain for up to 36 months. The main endpoint is to determine if HDx is non inferior to OL-HDF at reducing the combined outcome of all-cause death and stroke (ischemic or hemorrhagic), acute coronary syndrome (angina and myocardial infarction), peripheral arterial disease (amputation or revascularization) and ischemic colitis (mesenteric thrombosis).

Results: Now we have enrolled 513 patients, 44 excluded and 469 were randomized. 229 were allocated to HDx and 240 to OL-HDF. No differences were found in neither baseline characteristics, hemodialysis or pharmacological treatment, nor laboratory parameters. Follow up time was similar in both groups: 15.06 (12.8) vs 13.73 (11.51) months [HR 0.84 (0.50-1.40)] without differences in mortality: 29 (12.7%) vs 31 (12.9%) [HR 0.89 (0.54-1.48)] in HDx and HDF respectively (Figure 1).

Conclusion: These preliminary results from Mother study support that HDx is not inferior to OL-HDF in reducing the all-cause mortality outcome.

Figure 1: Data architecture of IDH decision support system.

**ULTRAFILTRATION RATES IN INCIDENT PATIENTS ON INCREMENTAL HAEMODIALYSIS WITH 1 SESSION PER WEEK: ARE THESE RATES DANGEROUS?**

Elena Jiménez Mayor1, André Rocha Rodrigues1, José Carlos Aguilar Aguilar2, María Elena Davín Carrero1, María Sandra Gallego Domínguez1, Jesus Pedro Alvarez1, Miguel Angel Suárez Santisteban2, Pedro Jesús Labrador Gómez3, María de Las Mercedes Acosta Rojas4 and Javier Deira Lorenzo1

---

**Background and Aims:** Most patients start haemodialysis (HD) with a fixed dose of three sessions per week, regardless of their residual renal function (RKF). This schedule is considered “standard HD or conventional HD” and is widely accepted without any randomised controlled trial (RCT) having examined whether other schedules with fewer sessions per week are inadequate or harmful. Incremental HD (iHD), by contrast, adjusts the number of sessions to the RKF, increasing the frequency to compensate for the drop in RKF. While iHD approaches precision medicine by customising the number of sessions, it raises concerns about the risk of under-dialysis and long intersession periods. In the absence of RKF, these long periods are associated with high weight gain (WGI), which leads to high ultrafiltration rates (UF rates). UF rates greater than 10 ml/kg/h are known to be associated with poor prognosis [1]. Pending ongoing RCT [2], our aim is to quantify WGI and UF rates in incident patients on iHD with a single weekly session (1HD/Wk).

**Method:** The policy of our Centre is to start with iHD in those patients with RKF and clinically stable. We start with 1HD/Wk if residual urea clearance (KrU) > 4 ml/min/1.73 m². We moved from 1 to 2, and from 2 to 3 sessions/week, depending on KrU and ultrafiltration rates. We analysed 2777 HD sessions of 66 incident iHD patients, with intersession period ≥ 6 days. Mean age was 73±12.5 years and 73% were male. WGI, rate UF and Blood Pressure (BP) pre- and post-HD were analysed for each session. We calculated the monthly dialysis dose using Solute Solver (www.ureakinetiQ.org). We considered an adequate dose if weekly stdKrU ≥ 2.1 or if EKRU + KrU ≥ 12 [3]. Pending ongoing RCT [2], our aim is to quantify WGI and UF rates in incident patients on iHD with a single weekly session (1HD/Wk).

**Results:** WGI was 1.47±1.3 kg (median 1.4), equivalent to ±1.5% of patient weight. According to BIS, pre-HD overhydration status was 1.9±1.6 (median 1.6L), similar to WGI. The UF rate, for each session, was 5.03±3.84 ml/kg/h (median 5). 9.1% of the sessions exceeded 10 ml/min/h and 2.6% exceeded 13 ml/kg/h. Pre-dialysis BP was 158±23/78±19 mmHg (median 157/76) and post-dialysis BP was 152±27/76±16 mmHg (median 150/75). RKF measured by urinary volume was 1931±491 ml (median 1900) and KrU was 5.1±1.8 ml/min/1.73m² (median 4.8). Dialysis dose was adequate, with a weekly stdKrU of 2.31±0.7 volumes (median 2.23) and EKR+KrU was 14.22±3.7 ml/min (median 13.8). Nutritional status as measured by PCR was 1.04±0.3 g/kg/day (median 1). LTI index at BIS was 12.1±4.8 kg/m² (median 12), desirable >10.5, and FTI index was 12.8±8 kg/m² (median 14), desirable >7.

**Conclusion:** Patients on iHD do not present large weight gains, nor are they subjected to high UF rates, avoiding significant changes in their BP during HD sessions. On the contrary, RKF allows them to maintain a low number of weekly sessions without presenting volume overload, underdialysis or malnutrition.

**TIO2/TI3C2 NANOCOMPOSITES FOR BILIRUBIN CLEARANCE FROM BLOOD**

Kaixi Chang and Baihai Su

West China Hospital, Sichuan University, Department of Nephrology, Chengdu, P.R. China

**Background and Aims:** The artificial liver treatment based on blood purification is an important and commonly used treatment for liver failure. Aggressive management of hyperbilirubinemia is one of the key steps to reduce mortality in patients with liver failure. Herein, targeting bilirubin in nanosized, we synthesized a TiO2/Ti3C2 nanocomposite from Ti3C2 MXenes via hydrothermal oxidation for bilirubin clearance from whole blood.

**Method:** Firstly, Ti3C2 MXene was prepared by hydrofluoric acid etching method reported in our previous work [1]. Then, it was transferred into Teflon-lined stainless-steel autoclaves (2 mg/ml, 30 ml) and was undergone the hydrothermal process at 180 °C for 6 h and 12 h. TiO2/Ti3C2 nanocomposites were obtained after lyophilization. Hemocompatibility evaluation assays include hemolysis ratio test, complement activation (human complement fragment 5a (C5a)), contact activation (Thrombin–anti-thrombin (TAT) complex) and platelet activation (platelet factor 4 (PF 4)) were systemically conducted in vitro to evaluate the feasibility of the novel nanocomposites (0.5 mg/ml) in contact with blood. We evaluated the bilirubin adsorption capacity of original Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) at the concentration of 0.5 mg/ml, respectively, in bilirubin solution (250 mg/L 10 ml) for 2 h at 37 °C in an air bath away from light. The sphere-forming properties of TiO2/Ti3C2 with polyethersulfone (PES), a commonly used blood purification material, were first verified using a liquid-liquid inversion method.
Figure 1: The hemocompatibility evaluation assays of the original Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) in vitro. (a), Haemolysis ratio and digital photos. (b), CSa levels after incubation of Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) in whole blood. (c), TAT levels after incubation of Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) in whole blood. (d), PF4 levels after incubation of Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) in whole blood.

Results: TiO2/Ti3C2 (6 h and 12 h) showed better hemocompatibility than the original Ti3C2 (0 h) (Figure 1). The bilirubin adsorption capacities by the original Ti3C2 (0 h) and TiO2/Ti3C2 (6 h and 12 h) were 354.11 mg/g, 492.83 mg/g and 492.52 mg/g, respectively. From the original Ti3C2 (0 h) to TiO2/Ti3C2 (6 h), the clearance rate of bilirubin improved from 70.82% to 98.57%. Therefore, we chose TiO2/Ti3C2 (6 h) to verify the sphere-forming properties of TiO2/Ti3C2 with PES. TiO2/Ti3C2-PES spheres were constructed successfully by a liquid-liquid inversion method. More 3D porous structure was observed via a scanning electron microscope (SEM) images and energy dispersive spectroscopy (EDS) mapping images (Figure 2).

Conclusion: The TiO2/Ti3C2 nanocomposite showed excellent bilirubin clearance capability, superior hemocompatibility, and the great application potential in the form of spheres for hemoperfusion, which may provide a promising choice in the performance enhancement of artificial liver.

deposition on the membrane with comparable clotting score: 2 (IQR 1-3) for RCA vs. 2 (IQR 1-2.25) for UFH (p = 0.40).

**Conclusion**: Given the higher activation of complement, leukocytes and platelets during HDx with UFH, we conclude that RCA offers superior biocompatibility compared to UFH during HDx. Whether improved biocompatibility has clinical relevance remains to be explored.

**MANAGEMENT OF HAEMODIALYSIS PATIENTS UNDERGOING RADIOACTIVE IODINE THERAPY FOR THYROID CANCER**

Raymond Lin1,2, Alessandra Malaroda3, William Ryder3, Veronica Wong3 and Nikki Wong1,2

1Nepean Hospital, Department of Nuclear Medicine and PET, Sydney, Australia, 2University of Sydney, Sydney Medical School, Sydney, Australia and 3Nepean Hospital, Department of Nuclear Medicine and PET, Sydney, Australia

**Background and Aims**: Radioactive iodine (RAI) 131I is used in the adjuvant treatment of thyroid carcinoma following thyroideectomy. 131I is renally excreted, with reduced clearance in patients with end-stage kidney disease (ESKD). There are no established protocols for RAI dosing, timing of dialysis and safety in this population [1]. We describe a single-centre experience with a modified protocol and setup for RAI in haemodialysis (HD) patients including serum 131I measurements to monitor for red marrow toxicity. We present the outcomes in two HD patients.

**Method**: A protocol was developed for performing HD post-RAI administration. HD sessions were performed at 24, 72 and 144 hours post-treatment. Custom HD plumbing was installed within existing lead-lined infrastructure. Specific considerations were made for radiation safety including emergency protocols, handling of blood samples, nursing education, patient self-cannulation and dose-reduction of thyrogen pre-treatment. In addition to standard dose-rate meter measurements of radiation, serum 131I measurements were taken pre- and post-HD as a more accurate measurement of red marrow toxicity.

**Results**: The two patients included in the study were aged 41 and 60 years. Special considerations for these patients included anuric state in one patient (bilateral nephrectomy) and morbid obesity in the other. Both had early-stage papillary thyroid cancer treated with thyroideectomy. Retained radioactivity measured by dose-rate meter is shown in Figure 1. The largest reduction in radioactivity occurred after the first HD session (approximately 60%). The highest risk of radiation exposure was in the 24 hours prior to the first HD session. Pre-and post-HD serum 131I measurements estimated the radiation dose to red marrow to be below 0.2Gy (maximum tolerated radiation dose for red marrow is 2.0Gy2). Radiation received by HD nurses is shown in Figure 2. Overall exposure was well within national regulatory dose limit of 0.5mSv for members of the public.

**Conclusion**: HD at 24, 72 and 144 hours produced a radiation clearance profile similar to controls with normal renal function. The effect of residual renal function on 131I clearance was minimal and HD was the main determinant of 131I clearance in ESKD. Non-routine serum measurements of 131I can be used to assess toxicity to red marrow and guide HD session timing during RAI therapy. Performing HD at 24 and 72hrs post- 131I resulted in a radiation burden to the red marrow well below the accepted radiotoxicity threshold of 2Gy [2]. RAI can be given safely to HD patients with thyroid cancer in centres with the appropriate protocol and setup.

LESS MICROBUBBLES ENTERED THE PATIENTS USING THE VENOUS CHAMBER EMBOLESS DURING HEMODIALYSIS
Ulfi Forsberg, Bernd Stegmayr and Per Jonsson
Umea University, Public Health and Clinical Medicine, Umea, Sweden

**Background and Aims:** The extracorporeal circuit (ECC) enables haemodialysis (HD) of patients. Air contamination of the blood appears when it passes the ECC and consequently microemboli (MBs) enter to the patient [1]. MBs were verified at autopsy of HD patients and covered by clots as microemboli deposited within tissue from lungs, heart and brain [2]. A venous chamber is inserted in the ECC to reduce contamination of MBs. However, chambers in clinical use have limited capacity to eliminate MBs from entering the return bloodline. In an in vitro preclinical study the Emboless chamber showed best results compared to common models in clinical use; the best of those was for Fresenius 5008 [3]. We compared if the venous chamber Emboless differs in capacity to limit MB exposure from the original venous chamber of Fresenius 5008 (F5008).

**Method:** Thirty-eight HDs were performed as 19 paired HD sessions. Eleven patients were included. Venous chambers used were either F5008 or Emboless, in a randomised order. Dialyzers, blood-pump speed, HD or HDF and ultrafiltration was kept similar between the pairs. Microembobles were measured at the ‘Inlet’ and ‘Outlet’ of the venous chamber with an ultrasound device adjusted for HD (hil mode, BCC200, GAMP3PT). Measurements were made for MBs between all sizes 20μm-500μm diameter. If HDF was performed the first 30min measured were by HD and the subsequent 30min by HDF (extended time if less than 1000 detected inlet MBs). The percentage of change in ‘Outlet’ versus ‘Inlet’ counts were compared (paired Wilcoxon test). Total reduction was 100% while increase of MBs (worsened) caused unlimited (+) percentage. If a diameter was without counts it was not included in the analysis.

**Results:** The median overall change of MBs were for F5008 −33% (mean −20 ±76%, N = 8544) and for Emboless −69% (mean −56 ±54%, N = 8402; and pairwise N = 8093; p<0.001). The Table 1 shows more results.

**Conclusion:** Less MBs and subsequently less microemboli entered to the patient using the EmbolessTM compared to using the Fresenius 5008 venous chamber during haemodialysis. Considering our previous autopsy studies this supports less tissue damage of the patients using EmbolessTM.

LIGHT CHAIN REMOVAL IN MULTIPLE MYELOMA PATIENTS WITH HFR-SUPRA HEMODIALYSIS: OUR EXPERIENCE
Salia V Pol Heres, María Jesús Moyano Franco, Fabiola Alonso García, Elena Jiménez Vibora and Mercedes Salguero Lazo
Hospital Universitario Virgen Macarena, Sevilla, Spain

**Background and Aims:** Kidney injury is a common complication in multiple myeloma (MM) and it has a negative prognostic implication. Most common cause of Acute Kidney Injury (AKI) in these patients is Light chain Cast Nephropathy, where free light chains precipitate in the tubules and bind with uromodulin, turning into intratubular casts that obstruct the tubules and also promote local giant cell reaction and interstitial inflammation and fibrosis. Free light chains (FLCs) can also damage the kidneys due to direct tubular toxicity when excessive amounts are reabsorbed by the proximal tubules. Targeted therapy to reduce FLC load can help recover renal function. Both total reduction and reduction speed are relevant for prognosis. FLC removal through extracorporeal techniques can be used as an adjuvant therapy, having an important part on the evolution of the disease. We gathered data from our experience treating MM patients with AKI with HFR-supra hemodialysis (HD) and analyzed the evolution and possible influence of this technique on renal recovery.

**Method:** This is an observational retrospective study. We included all patients with a diagnosis of multiple myeloma and acute kidney injury who received HFR-Supra hemodialysis in between years 2016-2022 in Hospital Virgen Macarena (Seville). We initially performed 6-10 daily HFR-Supra HD sessions and then modulated the frequency based on renal response (if renal replacement therapy had to be continued they underwent a usual hemodialysis regime 3 days a week). We continued these sessions until renal recovery was achieved or free light chain levels were reduced in agreement with the Hematology team. Measurement of pre and post dialysis FLCs was made always at first and last session and at least once in between, depending on the total number of sessions.

**Results:** 12 patients, with mean age at diagnosis 63.6 (43-86) years, presented with AKI stage KDIGO 3. 1 of them was oliguric. Median serum creatinine at diagnosis was 4.4 mg/dL [2.2-17], mean proteinuria was 4.1g/24h [0.7-8.7] and 66.7% had positive Bence Jones proteinuria (mean 2.3g/24h). 2 of the patients had previous chronic kidney disease stage 3a. All of them were diagnosed with Light Chain Multiple Myeloma (75% kappa, mean 10346 mg/L; 25% lambda, mean 5990 mg/L). Mean clonal bone marrow plasma cell was 20.7% [2-55]. According to the Revised International Staging System (R-ISS), 25% were stage 2 and 75% were stage 3. Renal biopsy was performed in 4 patients, all showed evidence of Cast Nephropathy. The indication for starting HFR-Supra HD was FLC removal in 9 patients, need of renal replacement therapy in 1 and both in 2 patients. We have experience in our center with using this therapy as an adjuvant treatment and often we start the technique in patients who present with AKI but would not necessarily have immediate need for renal replacement therapy. The goal is to remove FLCs and avoid further damage to the kidney tissue. Out of the 12 patients, 9 were able so stop dialysis (75%). They received an average number of 12,4 [3-41] sessions in 3,7 [0,2-25] months). Free light chain removal per session was 24% on average [5-43%]. All of them were started on bortezomib-dexamethason regime as initial chemotherapy for...

The Table shows values when divided into MB diameter size groups. P-value represent paired test. N represents the numbers of measurements.
MM. As per renal recovery, at 3 months 33.3% achieved complete response, 11.1% partial response and 55.6% minimal response. At 1 year, 42.9% achieved complete response, 14.3% partial response and 42.9% minimal response. One-year survival rate was 91.7% (1 patient died from respiratory sepsis less than 1 month after diagnosis).

**Conclusion:** HFR-Supra hemodialysis achieved a 24% free light chain removal per session on average. After presenting severe AKI (KDIGO 3), almost 43% of patients who received this adjuvant therapy obtained full renal recovery at 1 year and in 75% of patients withdrawal from hemodialysis was possible. 1 year survival was 91.7%.

**A 2-YEAR STUDY FOR CHANGE OF PLASMA BIOMARKERS INCLUDING LARGER MIDDLE MOLECULES IN DIALYTIC PATIENTS USING DIALYZERS WITH MEDIUM CUT-OFF MEMBRANES**

Jong Hwan Jung and Seon-Ho Ahn
Wonkwang University School of Medicine and Hospital, Internal Medicine, Iksan, Rep. of South Korea

**Background and Aims:** Uremic toxins with middle molecular weight usually develop uremic symptoms. The larger middle molecules are regarded as causative molecules of uremic symptoms. Medium cut-off (MCO) membrane newly developed can remove larger middle molecules which can be not removed through high flux membrane and hemodiafiltration. Larger middle molecules are mainly related to cardiovascular complications. Therefore, long-term use of MCO membrane may have beneficial effects in dialytic patients, in terms of lowering concentrations of larger middle molecules associated with cardiovascular complications. Now, we report interesting 2-year results of long-term use of MCO membrane in dialytic patients.

**Method:** Thirty-four patients undergoing hemodialysis were prospectively analyzed during 24 months. We randomly divided enrolled patients into two groups: control and MCO group. Patients in the control group used dialyzer with high flux membrane and patients in MCO group used MCO membrane.

We measured plasma levels of biomarkers with 3 or 6-month to investigate efficacy of the MCO membrane for small (3-month interval) to larger middle molecules (6-month interval). Particularly, we performed comparative analysis with larger middle molecules in both groups. We calculated reduction ratio of biomarkers per one session at 24-month.

**Results:** The levels of larger middle molecules at baseline did not show significant difference between two groups. However, compared with the control group, plasma sclerostin levels at 6-month and 12-month in MCO group did not increased significantly compared to baseline levels. Plasma sclerostin were lower in MCO group throughout 2 year, but the significant difference of plasma sclerostin levels between two groups unfortunately disappeared after 12 months. The levels of other biomarkers including FGF23, leptin and GDF15, also did not show significant difference between two groups. However, β2MG levels in MCO group compared to control group decreased significantly throughout 2 years (MCO group: 18-month, p = 0.001 and 24-month, p < 0.001, respectively; control group: 18-month, p = 0.003 and 24-month, p < 0.001, respectively). Interestingly, even in MCO group, there was no statically significant decrease in total protein and albumin levels after 24 months (p = 0.429 and p = 0.101, respectively) (Figure 1). The reduction ratio of larger middle molecules compared to small molecules per one session prominently increased in MCO group (sclerostin, p < 0.001; GDF15, p < 0.001; FGF23, p < 0.01; RBP4, p < 0.01; phosphate, p = 0.821; calcium, p = 0.827; CRP, p = 0.729 and β2MG, p = 0.286, respectively) (Figure 2).

**Conclusion:** Conclusively, in MCO group, the significant change of plasma sclerostin associated with cardiovascular complications after 12 months disappeared. However, in MCO group compared to control group, there was a continuous decrease of β2MG and RBP4 throughout study period. In addition, the clearance of larger middle molecules is also prominently high in MCO group. Interestingly, there were also no significant differences of albumin between 24-month and baseline in MCO group. Therefore, the MCO membrane can be a good tool for controlling uremic symptoms or sings without protein loss even when used for a relatively long time in dialytic patients.

Figure 1: The change of serological markers during 2-year treatment.
DIALYSATE SODIUM: IS IT STILL MYTH OR NOT?
Natasha Eftimovska-Otovikj1, Elizabeta Poposka1, Bojana Vrevezoska1, Marija Karakostova2 and Venco Vuinov3

1 General City Hospital “8th September” Skopje, Department of Nephrology and Hemodialysis, Skopje, Republic of North Macedonia, 2 Pehchevo, Republic of North Macedonia and 3 Vinica, Republic of North Macedonia

Background and Aims: Pre-hemodialysis serum sodium levels can vary among patients, therefore, a single dialysate sodium prescription may not be appropriate for all patients. The aim of the study was to investigate whether dialysis patients will have some beneficial effects of prescription of different models of dialysate sodium.

Method: 77 nondiabetic subjects performed 12 months hemodialysis (HD) sessions with dialysate sodium concentration set up at 138 mmol/L, followed by additional 4 models of dialysate sodium (each one 4 months sessions lasted) wherein dialysate sodium was set up: model 1: according to pre-hemodialysis serum sodium concentration, model 2: sodium concentration in UF fluid, model 3: sodium profiling (144-136 mmol/L, every hour decreasing of dialysate sodium during dialysis), model 4: stepwise dialysate sodium (starting dialysis with a dialysate sodium of 138 mmol/L and reducing it every week by 1 mmol/L sodium for the next 4 weeks). Blood pressure (BP), interdialytic weight gain (IDWG), thirst score, sodium gradient were analysed. After the standard dialysate sodium hemodialyses, the subjects were divided into normotensive, hypertensive and hypotensive based on the average pre-hemodialysis systolic BP during the standard dialysate sodium hemodialyses.

Results: Model 1: resulted in significantly lower BP (153.60±14.26 versus 133.61±11.88 mmHg; p = 0.000) and IDWG (2.21±0.93 versus 1.87±0.92 kg; p = 0.018) in hypertensive patients, whereas normotensive patients showed only significant decrease in IDWG (p = 0.004). Hypertensive patients had significant highest sodium gradient compared to other patients (p<0.05), followed by significant increase of 0.6% IDWG confirmed with univariate regression analysis. Thirst score was significantly lower in all patients with individualized-sodium HD and no relationship between the sodium gradient and the subjective feeling of thirst was confirmed (p = 0.368). Model 2: resulted in significantly lower BP in normotensive and hypertensive patients, with no influence on IDWG and thirst score compared to standard dialysate sodium (p = 0.474 and p = 0.212, retrospectively). Patients who were hypertensive, due to frequent collapses and unmeasurable blood pressure values, as well as for ethical reasons, were excluded from analysis with this dialysate sodium model. Model 3: confirmed significantly higher BP and IDWG in all 3 groups (p = 0.006) and significantly higher thirst score in normo and hipotensive patients (p = 0.000), with no influence in hypertensive patients. Model 4: significant decrease in SBP and DBP in hypertensive patients and insignificant increase in IDWG, but with no effects in normotensive and hypotensive patients on BP, IDWG and thirst score.

Conclusion: Model 1 resulted in better clinical outcome in hypertensive and normotensive patients compared to standard dialysate sodium, whereas other 3 models didn’t show any clinical benefits.

THE APPLICATION OF MODERN MEDICAL INFORMATION SYSTEMS WITH ARTIFICIAL INTELLIGENCE ELEMENTS FOR PERSONALIZED TREATMENT OF PATIENTS ON HEMODIALYSIS
Evgeny Shutov1,2, Stepan Bolshakov3 and Galina Kotlyarova3

1 City Clinical Hospital named after S.P.Botkin, Russia, 2 Federal State Budgetary Educational Institution of Further Professional Education “Russian Medical Academy of Continuous Professional Education” of the Ministry of Healthcare of the Russian Federation., nephrology, Moscow, Russia and 3 City Clinical Hospital named after S.P.Botkin, nephrology, Moscow, Russia

Background and Aims: The quality of life and survival of patients on hemodialysis significantly depend on modern technology. Treatment requires control of dynamically changing large volume of data, which must be analyzed and interpreted in real time. Achieving the ideal balance between adequate fluid removal, effective dialysis dose, and low risk of adverse events on the hemodialysis procedure is a complex multifactorial problem. The heterogeneity of the dialysis population, comorbid burden, the use of concomitant medications, nutritional status and adherence to diet, patient compliance are a noncomplete list of factors that must be considered when setting the dialysis regimen. Thus, despite significant progress in the technical aspects of the “artificial kidney devices”, personalization of the treatment regimen remains an important and difficult task. Introduction of modern automated medical information systems (MIS) for management of treatment and diagnostic process can provide invaluable assistance in treatment process and improve treatment outcomes. The aim of our study was to improve the prevention and treatment of hemodynamic disorders in hemodialysis patients using a special own program “Maximus”, which collects and analyzes indicators from dialysis machines in real time.

Method: The study was conducted from May to November 2022. The study included 120 patients on hemodialysis. The average age of the participants was 62.3±23.4 years. All participants underwent bioimpedance testing with a hydration score (InBody S10) compared to the prescribed dry weight at inclusion. A total of 9360 hemodialysis procedures (all HDF) were analyzed. The data of all procedures were collected directly from dialysis machines and analyzed in MIS in real time, identifying deviations from the target values. Episodes of both hypertension (140/90 mm Hg) and hypotension (100/60 mm Hg) were considered. MIS analyzed the actual duration of the procedure, blood flow rate, volume of fluid removal, rate of ultrafiltration and level of Na. In case of deviations from the established normal values, the system actively notified the doctor (via SMS/messengers) about detected deviations and proposed solutions. The medical staff timely corrected dry weight, duration of procedures, UF rate, volume of fluid removal, sodium content and blood pressure.

Results: In patients with arterial hypertension (63% of patients), mean systolic BP decreased by 12±6 mmHg and diastolic BP by 10±8 mmHg before dialysis procedure. In this group mean systolic BP decreased by 11±10 mmHg and diastolic BP by 9±8 mmHg during the procedure of hemodialysis. In patients with hypotension, due to “dry weight” increase, correction of Na level,
stabilization of BP level was achieved, and mean systolic BP increased by 14±5 mmHg, and diastolic BP by 9±5 mmHg before dialysis procedure. Correction of hemodynamically significant parameters led to a decrease in the incidence of both intradialytic hypotension and hypertension during the hemodialysis procedure.

Conclusion: Correction of treatment, carried out using MIS with SMS notification of medical staff, improved hemodynamic parameters. Modern medical information systems with a Decision Support System can improve the quality and efficiency of treatment, reduce the risk of cardiovascular complications in patients on hemodialysis.

8-ZONE LUNG ULTRASOUND AND BIOIMPEDANCE ANALYSIS FOR ASSESSMENT OF HYDRATION STATUS IN HEMODIALYSIS: A PROSPECTIVE SINGLE CENTRE EXPERIENCE

Andrea Curto, Inês Alexandre, Mariana Ramos, Catarina Brás, Afonso Santos, Anna Lima, Miguel Verdelho, Maria Adelaide Serra, Fernando Domingos and Pedro Campos

Hospital Fernando Fonseca, Nephrology, Amadora, Portugal

Background and Aims: Chronic volume overload is a major contributor to cardiovascular mortality in patients receiving maintenance hemodialysis (HD). Hence, accurately assessing volume status in this population is crucial. Bioelectrical impedance analysis (BIA) is a validated, non-invasive, and straightforward bedside technique that estimates total body water (TBW), extracellular water (ECW), intracellular water (ICW), and over hydration (OH). However, it is not suitable for use in patients with limb amputation or metallic medical devices. On the other hand, lung ultrasound (LUS) is used to evaluate extravascular lung water (EVLW) and has been shown to predict all-cause mortality and cardiac events in HD patients. Although a 28-zone LUS is the reference standard for LUS studies, recent studies have shown that an 8-zone LUS protocol can be as accurate. The aim of this study was to compare the performance of an 8-zone LUS protocol with bioelectrical impedance analysis to evaluate hydration status in an outpatient haemodialysis unit.

Method: Adult patients under thrice-weekly 4h HD sessions using high-flux membrane dialyzers for at least 1 month were prospectively enrolled between June and August 2022. We excluded patients with systemic infections, advanced neoplasia, metallic medical devices, decompensated cirrhosis, and limb amputations. The dry weight (DW) was established by the attending nephrologist, blind to the results. All measurements were performed in the first session of the week. BIA was assessed before HD using a portable whole body BIA device (BCM—Fresenius Medical Care D GmbH) and the OH was normalized to ECW. LUS using 8-zone protocol was performed before and after HD, with patients in the near-to-supine or supine position using a 2–5 MHz convex probe (Acuson X150®), Siemens, Germany), and the total number of B lines was recorded.

Results: A total of 37 patients with median age of 60 (IQR 15) years, 75% males, 65% with residual diuresis >300 mL/24 h were included. The median HD vintage was 9 (IQR 10) months, and median body mass index (BMI) of 22.7 (IQR 9) Kg/m². At the beginning of HD, the median systolic blood pressure (BP) was 140 (IQR 24) mmHg and the median diastolic BP was 79 (IQR 16) mmHg. The median interdialytic weight gain was 4.2% (IQR 2.8%) and median ultrafiltration (UF) was 2600 (IQR 1300) ml. The BIA showed median TBW of 38.2 (IQR 11) L, ECW 18.2 (IQR 7.73) L, ICW 20.8 (IQR 6.55) L, and normalized OH 0.138 (IQR 0.147). There was a positive correlation between BMI, TBW (r = 0.375, p = 0.045), and ECW (r = 0.486, p = 0.006), but not with ICW (r = 0.061, p = 0.755), nor normalized OH (r = 0.14, p = 0.468). Systolic BP, but not diastolic, was correlated with the water volume measured in both compartments (ECW: r = 0.498, p = 0.005; ICW: r = 0.421, p = 0.023, TBW: r = 0.423, p = 0.022). The 8-zone LUS showed a statistically significant (p<0.001) reduction in the number of B lines between pre and post HD evaluation (16.5 (IQR 17.25) lines to 8.5 (IQR 10.25) lines). Total evaluation time was under 8 minutes. When comparing LUS before HD with BIA assessment we found that the number of B lines correlated with the normalized OH (r = 0.454, p = 0.018), ECW (r = 0.501, p = 0.007), TBW (r = 0.418, p = 0.030), but not ICW (r = 0.239, p = 0.23). The total number of B lines post HD was also correlated with the ECW (r = 0.568, p = 0.002), TBW (r = 0.465, p = 0.017), and normalized OH (r = 0.408, p = 0.039).

Conclusion: The 8-zone LUS protocol provides a quick and efficient way to evaluate patients prior to HD sessions. Our study reveals a strong correlation between the total number of B lines determined by the 8-zone protocol and BIA parameters such as TBW, ECW, and normalized OH. This demonstrates that the 8-zone protocol can effectively be used in routine evaluations of HD patients. Although these techniques reflect different over-fluid compartments, they have a complementary role for fluid overload determination and dry weight guidance.

THE ROLE OF CYTOKINE ADSORBER IN REDUCTION INTERLEUKIN-6 LEVELS: A MATCHED CASE-CONTROL SINGLE CENTER ANALYSIS

Alexander Jerman1, Jakob Gubensek4, Jernej Berden2 and Vanja Peršič1
1University Medical Center Ljubljana, Department of Nephrology, Ljubljana, Slovenia and 2University Medical Center Ljubljana, Department for Intensive Internal Medicine, Ljubljana, Slovenia

Background and Aims: Extracorporeal cytokine adsorption is used with the aim to reduce pathogenic levels of cytokines in critically ill patients. Although technically and theoretically plausible, little convincing data exist to support wide use of cytokine adsorber in clinical practice. We aimed to retrospectively compare the time course of interleukin-6 (IL-6) in patients treated with or without the adsorber (CytoSorb®).

Method: In this retrospective, case-control study all patients treated between Jan 2017 and Dec 2021 in a medical ICU were screened and included, if at least two IL-6 measurements were available. Patients were divided to adsorber group and standard of care group based on the treatment received. Unmatched and matched groups were compared regarding IL-6, lactate, CRP, procalcitonin, and vaspessor demand at predefined time points. Mortality rates were also compared.

Results: We screened 3865 patients and included 52 patients in the adsorber group and 94 patients in the standard of care group. After matching, there were 21 patients in each group. Patients had similar age (53 (41, 68) vs. 61 (56, 67) years), ECMO was used in 24% (both groups) and renal replacement therapy in 100% of patients (both groups), baseline noradrenaline requirement (0.04 vs. 0.03 mg/kg/h), serum lactate (6.8 vs. 5.4 mmol/l), pH (7.27 vs. 7.21), CRP (182 vs 167 mg/l), and IL-6 (2441 vs. 2552 ng/l) were comparable between adsorber group and SOC group. There were no significant differences in the time course of IL-6, lactate, CRP, procalcitonin, and noradrenaline requirement between the groups. Two-day (33% vs. 28%) and ICU (57% vs. 62%) mortality and Kaplan-Meier survival curves (log-rank p = 0.9) were comparable.

Conclusion: In our matched case-control study, no difference in IL-6 or inflammatory parameters reduction, noradrenaline demand, or mortality was observed between patients, treated with adsorber (CytoSorb) or standard of care.
VALIDITY AND ADEQUACY OF ANIMAL MODELS IN HAEMODIALYSIS RESEARCH: A SYSTEMATIC REVIEW
Joost de Vries¹, Kim Wevers², Marianne Verhaar¹, Karin Gerritsen¹ and Merle Kebber¹

¹University Medical Centre Utrecht, Department of Nephrology & Hypertension, Netherlands and ²Radboud University Medical Center, Department of Anesthesiology, Netherlands

Background and Aims: with the worldwide dialysis population growing rapidly, improving haemodialysis (HD) outcomes is crucial and HD innovations are urgently needed. Prior to clinical application, novel HD technologies must undergo extensive preclinical testing. However, to date there is no consensus on the induction method of kidney failure in animal models nor which animal species is most suitable for research on HD innovations. Moreover, there is no consensus on which parameters should be used to validate adequate induction of kidney failure and functioning of novel HD devices. Using a systematic review approach, we summarized available literature of HD in kidney failure animal models.

Method: we performed a systematic search on PubMed and Embase for relevant studies up to February 4th 2022. After removal of duplicates, 5723 abstracts were screened for eligibility by three independent reviewers (JdV, KW and MK). Inclusion was based on publication of a HD intervention in an animal model with adequate (acute or chronic) kidney failure (independent of induction method). Detailed inclusion and exclusion criteria were registered in PROSPERO 2022 CRD42022307144. Data from individual reports, including animal species and sex, kidney injury parameters and HD details, were extracted in a pre-set data extraction form. Future efforts will focus on risk of bias and key quality indicators.

Results: of the 5723 abstracts screened, 195 records were included as full text and 41 full text articles were included for data-extraction (Figure 1). Current data extraction is completed for 31 articles (75%). Publication years range from 1973 to 2021 with over half (16/31) published after 2000. HD experiments were most frequently performed on dogs (45%), followed by rats (29%), goats (13%), pigs (10%), and sheep (3%) respectively. Parameters such as weight (81% reported), sex (58%) and age (29%) were not systematically reported. Most studies (67% of records reporting sex) used male animals only. Dog models were found in older studies, with no records after 2009. Other large animal studies were almost exclusively (88%) performed from the year 2007 onwards. Independent of animal species, studies mainly used acute kidney injury (AKI) models (84%), induced by bilateral nephrectomy (48%) or bilateral ureteral ligation (29%). The majority confirmed kidney failure by an increase in BUN and/or plasma creatinine. In AKI models, dialysis was on average initiated on AKI day 2 ± 0.8, and generally either HD (61%) or veno-venous hemofiltration...
LONG TERM EFFECT OF MEDIUM CUT-OFF DIALYZER ON MIDDLE UREMIC TOXINS
Irena Rambabova-Bushljetik1, Zhaklina Shterjova-Markovska1, Aleksandra Canevska-Tanaska1, Zoran Janevski1, Stefan Filipovski1, Igor Nikolov1, Galina Severova-Andreevska1, Oliver Bushljetikj2, Nikola Gjorgjievski1, Vladimir Pushevski1, Goce Spasovski1 and Lada Trajcheska1

1University Clinic of Nephrology, Skopje, Republic of North Macedonia and 
2University Clinic of Cardiology, Skopje, Republic of North Macedonia

Background and Aims: Better removal capacities for middle and large middle molecules in hemodialysis was achieved in (HD) treatment with the new medium cut-off (MCO) membranes. The aim of this study was to evaluate the long term removal efficacy of Theranova® in standard HD in comparison with standard high-flux HD.

Method: 11 patients were assigned to high flux and 11 to MCO membranes in 12-months observational study. Each patient was assessed every three months from T0 with high-flux dialyzers, T1 to T5 with MCO at first, third, sixth, ninth and twelfth month by measuring pre- and post-HD samples of β2-microglobulin (β2M), myoglobin, albumin, free light chains kappa (FLC-k), and free light chains lambda (FLC-λ). The cumulative change from as RR from T0 to T5 was defined as long term outcome.

Results: The data showed a higher average removal rate (RR) for all the uremic toxins with Theranova® dialyzers for β2M, myoglobin, FLC-k, and FLC-λ (66.1, 53.2, 59.2, 59.0%, respectively) compared to high flux (57.1, 10.8, 29.9 and 27.4%, respectively). The analyses on the cumulative RR from T0 to T5 found significant decrement of β2M, myoglobin, FLC-λ in MCO vs high flux group where those values significantly raised (14.9 ± 6.1, p = 0.043; 27.7 vs –7.8, p = 0.001; 21.9 vs –4.2, p = 0.017, respectively). The FLC-λ showed borderline significantly better removal with MCO (17.8 vs 8.4, p = 0.067). The distribution of patients with 12 month middle molecules reduction was much better in the MCO group. Albumin retention was better in MCO group and did not change between T0 and T5 (p = 0.824).

Conclusion: Compared to high-flux membranes, MCO membranes show greater permeability for middle molecules and albumin stability in long-term report. Their use in HD standard setting is effective and safe.

THERAPEUTIC PLASMA EXCHANGE AS A TOOL IN THE TREATMENT OF NEUROLOGICAL DISEASES: A SINGLE CENTER EXPERIENCE
Ana Carlota Vida1, Inês Sala3, João Fernandes2, Ana Castro2, Cristina Freitas2 and Luisa Lobato2

1Hospital Central do Funchal, Department of Nephrology, Funchal, Portugal and 2Department of Nephrology, Porto, Portugal

Background and Aims: Plasmapheresis is an extracorporeal technique that removes immunological active substances, such as antibodies or immune complexes, from plasma. Simultaneously, it can provide essential factors in deficit, when supplementing with plasma. Therapeutic plasma exchange (TPE) can be used in numerous diseases with systemic involvement and, more recently, it has assumed an increasingly relevant role in the treatment of neurological diseases. Our aim was to review neurological indications, technique prescription, clinical outcomes and complications of these procedures.

Methods: We conducted an observational retrospective single-center study of the neurological diseases treated with TPE in our unit. We analyzed all procedures performed between January 2010 and December 2012 and collected indications, technical factors, complications and clinical outcomes of all treatments conducted. TPE was performed removing 1 to 1.5 of plasma volume per session. All procedures used Human Albumin 5% as replacement fluid and two units of fresh frozen plasma (FFP) were given in the end of each session. Hypocoagulation of the extracorporeal circuit was maintained with unfractionated heparin.

Results: Seventy-seven cycles of TPE (a total of 421 procedures) were performed on 45 patients [55.6% female; median age of 51 years (SD±16.8)]. The main indications of TPE in neurological diseases included myasthenia gravis (n = 35), Anti-N-methyl-d-aspartate (NMDA) encephalitis (n = 7), Guillain-Barré syndrome (n = 7), neuromyelitis optica spectrum disorders (n = 6), acute disseminated encephalomyelitis (n = 5), paraneoplastic syndromes (n = 4) and multiple sclerosis (n = 2). Intravenous immunoglobulin was given before TPE in 25 cases, 34 patients were on steroid and 6 patients had received pyridostigmine. Eighteen patients had coadjuvant immunosuppression [Myophenolate mofetil or Azathioprine (n = 13), Rituximab (n = 3), tacrolimus (n = 1), Tocilizumab (n = 1) or Eculizumab (n = 1)]. The median number of TPE sessions per patient was 5 (range 1-20) and most cycles (63.6%) were performed every day for 3 sessions and 2 sessions every other day. Most of TPE (59.7%) was performed in ward, 27.3% in Intensive Care Unit (ICU) and 10 treatments were conducted in ambulatory. Near 84% of treatments were done through central venous catheters (CVC) and one patient had an arteriovenous (AV) fistula. Twenty-four (5.7%) complications were seen in 421 procedures. These complications were infection (18.2%), catheter-related (7.8%) and allergic reactions (1.3%). TPE procedure was terminated in 7.8% of sessions depending on these complications. Overall response to TPE were noted in 81.8% of patients and 6 patients had at least one relapse during follow-up.

Conclusion: TPE is an effective and safe treatment option in several neurologic diseases. In our center, principal indications for TPE were myasthenia gravis, NMDA encephalitis and Guillain-Barré syndrome. In this study, clinical outcomes were favorable in the majority of the cases, with a minimum rate of complications per procedure. Therefore TPE should be considered in an early phase of the presentation of disease. In relapsing diseases like myasthenia gravis, refractory to immunosuppression therapy, an AV fistula could be an alternative access to minimize the CVC-related complications.
HFR USING A HIGH-FLUX DIALYZER (SUPRA-H) AS NEW EFFECTIVE ALTERNATIVE TO ON-LINE HEMODIAFILTRATION: A SINGLE SESSION ANALYSIS

Alejandro Valero Antón¹, María Amparo Martínez-Gómez², Laura Pérez-Sánchez³, Julio Peiró⁴, Mercedes González Moya¹,⁵,⁶, Belén Vizcaíno¹,⁵,⁶, María Rodrigo⁴, Aina Quilis⁴, Paula Gandía Ureña¹, Manuel Parra¹, María Asuncion Sancho Calabuig¹,⁵,⁶, Mónica Clímente², Nuria Estañ³, Mariola D. Molina⁷ and Pablo Molina¹,⁵,⁶

¹Doctor Peset University Hospital, Nephrology, Valencia, Spain, ²Doctor Peset University Hospital, Pharmacy, Valencia, Spain, ³Doctor Peset University Hospital, Clinical Analysis, Valencia, Spain, ⁴Hospital Universitari de la Ribera, Clinical Analysis, Alzira, Spain, ⁵University of Valencia, Medicine, Valencia, Spain, ⁶Fisabio, Valencia, Spain and ⁷University of Alicante, Mathematics, San Vicente del Raspeig, Spain

Background and Aims: Hemodiafiltration with regeneration of the ultrafiltrate (HFR) is a highly biocompatible dialysis technique that combines convection, diffusion, and adsorption. SUPRA-H is a new HFR system which uses a high-flux dialyzer in the diffusive stage to improve large uremic toxin removal. The aim of our study was to compare the toxin removal of the SUPRA-H system with high-volume online-hemodiafiltration (OL-HDF).

Method: In an open, randomized, cross-over, single-center, controlled study, 16 adult chronic hemodialysis patients were treated with SUPRA-H or OL-HDF. Hemodialysis sessions were delivered with Flexya dialysis monitor (Medtronic) in the middle-week session, lasting four hours. OL-HDF session was performed in post-dilution mode with the same high-flux dialyzer (Phylter HF17G, Medtronic) as that used in the diffusive stage of the SUPRA-H system. All other dialysis parameters were kept constant in both study arms. The reduction rate (RR) of urea, creatinine, phosphate, β2-microglobulin (β2mglob), kappa (κFLC) and lambda (λFLC) free light chains, interleukin-6 (IL-6) p-Cresyl sulfate, indoxyl sulfate and albumin, was intrindividually compared for the two dialysis types with linear mixed models.

Results: Whereas urea RR was significantly lower, SUPRA-H had significantly higher RR for κFLC (Median: 58.63%, IQR: 49.91-70.24) than those obtained with OL-HDF (Median: 51.97%, IQR: 37.12-62.71; p = 0.03). The RRs for the other large and protein-bound uremic toxins tended to be higher with the SUPRA-H system (Figure 1). There were no significant differences in the RRs for creatinine, phosphate, IL-6, and albumin.

Conclusion: The new HFR system SUPRA-H, appears to be a potential technologic step ahead in terms of improved large molecule removal for dialysis patients, and might contribute to a more adequate dialysis therapy.

Figure 1: Comparison of uremic toxin reduction ratios (in percentages).
FACTORS ASSOCIATED WITH THE CIRCUIT LIFESPAN OF CONTINUOUS KIDNEY REPLACEMENT THERAPY (CKRT)
Yorikazu Hashimoto and Takuhiro Moromizato
Okinawa Prefectural Nanbu Medical Center and Children’s Medical Center, Renal and Rheumatology, Shimajiri, Japan

Background and Aims: Approximately half of patients in intensive care unit (ICU) experienced acute kidney injury (AKI). ICU patients with severe AKI and hemodynamic instability sometimes require continuous kidney replacement therapy (CKRT). Termination of CKRT circuits leads to blood loss, attenuation of therapeutic effects of CKRT, and a heavy workload and resource burden for medical staff. Identification of the factors which can prolong the lifespan of CKRT circuits is clinically essential. We aimed to elucidate the factors affecting the lifespan of CKRT circuits in ICU patients.

Method: We evaluated the lifespans of 559 CKRT circuits used for 63 ICU patients at the Okinawa Prefectural Nanbu Medical Center and Children’s Medical Center from April 1st, 2021 to March 31st, 2022. We enrolled all ICU patients who required CKRT. Our research team prospectively collected information on the patients’ basal characteristics, CKRT prescription, activated clotting time (ACT) after the hemofilter, CKRT circuit lifespan, and causes of termination of circuits prospectively. Effects of ACT were examined by grouping patients into three with their ACT values: <140, 140 ≤ and <180, and ≥180 seconds. The primary outcome of this study was a termination of the CKRT circuit within 24 hours after the initiation of the CKRT circuit. The secondary outcome was the cause of terminating CKRT circuits. Primarily, we examined the impacts of factors associated with CKRT circuit lifespan using multivariable Cox-proportional hazards regression.

Results: Our cohort’s median follow-up period of CKRT hemofilter was 18.5 hours. The total number of participants was 63, and 63.5% were male. In the multivariate Cox regression analysis, targeting ACT between 140 to 180 seconds was associated with a longer circuit lifespan (HR = 2.11(1.43-3.11), p < 0.0001) than the group of CKRT circuits with ACT < 140 seconds.

Based on our results, targeting ACT between 140 to 180 seconds extended the median survival time of the circuit lifespan to 1.4 times longer than the group of circuits with ACT less than 140 (Fig. 1). There were no differences in the causes of hemofilter occlusion among the three ACT groups. Notably, COVID-19 was not significantly associated with a reduction in circuit lifespans (HR = 0.63(0.35-1.11), p = 0.110).

Conclusion: Appropriate monitoring of ACT during CKRT may help prolong circuit lifespan, and the optimal ACT range was 140 to 180 seconds. In contrast, COVID-19 was not a risk factor for an early occlusion of CKRT circuits.

Figure 1: Difference in lifespan of CKRT circuits among three ACT groups.

Background and Aims: Sodium (Na) is a major determinant of extracellular fluid volume and osmolality homeostasis. Chronic fluid overload (FO) is present in 30 to 50% of hemodialysis patients (HD). HD patients are mostly treated with fixed dialysate Na concentration irrespective of plasma Na concentration. This fixed approach tends to displace patient’s osmolar set point and stimulates thirst and weight gain. An automated personalized dialysate Na alignment to patient’s natremia to avoid unwanted diffusive Na gain and toxicity change induced by HD seems preferable. Several studies exploring individualized dialysate Na prescription have reported inconsistent results. In this prospective interventional multicenter study, we aimed to explore the impact of dialysate Na individualization through isonatremic HD on interdialytic weight gain (IDWG) (primary outcome) and dialytic HD-related symptoms (secondary outcome). For this purpose, we have used the automated “Na Control” option for adjusting dialysate Na to minimize dialysate-plasma sodium gradient and deliver an isonatremic dialysis.

Method: This is a longitudinal study comparing 2 periods: Period-1 = observational phase (2 months) → Period-2 = isonatremic phase by activation of “Na Control” in isonatremic mode (2 months) → comparison of IDWG between both periods. The embedded “sodium control” option in HD machine was used in all cases of Period-2 to actively align dialysate sodium concentration to natremia and quantify net sodium mass transfer. Results are expressed as mean±SD or median [25th-75th].

Results: We present preliminary results obtained through 6 dialysis facilities including 51 patients, 33 (64.7%) females, 75 [65-81] years old, dry weight 71.9 [60.5-78.0] kg. Main findings are as follows: Firstly, an excellent agreement was observed between plasma Na concentrations, measured (laboratory) and estimated (machine) from HD monitor (mean difference before dialysis: 0.05, after dialysis: 0.62). Secondly, plasma Na estimated was as follows: before dialysis plasma Na (137.6 [136.2-139.0] vs 137.2 [136.0-139.3] and after dialysis plasma Na (139.0 [137.6-139.7] vs 137.1 [135.7-138.9]) in Period-1 and Period-2 respectively; Thirdly, the primary outcome (IDWG) as well as the diffusive Na balance were significantly reduced by isonatremic condition (IDWG: 1.27±0.92 versus 1.95±0.86 kg, p<0.0001; diffusive Na balance 13.9 [1.9-5.1] versus 0.7 [0.0-2.7] g of Na, p<0.0001).

Conclusion: Isonatremic dialysis condition automatically driven by “Na control” embedded in HD monitor was confirmed safe and easily implemented in clinical workflow. In addition, these preliminary results show that isonatremic dialysis improved dialysis patient perception and significantly reduced IDWG.

DESIGN OF A NEW DIAPHRAGM PRESSURE TRANSDUCER FOR DIALYSIS MACHINE

Mohammadamin Shahrokhiandehkordi1, Mahsa Galavani2 and Amir Torabi3

1 Pharmad Plast Pouyam Company, Manager of Research and Development Department, Iran, 2 Pharmad Plast Pouyam Company, CEO, Iran and 3 Shahrekord University, Department of Engineering and Technology, Iran

Background and Aims: Diaphragm pressure transducers can cause the dialysis process to be performed at higher quality. Pressure transduction is committed to concave, disc-shaped, impervious membranes that divide the respective chambers into two hermetically separate compartments: one contains liquid (blood/dialysate) while in the other there is trapped air. One of the sensitive parts in the design of a dialysis machine is the transducer to guide the flow toward the diaphragm and distributed the pressure over an area of its surface. The pressure is then measured by a transducer which is used as a pressure gauge. The proper design of the diaphragm makes it sensitive to pressure changes and as a result, the pressure can be measured with high accuracy. Simulation of the flow inside the transducer can be used as a tool for designing the transducer and its housing.

Method: The behavior of whole blood is non-Newtonian. Under high shear forces, viscosity approaches an asymptotic value that corresponds to blood viscosity when considered as a Newtonian fluid. The Carreau-Yasuda model is used to express the relationship between shear stress and shear strain. Three modified and three novel geometries are suggested for pressure transducers. Each geometry is discretized with meshing software. Pyramidal cells are used to mesh the computing domain. Ansys Fluent software is an analyzer program that is used to simulate the field of fluid flow, heat transfer, etc. The solution is selected based on pressure. Due to the complexity of the geometry and the convergence of the problem, only implicit formulation has been used for the model. The flow is assumed to be steady. The governing equation in this problem is continuity and momentum conservation and the k-ε model has been selected as for turbulent flow. Simple algorithm is considered for solving.

Results: The main output data is pressure distribution. Pressure and velocity distribution are related to each other. Figure 1 shows the velocity vector distribution in three modified schemes. The flow does not affect the pressure distribution inside the transducer housing for the straight port and is partially impressed in the shows-center port. The results of Figure 1 show that port location modification cannot affect the flow inside of the housing in such a way as to increase the sensitivity of the diaphragm. So, it was decided to redesign the geometry of the transducer’s housing so as to apply the pressure variation on the diaphragm more sensibly. A curved part is added to the lower face of the transducer to guide the flow toward the diaphragm and distributed the pressure to the entire surface of the diaphragm to reach a uniform pressure. To find the best port location three configuration is used; i.e. straight, 90-degree, and 120-degree. Figure 2 is the velocity vector distribution for the other three novel geometries. In these schemes, flow circulates in the housing and has an effect directly on the diaphragm. The 90-degree port of the newly designed transducer has not had proper performance and pressure is concentrated on one side of the diaphragm which is between the ports. The uniformity of pressure becomes higher in the 120-degree. But in the straight scheme, the concentration is located exactly in the middle of the diaphragm and it is a desirable and optimal condition that the designer is seeking.

Conclusion: A series of simulations are carried out in the Ansys Fluent software to investigate a diaphragm pressure transducer flow after port locations and housing geometry modifications. The results show that if the fluid is directed to the diaphragm tangentially, the concentration of pressure is located on the diaphragm while the uniformity is preserved. The results show that this consideration leads to an optimal design using a new housing geometry with a curved shape wall to deflect the flow and distributed the pressure uniformly.

ASSESSMENT OF FLUID STATUS BY COMBINATION OF LUNG ULTRASOUND, BIOIMPEDANCE, AND INFERIOR VENA CAVA MEASUREMENT IN HEMODIALYSIS PATIENTS

Robert Ekart1,2, Oriol Portals Martin3, Ricardo López Soto4, Tina Stropnik Galuša5 and Radovan Hojši6,5
1University of Maribor, Faculty of Medicine, Maribor, Slovenia, 2University of Maribor, Faculty of Medicine, Maribor, Slovenia, 3Facultad de Medicina, Medicine Campus, Barcelona, Spain, 4Universidad Autónoma de Nuevo León, Faculty of Medicine, Monterrey, Mexico and 5University Medical Centre Maribor, Clinic for Internal Medicine, Dept. of Dialysis, Maribor, Slovenia

Background and Aims: Assessment of fluid status in hemodialysis patients (HD) remains a major challenge for nephrologists. Fluid overload is one of the most common modifiable risk factors directly associated with hypertension. The purpose of our study was to investigate whether the combination of three bedside methods-lung ultrasound comets (LUC), multifrequency bioimpedance (MBIS), and inferior vena cava diameter (IVCD) measurement—could provide complementary information to guide the management of HD patients.

Method: We assessed MBIS, LUC at 28 typical sites, and IVCD in 18 HD patients enrolled in the HD maintenance program. LUC and IVCD measurements were performed three times-before, during, and after HD. For MBIS measurement, we used the Body Composition Monitor (Fresenius Medical Care, Bad Homburg, Germany), and for LUC and IVCD, we used an ultrasound machine (Esaote MyLabOmega, Genoa, Italy). Ultrafiltration during HD was not adjusted for LUC, IVCD, and MBIS only before and after HD. Overhydration (OH) was defined as > 2L with MBIS, > 15 LUC, and < 40% collapsibility index (CI) on IVCD.

Results: The mean age of participants was 61 (IQR, 47-74) years, and thirteen (72.2%) were male. The average dialysis vintage of our patients was 105 months (IQR, 30-155). According to the OH criteria before, during, and after HD, 13 (72%), 2 (11%) patients were overhydrated according to MBIS, 10 (56%), 7 (39%), 3 (17%) patients according to LUC, and 13 (72%), 12 (67%), and 11 (61%) patients according to CI. We found no correlation between systolic blood pressure (BP), diastolic BP, MBIS, LUC, and CI before, during, and after HD, except that systolic BP after HD correlated with MBIS (OH) after HD (r = 0.491; p = 0.039). Using the paired-samples T-test, we found a statistically significant difference between OH before and after HD (p < 0.001), between LUC before and during HD (p = 0.006), between LUC during and after HD (p = 0.002), and between LUC before and after HD (p < 0.001). Using the paired-samples T-test, no statistically significant difference was found between systolic, diastolic BP and CI before, during, and after HD.

Conclusion: Optimal assessment of fluid status in HD patients remains challenging and, according to our results, may require a combination of LUC and MBIS parameters.

Background and Aims: To observe the clinical efficacy and safety of fractionated plasma separation and adsorption integrated with continuous veno-venous hemofiltration (FPSA-CVVH) treatment in patients with acute liver failure (ALF).

Method: In this retrospective study, we enrolled patients with ALF (serum total bilirubin >10mg/dl or Model for End-Stage Liver Disease (MELD) Score >25) from 2017 to 2022. All patients received the treatment of FPSA-CVVH. The primary measure of treatment efficacy was the reduction ratios (RRs) of bilirubin after each session of FPSA-CVVH.

Results: 8 sessions per patient were performed using the Fresenius equipment. The median number of sessions per patient was 6. The mean exchange volume was 2.9 l/patient/session. The replacement fluid used was albumin on 100% of patients and 4 patients required albumin plus fresh frozen plasma. 75 percent of the patients had a positive response with partial remission or stability of the disease and 88 percent had no recurrences. Patients' neurological response to the therapy was the expected, and similar to the one reported in the medical literature.

Conclusion: In our experience, plasmapheresis is a safe and effective therapy in patients with neurological diseases that should be required as a therapeutic option. We, as nephrologists must be aware of this and promote the management of this technique by publishing the joint experience in neurology and nephrology to broaden the level of evidence in clinical practice. The importance of coordination in early referral by other different medical specialties may obtain better results.

THE CHANGES OF THE C REACTIVE PROTEIN LEVEL DURING THE CRRT PROCEDURE

Gordana Strazmester Majstorovic\textsuperscript{1,2}, Tijana Azasevac\textsuperscript{1,2}, Mira Markovic\textsuperscript{2}, Violeta Knezevic\textsuperscript{1,2} and Lada Petrovic\textsuperscript{1,2}

\textsuperscript{1}Medical Faculty, University of Novi Sad, Department for Internal medicine, Novi Sad, Serbia and \textsuperscript{2}University Clinical Center of Vojvodina, Clinic for nephrology and clinical immunology, Novi Sad, Serbia

**Background and Aims:** Continuous renal replacement therapy (CRRT) is recommended for critically ill patients (pts). Various infections and sepsis often occur in these pts. In addition to being frequently used as an inflammation parameter, C reactive protein (CRP) is considered an important regulator of inflammatory processes and may have an active role in atherosclerosis. Changes in its level can have indirect effects on these processes. The aim of this study was to monitor change of CRP level during the CRRT procedure and to evaluate the potential correlation between this change and other monitored parameters.

**Method:** The study was done as the observational, retrospectively prospective study on 154 pts, on whom 343 CRRT procedures (proc) were performed. All pts were treated at the Clinics of the University Clinical Centre of Vojvodina, by the Dialysis Department, during 2021 and 2022. Procedures that lasted longer than 3 hours were included. CRRT modalities were CVVHD and CVVHDF, with the use of different filters (EMiC2, K88/CiCa1000, oXiris, ST150), according to the device (MultiFiltrate, PrismaFlex) and anticoagulation used. Demographic, clinical and CRRT proc data were collected from the medical documentation. Blood for laboratory testing was sampled at the beginning and the end of the proc. An increase or decrease of CRP level by more than 5% compared to the initial value was considered significant. The collected data were statistically processed.

**Results:** From 154 pts, 86.83% were men, 13.17% women, with average (avg.) age of 56.52 years. From 343 proc, 41.69% were CVVHD, 58.31% CVVHDF, with avg. duration of 1033 min. Average ultrafiltration (UF) was 2670mL, with avg. UF/hour of 161.54mL/h. Average initial CRP level was 176.25mg/l, with avg. level of 174.6mg/l at the end of the proc. In 44.9% proc an increase and in 43.44% proc a decrease in the CRP level was verified. The CRP level did not change significantly during 11.66% proc (40/343). Patients’ age (p = 0.868) and gender (p = 0.752) did not affect the change in CRP level during CRRT proc. Procedures in which CRP level decreased lasted longer (1084min) than those with CRP level increase (1023min), but the difference is not statistically significant (p = 0.199). Prescribed CRRT dose (p = 0.485), nor total UF (p = 0.164) did not affect change in CRP level during proc. Hourly UF was significantly lower for CRRT proc during which CRP level decreased (148.18mL/h) compared to those with the CRP level increase (172.23mL/h) (p = 0.000). CRRT modality had a significant impact on changes of CRP level during the proc. In a higher percentage of CVVHD proc (48.32%) a decrease in CRP level was seen compared to CVVHDF proc (36.36%) (p = 0.035). A significant difference was found in the changes of CRP levels in relation to the filters used (p = 0.011). The use of the EMiC2 filter most often resulted in a decrease in CRP level (56.25%), compared to the use of other filters.
Septic condition was present in 85.91% of proc that ended with a decrease of CRP level and in 66.23% of proc with the CRP level increase (p = 0.000). In proc with the CRP level decrease, basal levels of PCT and fibrinogen were significantly higher than in those with the CRP level increase (p = 0.037, p = 0.000 retrospectively). Initial number of WBC did not differ between two groups (p = 0.424). Comorbidities such as diabetes (p = 0.489), malignancy (p = 5) or autoimmune disease (p = 25) did not affect change in CRP level during CRRT proc, nor did surgery precede the proc (p = 782). No association between the changes of CRP level during the CRRT proc and the subsequent pts mortality (p = 289) or recovery of renal function (p = 808) was found.

Conclusion: During the CRRT procedure, the level of CRP in significantly influenced by the average hourly ultrafiltration, the CRRT modality, the filter used, and the presence of septic condition, with high levels of PCT and fibrinogen.

OBSERVATIONAL PILOT STUDY TO EVALUATE THE RELATIONSHIP BETWEEN LUNG ULTRASOUND AND BIOIMPEDANCE IN HEMODIALYSIS

Gabriel Ledesma Sánchez, Veronica Ruth Mercado Valdivia, Yesika María Amezquita Orjuela, Raquel Díaz Mancebo, Ángel Gallegos Villalobos, Yolanda Hernández Hernández, Rocío Echarri Carrillo, Silvia Caldés Ruisánchez, María Covadonga Hevia Ojanguren and Antonio Cirugeda García

Infanta Sofía University Hospital, Nephrology, San Sebastián de los Reyes, Spain

Background and Aims: There is a clear relationship between volume overload and morbidity and mortality in hemodialysis patients, which makes it essential to accurately adjust the normohydration weight. For this, bioimpedance has become an indispensable tool in dialysis units. In recent years there has been a rapid development of lung ultrasound for the evaluation of pulmonary congestion through the quantification of B lines. Several studies have shown a correlation between the number of B lines and the volume overload estimated by bioimpedance in patients on dialysis. However, all these studies perform a 28-zone lung ultrasound protocol, which may be a limitation in clinical practice. Several studies have recently been published showing a correlation between 28-zone lung ultrasound protocol and simplified 4, 6, and 8-zone ultrasound protocols, which have been widely studied in patients treated in intensive care or emergency units. We set out to evaluate the relationship between bioimpedance and simplified 8-zone lung ultrasound protocol in hemodialysis patients.

Method: Pilot cross-sectional observation study that included 29 patients on hemodialysis at Infanta Sofía University Hospital during March 2022. Bioimpedance predialysis and postdialysis, 8-zone lung ultrasound protocol (delimited by the parasternal, anterior axillary, posterior axillary, and 4th intercostal space) and inferior vena cava ultrasound. Predialysis proBNP and Ca-125 were measured.

Results: There is a significant reduction in overhydration estimated by bioimpedance and in the number of B lines after the hemodialysis session (p < 0.05). No correlation has been established between the two parameters, neither pre-dialysis nor post-dialysis. Neither with the pre-dialysis levels of proBNP or Ca125. There is a correlation of r = 0.45 (p < 0.05) in the subgroup of patients of the afternoon shift (n = 9) between the number of B lines and extracellular water.

Conclusion: Lung ultrasound allows the evaluation of the degree of lung congestion, and therefore of extracellular water, becoming a useful tool for adjusting the dry weight of hemodialysis patients. In our study we found no association between the number of B lines in the simplified 8-zone lung ultrasound protocol. It is possible that this type of lung ultrasound is not sensitive enough in outpatients on hemodialysis, but it is sensitive enough in critically ill patients in whom lung overload is greater. Further studies with a larger number of patients are needed for evaluation.

PYTHON LANGUAGE TO APPLY DATA SCIENCE METHOD TO DAILY DIALYSIS PATIENT CARE

Ugo Donini¹ and Sara Donini²

¹Ospedale Privato Donus Nova (Gruppo GHC), Ravenna, Italy and ²Dialysis and Renal Transplant Unit, S. Orsola-Malpighi Hospital, University of Bologna, Bologna, Italy

Background and Aims: Python is a high-level programming language. It was created by Guido van Rossum in 1991 and it is known for being user-friendly thanks to a readable code and a clear syntax. Python is widely used in scientific computing and big data analysis. Dialysis monitors can collect and record a wealth of data concerning the patient during dialysis. The purpose of this study is: 1) writing a Python code that automatically processes dialysis data from a selected period and a) provides printouts with the most significant values acquired; b) prepares graphs to visualize the trend in the progression of the selected parameters over time. The printouts and graphs should help set up each dialysis session. 2) Stimulating the formation of a Python community within the nephrologists for the development of the data science style in daily practice.

Method: Hemodialysis sessions were carried out using monitors of Fresenius Medical Care (FMC) mod. 5008. FMC's Therapy Support Suite (TSS) application allows data obtained from the monitor and data entered by the nurse during the dialysis session to be saved on a dedicated server. TSS selected data are then exported to excel file. Using the open-source Python 3.9 program, with the support of Pandas, Numpy and Seaborn libraries, a code was written in order to: 1) load the excel file with the selected data, 2) isolate the data of interest, on a selected period of time, concerning patients currently on dialysis. 3) create the tables and graphs for individual patients to set up the current dialysis session.

Results: Running the Python script produces three main sheets to check body weight (W), hemoglobin (HB) values, and blood pressure (BP) values. Other parameters are also examined graphically, drawing the linear regression line of the main parameter and the superimposed plot of other parameters.

Conclusion: Data collected during individual dialysis sessions can provide valuable information about a patient’s condition and help healthcare professionals make informed decisions about their treatment. Python and its libraries provide the nephrology community with an open source and easy-to-use tool to automatically process each patient's data scientifically. In daily practice this method helps better understand and evaluate the dialysis treatment.

ROLE OF ONLINE HEMODIAFILTRATION (OL-HDF) IN THE
CONTINUOUS MEASUREMENT OF THE DIALYSIS DOSE
Francisco Alonso Alman, Yanet Parodis López, Sebastian Hillebrand Ortega, Nicanor Vega and Gloria Anton-Perez
Avericum Haemodialysis Centre, Las Palmas de Gran Canaria, Spain

Background and Aims: OL-HDF provides multiple advantages and benefits to patients compared to conventional high-flow hemodialysis (HFHD). Current monitors have a wide variety of biosensors and devices that provide continuous information on the patient's biological parameter and the efficiency of the dialysis session. Monofrequency bioimpedance (BIVA) provides information regarding the state of hydration (HE) and nutrition (EN) of our patients.

Method: Observational study in 493 patients, distributed in 8 dialysis centers and with a three different model of dialysis monitor. Demographic data, dialysis techniques and regimens, mean values for one month of ultrafiltration rate readings and KT are analyzed. The continuous measurement of DD is estimated by the ion dialysance biosensor. The OL-HDF technique is post-dilutional. The BIVA measurement is performed between 10 and 30 minutes after the end of the session. The Kt/V is estimated from the total TBW (V) by BIVA, using the Watson and Hume-Wiers formulas. Statistical analysis: descriptive, t-Student for statistics of groups and independent samples, Chi square for the association in cross tables.

Results: See Table 1.

Conclusion: Obtaining lower dialysis dose values in OL-HDF than in HFHD in some monitor models, despite longer dialysis times and greater dialyzer surface area, is probably due to dilution due to post- re-infusion and/or to the positioning of the dialysance sensors within the hydraulic circuit. This makes us think about the advisability of maintaining urea Kt/V measurements, by laboratory, to ensure adequate dialysis quality.

TRIAL OF ISOLATED HAEMODIALYSIS WITH PATIENT-ENTRY TENT AND HYPOCHLORITE MIST
Kazuhiko Shibata¹, Kiyotaka Imoto¹ and Masato Osawa²
¹Toshin Clinic, Yokohama City, Kanagawa Prefecture, Japan and ²Yokodai Central Clinic, Yokohama City, Kanagawa Prefecture, Japan

Background and Aims: The global spread of COVID-19 has posed a serious threat to patients receiving renal replacement therapy and to the staff who treat them. Every time they treat a patient or operate a machine, they have to wear personal protective equipment (PPE). In order to reduce the burden on our staff, we have introduced two pieces of equipment. One is a hypochlorous acid mist for room and surface disinfection using CLFine®. The other is an AIR ZIPPER® patient isolation tent in the existing isolation room. Both products were manufactured by Nipro Corporation of Osaka, Japan. However, there was no evidence to support the use of hypochlorous acid in an ultrasonic humidifier. Therefore, Nipro Corporation conducted a “28-day repeated inhalation toxicity study” on rats with a third party organisation and confirmed the results as toxicologically safe. According to the Occupational Safety and Health Act, also in the school environmental health, the concentration of chlorine in the air is 0.5 ppm or less (8 hours/day, 5 days/week or less). CL Fine® has shown an antiviral effect within these regulations. The size of the AIR ZIPPER® is about a fifth of the standard 10m³ size, down to about

AIR ZIPPER® mist for room and surface disinfection using CLFine®. The other is an AIR ZIPPER® patient isolation tent in the existing isolation room. Both products were manufactured by Nipro Corporation of Osaka, Japan. However, there was no evidence to support the use of hypochlorous acid in an ultrasonic humidifier. Therefore, Nipro Corporation conducted a “28-day repeated inhalation toxicity study” on rats with a third party organisation and confirmed the results as toxicologically safe. According to the Occupational Safety and Health Act, also in the school environmental health, the concentration of chlorine in the air is 0.5 ppm or less (8 hours/day, 5 days/week or less). CL Fine® has shown an antiviral effect within these regulations. The size of the AIR ZIPPER® is about a fifth of the standard 10m³ size, down to about
Powerful, high-efficiency particulate air filter pumps have been fitted to replace the air in the tent in less than 5 minutes at low flow rates (0.4 m3/min airflow), enabling it to operate below the negative pressure standard of 2.5 Pascal. In addition, the AIR ZIPPERR® is equipped with air intake valves that open and close in a single direction towards the inside of the tent. Prior to the introduction of the AIR ZIPPERR®, staff had to wear PPE with an N95 mask when operating the machine, puncturing and returning blood to the patient.

**Method:** Patients with a fever or who have been in contact with COVID-19 patients and infected patients were asked to enter the AIRZIPPERR®. Both exceedingly male/female:19/3, age:69.8 years, HD duration:5.38 years) with SARS-CoV-2 infection in our clinic. Fortunately, there was no transmission to staff or other patients, and no patients died.

**Conclusion:** These infection control measures helped to reduce staff workload and prevent infections. In conclusion, the present method should be equipped by all haemodialysis providers to deal with Covid 19 infections as well as with new infections in the future.

COMPARISON OF CLINICAL PERFORMANCE AND HEMOCOMPATIBILITY OF DIALYZERS APPLIED DURING POST-DILUTION ONLINE HEMODIAFILTRATION (HDF) – EMPORA III STUDY

Götz Ehlerding, Petra Ronova, Mária Krizsán, Bettina Griesshaber, Ansgar Erlenkötter, Robert Nitschel, Adam Zawada, Bertram Ottlinger, Jennifer Braun and Manuela Stauss-Grabo

1Zentrum für Nieren- und Hochdruckkrankheiten, Hannover, Germany; 2Fresenius Medical Care DS - s.r.o., Fresenius Nephrocare Praha 9 - Vysocany, Prague, Czech Republic; 3FMC Dialysis Center Kft., Péterfy II. Dialízis Központ, Budapest, Hungary; 4Fresenius Medical Care Deutschland GmbH, Global Biomedical Evidence Generation, Bad Homburg, Germany; 5Fresenius Medical Care Deutschland GmbH, Biotechnology, St. Wendel, Germany; 6Fresenius Medical Care Deutschland GmbH, Product Development, St. Wendel, Germany and 7Ottlinger Life Sciences, Brunnthal, Germany

Background and Aims: Performance and hemocompatibility are the two main functions of a hemodialyzer. Synthetic dialysis membranes made from polysulfone (PSU) or polyethersulfone (PES) are mainly used for dialysis treatments and are blended with the hydrophilic agent polyvinylpyrrolidone (PVP), to improve hemocompatibility during dialysis treatments. A novel PSU-based dialyzer (FX CorAL) with an increased and stabilized PVP content has been developed and has shown strong performance and a favourable hemocompatibility profile within previous short term clinical studies. In the present clinical study, we now investigated the performance and hemocompatibility of the FX CorAL vs. two comparators over a longer follow-up time and applied an extended panel of hemocompatibility biomarkers. This allowed us to analyse treatment-specific performance as well as an extensive intra- and interdialytic hemocompatibility profile.

Method: EMPORA III was a prospective, open, controlled, multicentre crossover trial with randomized treatment sequences conducted in DE, CZ and HU. It randomized stable patients receiving regular post-dilution online HDF to FX CorAL 600, FX CorDiax 600 (both Fresenius Medical Care) and xevonta Hi15 (B. Braun), each for 4 weeks. The primary outcome was β2-m removal rate (RR) during 4 hrs HDF. Non-inferiority (margin: 5%) and superiority of FX CorAL 600 versus comparators were tested at α = 0.25 (one-sided), with adjustment for multiple tests. Secondary endpoints were RR and/or clearance of β2-m and other molecules, as well as intra- and interdialytic changes of markers of complement activation (C3a, sC5b-9), cell activation / inflammation (white blood cells (WBC), PMN elastase, IL-6, IL-8, LTB-4, sICAM-1, hsCRP), platelet activation (platelet count, β-TG, TXB-2), and oxidative stress (MDA, GSH-Px). Intraindividual hemocompatibility markers were analysed descriptively as differences vs. the values determined at the start of the HDF session (LS means).

Results: Eighty-two patients were included and analysed in the safety population, with n = 76 presenting data for the primary outcome (ITT population). FX CorAL 600 showed the highest β2-m RR (LS mean: 76.31%), followed by FX CorDiax 600 (75.71%) and xevonta Hi15 (74.49%). Non-inferiority to its comparators was statistically significant (p<0.0001 each). Superiority was shown vs. xevonta Hi15 (p<0.0001), but not vs. FX CorDiax 600 (p = 0.0606). The secondary endpoints β2-m clearance as well as myoglobin clearance and RR affirmed these results; small molecule clearances and/or RR were similar between dialyzers. Analyses of hemocompatibility markers within one HDF session, found the following significant differences:

- C3a 15 min: FX CorAL: 31%; FX CorDiax: 59% (p = 0.003 vs. FX CorAL); xevonta: 41% (p = 0.029 vs. FX CorAL)
- sC5b-9 60 min: FX CorAL: 24%; FX CorDiax: 25% (p = 0.337); xevonta: 41% (p<0.0001)
- Cell activation / Inflammation
  - WBC 15 min: FX CorAL: -7.7%; FX CorDiax: -11.1% (p = 0.015); xevonta: -10.1% (p = 0.246)
  - Monocytes 15 min: FX CorAL: -30.9%; FX CorDiax: -30.3% (p = 0.533); xevonta: -38.2% (p = 0.012)
  - Neutrophils 15 min: FX CorAL: -3.0%; FX CorDiax: -7.5% (p = 0.019); xevonta: -6.1% (p = 0.258)
- PMN elastase 60 min: FX CorAL: 18%; FX CorDiax: 42% (p = 0.003); xevonta: 52% (p = 0.0003)
- LTB-4 15 min: FX CorAL: 170%; FX CorDiax: 217% (p = 0.047); xevonta: 186% (p = 0.539)
- Platelet activation
  - β-TG 60 min: FX CorAL: -15%; FX CorDiax: 4% (p<0.0001); xevonta: 18% (p<0.0001)

Hemocompatibility markers showed no interdialytic changes, i.e., no significant changes within treatment periods. Nine serious adverse events occurred in this study, none of which was dialyser related.

Conclusion: FX CorAL 600 efficiently removed middle and small molecules and was non-inferior to both comparators and significantly superior to xevonta Hi 15 in β2-m RR. The typical drop in WBC, monocyte, and neutrophil count during dialysis as well as the rise of complement (C3a, sC5b-9) and cell / platelet activation markers (PMN elastase, LTB-4 and β-TG) were lower or comparable during treatment with FX CorAL vs. both comparators, indicating superior hemocompatibility properties.
THE EFFECT OF HEMOPERFUSION ON SURVIVAL AMONG COVID-19 CRITICALLY ILL PATIENTS IN A TERTIARY HOSPITAL IN DAVAO CITY, PHILIPPINES

Joy Blossom Anne Lacang and Mark Anthony Tom
Davao Doctors Hospital, Department of Internal Medicine, Davao City, The Philippines

Background and Aims: Cytokine storm in COVID-19 is an excessive immune response through the overproduction of inflammatory cytokines which significantly increases mortality. Hemoperfusion has been granted Emergency Use Authorization (EUA) by the Food and Drug Administration (FDA) in an effort to eliminate circulating inflammatory mediators among COVID-19 critical patients to improve clinical outcomes and survival. This study aims to determine the 8 – day survival of critical COVID-19 patients who received hemoperfusion.

Method: This is a descriptive study conducted among critically ill COVID-19 patients who completed hemoperfusion treatment admitted from October 2020 to October 2021 in a tertiary hospital in Davao City, Philippines. The inclusion criteria were adult patients greater than 18 years of age with RT-PCR confirmed SARS-CoV-2 infection who underwent and completed hemoperfusion during hospitalization for COVID-19. While those patients who did not complete the hemoperfusion treatment because of hemodynamic instability or death were excluded. All of the patients classified as COVID-19 critical received the standard treatment for COVID-19 such as steroids (dexamethasone) and antiviral (Remdesivir). Among the 1,037 COVID-19 adult patients admitted from October 2020 to October 2021, 28 of them were classified as critical and received hemoperfusion, but only 19 patients completed the treatment.

Results: Majority of patients in the study were males (14/19, 73.68%) with a mean age of 59 years (SD 12.90). Hypertension (n = 15, 78.95%) and Diabetes Mellitus (n = 14, 73.68%) were the most common comorbid illnesses. Cough (n = 15, 78.95%), fever (n = 11, 57.90%), and dyspnea (n = 7, 36.84%) were the frequent symptoms. The laboratory parameters (median hemoglobin, leukocytes, thrombocytes, creatinine, and ALT were within normal range except for an elevated median AST (54 U/L). Forty-two percent (8/19) of patients survived at day 8 (Figure 1). Survivors had higher baseline oxygen saturation compared to non-survivors (89% vs 78%), but in both groups, the oxygen saturation increased after hemoperfusion (Figure 2). All inflammatory markers (CRP, ferritin, LDH, and procalcitonin) decreased among survivors.
Figure 2: Oxygen Saturation of Critical COVID-19 Patients Before and After Hemoperfusion.

Figure 3: A. CRP of Critical COVID-19 Patients Before and After Hemoperfusion. D. Procalcitonin of Critical COVID-19 Patients Before and After Hemoperfusion.

Figure 3: B. Ferritin of Critical COVID-19 Patients Before and After Hemoperfusion.
Figure 3: C. LDH of Critical COVID-19 Patients Before and After Hemoperfusion.

Figure 3: D. Procalcitonin of Critical COVID-19 Patients Before and After Hemoperfusion.

Figure 4: Median Time Between the Onset of Symptoms to Hospital Admission and Hemoperfusion.
post-hemoperfusion. However, the ferritin, LDH, and procalcitonin remained elevated among non-survivors (Figure 3A, B, C, D). The median time from symptoms onset to hemoperfusion initiation was longer in non-survivors compared to survivors (10 days vs 8 days) (Figure 4).

Conclusion: Close to half (42.11%) of the critical COVID-19 patients who underwent hemoperfusion survived at day 8. Therefore, hemoperfusion remains to be a beneficial adjunct treatment for critical COVID-19 patients especially if initiated early.

#4657

COMPARISON OF TWO BIOIMPEDANCE SPECTROSCOPY DEVICES: A PRACTICAL STEP FORWARD ON THE WAY TO DAILY BIOIMPEDANCE MEASUREMENTS FOR DIALYSIS PATIENTS

Sebastian Mussnig1, Simon Krenn2, Peter Wabel3 and Manfred Hecking1

1Medical University of Vienna, Department of Medicine III, Division for Nephrology and Dialysis, Vienna, Austria, 2AIT Austrian Institute of Technology GmbH, Center for Health & Bioresources, Medical Signal Analysis, Vienna, Austria and 3Independent Researcher, Germany

Background and Aims: Bioimpedance spectroscopy (BIS) is a non-invasive diagnostic tool to assess volume status and body composition through the measurement of voltage drops in alternating currents and subsequent extrapolation of extracellular (R0), intracellular (Ri), and total body (RInf) resistances. Currently available devices mostly rely on disposable electrodes and require supine body position. Here we tested whether a new, more versatile BIS device with reusable electrodes matches an established system in various setups, aiming to enable daily BIS-measurements in the near future.

Method: Two BIS devices ("Cella" and the "Body Composition Monitor" [BCM]) were compared both with four resistance testboxes (circuit boards with resistors and capacitors simulating different body conditions) and in 40 healthy volunteers. In-vivo comparisons included supine hand-to-foot (HF) reference measurements with adhesive disposable electrodes and hand-to-hand (HH) measurements with adhesive disposable and prototype reusable electrode sets (Figure 1).

Results: Analyses of testboxes were reproducible in both devices (intra-device coefficients of variation <1%). Mean differences from testbox components were similar and small for R0 (2-3 Ohm) but not for Ri, where Cella was off by 101 Ohm compared to the BCM’s 29 Ohm in a testbox designed with a deliberately low R0/Ri ratio. In-vivo, HF measurements with disposable electrodes differed significantly between both devices (p < 0.001). Prototype reusable HH electrodes exhibited a bias towards larger resistances than HF measurements (R0: 738.36 Ohm vs. 643.09 Ohm; Ri: 1508.18 Ohm vs. 1257.17 Ohm; RInf: 500.03 vs. 423.81 Ohm, respectively) and the HH/HF ratio varied between 1.0-1.4 (R0 and RInf) and 0.9-1.6 (Ri).

Conclusion: While the Cella BIS device was shown to produce results with comparable consistency to the BCM in-vivo, the latter measured more accurately under testbox conditions. Accuracy of in-vivo measurements could not be determined for lack of gold-standard measurements. Implementation of HH reusable electrodes will require per-patient calibration against HF measurements due to the large inter-patient fluctuations in the HH/HF ratio. We recommend further longitudinal analyses of intra-patient HH/HF ratios to investigate long-term variabilities.
Figure 1: Setups, Absolute and Normalized Resistances of BIS Measurements. Panels A-E illustrate all in-vivo BIS measurements conducted within this study (Cella: Setups 1, 3 and 5-10; BCM: Setups 2 and 4). Setups 1 and 2 were carried out after participants lay flat on their backs for 10 minutes to achieve fluid equilibrium and were followed by Setups 7 and 8, 5 and 6 and finally 3 and 4. Setups 9 and 10 took place prior to the 10-minute-long supine body positioning right after the participants’ arrival at the study facility. The sequence of setups was rearranged to reflect the increase in normalized error to Setup 1. Panels F-J depict $R_{\infty}$, $R_0$ and $R_i$ in absolute numbers while Panels K-O present normalized $R_{\infty}$, $R_0$ and $R_i$ values, computed by dividing measurements of Setups 2-10 by Setup 1 on an intra-patient basis. Colored points depict mean relative values and error bars delimit mean ±1.96 standard deviations of the mean. BIS, bioimpedance spectroscopy; BCM, Body Composition Monitor; $R_{\infty}$, resistance at infinite frequency; $R_0$, extracellular resistance; $R_i$, intracellular resistance.
Background and Aims: Symptoms associated with the accumulation of large uremic toxins (the development of chronic inflammation, accelerated progression of cardiovascular diseases and an increase in the incidence of protein-energy malnutrition) are common for patients who get chronic hemodialysis (HD) for a long time. HD effectively removes small and medium molecules (up to 15 kDa), while convection techniques, which are not always available, are used to remove substances of higher molecular weight. An alternative strategy for removing uremic toxins, especially large medium molecules, is the use of sorption techniques. The aim of the study was to compare the removal efficiency of substances with a molecular weight from 11.8 to 45 kDa using HD on a high-flux membrane and a combination of a high-flux membrane with hemo sorption.

Method: The study included patients with a duration of hemodialysis therapy for more than 5 years. Blood sampling was carried out before and after the procedures, in the average RRT session per week. The following indicators were determined: β-2-microglobulin, leptin, free light chains (FLC) κ and λ, IL-6. The first HD session was performed on a Fresenius Px 80 high-flux membrane. The second procedure (one week after) was carried out using the same filter, but with the connection of a Jafon HA130 sorption column (HD+HP). The duration of the both procedures was 4 hours. Blood flow did not exceed 300 ml/min.

Results: Total 10 patients were included in the study. Mean duration of renal replacement therapy was 12±5 years. The ratio of men and women was equal. Mean age 54±12 years. All patients used AV fistulas as vascular access. When determining and comparing the concentrations of β-2-microglobulin, leptin, IL-6, a comparable significant decrease in concentrations was noted after both procedures without significant statistical differences between the methods. At the same time, the efficiency of FLC removal on HD and HD+GP was convincingly different:

- average kappa-FLC concentration change after HD was +1.8±9.1 mcg/ml, after HD+GP: -9.4±7.5 mcg/ml, p = 0.04.
- average lambda -FLC concentration change after HD/HD+GP was +3.2±16.3 and -12.9±4.4 mcg/ml respectively, p = 0.02.

Conclusion: The use of sorption techniques as an adjunct to standard HD therapy can increase the excretion of medium-large molecular substances, such as FLC kappa/lambda, which may help reduce the severity of symptoms associated with the accumulation of these uremic toxins. Additional studies are required to evaluate the clinical effectiveness of the new sorption method in chronic HD.

Figure 1: Change in free light chain concentrations both fractions (kappa/lambda) after HD and HD+HP.
function was not related in this review to increased patient survival. Analytical parameters such as peak creatinine, hypoalbuminemia and type and amount of circulating LC could be studied as prognostic factors in this entity.

FRENCH EXPERIENCE OF HOME HEMODIALYSIS PATIENTS TREATED WITH NXTAGE HAEMODIALYSIS CYCLER WITH THE PURE FLOW SL SYSTEM

Hadia Hebib1, Fabien Berthy2, David Attal2, Christophe Ridet2 and Edet Stephane2,3

1NephroCare Villejuif Hemodialysis center, Villejuif, Ile de France, Villejuif, France, 2Fresenius Medical Care, FRESNES, France and 3Anider association, centre hospitalier de Rouen, Nephrology and Hemodialysis, Rouen, France

Background and Aims: NxStage haemodialysis cycler with the Pure Flow SL system was introduced for the first time in France in June 2022. This system is designed to produce an ultrapure dialysis fluid and mixing a concentrate to the source water to prepare 60 L batch of dialysate. It can be used for a maximum of 3 home treatments. No major plumbing modifications are required to install this system at home. Here, we report to our knowledge the first French clinical evaluation of the use of the Pure Flow system in haemodialysis patients using this device and trained in NephroCare Villejuif haemodialysis center and Rouen Hospital.

Method: This retrospective study was performed in a cohort of 8 haemodialysis patients From June 2022 to January 2023. We describe the clinical benefits of Pure Flow including dialysis demographics, dialysis vintage, and short-term biological parameters. Patient related outcomes based on a specific questionnaire, at 3 and 6 months are also analyzed

Results: 8 patients were included with 5 women. The mean age was 48 years. The dialysis vintage was 24 months. The median follow-up was 4 months. 2 Patients were treated by pre-mixed 5L dialysate bags 6 months prior the implementation of Pure Flow, and 6 patients started the haemodialysis program directly with Pure Flow after a period of 10 days of training. We show that PF provide adequate dialysis dose. The mean stdk/V was 2.3. The mean of weekly dialysate volume was 146L. We note optimal ultrafiltration rate, improvement of biological markers of adequacy. Moreover, good results technique survival was recorded. We also show Reduced handling, and setup

Conclusion: The NxStage with Pure Flow system is a major advantage against the premixed bags with a simple installation and a low water consumption. Its use is associated with great clinical outcomes in patients. The Pure Flow should reduce shipments and storage of dialysis treatments and facilitate the development of home haemodialysis in France. Prolonged follow-up on a cohort with a larger number of patients is necessary and will allow an appropriate evaluation of the clinical benefit of the use of the Pure Flow.

#3798
A MULTICENTER CLINICAL STUDY OF CELLULOSE TRICATECT MEMBRANES AND POLYSULFONE MEMBRANE DIALYZERS IN MAINTENANCE HEMODIALYSIS PATIENTS

Chen Chen and Guang-Yu Zhou

ShengJing Hospital of China Medical University, Second Blood Purification Center, Shen Yang, P.R. China

Background and Aims: With the continuous improvement of dialysis membrane materials, polysulfone (PS) has replaced traditional cellulose membranes with excellent biocompatibility and dominates the market applications. In our clinical work, we found that the allergic reaction disappeared after the application of cellulose triacetate (CTA) in patients who were allergic to PS. In this study, we compared the differences in biocompatibility and solute clearance of CTA and PS dialyzers during long-term dialysis treatment.

Method: In this study, a multicenter clinical study was conducted, and patients attending Fuja dialysis Bureau Hospital, Northeast Hospital and Shengying Medical College Affiliated Central Hospital receiving maintenance haemodialysis from April 2019 to April 2020 were selected as the study population. The patients were divided into a polysulfone membrane group (n = 10) and a cellulose triacetate membrane group (n = 13) based on whether they tolerated the polysulfone membrane dialyzer, and all patients in the CTA group had an allergic reaction to the polysulfone membrane dialyzer.

Results: There were no statistically significant differences between the two groups in the comparison of basic information such as age, gender, dialysis age and primary disease. Before the application of CTA and PS dialyzer treatment, there was no statistically significant comparison between groups for all observed indicators. After application of CTA and PS single dialysis: (i) The difference between the 2 groups of β2-MG (Z = -2.039, P = 0.041) and TNF-α (Z = -2.491, 0.013) was statistically different. (ii) There were no statistically significant differences between two groups in the comparison of hematological system, such as WBC, PLT, Hb; complement, such as C3, C4; inflammatory factors, such as IL-1, IL-6, hs CRP, IgE; uremic toxins, such as P, CR, BUN, PTH (P > 0.05). After the 12th month of regular hemodialysis treatment with PS and CTA: (i) The differences between the 2 groups for P (Z = -2.096, P = 0.036), BUN (Z = -2.038, P = 0.042), and spKt/V (Z = -2.147, P = 0.049) were statistically significant. (ii) The difference between the 2 groups after 12 months of regular hemodialysis treatment (P = 0.114, P = 0.041) and before dialysis was not statistically different between groups, and the other indexes mentioned above were not statistically different.

Conclusion: After a single dialysis session, TNF-α in the PS group was elevated and the biocompatibility of CTA was better than PS. The CTA group had better clearance of β2-MG than PS, and spKt/V reached the standard. After long-term dialysis, the effect of CTA on inflammation and complement system was not different compared with PS, and there was no difference in biocompatibility between the two membranes. spKt/V in the CTA group reached the standard, and the clearance of BUN and P was better than that of PS.

TRIBOELECTRIC EVALUATION OF ARTERIOVENOUS FISTULA FOR HAEMODIALYSIS: A PILOT STUDY

Pierangela Presta1, Giuseppe Olivera2, Michela Musollino1, Giuseppe Fabiano3, Nazareno Carullo1, Annarita Armeni1, Salvatore Chiarella1, Michele Andreucci1, Antonio Fiorillo1, Davide Bolignano1, Salvatore Pullano2 and Giuseppe Coppolino1

1Renal Unit, “Magna Graecia” University of Catanzaro, Catanzaro, Italy, Catanzaro, Italy and 1BATS Laboratory, “Magna Graecia” University of Catanzaro, Catanzaro, Italy, Catanzaro, Italy

Background and Aims: Determination of stenosis in an arteriovenous fistula (AVF) for hemodialysis is an essential step in the management of patients with end-stage kidney disease. Stenosis, or narrowing of the blood vessels, can significantly reduce blood flow and ultimately lead to thrombosis and dysfunction of the AVF. Therefore, accurate and frequent surveillance is crucial for detection of stenosis and for the proper management of AVF. Surveillance of AVF is based on direct methods including ultrasound imaging and magnetic resonance angiography both dependent from examiner availability and not ever regularly repeatable.

The triboelectric effect refers to the phenomenon where certain materials become charged after coming into contact with another material. In blood vessels the rubbing of erythrocytes against each other and arterial and vein wall generates a negative triboelectric charge and an electric potential range directly related to flow rate. The aim of our study was firstly to investigate the potential reliability of a wearable device able (Figure 1A) to record this constant potential and consequently evaluating the aptitude of waveforms generated to detect AVF stenosis in comparison to standard doppler evaluation.

Method: Between September 2022 and January 2023, we screened forty-eight patients from two hemodialysis centers in Catanzaro (Italy) Patients were divided in two groups basing on the assessment from two blinded experienced examiners for recognized criteria for stenosis: 2 major criteria (reduction of vessel size greater than 50% and a ratio between systolic peak velocity (SPV) in the stenotic region and SPV in pre-stenotic region major of 2 (>2)) and a supplementary finding like drop of the access flow (QA) below 500ml/min or drop of QA ≥25% as compared to the previous measurements in FAV with QA <1000ml/min or residual diameter <2mm). Patients were then evaluated using the PVDF/Kapton triboelectric sensor placed in contact with the skin on the lower surface, and with the thumb in contact with the upper surface to close the circuit and graphically recording typical pattern waveform generated. AVFs were analyzed considering the following acquisition sites: the chamber which corresponds to the site where surgery anastomosis was performed, a site located 5 cm from the chamber, and finally at the level of the humeral artery.

Results: There was an almost perfect (R = 0.97) correlation between the blood flow measured at the humeral artery level and the maximum-time derivative
equation computed for each patient (Figure 1B). Based on doppler evaluation, 14/48 patients (29%) were classified as stenotic. Of these, 13 patients (93%) presented a typical wave pattern (B-point) with a 'Notch' shape (Figure 1D) which, conversely, was found in only 1 patient out of 34 without evidence of stenosis. The presence of Notch reflected the presence of stenosis with a Sensitivity of 92.8% (95%CI 66.1 to 99.8%), a specificity of 97% (95%CI 84.7 to 99.9%), holding an overall accuracy of 95.8% (95%CI 85.7% to 99.5%). Patients without stenosis assumed a different waveform (Figure 1C).

Conclusions: In chronic hemodialysis patients, the evaluation of AVF by a biosensor based on triboelectric potential measurement might represent an accurate and easy-to-perform surrogate of standard eco-doppler method for a quick and reliable evaluation of AVF functioning and, particularly, for a rapid risk stratification of patients with high suspect of AVF stenosis.

#5411
CARDIO-FISTULA RECIRCULATION REDUCTION IN OLDER ADULTS: IT'S NOT THAT EASY

Aleksei Zulkarnaev1, Vadim Stepanov1, Andrey Vatazin1 and Ekaterina Parshina2

1Moscow Regional Research and Clinical Institute, Moscow, Russia and 2Saint Petersburg State University Hospital, Russia

Background and Aims: Older adults are approximately 40% of all prevalent HD patients [ERA Annual report]. Cardiovascular disease is the leading cause of death in this cohort. It is well-known that the cardiotoxic effect of arteriovenous fistula (AVF) is fully realized when cardio-fistula recirculation (CFR) is above 20-30%. We believe that the reduction of AVF blood flow (Qa) in the elderly is often less effective than in the younger patients. Aim: to evaluate the outcomes of Qa reduction in the elder and the younger HD patients.

Method: The prospective cohort study included 21 patients over 60 years old and 36 patients under 60 years old: the median age was 74 years [IQR 69; 78, min-max 64-81] and 41 years [IQR 35; 45, min-max 31; 55], respectively. Qa before reduction was more than 25%: 32.8% [IQR 29.2; 35.1, min-max 27.3; 38.9] and 33% [IQR 31; 35.125, min-max 27.1; 39.3], respectively. Qa reduction was performed by banding of the paraanastomotic AVF segment with intraoperative control (Doppler ultrasonography) until reaching Qao of 1.5 l/min or less.

Results: In all patients, we noted a significant (p<0.0001 in all cases) decrease in Qa as a result of the banding: in older adults from 2.1 l/min [IQR 1.9; 2.4, min-max 1.8; 2.8] to 1.2 l/min [IQR 1.1; 1.4, min-max 0.8; 1.5], delta Qa was -1 l/min [IQR -1.2; -0.9, min-max -1.5; -0.7], in younger patients from 2.8 l/min [IQR 2.5; 3.1, min-max 1.9; 3.5] to 1.3 l/min [IQR 1.1; 1.4, min-max 0.9; 1.5], -1.5 l/min [IQR -1.7; -1.3, min-max -2.3; -0.9], respectively. In both older and younger patients, we noted a significant decrease in CFR - Fig. 1. However, after Qa reduction, only 5 of 21 elderly patients had CFR value less than 20%. Thus, 17 of 21 patients had CFR in the «gray zone» - 20-30%: 22.8% [IQR 21.85; 27.3, min-max 21; 29.2]. In younger patients, 25 of 36 had CFR less than 20% after Qa reduction, while 11 stayed in the «gray zone» - 21.15% [IQR 20.575; 22.3, min-max 20.3; 23.4]. The probability of reducing CFR to a safe level (less than 20%) after surgery was significantly less in the elder patients: RR = 0.3429 [95% CI 0.1495; 0.6852], p = 0.0011. We consider the lower baseline cardiac output in the elderly to be the main reason of the lower efficacy of Qa reduction: the difference between medians (older adults-younger patients before Qa reduction, Hodges-Lehmann method) was 1.9 l/min [95% CI 1.5; 2.4], p <0.0001. At the same time, Qa before reduction did
Changes in ejection fraction as a result of Qa reduction in HD patients > 60 and < 60 years old.

not differ much between the older and the younger: 0.61/ min [95% CI 0.4; 0.8], p < 0.0001. Moreover, the reduction of Qa in elderly patients led to a decrease in the ejection fraction (EF), which was not noticed in young patients - Fig. 2. Notably, in all patients of both groups the initial value of the EF was more than 55%. We believe that this can be explained by an abrupt increase in afterload against the background of a decreased compensatory heart capability in the elderly. At the same time, decrease in the EF after Qa reduction in the elderly may indirectly indicate that conventional EF in the elderly is maintained by a presence of a high-flow AVF. Evaluation of EF against this background creates a putative picture of well-being and can mask the development of heart failure with reduced EF for a long time.

Conclusion: We noted a lower efficacy of Qa reduction as a method of reducing both cardio-fistula recirculation and cardiovascular risk in the elderly patients compared to the younger patients on maintenance HD. Elder patients seem to require a different approach to reduce cardiovascular risk than younger patients.

EFFECT OF TRISODIUM CITRATE 30% VERSUS HEPARIN AS A CATHETER LOCK SOLUTION ON INFLAMMATORY RESPONSE AND DIALYSIS ADEQUACY IN HEMODIALYSIS PATIENTS
Magdy Elsharkawy1, Lina Khedr1, Ahmed Kamal2 and Ahmed Emara1

1 Ain Shams University, Nephrology Department, Cairo, Egypt and 2 Nasser Institute Hospital, Nephrology Department, Cairo, Egypt

Background and Aims: In hemodialysis (HD) patients, the majority of bloodstream infections are caused by infection of vascular access catheters. Commonly, Central venous catheters (CVCs) are the only option when HD is needed for patients without definitive vascular access. However, in addition to infection, CVCs are associated with other complications, such as thrombosis, and dysfunction, leading to higher mortality and expenditures. In Egypt, recent data show that 6.6% of HD patients use catheters as a vascular access, of which short term catheters represent 59.6% and 40.4% with long-term catheters. Many data show that the use of HD catheter-locking solutions could contribute to reduction of catheter-related complications, especially infections.

Aim: to assess the possible effect of using Trisodium citrate 30% (TSC 30%) in comparison to unfractionated heparin, as a lock solution for HD catheters, on inflammatory status, incidence of catheter related Bacteremia (CRB) and dialysis adequacy in HD patients.

Method: This was a randomized controlled clinical trial, conducted on 70 prevalent HD patients on regular dialysis using HD catheters as a vascular access, recruited from hemodialysis unit in Nasser Institute Hospital in Cairo government at the time of catheter insertion. Patients were divided into two groups: Citrate Group; 35 patients received trisodium citrate 30% as a catheter lock after HD session, Heparin Group; 35 patients received unfractionated heparin (5000i.u) as a catheter lock solution after HD session. Both groups were followed up for 3 months period and monitored for signs of CRB. Also, Urea reduction ratio (URR) were measured monthly. Highly sensitive CRP were measured at baseline and 3 months after start using the lock solutions. Blood cultures were withdrawn in patients who developed signs of CRB.

Results: In our study, the catheter-related bacteremia (CRB) episodes were significantly lower in the Citrate group when compared to Heparin group. Only 2 patients (5.7%) in Citrate group had CRB, whereas in Heparin group, 8 patients (22.9%) had CRB (P = 0.04) (Fig. 1). Also, Bacteremia-free time was longer in the Citrate group. The mean bacteremia free time in Citrate group was 10.97 ± 2.36 weeks, while in Heparin group it was 9.43 ± 3.91 weeks.

Figure 1: Comparison between the two studied groups according to CRB.
CRB: Catheter Related Bacteremia.
Figure 2: Kaplan-Meier curve for Bacteremia Free Time.  
Group 1 = citrate group.  
Group 2 = heparin group.

Figure 3: Comparison between the two studied groups according to CRP.  
CRP: C-reactive protein.

Figure 4: Comparison between the two studied groups according to URR.  
URR: Urea Reduction Ratio.
(P = 0.032) (Fig. 2). At base line, there was no significant difference between both groups regarding hsCRP (P = 0.596) and WBCs (P = 0.528). While after 3 months of using TSC 30% as a lock solution, there was a significant difference as regards levels of hsCRP (P = 0.030) (Fig. 3) and WBCs (P = 0.036), with the higher levels of inflammatory markers showed in Heparin group. There was no difference between the two studied groups regarding thrombosis events. However, dialysis adequacy and catheter performance, assessed by URR, were higher in citrate group compared to heparin group after 3 months (P = 0.005) compared to baseline (P = 0.108) (Fig. 4).

Conclusion: we may conclude that, using Trisodium citrate 30% as lock solution for HD catheters was associated with reduction in the inflammatory markers and CRB incidence compared to the standard heparin lock. Also, its use was associated with better catheter performance and dialysis adequacy. We therefore believe that TSC 30% may be a potential alternative to standard heparin as a catheter lock solution for HD patients.

Figure 2: Correlation between change in flow during 28 days of AVF maturation and end-diastolic volume at the first day post-AVF creation (EDV1).

Conclusion: Hemodynamic parameters of the brachial artery, precisely peak systolic volume and end-diastolic volume at the first day post-AVF creation, play a significant role in AVF maturation. CDU measurements of those hemodynamic parameters at day 1 may be useful for an early identification of AVF maturation outcomes.

Figure 1: Correlation between change in flow during 28 days of AVF maturation and peak systolic volume at the first day post-AVF creation (PSV1).
presence of complications was statistically related to age (p = 0.046), with more events in older patients at the time of AVF construction. There was no statistical difference between complications’ occurrence and AVF type, sex, gender, PLR, and NLR.

**Conclusion:** The utilization of AVF for HD has been growingly recognized as a safe and efficient alternative for the performance of KRT in pediatric patients. Although larger studies are needed, we demonstrate positive results in its usage in younger patients, as complications were associated with older age. PLR in a pediatric population, with high primary and secondary patency rates. Although larger studies are needed, we demonstrate positive results in its usage as a safe and efficient alternative for the performance of KRT in pediatric patients.

**Conclusion:** This study has not established nor confirmed to any meaningful degree any relationship between the anastomotic angle using 45° as a cut-off and the maturation rate of AVF in Chinese patients at 3 months. Our overall AVF maturation rate was very high and none of the traditional risk factors for failed AVF nor the degree of anastomotic angle have any demonstrable effect on AVF maturation. The success might have been in part due to the skill and dedication of the nephrologists as operators. A prospective study involving a bigger patient group is necessary to further explore the effect of anastomotic angle on AVF maturation if any.
Conclusion: In our study sample, most patients started HD through a CVC, despite the majority having at least 3 months of pre-HD nephrology care. When adjusting for other covariates in a multivariate model, the first VA did not present a strong association with survival outcomes. The appropriate VA in the very elderly patient is an ongoing debate, and doubts remain regarding the applicability of the “Fistula First, Catheter Last” policy in octogenarian and nonagenarian patients. Our results are in line with recent reports which suggest that initial CVC use with later placement of an AVF, shortly after HD initiation, does not confer worse prognosis than initial AVF use in very elderly patients [2]. One of the limitations of our study was not having collected data regarding timings of AVF construction and use, which might have been informative regarding the impact of catheter-dependence time in survival.

A national strategy should be implemented to improve CKD care, aiming to increase both the rate of AVF usage at HD, and the conversion from CVC to AVF in the six months.

Figure 1: mNTRC, gentle movement in and out though a venotomy of proximal to cuff part of a CTC with flashing.
published with modification including mandatory CTC lines flushing and locking lines with antithrombotic agent after the dialysis session.

**Results:** A number of 205 mNTCR were performed in 110 patients with CTC. Effective blood flow CTC was obtained after 115 procedures (56%), partial failure followed 73 procedures (35.6%), and 17 attempts (8%) failed. Over 90% interventions improved a CTC patency allowing start of effective haemodialysis. The procedure could be successfully repeated with similar effect after the first, and the second attempt (28 vs 22 hemodialyses performed respectively). In the group of 50 elderly patients (median age 74 years) with CTC as the only vascular access, mNTCR was successful in 31 patients allowing dialysis continuation for median period 54 months. The mNTCR is safe as minor complications were observed after 5.1% of all procedures.

**Conclusion:** The novel mNTCR manoeuvre was safe and effective in a majority cases of CTC dysfunction. It permitted immediate dialysis without time-consuming fibrinolytic agents usage protocols before the dialysis session, saving costs and nursing staff time.

**VALUE OF ARTERIAL CALCIFICATION DETECTED BY UPPER LIMB DOPPLER ULTRASOUND IN ADVANCED CHRONIC KIDNEY DISEASE**

Catarina Marouço, Pilar Simões, Tiago Assis Pereira, Juliana Francisca Da Costa e Silva Barbosa Damas, Ana Carina Ferreira, Rita Magriço and Cristina Jorge

Hospital Curry Cabral, Nephrology Department, Lisboa, Portugal

**Background and Aims:** Vascular calcification is a common complication of chronic kidney disease (CKD), particularly in end-stage renal disease (ESRD) and is predictive of subsequent cardiovascular disease and mortality. The aim of the present study was to evaluate the relationship between arterial calcification assessed by doppler ultrasound (DUS) performed by the same team of-care therapy for CKD-MBD.

**Calcifications can be a surrogate of CKD-MBD and cardiovascular burden.**

Vascular calcification on DUS was associated to mortality. In patients with vascular calcifications, moderate/severe calcification was associated with diabetes mellitus (OR 2.85, p < 0.000), male gender (OR 1.69, p < 0.012), PAD (OR 2.43, p < 0.001) and hemodialysis therapy for more than 5 years (OR 3.00, p < 0.010). Cinacalcet, phosphate binders, serum calcium, phosphorous, PTH and mortality did not correlate with calcification severity. In the multivariate logistic regression analysis adjusted to age, gender, PAD and serum calcium, only phosphate binders and cinacalcet use were predictive of absence of vascular calcifications, however no causality could be advanced with these data. Serious calcification, in our multivariable model, only PTH had statistical significance. It is widely recognized the importance of monitoring serum PTH, calcium and Pi to reduce the adverse clinical events associated with CKB-MBD. Widespread implementation of DUS in pre-surgical mapping for VA construction is also an opportunity for vascular study and features as calcifications can be a surrogate of CKB-MBD and cardiovascular burden.

**Results:** The demographics and biochemistry of the study population are summarized in Table 1. Arterial calcification was observed in 91.6% (n = 416) of the patients, 62.3% (n = 229) had mild calcification and 37.7% (n = 157) presented moderate/severe calcification. In univariate analysis, male gender (OR 2.2, p < 0.023), age (OR 1.03, p < 0.003), phosphate binders (OR 0.55, p value < 0.03) and cinacalcet use (OR 0.28, p < 0.019) were independently associated with the presence of arterial vascular calcification. Presence of vascular calcification on DUS was associated to mortality. In patients with vascular calcifications, moderate/severe calcification was associated with diabetes mellitus (OR 2.85, p < 0.000), male gender (OR 1.69, p < 0.012), PAD (OR 2.43, p < 0.001) and hemodialysis therapy for more than 5 years (OR 3.00, p < 0.010). Cinacalcet, phosphate binders, serum calcium, phosphorous, PTH and mortality did not correlate with calcification severity. In the multivariate logistic regression analysis adjusted to age, gender, PAD and serum calcium, only phosphate binders and cinacalcet use were predictive of absence of vascular calcifications, however no causality could be advanced with these data. Serious calcification, in our multivariable model, only PTH had statistical significance. It is widely recognized the importance of monitoring serum PTH, calcium and Pi to reduce the adverse clinical events associated with CKB-MBD. Widespread implementation of DUS in pre-surgical mapping for VA construction is also an opportunity for vascular study and features as calcifications can be a surrogate of CKB-MBD and cardiovascular burden.

**Conclusion:** Concerning CKB-MBD related markers our study showed that only phosphate binders and cinacalcet use were predictive of absence of vascular calcifications, however no causality could be advanced with these data. Serious calcification, in our multivariable model, only PTH had statistical significance. It is widely recognized the importance of monitoring serum PTH, calcium and Pi to reduce the adverse clinical events associated with CKB-MBD. Widespread implementation of DUS in pre-surgical mapping for VA construction is also an opportunity for vascular study and features as calcifications can be a surrogate of CKB-MBD and cardiovascular burden.

**Table 1: Demographics and biochemistry of study population.**

| Age (y) | 65.52 ± 15.28 |
| Male (%) | 57.05 (n = 259) |
| Pre-dialysis (%) | 57.96 (n = 262) |
| HD < 1 year (%) | 28.98 (n = 131) |
| HD > 1 and < 5 years (%) | 6.19 (n = 28) |
| HD > 5 years (%) | 6.86 (n = 31) |
| CKB etiology (%) | |
| ADPKD | 4.42 (n = 20) |
| Diabetic nephropathy | 21.46 (n = 97) |

**A NOVEL INVESTIGATION OF AVF WITH A SECOND HARMONIC GENERATION MICROSCOPY IN PATIENTS WITH END STAGE RENAL DISEASE**

Vilute Gabriele Samsone1, Mykolas Maciulis2, Marius Miglinaš3-1, Laurynas Rimsevičius1,2, Sofija Saulė Kaubrytė1, Edwardas Zurauskas4, Danielius Samsonas5, Birute Vaisnytė5, Simonas Jonas Norvydas5 and Virginijus Barzda5,6

1Faculty of Medicine, Vilnius University, Lithuania, 2Laser Research Center, Faculty of Physics, Vilnius University, Lithuania, 3Nephrology Center, Vilnius University Hospital Santaros Klinikos, Lithuania, 4Department of Pathology, Forensic Medicine and Pharmacology, Vilnius University, Faculty of Medicine, Lithuania, 5Center of Vascular and Endovascular Surgery, Vilnius University Hospital Santaros Klinikos, Lithuania and 6Department of Physics and Department of Chemical and Physical Sciences, University of Toronto, Canada

**Background and Aims:** The population of patients with end-stage renal disease is rapidly growing and hemodialysis (HD) remains the most common treatment option. In clinical practice, the formation of arteriovenous fistulas (AVFs) is considered a priority in order to ensure optimal vascular access for HD patients. One of the complications in the formation of AVF is the hyperplasia of the neonotal layer of the vein, which leads to the failure of the fistula. The impact of the arrangement of collagen fibers in the veins of AVFs is little studied and opens wide opportunities for investigations. The structural tissue can be imaged with polarimetric nonlinear microscopy. Collagen fibers have a non-centrosymmetric structure, so they can be effectively imaged by second harmonic generation (SHG) microscopy [1]. The polarimetric nonlinear microscopy, exploiting the multidimensional tensor nature of light-matter interactions, is emerging as a valuable research tool in biomedical investigations and applications to digital pathology, and is only now becoming technically feasible for potential clinical translation [2,3]. This proposal represents a novel application of multidimensional polarimetric nonlinear microscopy in histopathology, and biomedical imaging. The aim of this study is to determine the influence of the arrangement of collagen fibers in veins on the formation efficiency of AVFs by using the innovative method of nonlinear SHG microscopy.

**Method:** In this prospective study, we first used a novel SHG microscopy method to investigate AVFs venous intima hyperplasia. V. Cephalica segment is being obtained during arteriovenous fistula formation surgery from patients with end stage renal disease and after the removal of aneurysmatic or fibrotic AVF. Cross-sections of venous specimens are being fixed in 10% buffered

Abstracts i735
formalin and stained with hematoxylin and eosin (H&E). Further, sample investigation is being performed in Laser Research Centre, Vilnius University using a home-built multiphoton laser-scanning microscope. The investigation is being performed with the permission of Lithuanian Biomedical Research Ethics Committee.

**Results:** We determined the arrangement of collagen fibers in veins before AVF formation and after the removal of aneurysmatic AVFs. It was observed that tunica intima of V. Cephalica is dominated both by endothelial cells and connective tissue made up of high-density collagen fibers. Whereas tunica adventitia consists mainly of collagen fibers. Collagen in tunica intima and adventitia are found to be highly noncentrosymmetric. Thus a strong SHG signal, resulting in high-contrast structural visualization of the V. Cephalica segment is generated.

**Conclusion:** Our initial investigations of AVF show clearly visible collagen fibers. The future work will focus on the structural changes of collagen fibers in the vein intimal hyperplasia. Further investigations need to be done to create artificial intelligence-based identification of new predictive collagen markers.

**A NOVEL SELF-SEALING DIALYSIS PORT EVALUATION**

Jacob Wright1, Alan Benvenisty2, Kenneth Nakazawa2, Marina de Cos Gomez2, Philip Nasser3, Hynton Gordon4, Jonathan Cohen4, Kirk Campbell1, Eric Lima5 and Evren Azeloglu1

1Icahn School of Medicine at Mount Sinai, Surgery, New York, United States of America, 2Icahn School of Medicine at Mount Sinai, Comparative Medicine and Surgery, New York, United States of America, 3Icahn School of Medicine at Mount Sinai, Biomechanics Core, New York, United States of America, 4Icahn School of Medicine at Mount Sinai, Comparative Medicine and Surgery, New York, United States of America and 5 The Cooper Union, New York, United States of America

**Background and Aims:** There are several complications associated with hemodialytic vascular that arise from the incorrect cannulation, including aneurysms, infection, vessel damage, and uncontrolled bleeding. These risks severely limit treatment opportunities for self-cannulation by patients, which is necessary step for home hemodialysis. To improve quality of life and reduce complications, we developed a novel access port, called Safe Entry Port for AV fistulae (SEAL), that integrates with fistulae, guides cannulation, and uses an internal colinear valve to prevent aneurysms with minimal risk of back-bleeding and infections (Figure 1A-C).

**Method:** The device was additively manufactured using direct metal laser sintering of FDA-approved Ti-6Al-4V. It was then polished and coated with silver-doped titanium nitride (TiN/Ag). The operation of the valve was tested in a mock circulation system using a peristaltic pump and Tyvek tubing to produce a pulsatile hydrostatic pressure gradient. The antimicrobial properties of the valve coating were evaluated in vitro against biofilm formation using standard assays for bacterial spreading area and turbidity. A custom computer-controlled robotic cannulation system was created to fatigue test the port as well as to determine the needle force required to open the valve. Finally, the device was implanted subdermally on a mature brachiophedic arteriovenous fistula of an adult sheep and cannulated biweekly for six weeks.
Device integration and host tissue reaction were evaluated using standard histopathological methods and micro-CT scanning.

**Results:** SEAL is engineered to integrate directly over a fistula via a Ti matrix (a mesh of small holes covering the sides of the device for interaction with host tissue). No fluid leaked through the valve during *in vitro* testing even under physiologically high circulatory pressure. In repeated cannulations of the device during *ex vivo* simulations with 14G dialysis needles, the peak force required to engage the valve recorded in our dialysis fatigue cycling simulation was $160.5 \pm 0.02$ mN (Figure 1D, E). The device withstood cannulation cycles equivalent to 14 years of dialysis. Furthermore, the colinear valve smoothly opened for continuous flow through the needle guide (Figure 1F-I) and closed automatically under the tensile force similar to that of subcutaneous tissue. Antimicrobial TiN/Ag coating showed significant reduction in bacterial growth in both biofilm assays (Figure 1J,K). In preclinical trials, no signs of infection or backbleeding were observed during the continuous six-week cannulation period; vascular access was continuous with no resistance or complications.

**Conclusion:** We show that SEAL nearly eliminates backbleeding risk both *in vitro* and *in vivo*. The TiN/Ag coating of the colinear valve significantly limits bacterial biofilm formation *ex vivo*. Preclinical studies in the sheep model show that the device implanted on a mature fistula can easily be cannulated twice a week without any infection, cannulation complications, or backbleeding for an extensive period. SEAL has the potential to change the future of dialysis treatments, improve the quality of life for patients due to the reduction of complications, and allow improved access to home hemodialysis.
#6345 HIGH BRACHIAL ARTERY BIFURCATION AND CLINICAL IMPLICATIONS UPON HEMODIALYSIS VASCULAR ACCESS PLANNING
Pilar Simões, Juliana Francisca Da Costa e Silva Barbosa Damas, Tiago Assis Pereira, Catarina Maruço, Mafalda Sobral, Sofia Corado, Sofia Carellha, Ana Pena, Bernardo Do Sacramento Marques Da Costa and Cristina Jorge
Centro Hospitalar Universitário de Lisboa Central, Portugal

Background and Aims: Preoperative ultrasound mapping provides information about overall vessel, caliber, flow and anatomic variations, useful for hemodialysis (HD) vascular access planning. High bifurcation of the brachial artery (HBBA) is one of such variations, established early upon fetal development. Its implications in arteriovenous HD access creation are fairly unknown. The present work aims to characterize the prevalence and demographic characteristics of patients presenting with HBBA and study its impact upon HD vascular access planning, construction and patency.

Method: We developed a retrospective study focusing on 457 patients accessed from 2018 to 2021. Demographic data and presence of HBBA were registered as well as vessel diameter and peak systolic velocities (PSV) for brachial and radial arteries. Theoretical feasibility for each specific access (i.e., radiocephalic, brachiocephalic, brachiobasilic and prosthetic fistulae, according to ultrasound evaluation), final choice of access and 30-day patency were also gathered. Categorical variables are presented as frequencies and percentages and continuous variables as means and standard deviations or medians and interquartile ranges, as appropriate. Logistic regressions were adjusted considering sex, race, arm dominance and HBBA as independent variables.

Results: From a total of 457 patients, 193 (42.2%) were women and 264 (57.8%) were men. Mean age was 65.4 ± 15.3 years. 383 (83.8%) were Caucasian and 427 (93.4%) were right-handed. High bifurcation of the brachial artery was present on both arms of 6 (1.3%) patients, only one arm on 62 (13.6%) and on none of the remaining 389 (85.1%) patients. We found an association between being non-Caucasian and presenting with HBBA (27% vs 12.5%, p-value = 0.01) but not with sex or arm dominance. Considering all patients, female sex was associated with smaller radial artery diameter, (2.0 ± 0.7 mm vs 2.2 ± 0.6 mm, p < 0.01). HBBA was not associated with a significant difference on arterial diameters (adjusted for sex and race) and there were also no significant differences when comparing dominant vs non-dominant arms. We found no association between HBBA and the theoretical feasibility of a radiocephalic fistula but rather with the choice of arteriovenous graft as the only possible access (26.5% vs 19.5%, p-value = 0.044). A total of 379 (77.0%) patients proceeded to vascular access construction: 59 (15.6%) radiocephalic fistulas, 229 (60.4%) brachioccephalic fistulas, 31 (8.2%) brachiobasilic fistulas and 60 (15.8%) arteriovenous grafts were created, with no differences between HBBA and non-HBBA groups. There was, however, an association between non-Caucasian patients and the choice for a more proximal access (p = 0.001) as well as the need for surgical or angiographic reintervention within 45 days after access creation (11% [95% CI: 6.0% - 16.7%], p-value = 0.002).

Conclusion: Our study suggests that presenting with HBBA is not necessarily associated with lower quality vessels and less distal access construction. However, this variation seems to be more frequent among non-Caucasians, who appear to receive more proximal accesses, in greater need for early intervention than their counterparts. Further investigation is necessary to understand if apart from diameter or PSV, HBBA could influence other determinants of access placement choice, such as distance from brachial artery to cephalic or basilic vein or risk of distal hypertension syndrome.

#6792 VASCULAR ACCESS SURVIVAL OUTCOME IN ELDERLY HEMODIALYSIS PATIENTS: A SINGLE-CENTER RETROSPECTIVE STUDY
Bongkok Surattichaiyakul
Bhumiranjagarindra Kidney Institute Hospital, Bangkok, Thailand

Background and Aims: Elderly hemodialysis patients usually have lower life expectancy of vascular access than another age-group. Our center, elderly patients are the most of population of hemodialysis patients. Prior to initiate hemodialysis, planning of first vascular access has been established by patients, nephrologist, and vascular surgeon. The calculation technique for arteriovenous fistula (AVFs) has been determined by experienced hemodialysis-nurse and patient preferences. The aim of this study was to analyze the survival outcome of the access depending on the vascular type in the elderly.

Method: The study was collected retrospective data between Jan 1, 2013, and December 31, 2022. We identified elderly patient (age ≥65) who initiate in-center hemodialysis and first-use vascular access in our center, including arteriovenous fistulas, graft, tunnel-catheter. Outcomes were vascular access patency and subgroup analysis for non-extreme elderly group and extreme (age ≥80) elderly group. A χ2 test, Kaplan-Meier analysis were performed.

Results: Overall number of elderly patients who initiated hemodialysis are 170: 63 AVFs-first (74% buttonhole cannulation technique), 21 grafts-first and 86 forter nal-catheters. Mean survival of vascular accesses are higher in AVFs group (78 months in AVFs, 52.5 months in grafts, 53.3 months in tunnel-cather P = 0.012). The outcome was consistency in the subgroup age 65-80 (89.0 months in AVFs, 47.3 months in grafts, 47.2 months in tunnel-cather P = 0.005). However, mean vascular access survival did not differ in subgroup age ≥80 (56.3 months in AVFs, 58.4 months in grafts, 56.4 months in tunnel-cather P = 0.98).

Conclusion: In our single center data, vascular access patency of elderly patients was highest in AVFs-first group and AVFs should be the first choice for elderly patients who would initiate hemodialysis especially non-extreme elderly group.

#3179 PREDICTORS OF VASCULAR ACCESS THROMBOSIS IN MAINTENANCE HEMODIALYSIS PATIENTS – QA, KT/V AND CONVEXTIVE VOLUME
Nuno Rodrigues1 and Artur Jorge Pereira Mendes2
1 Davita Portugal, CAV Davita Lisboa, Lisboa, Portugal and 2 Davita Portugal, CAV Davita Lisboa, Lisboa, Portugal

Background and Aims: Vascular access (VA) is vital for hemodialysis (HD) treatments and should allow to achieve the recommended dose of dialysis. Thrombosis is the primary cause of VA failure in grafts (AVG) and fistulas (AVF) and should be avoided as it can lead to significant patient morbidity and mortality. However, despite its importance, predictors of VA thrombosis are not completely established. Even if large randomized controlled trials are lacking to clearly identify the ideal surveillance strategies and benefits of surveillance, evidence suggests that when combined with preemptive interventions, prospective monitoring and surveillance and early detection of dysfunctional VA may reduce the thrombosis rate and improve its long-term patency. Several monitoring and surveillance techniques of VA can be used, from unexplained drop in dialysis adequacy (Kt/V and convective volume) to the noninvasive estimation of VA blood flow (Qa). The aim of this study was to assess whether these parameters can predict VA thrombosis.

Method: We retrospectively evaluated all episodes of VA thrombosis admitted in our Vascular Access Centre (VAC) between July 2019 and December 2022. Patients’ demographics, VA characteristics and data from dialysis sessions were collected. Descriptive statistics were calculated and expressed as mean (standard deviation) or median (IQR) or count (%), as adequate. Values were compared using Mann-Whitney for independent samples and Pearson chi-squared test with 95% confidence intervals (CI). The predictors of VA thrombosis studied were Qa, Kt/V and convective volume (CV), in the case of thrombosis on hemodiafiltration. Qa was measured using the thermodilution method called blood temperature monitoring (BTM®), and Kt/V and CV with Online Clearance Monitoring (OCM®). In this study, we evaluated the ratio between the last measured value of Qa prior to the thrombosis episode and the average of the previous three months (Qa trend), and the ratio between the last measured value of Kt/V and CV before the thrombosis episode and the average of the previous month (Kt/V trend and CV trend, respectively) as predictors of VA thrombosis.

Results: From July 2019 and December 2022, we treated, in our VAC, 386 VA thrombosis episodes in 226 patients. In our study population, mean age was 71.1 (± 13.2) years, 64% were male, 31% had diabetes. The dialysis vintage was 51 (69) months and the VA vintage was 42 (62) months. 70.2% of the VA thrombosis were on AVF. Prior to thrombosis the median of Qa obtained by BTM was 650 (495) mL/min, the median of k/t/V was 1.63 (0.62) and the median of CV was 22.4 (6.3). The average of the previous values for Qa, Kt/V and CV were 658 (333) mL/min, 1.53 (0.35) and 23.5 (3.9) L. The median (IQR) trend of Qa trend, Kt/V trend and CV trend were -8.5 (33.3) %, -6.0 (28.2) % and -2.5 (17.0)%. We found no statistical significance for Qa trend and CV trend between AVF and AVG as predictors of VA thrombosis, but the reduction in Kt/V values was significantly more pronounced in AVF (-6.8%; Q1 -20.1% to Q3 0.7%) than in AVG (-3.8%; Q1 -18.0% to Q3 -5.0%) (p = 0.007) as predictor of thrombosis. In 68.9% of VA thrombosis, we noticed a reduction in Kt/V value before the episode (73.8% in AVF and 57.5% in AVG, p = 0.002). We found no statistically significance in the reduction of Qa and CV values between AVF and AVG thrombosis episodes.
Conclusions: Our study showed that Ki/V trend was a better predictor of VA thrombosis than Qa trend and CV trend, especially in AVF.

#5014

VALIDATION AND APPLICABILITY OF A MONITORING SYSTEM FOR VASCULAR ACCESS IN HAEMODIALYSIS: A MULTICENTRE STUDY

Silverio Rotondi1, Ersilia Satta2, Carmine Romano3, Achille Iannone2, Massimo Romano2, Kamela Korreschi1 and Sandro Mazzaferro2

1Sapienza University of Rome, Roma, Italy and 2NefroCenter - Gruppo Dialisi Campano - Frattamaggiore, Frattamaggiore, Italy

Background and Aims: Routine systems for monitoring vascular access (VA) performance are lacking. We recently showed that with a VA triage system it is possible to improve the average value of a number of VA efficiency parameters and that the VA triage score was associated with clinical outcomes. The triage categorization is generated monthly by a scoring system which is based on a number of parameters (blood flows, VA pressure values, end HD circuit clots and a dedicated score of the external VA examination, Ki/V) recorded at each session by the staff on a dedicated electronic spreadsheet. According to threshold values, triage classified each VA in Green (G), Yellow (Y) or Red (R), thus indicating the VA performance and the clinical risk of complication linked to VA. In our open label single centre study, with three years of follow-up, the average VA score improved significantly and G VA associated with lower mortality, compared to the Y and R VA. Aims: To validate the ability of the triage system to early identify VA with increased risk of complications.

Methods: In this interventional prospective, blinded multicentre study, each centre used the VA triage electronic spreadsheet without knowledge of the generated triage. After six months of system implementation, two years of follow-up (01/01/2020 - 01/12/2021) were planned to record VA related events. Two external reviewers evaluated the records. A minimum of three months VA follow up was necessary for patients enrollment.

Results: From 18 HD centres we enrolled 757 patients, aged 64.5±15.5 y.o.; 27% diabetics; HD since 24.4±2.4 months; 369 (48.7%) with arteriovenous fistula (AVF) and 388 (51.3%) with permanent central venous catheter (CVC). During 11.4±5.6 months of follow-up (range 3-23), 10853 are HD sessions were recorded on the triage electronic spreadsheet, with 214 total clinical events and an event free time of 224.5±172 days (range 4-713). The VA related events were 130 (70.1%) during 16.3±2.2 months of follow-up (range 3-23) with an event free time of 230±160 days (range 11-713). The VA Triage was: 60% Green, 35% Yellow and 5% Red. In the 369 patients with AVF the VA Triage was: 61% Green, 36% Yellow and 3% Red; The AVF Triage Green group showed: lower incidence of VA related events respect to the AVF Triage Yellow and Red group (30% vs 48%; P: 0.05; higher time-free from VA events (AVF Green vs AVF Yellow-Red: log-rank test: 0.04). Similar results were confirmed in the CVC groups: VA events incidence Triage Green 15% vs Triage Yellow-Red 40% (p: 0.001; time-free from VA events log-rank Test 0.001).

Conclusion: Our VA triage system identifies 40% of vascular accesses as yellow-red triage. These VA were not identified as at elevated clinical risk by the dialysis staff and only the Triage system was able to highlight them as critical. Notably the VA access with Yellow and Red Triage independently from the VA typology had an higher risk of clinical complications that according to the time survival curve could be detectable roughly 237.8 days before the event developed. The Triage system was able to identify early the VA with increased clinical risk and it may be a useful tool to prevent VA complication.

#4500

IMPLEMENTATION OF A NEW GENERATION DIGITAL STETHOSCOPE FOR ARTERIOVENOUS FISTULA MONITORING IN HEMODIALYSIS PATIENTS

Nazareno Carullo, Pierangela Presta, Michela Musolino, Giuseppe Fabiano, Maria Giovanna Bianco, Giuseppe Oliva, Annarita Armeni, Salvatore Chiarella, Michele Andreucci, Antonio Fiorillo, Davide Bolignano, Salvatore Pullano and Giuseppe Coppolino

“Magna Graecia” University of Catanzaro, Catanzaro, Italy

Background and Aims: The management of complications of arteriovenous fistula (AVF) for hemodialysis, principally stenosis, remains a major challenge for clinicians with a substantial impact on health resources. Stenosis not infrequently preludes to thrombotic events with the loss of AVF functionality. A frequent monitoring with physical examination is at the basis for an appropriate clinical care. It includes a regular inspection, palpation and auscultation of the arm. A normally functioning AVF, when listened by a stethoscope, has a continuous systolic-diastolic low-frequency murmur while with stenosis the frequency of the murmur increases and the duration of diastolic component decreases, disappearing in severe stenosis. These evidences are strictly subjective and dependent from operator skill and experience. New generation digital stethoscopes are able to record sound and subsequently dedicated software allows to extract quantitative variables (amplitude and frequency) that characterize the sound in an absolutely objective and repeatable way. The aim of our study was to analyze with an appropriate software listenable sound from AVFs taken by a commercial digital stethoscope and to investigate the potentiality to develop an objective new monitoring system to detect stenosis.

Method: Between September 2022 and January 2023, we screened forty-eight patients from two hemodialysis centers in Catanzaro (Italy). Patients were screened from two blinded experienced examiners for recognized criteria for stenosis by doppler ultrasound (DUS). We recorded the sound coming from the AVFs using a 3M™ Littmann® CORE Digital Stethoscope 8570 (Figure 1-A), in standardized sites: on the anastomosis chamber, at a distance of 5 and 10 cm from it, on the site of stenosis and immediately after. The sound waves were transformed into quantitative variables (amplitude and frequency) using a sound analysis software.

Figure 1:
Results: Based on doppler evaluation, 14/48 patients (29%) were classified as stenotic of which three were hemodynamically significant. The sounds detected in the stenosis sites had a significant higher average frequency compared to non-stenotic sites (Figure 1-B). Characteristics of sound waves were significant different for stenotic and non-stenotic patients in term of average power, mean amplitude and mean frequency. Analysis of waves permitted us to determine peculiar shape for stenosis and another for normal AVF (Figure 1-C,D).

Conclusions: The analysis of sound waves by a digital stethoscope permitted us to distinguish between stenotic and no stenotic AVFs. The standardization of this technique and the introducing of data in a deep learning algorithm could allow an objective and fast method for a frequent monitoring of AVF.

HEMODIALYSIS CATHETER-RELATED RIGHT ATRIAL THROMBOSIS AND PULMONARY EMBOLISM: ANTICOAGULANT THERAPY MAY NOT BE REQUIRED

Tian-Lei Cui1, Qiu Li2 and Yan Zhao3

1West China Hospital of Sichuan University, Nephrology, Chengdu, P.R. China, 2West China (airport) Hospital of Sichuan University, Nephrology, Chengdu, P.R. China and 3West China School of Nursing, Sichuan University, General Practice Ward, Chengdu, P.R. China

Background and Aims: Though tunneled cuffed catheters (TCCs) are frequently inserted for treating thrombotic malfunction, it is unclear whether such exchanges are associated with an increased risk of pulmonary embolism (PE). This study sought to investigate the incidence of PE among patients with hemodialysis catheter-related right atrial thrombosis (CRAT).

Method: We conducted a retrospective cohort study on 180 hemodialysis (HD) patients treated in the West China Hospital with a diagnosis of CRAT between May 2018 and March 2020. All cases with CRAT were treated with catheter replacements (guidewire exchange or insertion at new sites) and the tip of new catheters were adjusted to be away from the original position and close to the right atrial. Antiplatelet therapy was started after the surgery with dipyridamole. All patients maintained routine hemodialysis without any thrombolysis or thrombectomy. We investigated the PE incidence and mortality among them.

Results: Of the 180 patients undergoing catheter replacement and with CART, 10 patients had asymptomatic PEs pre-operation and 3 additional patients developed PE post-operation. During follow-up, two patients died of pneumonia and acute myocardial infarction, respectively, but no patients died due to PE or other thrombosis complications.

Conclusion: The incidence of PE among HD patients with CRAT is low (5.6%), and there does not appear to exist an elevated risk of fatal PE. Combined catheter.

PREVALENCE OF INFECTIONS ASSOCIATED WITH THE HEMODIALYSIS CATHETER IN MEXICO CITY

Rosa María Zaragoza Rodríguez¹, Jose Andres Santos Flores² and Aldo Antonio Moreno Zaragoza³

¹Petróleos Mexicanos, Chief nephrologist of the service, Ciudad de México, Mexico. ²Facultad de Estudios Superiores Zaragoza UNAM Campus I, Social service medical intern, Ciudad de México, Mexico and ³University De Lorraine, Resident doctor, Nancy, France

Background and Aims: In hemodialysis, intravenous catheter is the most frequent vascular access to begin treatment in patients with chronic kidney disease. Infectious complications are a frequent adverse effect of the vascular access, they may cause vascular access retreat and serious diseases like septic shock, bacterial endocarditis, septic arthritis, venous thromboembolism and death (between 5 and 10%). Leading microorganisms of hemodialysis infection are Gram positive bacteria, while Gram negative are less common.

Method: Study type and design: Used a descriptive, retrospective, open, observational and analytical cross-sectional study. Sampling type: Non-probabilistic of consecutive cases. Population: Patients diagnosed with CKD 5 KDIGO on renal function replacement therapy with hemodialysis through a temporary or permanent catheter in a private kidney care unit in Mexico City from October 2014 to September 2022.

Results: We identified 168 cases of CRBSI throughout the 8 years of the study. We found a prevalence of 0.86% for every 100 hemodialysis and a cumulative incidence of 4.97% for every 100 hemodialysis. Leading etiology pathogens of CRBSI in the kidney care unit were Gram negative bacteria (76.8%), mainly Enterobacter cloacae (20.8%), Escherichia coli (13.7%), Stenotrophomonas maltophilia (11.9%) and Burkholderia cepacia (4.2%). We found that 51.8% of the Gram negative CRBSI were due to multiresistant bacteria, which led to 5 directly related deaths. On the other hand, Gram positive bacteria caused 23.2% of CRBSI. Staphylococcus aureus and Staphylococcus epidermidis were the most frequent with 8.9% and 8.3%, respectively, with no related deaths.

Conclusion: Unlike international literature, in our study, gram negative bacteria were the main agents of CRBSI. The prevalence of CRBSI in our study was high, however, infection directly related mortality remained low. These results led us to investigate the origin of the vascular access infection. In an attempt to reduce the number of CRBSI, we emphasized preventive measures,
especially hand hygiene of healthcare professionals within the kidney care unit and with the patient’s personal environment at home. We would like to recall that empirical therapy should be based on the results of the kidney care unit microbiology and antibiotic sensitivity, to reduce CRBSI episodes and bacterial resistance.

#3226
DEVELOPMENT AND USABILITY ASSESSMENT OF AN AI-ENHANCED DASHBOARD SUPPORTING AVF MANAGEMENT IN CLINICAL PRACTICE
Francesco Bellocchio1, Federica Gervasoni1, Jaroslav Rosenberger2, Len Usvayt1, Mario Cioffi1, Mario Garbelli1, Michaela Sagova1, Milind Nikam6, Tomas Jirka1, Stefano Stuard7, Vratislava Kovarova7 and Luca Neri1

1Fresenius Medical Care Italia SpA, Italy, 2FMC - Dialysis Services, Slovakia, 3Fresenius Medical Care, United States of America, 4Fresenius Medical Care Italia SpA, Italy, 5Fresenius Medical Care, Czech Republic, 6Fresenius Medical Care, Singapore and 7Fresenius Medical Care, Germany

Background and Aims: Despite the rise in publications reporting Artificial Intelligence (AI) solutions in healthcare, their usage in clinical practice remains limited. Prominent barriers for their implementation in clinical practice are the lack of integration of AI-based tools in the hospital health information system and clinical workflows. We previously developed an AVF Failure risk score to assess the expected incidence of AVF failures within 3 months based on routinely collected dialysis data. The risk score showed high accuracy (AUC = 0.81) and calibration. Based on this risk score, we developed an AI-enhanced dashboard supporting the management of AVF in hemodialysis patients. The usability and usefulness of the AI-enhanced AVF management dashboard was evaluated in a pilot quality improvement program.

Method: A quality improvement framework was used to evaluate the usability of an AI-enhanced dashboard for AVF management (Fig. 1A). First, healthcare professionals (HCP) were involved to provide inputs for model design, endpoint definition, and potential predictors through various qualitative interview techniques such as brainstorming sessions and focus groups (Phase I). A machine learning model was then developed to assess the expected incidence of AVF failure within 3 months. The model used routinely collected clinical data to minimize additional burden on clinical workflow. (Phase II). After developing and validating the model, a model error analysis was conducted using case studies methodology to improve model performance (Phase III). Once the model reached a good accuracy, think-aloud interview was used to abstract HCP needs and to design a user interface for model output. A user-friendly dashboard was developed to display the risk of AVF failure within 3-months and patient’s vascular access history (Phase IV). This solution was integrated in the health record system and updated monthly with the latest risk score and medical information. A pilot quality improvement program was conducted in 15 clinics across 4 countries (IT, CZ, SK, SG) from May to December 2022. HCP were asked to evaluate their agreement with the risk score using a 5-point Likert scale (completely disagree to agree) and assess the usefulness of the dashboard in clinical decision making. At this stage the dashboard is not used for medical decision making (Phase V). The evaluation results were compiled into a monthly report and shared with all the HCP involved in the project to promote awareness and engagement. After 3 months of usage, a round-table discussion was held with all participants to gather their feedback and discuss clinical cases (Phase VI).

Results: Access to the AI-enhanced dashboard increased during the evaluation period. In the first two months of the pilot quality improvement program, the AI-enhanced dashboard was evaluated for 20% patients with an AVF, a proportion that doubled by the end of the program (Fig. 1B). HCP reported 90% agreement with risk model rating (Fig. 1C), suggesting that the model capture relevant physiological status of the patient and its output is understandable by the healthcare staff. Qualitative analysis of round-table discussions showed that the dashboard is perceived as useful and clear. HCP suggested few changes in the user interface to enhance actionability and improve clinical workflow integration.

Conclusion: Our results support the usefulness and intelligibility of the AI-enhanced AVF management dashboard. The advance of AI-models highlighted the importance to develop new strategies for their integration and evaluation in clinical practice. The engagement of HCP in the early phases of AI-model design and development grants a continuous feedback loop bringing clinical and AI world together. A clinical perspective in dashboard design reflects the needs of healthcare professionals and enhance consideration of patient medical needs. The synergy between theoretical and clinical perspective is crucial to improve model performance, usability, and implementation in clinical practice.

Figure 1: A) Workflow of the improvement framework. B) Percentage of evaluated dashboard’s entry C) Percentage of agreement reported by HCP.
#4046 ADVANCED CHRONIC KIDNEY DISEASE, PREOPERATIVE ISOMETRIC EXERCISE AND VASCULAR ACCESS: LET’S CLEAR THE DOUBTS

Irati Tapia González 1, Vicent Esteve Simó 1, Sara Ibáñez Pallares 2, Fátima Moreno Guzmán 1, Diana Oleas 1, Jorge Mario Alfonzo Julia 1, Verónica Duarte Gallego 1, Mónica Pou Potau 1, Anna Saurina Solé 1 and Manel Ramírez de Arellano Serna 1

1Hospital Terrassa, Consorci Sanitari Terrassa, Barcelona, Nephrology, Terrassa, Barcelona, Spain and 2Hospital Terrassa, Consorci Sanitari Terrassa, Barcelona, Vascular Surgery, Terrassa, Barcelona, Spain

Background and Aims: Arteriovenous fistula (AVF) is the best vascular access for hemodialysis. However, the role of preoperative isometric exercises in patients with advanced chronic kidney disease (CKD) who are candidates for AVF is unclear and not well reported in the literature. The main objective of this study was to evaluate the effect of preoperative isometric exercise on vascular territory in advanced CKD prior to AVF creation.

Method: An 8 months prospective single-center study. We performed an isometric preoperative exercise program for 4 weeks on the non dominant arm (exercise arm) and was compared with the dominant arm (control arm) performing usual activity in our advanced CKD patients. Demographic data, upper limb muscle strength (ULMS), Doppler ultrasound (DUS) measurements (forearm and distal cephalic vein (FCV, DCV) diameter, basilic vein (BV) diameter and depth, peak systolic velocities (PSVs) and diameters in the radial artery (RA) and braquial artery (BA), as well as percentage of patients candidates to AVF in both arm (exercise and control arm) according to Spanish Clinical Guidelines of Vascular Access (VA) and possible medical complications were analyzed.

Results: 27 patients. 67.7%men. Mean age 70.3±10.4years. Mean cardiovascular risk factors: HBP (93.5%) and DM (64.5%). Exercise arm was left side in 87.1%. A significant increase was observed in ULMS only in exercise arm at the end of study (23.8±6.8=7Kgs vs 27.6±9.5Kgs, p = 0.001). Related to DUS measurements, there were not differences between groups on vein diameter. However, a significant increase was observed in RA PSV (57.2±15.3 vs 62.6±17.4cm/sec, p = 0.044), BA diameter (4.6±1.0 vs 4.9±0.9mm, p = 0.029) and percentage of patients who could be candidates to AVF (70.4 vs 92.6%, p = 0.034) in exercise arm at the end of the study. We did not observe any related complications (pain, hypotension or muscle injury).

Conclusion: Preoperative isometric exercises would increase the percentage of performing a native AVF in those advanced CKD patients candidates for HD. Similarly, our results suggest that preoperative isometric exercise could be a useful tool to improve the vascular territory, mainly arterial, in our patients. However, more studies are required to confirm our results.

#6597 THE EFFECT OF PATHOGEN ON THE OUTCOME OF HEMODIALYSIS CATHETER-RELATED BLOODSTREAM INFECTIONS IN HOSPITALIZED PATIENTS: A SINGLE CENTER ANNUAL RECORD

Petros Kalogeropoulos, Ourania Tsetsorou, Ioanna Tsoympy, Petros Nikolopoulos and Sophia Lionaki

Department of Nephrology, 2nd Propaedeutic Internal Medicine, Medical School, National and Kapodistrian University of Athens, “Attikon” University Hospital, Athens, Greece

Background and Aims: Tunneled double-lumen catheters are increasingly used as permanent vascular access in hemodialysis patients, particularly in those with limited vascular access options. Catheter-related bloodstream infection (CRBSI) is a major cause of hospitalization with increased mortality and cost. The purpose is to study the effect of the pathogen on the clinical course of the hemodialysis patients with CRBSI.

Method: Patients hospitalized in our department from 11/2021 to 12/2022 with established CRBSI were retrospectively studied. Their demographics, duration of hospitalization, microbiological data, central venous catheter management and hospital outcome were recorded.

Results: A total of 27 patients with median age (SD) 68.03 (16.93) years were treated, 12 (44.4%) were men. The following pathogens were isolated from the blood cultures: Staphylococcus aureus in 7 (25.9%) patients, coagulase-negative Staphylococcus in 10 (37%) patients, Gram-positive bacteria in 4 (14.8%) patients, Gram-negative bacteria in 3 (11.1%) patients, candida in one (3.7%) patient, and 2 (7.4%) patients had negative cultures. Mean SD duration of hospitalization was 16.85 (13.15) days for all patients. Patients in whom Staphylococcus aureus and Candida were isolated had longer hospital stay than other infections with a mean (SD) 29 (18) days and 41 days respectively (p = 0.014). Metastatic infections occurred in 4 (14.8%) patients, of whom 2 had endocarditis, one endocarditida and pulmonary abcess, and one endocarditis, lung abscess and brain abcess. All 4 patients isolated Staphylococcus aureus in blood culture out of a total of 7 (57,1%) patients with this pathogen (p = 0.02). 3 of 7 (42,8%) patients with Staphylococcus aureus, 1 of 10 (10%) with coagulase-negative Staphylococcus, and 1 of 3 (33,3%) with Gram-negative bacteria died (p = 0.385). In 26 of the 27 patients (96.3%) central venous catheter was removed.

Conclusion: The majority of patients in the present sample required central venous catheter removal. The type of pathogen seems to play an important role both in the duration of hospitalization and in the occurrence of metastatic infections.

#6656 PATIENTS’ PERSPECTIVES ON HAEMODIALYSIS ACCESS: A QUANTITATIVE STUDY

Thomas Quarrell 1, Max Tagg 2, Ruth Silverton 1, Regin Lagaac 1 and Anil Chalisey 1

1Cambridge University Hospitals, Renal, United Kingdom and 2University of Cambridge School of Clinical Medicine, United Kingdom

Background and Aims: Vascular access is an essential requirement for hemodialysis (HD). There is strong evidence that an arteriovenous fistula (AVF) is preferable to access via a central venous catheter (CVC) for long term haemodialysis, yet many patients opt for access via a CVC. We performed a cross-sectional study to assess patient preferences regarding vascular access. The quantitative component of this work is presented here.

Method: Questionnaires were administered to patients attending dialysis at four sites in the East Anglia region of the UK (n = 380). Additional patient data was collected from medical records. Analysis was performed using the R software.

Results: 63% (n = 238) of patients completed the survey. The median age of respondents was 75 years (range 24-95 years), 64% were male (n = 153), the median length of time on dialysis was 23 months, and 64% (n = 152) were using an AVF. There was no significant association between age and form of access (p = 0.11). 65% of respondents believed that an AVF was the best access route for health, 10% believed a CVC was the best route, and 25% were unsure. This was not significantly affected by the participant’s access route at the time of the study (p = 0.91) or self-reported pre-dialysis education (p = 0.09). Respondents who believed that the health professional caring for them preferred AVFs were significantly more likely to believe that AVFs were best for their health (p < 0.0001 for both medical and nursing staff preference). However, overall, there was uncertainty about the preferred haemodialysis access of health professionals, with 40% and 47% of respondents unsure regarding the preference of medical and nursing staff, respectively. These patients were also more likely to respond as ‘unsure’ as to which access type was better for their health. We asked participants to rate 16 possible concerns they may have about access on a 1-9 scale (Figure 1). The most highly rated concerns were related to sleeping, pain, bleeding and access longevity, each receiving a rating of ≥2 in nearly 40% of participants. Notably, infection risk was rated as the lowest priority concern, only receiving a rating of ≥2 in 5% of participants. Concerns were similar regardless of the active form of access. 63% (n = 54) of respondents with a CVC would not consider changing to an AVF. The decision to switch from CVC to AVF was not significantly associated with age (p = 0.69), or the number of AVF operations a patient had undergone in the six years prior to the study year (p = 0.94). The decision was also not associated with respondent belief regarding the best access type for health (p = 0.84). Differences in access concerns could not significantly explain the decision to or not to switch from CVC to AVF. However, analysis of free-text responses identified peer experiences as a strong influence on the decision to switch.

Conclusion: Most HD patients are aware that an AVF is associated with better health outcomes than a CVC. Despite this, a large proportion of patients dialysing via a CVC do not wish to change their access, with many reporting concerns of bleeding, needling pain, and difficulty sleeping. Infection risk was not a consideration for most patients. Additionally, we found that patients reported significant uncertainty about doctor and nurse preference for haemodialysis access. These findings are mirrored by analysis of the free text responses to the questions in this study. In particular, peer experiences were a significant determinant of the decision to switch from a CVC to AVF. The findings suggest that when we discuss vascular access with patients, a broad scope of topics should be addressed, beyond health outcomes alone, to allow for effective decision making. They also suggest that there is room to improve the communication of our perspectives as healthcare workers, both from a nursing and medical perspective.
Figure 1: Patients’ rating of haemodialysis-access related concerns on a scale of 1-9, with 1 being the lowest concern and 9 the highest concern. No patient rated any concern above 5.

Figure 2: Response of patients with a CVC for haemodialysis access when asked if they would consider an AVF.
PERCUTANEOUS ARTERIOVENOUS FISTULA CREATION: A DUBAI HOSPITAL EXPERIENCE

Tarek Eleraky¹, Ayman Saleh², Dileep Kovilazhikam³ and Amna Alhadari²

¹Dubai Hospital Helipad, Nephrology Department, Dubai, United Arab Emirates, ²Dubai Hospital, Radiology and Interventional Radiology, Dubai, United Arab Emirates and ³Dubai Hospital, Nephrology Department, Dubai, United Arab Emirates

Background and Aims: Targeting to improve the quality of care for chronic kidney disease patients (CKD) a non-surgical creation of native arteriovenous fistulae (AVF) with potentially cosmetic advantages, was offered for CKD patients in Dubai. The procedure started in January 2021 and the follow up continued till January 2023. The goal of this report is to share the original first experience in Dubai for this technique using 4F WavelinQ EndoAVF System.

Method: Fourteen patients underwent sonographic vascular mapping for endovascular AVF creation using 4F WavelinQ EndoAVF System. Nine patients were deemed suitable for Endovascular AVF creation and underwent the procedure under regional anaesthesia. Concomitant ulnar artery and ulnar vein or the concomitant radial artery and radial vein was used for the procedure.

Results: In this case series, the patients have a mean age of 53 ± 17 years, majority of the cases were men (77.8%). All cases were hypertensives (100%) with 2 cases (22.2%) have biopsy proven Glomerulonephritis and 5 cases (55.5%) were diabetics. The technique succeeded (defined by blood flow from used artery to concomitant deep vein and through perforator vein to superficial vein) in all patients (100%). Maturation success (defined as estimated fistula flow rates exceeded 500 mL/min and access vessel diameter was more than 4 mm) with multiple venous outflows was achieved in 8 cases (88.1%). One case (11.1%) showed primary maturation failure. Five cases (55.5%) achieved successful cannulation with excellent blood flow and reliable arterial and venous pressure during dialysis. Time to maturation was 35 ± 17 days and time to successful cannulation averaged 63 ± 45 days. Among patients achieving maturation success, one patient requested AVF closure (using coil embolization) due to mild to moderate upper limb oedema that required reintervention, one case underwent pre-emptive kidney transplantation and did not require to use the AVF and one patient refused using the AVF. In our study 3 cases (33.3%) required reintervention to facilitate maturation. It worth mention that among the 3 cases underwent reintervention, one case requested closure of the fistula and one case refused to use the fistula and only one case of the successful cannulation group underwent single reintervention.

Conclusion: In our limited experience, AVF creation using Endovascular technique resulted in dependable haemodialysis access with reliable maturation time, achieving excellent patency in the successful cannulation group with high blood flow rate and accepted arterial and venous pressure during dialysis. It also showed that the procedure was safe with better cosmetic shape and no scars. However more studies with bigger sample size are needed for better evaluation of the technique and to confirm the endovascular AVF creation proper position in the guidelines for vascular access creation in haemodialysis.
Background and Aims: Central tunnelled catheter (CVC)-related infections are a leading cause of catheter lost and being the source of significant morbidity and mortality of end stage kidneys disease (ESKD) patients. The study aimed to evaluate the impact of the implementation of the own REDS/MEWS scale for combined assessment of ESKD patients dialyzed with the CTC on the frequency of infective complication.

Method: A group of 52 ESKD patients dialysed through a CTC were evaluated, pre-dialysis on every session, using the REDS/MEWS scale for 24 months years and results as well as follow up of participants were compared with a two years period of time before the tool was introduced.

Figure 1: REDS/MEWS scale chart (sample).
MEWS – modified early warning score, CTC – central tunnelled catheter.
Results: Two-years cumulative incidence of CTC exit site infection (ESI) has dropped significantly (log-rank \( p < 0.001 \)) from 0.87 episode per 1000 catheter days (52.3%, CI95 [34.2%; 67.3%]) in time before REDS/MEWS was used to 0.28 episode per 1000 catheter days (19.3%, CI95 [7.3%; 30.1%]) in REDS/MEWS time. There were also significantly less episodes of ESI complicated with catheter related blood stream infection (CRBSI) requiring CTC removal (0.8 episode per 1000 catheter days; 20.6%, CI95 [8.4%; 33.2%]) vs. 0.4 episode per 1000 catheter days; 5.4%, CI95 [1.1; 8.7%]; log-rank \( p = 0.05 \), in pre – REDS and REDS time respectively. There was no serious complications as infective endocarditis, vertebral disc abscess among patients due to early detection and treatment of possible CTC related infection.

Conclusion: The REDS/MEWS scale appears to be a simple, cost-effective tool reducing frequency of the CTC related infective complication and the type of vascular access loss.

#6934

INFLAMMATORY STATUS PRIOR TO THE CREATION OF ARTERIOVENOUS FISTULAS FOR HEMODIALYSIS: IS IT DETERMINING?

Luis Guillermo Piccone Saponara1, Nancy Giovanna Uribe Heredia2, Guillermo Ferrer García3, Gloria García Conejo1, Roger Abdurrahman Cox Conforme3, Eliana Olazo Gutierrez3, Maria Paz Castro Fernández3, Sara Anaya Fernandez3, Agustin Carreno1 and María Del Carmen Vozmediano Poyatos3

1Ciudad Real, Spain, 2Spain and 3Spain

Background and Aims: Clinical practice guidelines recommend an arteriovenous fistula (AVIF) as the preferred vascular access for hemodialysis and is associated with a lower incidence of morbidity and mortality. However, primary vascular access (VA) failure is not uncommon. Low-grade inflammation is present in ERCT. We identified the inflammatory parameters that influence the primary patency of the vascular access for hemodialysis.

Method: Cross-sectional study; We included all VAs made between October 2009 and April 2022. We evaluated the initial performance after the creation of the VAs. Demographic variables (age, sex), CKD etiology, and associated comorbidity were collected. Statistical analysis with SPSS 25.0. Categorical variables are expressed as percentages and compared using the Chi2 test. Quantitative variables are expressed as mean ± standard deviation and the t-student test was used to compare them. Statistical significance for a value of \( p<0.05 \).

Results: 712 VA performed in 546 patients were reviewed between October 2009 and April 2022. 617 autologous VA (86.7%) and 95 prosthetic VA (13.3%) were performed. The mean age of the patients was 65.4 ± 14.1 years and 67.4% were male. The most frequent etiology of CKD was diabetic nephropathy (30.5%), followed by unknown (17.3%) and glomerulonephritis (16.4%). 91.4% of the patients presented arterial hypertension (HTA), diabetes mellitus (DM) 47.5%. 72.6% of the VA presented primary permeability. In the univariate analysis using Chi2 and T student, AHT (p<0.001), treatment with statins (p<0.001), antaggregation (p<0.001), normal fibrinogen levels (p = 0.003), and CRP (p<0.001) reached statistical significance. = 0.039. When recoding the PCR in relation to its normal values, the pathological levels were associated with primary failure after the creation of AVFs.

Conclusion: In our study, inflammatory states with elevated CRP and ferritin were associated with primary failure in initial functioning after the creation of AVFs. On the contrary, arterial hypertension and treatment with statins prior to the creation of AVFs are associated with their primary permeability.

#6572

FLUORINATED GRAPHENE REDUCES PLATELET ACTIVATION AND ADHESION ON HEMODIALYSIS CATHETER

Chen Liu1, Zhuang Liu4, Ling Zhang1 and Ping Fu1,3

1Kidney Research Institute, West China Hospital of Sichuan University, Department of Nephrology, Chengdu, P.R. China, 2School of Chemical Engineering, Sichuan University, Chengdu, P.R. China and 3Kidney Research Institute, West China Hospital of Sichuan University, Department of Nephrology, Chengdu, P.R. China

Background and Aims: Catheter thrombosis remains one of the major complications of hemodialysis. Superhydrophobic surfaces are suggested to be capable of creating an energy barrier that prevents cells and proteins from contacting with the catheter surface directly, making catheter less thrombotic. Fluorinated graphene (FG) is a superhydrophobic material. It has been applied to create self-cleaning surfaces. It also shows good biocompatibility. Based on these features of FG, we prepared an FG coating on hemodialysis catheter attempting to reduce clinical thrombotic events.

Method: FG suspension was made in a solution of 95 wt.% ethanol, 5 wt.% deionized water and 3 wt.% 1H,1H,2H,2H-Perfluorooctyltriethoxysilane (POTS, C14H15F17O3Si). Immediately following the plasma activation, catheter segments of 1 cm\(^2\)(Gamcat, GDHK1325) were spray coated with FG suspension both inside and outside the catheter lumen. Samples were air-dried for later use. We tested the hemolysis rate, platelet activation and adhesion performances, and the partial thromboplastin time (PTT) of the FG-coated samples. Test for hemolysis was performed with FG-coated catheter and the isotonic extract of the FG coating in direct contact with fresh rabbit blood respectively. Platelet activation and adhesion was performed according to the ASTM F2388-19 standard and also assessed by scanning electron microscope. PTT assay was performed according to the ASTM F2382-18 standard.

Results: FG-coated catheter is hydrophobic and shows a water contact angle of 150° (Figure 1a). It reduced 83.5% of platelet adhesion per 100 μm\(^2\) catheter surface area and avoided 53.86% of platelet loss from the blood when compared to uncoated catheter (Figure 1b, 1c). It has a hemolysis rate of less than 2% in both direct blood contact test and the extract test (Figure 1d). The PTT of FG-coated sample was 88.92±1.31s versus 83.03±4.94s of the uncoated catheter yet with no statistical significance (P>0.05) (Figure 1e).

Conclusion: FG coating has great hemocompatibility. Though no significant improvement was observed in the PTT assay, FG coating still significantly reduced the adherent and activated platelet on catheter, which seems promising to reduce thrombotic events. Yet, more tests needed to be performed, and the antithrombotic ability of FG coating in the fluid state needs to be further confirmed in the following study.
The effect of acupressure applied to different fistula area on fistule needle entry pain

Gülay Turgay1, Banu Çevik2, İşılay İnanoğlu3 and Semiha Kaya4

1Baskent University, Turkey, 2Baskent University Hospital, Turkey, 3Baskent University, Turkey and 4Baskent University Hospital, Turkey

Background and Aims: This study was conducted to determine the effectiveness of acupressure application on Hegu point on the severity of acute pain caused by fistula needle in patients with brescia-cimino, snuff-box and antecubital fistula.

Method: This study was randomized control study which was conducted with 66 intervention and 65 control participants, recruited from a dialysis centre of a foundation university in Turkey between October 2021 and February 2022. Simple randomization was used for sample selection in the study. The participants in the intervention group were divided into 3 groups according to the fistula area. The first group was consisted of participants with brescia-cimino fistula, the second group was consisted of participants with snuff-box fistula, and the third group was consisted of participants with antecubital fistula. The of all 22 participants were assigned to each group in the intervention group. Acupressure was applied 3 minute before needle placement in the fistula area of the participants in the intervention group. No intervention was made in the control group in the study. Data were collected using Descriptive Information Form and pain scale (Numeric Analog Scale-NRS). NRS was used to determine the severity of acute pain experienced by patients during fistula needle insertion. Since the data of the study showed normal distribution, the data were analyzed with parametric tests. The independent sample t-test was used to examine the homogeneity of the data between the two groups. Spearman correlation analyses were used to compare categorical variables. Statistical significance was assumed at p < 0.05.

Results: In the study, the groups are similar to each other (p>0.05). In the study, the mean age of the participants in the intervention group was 60.50±15.19, and 40.9% of them were in the 61-75 age group. The mean duration of hemodialysis was 7.31±3.31 (min:1-max:20). Of the participants, 43.9% had antecubital, 33.3% had a brescia-cimino fistula and 27.7% had a snuff-box fistula. The mean age of the participants in the control group was 60.84±15.34 years, and 33.8% of them were in the 61-75 age group. The mean duration of hemodialysis was 7.27±4.29 (min:1-max:20). 35.4% of the participants had antecubital, 30.8% had brescia-cimino fistula and 33.8% had snuff-box fistula. While there was no decrease in the severity of acute pain during fistula needle insertion in the participants in the control group, a significant decrease was found in the mean acute pain severity scores experienced by the patients in the intervention group, where acupressure was applied to the Hegu (LI4) acupuncture point (p<0.05, Table 1). In the study, there was a difference within the groups in terms of the mean acute pain severity scores of different fistula areas in the intervention group but, there was no difference in acute pain severity scores between the groups in three different fistula areas.

Conclusion: The results of this study support that acupressure applied to the Hegu acupuncture point was effective in reducing acute pain at fistula needle insertion in different dialysis fistula area. In addition, the results of the study provide a practical and cost-effective reference for dialysis nurses in acute pain management.
Table 1: Distribution of NRS pain scores in each three session follow-ups of the participants in the intervention and control groups (n = 131).

THE USE OF FAR INFRARED LIGHT DURING HEMODIALYSIS SEEMS TO MAINTAIN ARTERIOVENOUS FISTULA BLOOD FLOW BETTER THAN USING A HEAT PAD - A PILOT STUDY

Anna Vb Wärme1, Björn Peters2,3, Salmin Nasic4 and Bernd Stegmayr5

1Institute of Medicine, Department of Internal Medicine and Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Skövde, Sweden, 2Skaraborg Hospital, Nephrology, Skövde, Sweden, 3Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Department of Molecular and Clinical Medicine, Gothenburg, Sweden, 4Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Department of Molecular and Clinical Medicine, Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Skövde, Sweden, 5Skaraborg Hospital, Research and Development Center, Skövde, Sweden and 6Department of Public Health and Clinical Medicine, Umeå University, Umeå, Sweden

Background and Aims: The use of the native arteriovenous fistula (AVF) in chronic hemodialysis (HD) patients yields great challenges to keep a patent AVF, especially among those with diabetes mellitus and cardiovascular disease. Often repeated radiological interventions or surgery of the AVF is necessary. Accumulation of advanced glycation end products (AGE) in tissue is shown to contribute to the complications of diabetes mellitus and uremia [1]. Far infrared light (FIR) irradiation of the AVF have shown protective effects in maintaining AVF blood flow [2,3]. Using a heat pad (HP) to stimulate vascular flow is another alternative. Primary aim of the study was to compare if the use of a HP is as good as FIR to maintain AVF blood flow. Secondary aim: Evaluate change in AGE accumulation in tissue after FIR and HP treatment.

Method: This pilot study included HD patients with a native lower arm AVF. Eighteen patients were randomly assigned to treatment during HD: Ten patients to FIR and another group of eight patients to use HP (Two of the HP-patients refused to fulfill the study). Before and after a period of 15 HD treatments each, blood tests, AVF blood-flow measured with a Transonic® were performed. FIR-exposure during 15 HD treatments was better maintained among patients treated with FIR than with HP SAF as a predictor for atherosclerosis was not changed. Long-term exposure to FIR may be necessary.

GENDER DIFFERENCES IN VASCULAR ACCESS FOR INCIDENT HAEMODIALYSIS PATIENTS: A REGISTRY-BASED STUDY

Ramon Roca-Tey1, Jordi Comas2 and Jaume Tort2

1Hospital Universitari Mollet, Fundación Sanitària Mollet, Department of Nephrology, Mollet del Vallés, Barcelona, Spain and 2Organització Catalana de Transplantaments (OCATT), Health Department Generalitat of Catalonia, Registr de Malals Renals de Catalunya (RMRC), Barcelona, Spain

Background: Gender disparities of some aspects of vascular access (VA) for haemodialysis (HD) have been reported. Aims: To analyze the VA profile of incident HD patients (pts) depending on gender in Catalonia.

Method: Data from the Catalan Renal Registry of 22,859 end-stage kidney disease (ESKD) pts older than 18 years of age starting HD therapy was examined over a 24-year period (1997-2021). Results: Male (n = 14,921) and female (n = 8038) characteristics were different regarding age (66.2±14.2 vs 67.2±14.4 years), normal functional status (40.2% vs 33.2%), cardiovascular disease (58.3% vs 48%) and obesity rate (body mass index BMI 30 kg/m²; 16.1% vs 25.7%) (for all comparisons, p<0.001). The distribution of the first VA used for starting HD was different in men vs women: fistulae AVF (46.1%, n = 6308 vs 41.3%, n = 3088), graft AVG (0.8%, n = 108 vs 1.7%, n = 129) and tunnelled catheter (20.4%, n = 2789 vs 23%, n = 1719) (for all comparisons, p<0.001); without differences for non-tunnelled catheter (32.8%, n = 4488 vs 34%, n = 2537) (p = 0.083). Percentage of both men and women starting HD by AVF it decreased progressively from 1997 (53.4% and 41.8%, respectively) to 2021 (37.3% and 33.2%, respectively) (p<0.001 and p=0.032, respectively). Percentage of incident men with AVF: it was higher than women in 1997 (53.4% vs 41.8%, p = 0.002) but this difference decreased over time and was no longer significant in 2021 (37.3% vs 33.2%, p = 0.22). Probability of starting HD by AVF: it was independently associated with male gender (odds ratio 1.32 [95% confidence interval: 1.23–1.41], p<0.001) after adjusting for age, primary kidney disease, functional status, BMI, cardiovascular disease and ESKD presentation (multivariate logistic regression analysis). By using a competing risk model, the hazard ratio (HR) for receiving a kidney graft (KG) within five years from starting HD, depending...
on the first VA used to start HD (AVF vs catheter), was: 1.82 (95% CI: 1.69-1.95, p < 0.001) for men and 2.32 (95% CI: 2.11-2.55, p < 0.001) for women. In comparison with men that started HD by AVF, the HR of women for receiving a KG within five years from starting HD by AVF was 1.12 (95% CI: 1.04-1.21, p = 0.002). In comparison with women that started HD by catheter, the HR of men for receiving a KG within five years from starting HD by catheter was 1.13 (95% CI: 1.03-1.24, p = 0.007). The HR of death within five years from starting HD, depending on the first VA used to start HD (catheter vs AVF), was: 1.55 (95% CI: 1.47-1.63, p < 0.001) for men and 1.95 (95% CI: 1.81-2.11, p < 0.001) for women. In comparison with men that started HD by catheter, the HR of death for women within five years from starting HD by catheter was 1.01 (95% CI: 0.95-1.06, p = 0.81). In comparison with women that started HD by AVF, the HR of death for men within five years from starting HD by AVF was 1.26 (95% CI: 1.17-1.36, p < 0.001).

Conclusions: 1) Although AVF was the main type of VA used for starting HD in both sexes, the percentage of AVF was significantly lower in women at the expense of AV and tunneled catheter. 2) Male gender was an independent factor associated with a 32% greater probability of starting HD by AVF than female. 3) Women initiating HD by AVF were more likely to receive a KG over time than men with an AVF. 4) Men and women shared the same probability to die over time after starting HD with a catheter. 5) Men starting HD by AVF were more likely to die over time than women with an AVF. 6) Regardless of gender, initiating HD by catheter was associated with a lower probability of receiving a KG and a higher probability of dying over time compared to AVF.

HOSPITAL MANAGEMENT OF AN INTEGRATED CLINICAL PRACTICE UNIT OF VASCULAR ACCESS FOR HEMODIALYSIS: A CHALLENGE FOR IMPROVING HEALTHCARE QUALITY?

Vicent Esteve Simó, Elisabeth González Lao, Àngels Esquerra Allué, Irati Tapia González, Sara Ibáñez Pallares, Sandra Rubió and Manel Ramírez de Arellano Serna

1. Consorci Sanitari Terrassa, Functional Unit Vascular Access (FUVA), Nephrology Department, Spain, 2. Consorci Sanitari Terrassa, Quality of Care and Patient Safety Department, Spain, 3. Consorci Sanitari Terrassa, Control Management and Analysis Information, Spain, 4. Consorci Sanitari Terrassa, Functional Unit Vascular Access (FUVA), Vascular Surgery Department, Spain and 5. Consorci Sanitari Terrassa, Nephrology Department, Spain

Background and Aims: Vascular access (VA) for haemodialysis (HD) is essential for renal patients due to its high morbimortality and economic cost. Integrated Clinical Practice Units (ICPU) allows health organizations to establish comprehensive care, improve the quality and safety of care processes, as well as favor the accessibility of health care. The VA multidisciplinary teams for HD are crucial in the proper management of VA, although their implementation in daily clinical practice is not fully consolidated. The aim of this study was to analyze the effectiveness of the healthcare processes in patients with VA for HD after the creation of our ICPU focused in the multidisciplinary management of the VA (FUVA) through quality of care indicators.

Method: 12 years retrospective uncinicentric study analyzed in two periods: first period (2010-2015) and second period (2016-22) after FUVA creation. The indicators include sociodemographic data, processes activities (first and successive visits, endovascular procedures, type and number of surgical interventions, delayed time for interventions, mean hospitalisation stay, and successive visits, endovascular procedures, type and number of surgical interventions). The local Ethics and Research Committee has approved the conduct of the retrospective study. In this study, the definition of a CRBSI is taken from Kidney Disease Outcomes Quality Initiative (KDOQI) Vascular Access-2019 update as 1) clinical manifestations (fever ≥ 37.5°C or rigors or presence of clinical signs of infection); 2) confirmation of bacteremia (blood cultures growing the same organism from the dialysis catheter and a peripheral vein), with either positive semiquantitative (>15CFU/catheter segment), or quantitative (>10^6 CFU/catheter segment), differential period of catheter culture versus peripheral blood culture (BC) positivity of 2 hours; 3) exclusion of another source of infection. Information including patient demographics, causes of kidney failure, and duration of TDC was obtained.

METICULOUS CATHETER CARE CAN REDUCE CATHETER-RELATED BLOODSTREAM INFECTIONS SIGNIFICANTLY IN HEMODIALYSIS PATIENTS – A 5-YEAR SINGLE CENTRE STUDY

Yanfen Ma1, Quizhen Tan1, Shaofang Xian1, Weichu Yao1,2, Gang Wang1, Liwen Cui1 and Ming-Chu Pearl Pai1,2

1. The University of Hong Kong-Shenzhen Hospital, P.R. China, 2. Shenzhen University Health Science Center, Medicine, Shen Zhen, P.R. China and 3. The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, P.R. China

Background and Aims: The use of central venous catheters as hemodialysis (HD) vascular access is a leading contributor to a high rate of bloodstream infection. Our dialysis unit in China has followed the China National Infection Control Policy for HD unit as well as developed its own specific dialysis catheter care protocol using the Centre for Disease Control and Prevention (CDC) guidelines as a template. By doing so, our HD unit has achieved a tunnelled catheter death rate of 0.0229 per 1000 catheter days in the past 5 years. This report, aims to share our experience with the other units.

Method: We have undertaken a retrospective analysis to determine our catheter-related bloodstream infection (CRBSI) rate, The Local Ethics and Research Committee has approved the conduct of the retrospective study. In this study, the definition of a CRBSI is taken from Kidney Disease Outcomes Quality Initiative (KDOQI) Vascular Access-2019 update as 1) clinical manifestations (fever ≥ 37.5°C or rigors or presence of clinical signs of infection); 2) confirmation of bacteremia (blood cultures growing the same organism from the dialysis catheter and a peripheral vein), with either positive semiquantitative (>15CFU/catheter segment), or quantitative (>10^6 CFU/catheter segment), differential period of catheter culture versus peripheral blood culture (BC) positivity of 2 hours; 3) exclusion of another source of infection. Information including patient demographics, causes of kidney failure, and duration of TDC was obtained.
Results: The Covidien Palindrome chronic catheters have been used in the majority of our patients during the study period. All tunnelled dialysis catheters were placed by the nephrologists under radiological guidance in the Hospital’s sterile Digital Subtraction Angiography (DSA) Suite. In the study period (2017-2021), an average of 235 prevalent patients were receiving dialysis in the HD unit. A total of 212 tunnelled dialysis catheters have been inserted and managed according to our local dialysis access pathway and catheter care protocol. The TDC days have been calculated by adding all the catheter days until the catheters have been removed or the patients have been transferred out of our HD unit. There was a total of 43,585 catheter days. The average waiting time for arteriovenous fistula (AVF) surgery was two weeks. The mean duration of TDC use was 107.8±14.8 days, range 1-1827 days. The incidence of confirmed tunnelled CRBSI was 0.0229/1000 catheter days.

Conclusion: Our local catheter care protocol is similar to the CDC's “scrub-the-hub” protocol. 2% chlorhexidine with 70% alcohol has been used for the scrubbing and disinfection but we have a few additional steps. In our practice, great attention is given to the cleansing of the clamps. 1) Prior to removal of the caps, the clamps are opened and the surroundings are cleaned and disinfected thoroughly. 2) Two nurses are assigned to connect the bloodlines to the hubs, hence the risk of hub contamination is reduced. 3) The point of connection between the hubs and the bloodlines is protected with a gauze dressing in 3 layers during the entire duration of the dialysis. We believe our success with a very low rate of CRBSI has been the result of strict adherence to 1) good and general hygiene, 2) a well-designed dialysis catheter care protocol, 3) good use of a vascular access nurse, 4) short-duration of TDC days, and 5) short waiting time for AVF. Limitations: We may have underestimated the true rate of CRBSI because of the inherent nature of the diagnostic criteria as mentioned above. Although it is unlikely that a blood culture would have been missed before the onset of symptoms, we cannot exclude the possibility that asymptomatic bacteria may have been present before the onset of symptoms. In conclusion, we believe our success with a very low rate of CRBSI has been the result of strict adherence to 1) good and general hygiene, 2) a well-designed dialysis catheter care protocol, 3) good use of a vascular access nurse, 4) short-duration of TDC days, and 5) short waiting time for AVF.

Method: Prospective analysis of all adult patients with CKD who were referred for VM, at a tertiary center, between March 2021 and August 2021. No patients were excluded. Preoperative DUS by a single experienced nephrologist was carried out. HGS was measured using a Hand Dynamometer and PAD was defined as ABI<0.9. According to distal vasculature size (<2mm) sub-groups were analyzed.

Results: 80 patients were included and 67.5% were male, mean age 65.7±14.7 years and 51% were on Renal Replacement Therapy (RRT). Twelve (15%) participants had PAD. HGS was higher in dominant arm (20.5±12.0 kg vs 18.8±11.2 kg). Fifty-eight (72.5%) patients had vessels smaller than 2 mm in diameter. There were no significant differences between groups concerning demographic and comorbidities (diabetes, PAD). HGS was significantly higher in patients who had vessels greater than or equal to 2 mm in diameter (26.1±15.5 kg vs 18.4±9.7 kg, p = 0.010).

Conclusion: Greater HGS was associated with more developed distal vessels. Low HGS might be an indirect sign of poor vascular characteristics, which might help predict the outcomes of VA creation and maturation.

ULTRASOUND-GUIDED RIGHT INTERNAL JUGULAR TUNNELED CATHETER INSERTION FOR HAEMODIALYSIS: PRACTICES AND OUTCOMES FROM A SINGLE CENTRE
Chittesh Ramgobin, Bilal Khurshid, Sharmilee Renganarajan, Adele Green, Dimitrios Poullakos, Maharajan Raman, David New, David Lewis and Rajkumar Chinnadurai
Salford Royal Infirmary, Northern Care Alliance Foundation Trust, Department of Renal Medicine, Salford, United Kingdom

Background and Aims: Internal jugular vein tunnelled catheters are important vascular access for haemodialysis (HD). In our practice, Left-sided internal jugular (IJ) catheter insertion is performed in radiology under direct X-ray screening. Most right-side internal jugular (RIJ) catheters are inserted under ultrasound guidance in dedicated renal procedure rooms. Vascular access can become challenging with the potential for venous stenosis and thrombosis with catheter use. The aims of this study are to evaluate our practices and outcomes of non-radiologically inserted RIJ tunnelled HD catheters and to investigate the predictors of procedure failure.

Method: 200 successive RIJ tunnel HD catheters inserted from June 2016 under ultrasound guidance at our centre were included in this analysis. Data including demographics, co-morbidities, first or higher order insertion, outcome (success or failed attempt), and immediate complications were collated from electronic patient records. Binary logistic regression analysis was conducted to investigate the predictor for failure in catheter insertion.

Results: Of the 200 patients, 152 (76%) were first-time insertions and 48 (24%) were second or higher order insertions. The median age of our cohort was 58 years, with a predominance of males (68%) and white ethnicity (82%). 36.5% were diabetic, with 37.5% having a history of cardiovascular disease. Nearly 30% of patients were on an antplatelet agent, and 8% were on anticoagulants, which were appropriately managed before line insertion. Pre-operative median haemoglobin was 93 g/dl, with clotting screen and platelet counts in the target range. There was a statistically significant difference in the success of insertion, depending on the insertion being first or subsequent (96.1% vs 81.2%; p = 0.001). The reason for failure in insertion included on-table observation of a small calibre vein on ultrasound or failure to thread wire/dilator due to possible stenosis or thromboses. All line rewire (12/48) procedures were performed successfully. Immediate complication (<1 week) was recorded in 9% of patients, predominantly tunnel bleeding (n = 7) and malposition (deep or high; n = 7) (Table 1). Second or higher-order RIJ catheter insertion showed a higher risk for failure in a multivariable binary logistic regression analysis. (OR: 6.4; CI: 2.1-20.5; P = 0.002) (Figure 1). Of the higher-order insertions, the longer duration between the first and subsequent catheters showed a higher risk for failure (OR:1.19; CI:1.04-1.4; p = 0.010).

Conclusion: Second or higher-order catheter insertions with a longer duration between the first and the subsequent insertion carry a significant risk of failure due to vein stenosis and thrombosis. Therefore, a careful case-to-case triaging of patients based on previous access history is warranted before listing patients for routine ultrasound-guided insertion.

#3866
PREOPERATIVE ASSESSMENT FOR VASCULAR ACCESS: VASCULAR MAPPING AND HANDGRIPT STRENGTH
João Fortes, Bernardo Marques Da Silva, João Fernandes, Hugo Silva, Alice Fortes, José António Lopes and Joana Gameiro
Portugal

Background and Aims: A reliable vascular access (VA) is required for patients receiving chronic haemodialysis (HD) treatment. VA choice is complex and must consider patient characteristics, predicted patency and risk of primary failure. Vascular mapping (VM) by duplex doppler ultrasonography (DUS) can aid in the planning of which VA to place. Peripheral artery disease (PAD) is associated with higher AVF failure and can be assessed by calculating the ankle-brachial index (ABI). Muscle strength is independently associated with mortality risk and can be evaluated with handgrip strength (HGS). This study aims to describe and analyze clinical anthropometric and laboratory characteristics of patients referred for vascular mapping prior to VA creation and to correlate VM data, HGS, and ABI.

Method: Prospective analysis of all adult patients with CKD who were referred for VM, at a tertiary center, between March 2021 and August 2021. No patients were excluded. Preoperative DUS by a single experienced nephrologist was carried out. HGS was measured using a Hand Dynamometer and PAD was defined as ABI<0.9. According to distal vasculature size (<2mm) sub-groups were analyzed.

Results: 80 patients were included and 67.5% were male, mean age 65.7±14.7 years and 51% were on Renal Replacement Therapy (RRT). Twelve (15%) participants had PAD. HGS was higher in dominant arm (20.5±12.0 kg vs 18.8±11.2 kg). Fifty-eight (72.5%) patients had vessels smaller than 2 mm in diameter. There were no significant differences between groups concerning demographic and comorbidities (diabetes, PAD). HGS was significantly higher in patients who had vessels greater than or equal to 2 mm in diameter (26.1±15.5 kg vs 18.4±9.7 kg, p = 0.010).

Conclusion: Greater HGS was associated with more developed distal vessels. Low HGS might be an indirect sign of poor vascular characteristics, which might help predict the outcomes of VA creation and maturation.

NEPHROFLOW FOR ESTIMATION OF VASCULAR ACCESS FLOW FOR HEMODIALYSIS: WHEN TO MEASURE?
Pablo Alejandro Sarduy Coronado¹, José Luis Merino Rivas², Cecilia Peña Peña², Noelia Abad², Blanca Bueno Antúnez², Beatriz Espejo Marchante², Jesús Martin-Centellas² and Vicente Paraíso²

¹Hospital Virgen de la Luz, Cuenca, Spain and ²Hospital Universitario del Henares, Coslada, Spain

Background and Aims: Current guidelines emphasize the need for surveillance of vascular access (VA) for hemodialysis (HD), especially arteriovenous fistulas (AVF). Detecting a reduction in VA flow is a useful tool to anticipate the complications of VA such as thrombosis. The DMed NephroFlow (NIPRO®) system, based on ultrasound dilution (UD) methods, has been shown to be comparable to the classic Transonic® measurement system for estimating VA flow and can be applied for VA surveillance. Our objective is to determine if there are significant differences when performing flow measurements with NephroFlow® between the first hour and the second hour of the HD session, as well as between any of the three days in which the patient attends HD.

Method: For two consecutive weeks, patients with AVF or graft (gAVF) on HD in our unit underwent VA flow measurements using the NephroFlow® system at the first and second hour of HD, on the 3 days that they attended HD sessions. Interspersing the first hour with the second each week to avoid significant loss in HD quality. For the study, we proceeded according to the usual recommendations of stable flow at 250 ml/min, corresponding ultrafiltration rate, needles in the same vein, without change in dry weight, with the same nurse staff, and transferring all patients to conventional HD.

Results: Twenty-one patients have been included, 13 male and 8 female, mean age 68±12.3 years. The mean time on HD was 36±23 months. The type of VA was: 10 patients presented a radiocephalic AVF, 5 brachiocephalic AVF, 2 patients a brachio basilic AVF, and 4 patients a gAVF. The estimated mean flow obtained by NephroFlow® in the first hour of all sessions and in the second hour was 1056±754 and 1130.16±769 ml/min, respectively; intraclass correlation index was 0.737 and K-W Test H 0.349 (p<0.05). The mean flow on the first day was 1129±794.5 ml/min, ICC = 0.662; second day 1027.5±729 ml/min, ICC = 0.812; third day 1121.5±42 ml/min, ICC = 0.774. In all cases p<0.05.
Conclusion: No significant differences have been observed in the VA flow estimated with the NephroFlow® ultrasound dilution system, neither at measurement time (the first or the second hour of HD session) nor day of performance (first, second or third day of HD session of the week). NephroFlow® UD system may be a useful tool for VA surveillance and could be applied when is necessary.

#6728
ALCOHOL LOCK FOR PROPHYLAXIS AGAINST PERMCATH CRBSI: IS IT A BOON?
Prem Varma and Mahak Singla
Primus Super Speciality Hospital, Nephrology, New Delhi, India

Background and Aims: Introduction: Catheter related blood stream infection (CRBSI) is a dreaded complication in patients with tunneled dialysis catheter and often results in catheter loss. Antibiotic lock, a preventive strategy, is not followed for fear of emergence of resistant strains. We have reported usefulness of 70% alcohol lock in cases of established CRBSI. The present study was aimed to find usefulness of alcohol lock for CRBSI prophylaxis.

Method: This is a single centre observational pilot study. Dialysis patients with Permcath as vascular access were randomised into two groups. Both groups were similar in age, sex and comorbidities. Both groups received routine heparin lock after each dialysis session. Group A in addition also received 70% alcohol lock, once a fortnight. Patients with minimum follow up of 60 days were included in the study. Diagnosis of CRBSI was made by IDSA criteria.

Results: Forty five patients with permcath were divided in Group A (29 patients) and Group B (16 patients). In Group A, 21 and in Group B, 12 patients completed the study. In Group A, during a mean follow up of 2988 catheter days, 5 patients (23%, 1/600 days) developed CRBSI (2 pseudomonas, two staphylococcus aureus and 1 Klebsiella) and in group B, 4 patients (33%) with mean follow up of 1611 catheter days (1 in 403 catheter days) developed CRBSI (p = 0.69) (2 Klebsiella, two staphylococcus). There was no case of catheter leak, crack or block in either group. Results showed a trend towards better outcome in alcohol lock group though because of small number, statistical significance couldn’t be reached.

Conclusion: This pilot study found usefulness of alcohol lock in preventing CRBSI. Alcohol lock is cheap and there was no apparent catheter damage with alcohol over 6 months period. A larger study can confirm our findings.

MONOCLONAL GAMMOPATHY AS A RISK FACTOR FOR ARTERIOVENOUS FISTULA PRIMARY FAILURE
Catarina Almeida1, João Peixoto2, Vítor Martins3, Clara Nogueira4, Susana Pereira4, Ana Ventura4 and Maria Clara Almeida1
1Centro Hospitalar Vila Nova de Gaia / Espinho, Nephrology, Portugal and 2Centro Hospitalar Vila Nova de Gaia / Espinho, Angiology and Vascular Surgery, Portugal

Background and Aims: Arteriovenous fistula (AVF) is the preferred vascular access for hemodialysis (HD) in most patients. However, postoperative complications such as primary failure (PF) with a reported incidence between 20-60% remain a major problem. Patients diagnosed with monoclonal gammopathy (MG) are at increased risk of thrombotic events, either due to the disease itself or the chemotherapy used for its treatment. The aim of this study was to evaluate whether the presence of MG was associated with primary AVF failure.

Method: We performed a retrospective single-center case-control study including 103 patients observed in our vascular access consultation for planning their first HD access. Demographic and clinical data were collected, such as the presence of diabetes, hypertension, cardiovascular disease and MG. Distal AVF was the access of choice when possible. Primary failure was defined as incapacity to use AVF for HD because of failure to mature or thrombosis. Univariate analysis was performed, and a logistic regression was applied to access predictors of PF. A p-value inferior to 0.05 indicated statistical significance.

Results: In total 14 (13.6%) patients had MG (11 multiple myeloma, 1 light-chain deposition disease, 1 proliferative glomerulonephritis with monoclonal immunoglobulin deposits and 1 amyloid light-chain amyloidosis). Regarding the AVF location, 13 patients constructed a constructed a distal AVF and 1 patient a proximal AVF. When compared to the group of 89 patients who did not have MG, there were no significance differences in sex, age, prevalence of diabetes and cardiovascular disease neither in AVF construction site. Arterial hypertension was more frequent in the group of patients without MG (93.2% versus 64.3%, p = 0.007). PF occurred in 57.1% (8/14) of patients with MG and in 27% (24/89) of those without MG (p = 0.032). In logistic regression, the presence of MG was the only predictor of primary AVF failure (OR 4.39 95% CI: 1.23-15.75).

Conclusion: In our study, we found that a patient with monoclonal gammopathy has a 4-fold increased risk for primary AVF failure comparing to the general chronic kidney disease patients. Therefore, a careful evaluation must be made when planning for AVF placement in these patients, balancing individual life’s expectancies and monoclonal gammopathy prognosis.

CATHETER-ASSOCIATED BLOODSTREAM INFECTIONS IN A HOSPITAL DIALYSIS UNIT – SEASONAL INFLUENCE AND COVID-19 PANDEMIC
Irene Galindo Marin, Carmen Mon Mon, Milagros Ortiz, Maria Sanchez, Rosa Camacho, Carolina Lentisco, Irene Oñate, Juan Carlos Herrero Berron and Aniana Oliet
Hospital Severo Ochoa, Nephrology, Spain

Background and Aims: Catheter-associated bloodstream infections (CRBSI) are an important source of morbidity and mortality among patients receiving hemodialysis through a central venous catheter (CVC). Despite of the efforts to choose the arteriovenous fistula as the first vascular access, a large proportion of end stage kidney disease population initiates dialysis using these catheters. Thus, efforts to prevent catheter-associated bloodstream infections remain important. The aim of our study is to analyze the outcomes of the episodes of CRBSI in our dialysis unit. Secondly, we evaluated the seasonal distribution
and the possible impact of infection-control measures implemented during COVID-19 pandemic.

Method: We conducted a single-center retrospective observational study of all cases of tunneled dialysis catheter-associated bacteremia that need hospitalization during a nine-year period (January 2013 – December 2022).

Results: A total of 67 episodes of catheter-associated bloodstream infections in 52 hemodialysis patients were registered. This translates into a total of 2 episodes per 1000 catheter-days. Among all patients, the mean age was 68.5 years, 74.6% were men and 25.4% women. Five patients (9.6%) had any type of immunosuppressive treatment. Nearly 88% used a tunneled jugular catheter as definite vascular access and the remainder used a femoral one. Eighteen of all episodes (26.9%) occurred during the first thirty days of catheter implantation. Ten of all patients (19.2%) suffer at least a second infection during the follow-up period, without differences in clinical and demographic characteristics. The microbial etiology of the infections were Gram-positive organisms in 67.2% and, within these, 83% were Staphylococcus Aureus. The catheter had to be removed in 65.7% of all cases and there were significant difference (p<0.01) between Gram negative infections (preservation of 70%, successfully treated with prolonged antibiotic therapy) and Gram positive ones (preservation 12%, 3 cases of S. epidermidis and 2 cases of S. Aureus due to limited vascular tree). Admission to the intensive care unit was required in five patients and there were only two cases of endocarditis as metastatic complication. There was no death related to CRBSI. About the seasonal distribution, the majority of episodes occurs in summer and spring (43.3% and 23.9% respectively), whereas in autumn and winter there were fewer cases registered (16.4% and 16.4% in both). Despite of the increasing use of CVC as definite vascular access in our dialysis unit (almost 60%), the rate of CRBSI has been declining in parallel over the years. Since 2018, we reported less than 0.5 episodes per 1000 catheter-days. Conclusion: This study shows a low frequency of CRBSI compared to previous studies. Among all episodes, the predominant infecting organism was methicillin-sensitive Staphylococcus Aureus (14.7% were methicillin-resistant). The early catheter removal, especially in aggressive strains as S. Aureus, reflects a low number of serious complications, with uncommon metastatic infections and no death directly related to CRBSI. A large proportion of infections were in summer; it may be attributable to hiring of less experienced professionals. We identified a substantial decline in rates of CRBSI coincident with COVID-19 pandemic. Nevertheless, this reduction was apparent beginning nearly two years before pandemic. This suggests that factors other than changes in infection-control practices during the pandemic are partially responsible of that.

OUTBREAK OF RALSTONIA SPP AND BURKHOLDERIA SPP CATHETER-RELATED BLOODSTREAM INFECTION IN A HAEMODIALYSIS UNIT

Mauro Valente1, Francesca Orecchioni1, Fabiana Brigante1, Maria Ilaria Moretti1, Marcello Derrico1, Marco Moretti2, Marcello Tavio1, Maria Soledad Ferreiro Cotorrelo1, Veronica Pasquali1, Massimo Marchi2 and Andrea Ranghino1

1AOU delle Marche, Nephrology, Dialysis and Renal Transplantation Unit, Ancona, Italy; 2AOU delle Marche, Laboratory Medicine, Ancona, Italy; 3Polytechnic University of the Marche Region, Department of Biomedical Sciences and Public Health, Section of Hygiene, Preventive Medicine and Public Health, Ancona, Italy; 4AOU delle Marche, Unit of Emerging and Immunosuppressed Infectious Diseases, Department of Gastroenterology and Transplantation, Ancona, Italy; 5AOU delle Marche, Health Care Medical Directory, Ancona, Italy and 6Fresenius Medical Care, Crema, Italy

Background and Aims: Ralstonia (RB) and Burkholderia (BB) species are environmental Gram-negative bacilli responsible for several nosocomial infections in immunocompromised or frail patients. RB and BB may contaminate medical devices because of their ability to survive in a biofilm and with low nutrient requests. Reports of infection outbreaks due to RB and BB are very few and only in sporadic cases, the source of contamination was identified. We describe here: i) how we managed an outbreak of bacteremia caused by RB and BB occurred in our dialysis unit, ii) what we have done to identify the source of infection and iii) the countermeasures we adopted to reduce the risk of new events.

Method: From 7 to 16 April 2021, 6 out of 39 (15.4%) hemodialyzed (HD) patients with a long-term indwelling central venous catheter (CVC) developed symptoms related to infection. Blood cultures revealed the presence of RB and BB. Thus, a prompt check of the blood cultures of all HD patients with CVC was performed. Blood samples were inoculated in an automated microbial detection system (VIRTUO BIOMERIEUX) and subsequently, blood positive samples were inoculated in Chocolate and Columbia blood Agar plates. In addition, a microbiological analysis of disinfectants, drugs used in dialysis unit and samples collected from the reverse osmosis water unit (ROW) and from the ROW delivery line were performed. None of the samples obtained from the ROW and from the ROW delivery line resulted positive. Thus, a microbiological analysis of the biofilm attached on the loading pipes (LP) and on the loading plastic tubes (LPT) that connect the hemodialyzer consoles (HC) to the ROW delivery line were performed. Briefly, LPT were subjected to ultrasound sonication at 30–40 KHz (BactoSonic-Bandelin), to disrupt the bacterial biofilm. The material obtained from sonication was cultured. Bacteria was identified by an automated mass spectrometry (MALDI-TOF VITEK® MS, Biomerieux).

Results: Bacteremia due to RB and BB was confirmed in 7 out of 39 (17.9%) of the hemodialyzed patients with a long-term indwelling CVC. 1 out of 7 was asymptomatic. Baseline characteristics of the 6 symptomatic patients were: mean age 68±16 years; mean C-reactive protein 4.48±1.3 mg/dl; mean procalcitonin 13.27±11.07 ng/ml; mean body temperature 37.9±1.4°C. The antibiotic therapy was decided according to antibiogram and included meropenem and ciprofloxacin. CVC were removed in all infected patients between 6 to 11 days from the diagnosis. Concomitantly, a new one was placed. None of the HD patients with arterio-venous fistulae developed bacteremia. RB and BB were isolated in the biofilm of 11 out of 37 LPT. Thus, we modified the ROW delivery line in order to set up a scheduled chemical and physical disinfections of the ROW delivery line with the hemodialysis consoles connected avoiding the risk of new contamination of the LPT and loading pipes. Briefly, on alternate months the whole system that include ROW delivery line (PE-Xa Medical Device, Fresenius Medical Care), loading pipes, LPT and hemodialysis consoles are disinfected by hot water (90°C) produced by a water heater (AquaB plus HF, Fresenius Medical Care) and by chemical disinfectant, 5% peracetic acid according to the protocols made by the console fabricant. In addition, we added to the reverse osmosis system a filtration module of 0.01 μm (Aquapor, Fresenius Medical Care) prior to the ROW delivery line. Figure 1. Awaiting for the modification of the ROW delivery line, the patients with CVC

Figure 1: Hemodialysis water treatment system scheme.
were dialyzed using a portable water treatment unit. After more than 14 months from the modification of the whole system for production and delivery of ROW none of the hemodialyzed patients developed infection by RB and BB.

**Conclusion:** Our experience suggests that infection outbreak by unusual bacteria such as RB and BB could be successful treated using antibiotic therapy. Nevertheless, in dialysis unit the source of infection should be investigated in order to adopt the countermeasures necessary to reduce the risk of new infections.

**ARTIFICIAL INTELLIGENCE APPLIED TO VASCULAR DOPPLER ULTRASOUND MODELS FOR PREDICTING UNDERDEVELOPMENT OF VASCULAR ACCESS IN NEPHROLOGY**

Alfonso Lara Ruiz, María Jesús Moyano Franco, Fernando Bertomeu Moreno, Javier Burgos Martín, Melissa Cintra and Mercedes Salguiera Lazo

Hospital Universitario Virgen Macarena, Nephrology, Sevilla, Spain

**Background and Aims:** The vascular access of choice for hemodialysis patients is the arteriovenous fistula (AVF). There is a high rate of early primary failure and loss of primary AVF patency. Monitoring of vascular access is essential for early diagnosis of complications and prolonging survival. Models based on Artificial Intelligence (AI) and Machine Learning (ML) can be used for this.

**Method:** Retrospective descriptive study of the Vascular Doppler Ultrasound (VDU) in adults carried out since January 2019 to January 2022 in our AVF follow-up nephrology clinic. We analyze the results and create AI-based AVF underdevelopment prediction models. We included clinical, demographic and ultrasound variables. Patients were undergoing AVF post-surgery follow-up (VDU by protocol at 3-4 weeks after AVF surgery) or were referred to the clinic with signs of AVF dysfunction. The insufficient development of the vascular access is established as an objective variable. SPSS 20 Statistical Package. Automated Learning Analysis (ML) with Orange ML and BigML.

**Results:** 243 VDU were performed. Of the total, 139 (57%) were follow-up post-surgical VDU per protocol and 104 (43%) were AVF dysfunction VDU. Using supervised ML Analysis techniques with random sampling of 80% of the instances for Training and 20% for Test, we obtain prediction models for the underdevelopment (UD) attribute of AVF. Decision tree algorithm, Area under the curve (AUC) 89%, Classification accuracy (CA) 90%, Precision 90%. Random Forest Algorithm (RF) (AUC) 95%, (CA) 86%, Accuracy 81%. Near Neighbor Algorithm (K-NN) (AUC) 88%, CA 82%, Accuracy 78%. Convolutional Neural Networks (NNC) (AUC) 82%, CA 74%, Accuracy 60%. Algorithm with unsupervised technique of clustering in k-Means 3 clusters are obtained. The variables that best correlate with the objective variable are access flow, vein diameter, resistance index (RI) proximal, (RI) distal, and diameter of the anastomosis.

**Conclusion:** The vascular ultrasound systematized by the nephrologist facilitates the early diagnosis of complications that lead to early intervention. Analysis of the data with techniques (ML) can facilitate early diagnosis AVF poor development requiring close monitoring or intervention. The development of a nephrology clinic for monitoring vascular access could avoid invasive and unnecessary procedures for the patient.

**EARLY EXPERIENCE OF ENDOVASCULAR CREATION OF ARTERIOVENOUS FISTULA IN SOUTHEAST ASIA**

Kok Pan Loo1, Ru Yu Tan1, Chee Woon Tan1, Tze Tec Chong1, Kiang Hiong Tay1, Hsien Tsung Tan1, Kun Da Zhuang3, Apoorva Gogna1 and Chieh Suai Tan1

1Department of Renal Medicine, Singapore General Hospital, Singapore,
2Department of Vascular Surgery, Singapore General Hospital, Singapore and
3Department of Vascular and Interventional Radiology, Singapore General Hospital

**Background and Aims:** Creation of native arteriovenous fistulae(AVF) has been traditionally through open surgical technique. Endovascular creation of AVF (EndoAVF) has been shown to be an effective alternative to open surgery in Europe and North America. In Asia, EndoAVF creation is a novel technique and we report our early experience of EndoAVF creation in a case series of 18 patients.

**Method:** Between Nov 2021 to Aug 2022, ultrasound vein mapping was performed in a total of 39 patients. Eighteen patients were deemed suitable for EndoAVF and proceed for the procedure. EndoAVF creation was attempted by multidisciplinary team comprising of vascular surgeon, interventional radiologists and nephrologists. The patients were prospectively followed-up for at least 6-months. Baseline demographics, vascular characteristics, unassisted maturation, functional patency and freedom from intervention were studied.

**Results:** Table 1 shows the baseline demographics of the participants. Twelve patients (67%) were already initiated on hemodialysis via tunneled dialysis catheters during the procedure. EndoAVF was successfully created in 16 (89%) patients. Of which, 13 (72%) were WavelinQ while the remaining 5 (28%) were Ellipsys EndoAVF. The reasons of failures were inability to cannulate artery (n = 1) and vein (n = 1). Minor complications occurred in 6 patients: extravasation in 5 cases and hematoma in 1 patient. The brachial artery flow rates at creation and 1-month post-creation were 558 ± 328 and 583 ± 215 mls/min, respectively. Two participants (11%) underwent interventions to facilitate maturation of the EndoAVF. The median time to maturation was 70 (IQR 49 – 106) days while the median time to first successful 2-needle cannulation was 77 (56 – 127) days. At 6-months, 8 (50%) of EndoAVFs that were successfully created required further intervention to maintain patency, while 1 EndoAVF was abandoned from failure to mature despite intervention.

**Conclusion:** EndoAVF can be created successfully in a Southeast Asian population. Further studies with more patients and longer follow-up periods are needed to assess long-term outcomes.

ENDOVASCULAR CREATION OF AN ARTERIOVENOUS FISTULA (ENDOAVF) FOR HEMODIALYSIS ACCESS: A RETROSPECTIVE MONOCENTRIC EXPERIENCE

Ludovica Odone1, Jacopo Gianassi1, Egrina Dervishi1, Roberta Cutruzzula1, Costanza Gaudio1, Giacomo Gabbani2, Gianmarco Falcone2, Fabrizio Fanelli2 and Calogero Cirami2

1 AOUCareggi, Nephrology Dialysis and Transplantation, Firenze, Italy and 2 AOUCareggi, Vascular and Interventional Radiology, Firenze, Italy

Background and Aims: Functioning vascular access is an essential element for life-saving hemodialysis therapy. Surgical creation of a radiocephalic arteriovenous fistula (AVF) is the gold standard of vascular access for hemodialysis. However, an endovascular approach to arteriovenous fistula creation (endoAVF) has increasingly gained acceptance over the last years as an alternative to the conventional surgical method. It offers a minimally invasive method for the formation of arteriovenous shunts and allows the creation of fistulas with minimal vessel trauma. There are currently two technologies available for this purpose, the Ellipsys Vascular Access System (Medtronic, Avenu Medical, San Juan Capistrano, Calif) and the Wavelinq endoAVF System (BD Medical, Franklin Lakes, NJ). At our centre (Careggi University Hospital, Florence), we developed an integrated service, based on a multidisciplinary approach between Interventional Radiology and Interventional Nephrology available for this purpose, the Ellipsys Vascular Access System (Medtronic, Avenu Medical, San Juan Capistrano, Calif) and the Wavelinq endoAVF System (BD Medical, Franklin Lakes, NJ). At our centre (Careggi University Hospital, Florence), we developed an integrated service, based on a multidisciplinary approach between Interventional Radiology and Interventional Nephrology for percutaneous arteriovenous fistulas utilizing both Ellipsys and Wavelinq. We describe our experience with a case series of 39 patients, showing feasibility and outcome of this treatment option.

Method: Between December 2020 and January 2023 we created an endoAVF in 39 patients. Patients were suitable for the procedure after a pre-therapeutic ultrasound vascular mapping showed adequate brachial, radial and ulnar vessels and no ipsilateral central venous stenosis. After procedure, we performed a regular clinical and ultrasound monitoring. Therefore, we collected data regarding patient characteristics, initial technical success rate, number of access lost and number of endoAVF meeting primary and secondary patency.

Results: Of the total of 39 patients treated with endoAVF, 29 (74.3%) were male, with a mean age of 60.1 ± 33.9 years. The Wavelinq procedure was performed in 32 patients (82.0%) and the Ellipsys procedure in 7 patients (17.9%). Initial technical success was achieved in 38 (97.4%) cases, while in 1 case we had a primary failure of the fistula (Figure 1). Among these 38 patients, 4 (10.5%) were lost to follow-up because of death from other causes (3 patients) and because of kidney transplantation (1 patient), while 2 other patients (5.2%) have not required hemodialysis yet. Of the remaining 32 patients, we had 2 fistulas lost because of complications and a cumulative functional patency of 93.7% (30 fistulas), with a primary patency rate of 76% (23 fistulas).

Conclusion: The endoAVF appears to be feasible and safe for the creation of arteriovenous fistula suitable for hemodialysis access. Our data show an high functional cumulative patency of the endoAVF and a good primary patency, reducing the necessity of further interventions. Furthermore, in the prevalent hemodialysis population, the minimally invasive endovascular arteriovenous fistula procedure should help improving long wait times for vascular access creation. Further studies with more patients and multicentric data are needed to assess long-term outcomes.

ALCOHOL LOCK IN CRBSI: A PANACEA

Prem Varma and Mahak Singla

Primus Super Speciality Hospital, Nephrology, New Delhi, India

Background and Aims: CRBSI is a dreaded complication of permcath, with a reported incidence of 1.1 – 5.5 episodes/1000 days. Many of these patients especially those infected with Staphylococcus aureus, Pseudomonas aeruginosa or fungal growth require catheter removal. 70% alcohol possibly breaks the biofilm in the catheter and exposes hidden bacteria to antibiotics. This study was done to find the usefulness of 70% alcohol lock in patients with established CRBSI.

Method: All dialysis patients in our centre with permcath as vascular access were the subjects of the study. All patients were given heparin lock after each dialysis session. CRBSI was diagnosed as per CDS/IDSA criteria. All patients with CRBSI in addition to antibiotics were also given 70% alcohol lock (2 ml in each port) for 3 consecutive days. Outcome of these patients in term of clinical response and need for catheter removal was studied. The catheter outcome of this group was compared with our patients (retrospective controls) who were given only antibiotics and not given alcohol lock.

Results: Over last two years 166 permcaths were placed in our institution. Eighty nine of them continued dialysis in our centre. Their total follow up period was 12028 days (30-720 days). There were 18 episodes of CRBSI in 14 of these patients (1.5 episodes per 1000 catheter days). Three of these patients (16.67%) required catheter removal, rest all improved with antibiotics and alcohol lock. Over a follow up of 150 days (30 –420 days), these patients have been doing well and there has been no episode of catheter leak or break or block. On comparing with our retrospective control of 22 patients with CRBSI, who were not given alcohol lock, 15 (68.18%) required catheter removal (P = 0.001).
Conclusion: The present study though on small numbers, shows that alcohol lock works as a boon in the setting of established CRBSI. It avoids catheter removal in majority of patients.

#3438

OUTCOME OF HEMODIALYSIS TUNNELED CUFFED CATHETER PLACEMENT BY THE NEPHROLOGIST AT THE DIALYSIS UNIT Sander Camp1,2, Dieter De Clerck1,2, Wilfried Cools1,2 and Patricia Van Der Niepen2

1UZ Brussels, Jette, Belgium and 2Vrije Universiteit Brussel Campus Jette, Jette, Belgium

Background and Aims: A large proportion of patients starts dialysis treatment with a temporary catheter which is afterwards replaced by a tunneled cuffed catheter (TCC) by the surgeon or interventional radiologist. This implies a certain dependency on the availability of the surgeon or radiologist. During this waiting time, the patient is exposed to a temporary catheter, which is accompanied by a higher risk of infection. At the UZ Brussels, until 2017 TCCs were placed at the operating room by the surgeon. In September 2017 nephrologists at the UZ Brussels started to place TCCs at the dialysis unit, without the use of fluoroscopy, to lower the time of exposure to a temporary catheter.

Method: We did a retrospective analysis of 100 patients who got a TCC placed at the dialysis unit from September 2017 until February 2021 (nephrologist group); as a control group we evaluated the last 100 patients who got a TCC by the surgeon before this period. We evaluated complications (during procedure and within the first month), catheter function during the second week and after three months, and waiting time to get a TCC. Logistic regression analysis was performed to detect differences in complication rate and catheter function. Two-way analysis of variance was performed on the log transformed waiting times.

Results: In both groups, comorbidities such as diabetes mellitus, history of cardiac surgery and presence of a pacemaker or port-a-cath at the time of catheter insertion were comparable. In both groups almost half of the patients were taking antplatelet therapy. In the nephrologist group more patients got a catheter because of AKI (32% versus 15%) and less patients had a planned admission (19% versus 42%). More patients had a TCC placement after an ICU admission (33% versus 18%) and only few of the catheter placements were replacements of in situ TCC’s (3% versus 35%). In the nephrologist group, catheters were inserted in the right (93%) and left jugular vein (7%). In the surgeon group, catheters were inserted in the right (71%) and left jugular vein (23%) and in the subclavian vein (6%). In the nephrologist group there were no failed procedures, but 2 left jugular vein catheters were not in the correct position (turning upwards in the superior vena cava). In 3 patients the carotid artery was punctured and 3 patients had a significant exit site bleeding. In the surgeon group, 3 patients had a failed procedure and 2 patients had a carotid puncture. Analysis of late complications in the nephrologist group showed a bleeding from the exit site in 8 patients, development of bacteremia in 2 patients and the neck wound opened up in 2 patients. In the surgeon group 9 patients had an exit site bleeding, 4 patients had an exit site infection, 2 patients had a bacteremia, 1 patient had a catheter cuff becoming visual at the exit site, 1 patient had a catheter dislocation, 1 patient had a vena cava superior syndrome and 1 patient had a large hematoma. The presence of AKI and the use of antplatelet therapy were found to be risk factors of getting a late complication. Getting a catheter placed by the nephrologist lowered the risk, even after correction for AKI and antplatelet therapy, with an odds ratio of 0.414 (p = 0.044). In the nephrologist group, 92% of catheters had a good early function, compared to 84% in the surgeon group. At three months, about half of the catheters were still in use. Catheter function was correct in 87% in the nephrologist group versus 77% in the surgeon group. In patients who first started with a temporary catheter, the mean waiting time to get a TCC in the nephrologist group was 1.6 days compared to 4.5 days in the surgeon group (p < 0.001). In patients who got immediately a TCC the mean waiting time was 0.6 days in the nephrologist group compared to 2.4 days in the surgeon group (p < 0.001).

Conclusion: In patients who have to start dialysis urgently, TCC’s can be placed without fluoroscopy by the nephrologist at the dialysis unit in a safe and efficient manner. This lowers the need for temporary catheters, and shortens the waiting time for getting a TCC.

#6848

DIABETES AND HEMODIALYSIS ARTERIOVENOUS ACCESS CONSTRUCTION – A RETROSPECTIVE STUDY IN A SINGLE CENTER

Catarina Marouço1, Juliana Francisa Da Costa e Silva Barbosa Damas1, Tiago Assis Pereira1, Miguel Bigotte Vieira1, Sofia Carellha2, Ana Pena2, and Cristina Jorge1

1Hospital Curry Cabral, Nephrology Department, Lisboa, Portugal and 2Hospital Curry Cabral, General Surgery, Portugal

Background and Aims: The preferred vascular access for patients with end-stage renal disease is native arteriovenous fistula (AVF). However, in some patients, given their co-morbidities, vascular access (VA) construction is not feasible. Diabetes Mellitus (DM) is described as one of the main factors associated with vascular access failure. The aim of this study is to characterize in a non-diabetic versus diabetic population the pre-surgical vascular mapping by doppler ultrasound (DUS), as well as analyze which VA could theoretically be constructed, what VA was effectively were constructed and its patency between the two groups.

Method: We present a retrospective study of a cohort of patients that were evaluated by DUS for pre-surgical planning and VA construction from 2018 to 2021. We collected demographic, clinical and DUS parameters. The feasibility for VA construction was classified in pre-surgical evaluation as possible, non-advisable or as borderline. The patency after surgery was observed until day 45.

Results: We analyzed a total of 355 patients. Almost half of the population had diabetes (n = 161, 45.4%). The demographics and clinical parameters are summarized in Table 1. Concerning pre-surgical vascular mapping, we observed that patients with diabetes had more severe calcifications than the non-diabetic group. Table 2 summarizes the doppler characteristics of right and left radial and brachial arteries in both groups. Regarding the feasibility of VA construction, the non-diabetic group was more likely to receive a radiocephalic fistula than the diabetic fistula (33% vs 23.6%, pvalue 0.12). Surprisingly, in our study the non-diabetic group had also more patients that could only sustain a prosthetic fistula (15.5% vs 12.4%, pvalue 0.41). Diabetic patients showed more likelihood to construct proximal fistulae (67.4% vs 56.8%, p = 0.06). In terms of what type of VA was effectively created, more radiocephalic fistulas were performed in the non-diabetic group (13.9% vs 7.5%, pvalue 0.17). In the diabetic group more brachiocephalic fistulas (65.6% vs 62.4%, pvalue 0.17) and more prosthetic fistulae (19.4% vs 14.4%, pvalue 0.17) were constructed.

Concerning VA patency at 45 days the diabetic group demonstrated higher rates but with no statistical significance (88.4% vs 83.2%, pvalue < 0.18). Only 2 patients in the non-diabetic group were on dialysis treatment within 45 days. The demographics and clinical parameters are summarized in Table 1. Concerning pre-surgical vascular mapping, Table 2 summarizes the doppler characteristics of right and left radial and brachial arteries in both groups. Regarding the feasibility of VA construction, the non-diabetic group was more likely to receive a radiocephalic fistula than the diabetic fistula (33% vs 23.6%, pvalue 0.12). Surprisingly, in our study the non-diabetic group had also more patients that could only sustain a prosthetic fistula (15.5% vs 12.4%, pvalue 0.41). Diabetic patients showed more likelihood to construct proximal fistulae (67.4% vs 56.8%, p = 0.06). In terms of what type of VA was effectively created, more radiocephalic fistulas were performed in the non-diabetic group (13.9% vs 7.5%, pvalue 0.17). In the diabetic group more brachiocephalic fistulas (65.6% vs 62.4%, pvalue 0.17) and more prosthetic fistulae (19.4% vs 14.4%, pvalue 0.17) were constructed.

Concerning VA patency at 45 days the diabetic group demonstrated higher rates but with no statistical significance (88.4% vs 83.2%, pvalue < 0.18). Only 2 patients in the non-diabetic group were on dialysis treatment within 45 days.

arterial hypertension, showed to be predictive for VA patency, in the univariate and multivariate analysis that included age, sex, diabetes and ethnicity (OR 0.3, p-value <0.09 and OR 0.32, p-value <0.019 respectively).

Conclusion: We found that diabetic patients had significantly more comorbidities (older age, obesity and peripheral artery disease). Regarding the construction of a VA, in diabetic patients there was a lower probability of creating a radiophlebic fistula but a similar possibility of constructing a proximal fistula. Besides that, after VA construction, no differences were found between the two groups in terms of vascular patency. Although diabetic status reduced the probability for radiophlebic fistulas, once VA construction was successful no differences in VA survival at 45 days was verified.

#5737
THE ASSOCIATION OF SERUM IRISIN WITH EARLY PATENCY LOSS OF ARTERIOVENOUS FISTULA
Xiejia Li, Hong Wu, Zheng Li, Lingzi Yang and Hong Liu
The 2nd Xiangya Hospital of Central South University, Department of Nephrology, Changsha, P.R. China

Background and Aims: In patients receiving hemodialysis (HD), arteriovenous fistula (AVF) is the preferred form of vascular access owing to its long-term patency and low risk of infection. Early patency loss of AVF (<1 year) is associated with higher risk of mortality and morbidity. Irisin is thought to play a protective role in the regulation of endothelial function and vascular calcification. However, the relationship between serum irisin level and early patency loss of AVF is unclear.

Method: In 73 end-stage kidney disease (ESKD) patients, including pre-dialysis patients who receive AVF placement for the first time (n = 10), HD patients with early patency loss of AVF (n = 24), HD patients that lose AVF function more than 1 year (n = 39), fasting (>8 hours) serum irisin levels and other biochemical parameters (hemoglobin, serum albumin, calcium, phosphate, intact parathyroid hormone, triglyceride, total cholesterol, D-dimer, fibrinogen, FGF23, C-reactive protein) were measured before receiving placement or after AVF thrombosis. All patients had radial-cephalic fistula.

Results: Among 73 patients (median age 58 years, 60.3% male, 31.5% diabetes mellitus (DM)), patients with early patency loss of AVF had significantly higher serum irisin levels compared with pre-dialysis patients and HD patients whose AVF patency maintained more than 1 year. The increase of irisin may be related to its putative role in compensatory mechanisms against vascular injury, which is then lost with longer dialysis duration and aggravated vascular damage.

**D3 - EPIDEMIOLOGY & OUTCOME**

#2559
**THE EFFECT OF INTRADIALYTIC EXERCISE ON CARDIAC OUTCOMES IN HEMODIALYSIS PATIENTS**

Mei Huang1, Aiili LV2, Honghong LV3, Feng Yang3, Yan Li1, Yan Hua1 and Chunping Ni1

1Air Force Medical University, School of Nursing, P.R. China, 2Xi’an Jiaotong University, Health Science Center, P.R. China and 3Second Affiliated Hospital of Air Force Medical University, P.R. China

**Background and Aims:** Cardiovascular disease is the main cause of death of hemodialysis patients, accounting for 42% of all deaths. Because exercise can reduce many risk factors of cardiovascular disease in these patients, we observed the effect of intradialytic exercise on left ventricular structure and function.

**Method:** A randomized controlled trial was used. Participants were randomly divided into control group and exercise group. Among them, the exercise group carried out intradialytic aerobic and resistance exercise for 3 months, 5-6 times every two weeks, according to their dialysis frequency. The left ventricular end-diastolic volume, mass and ejection fraction were measured by echocardiography before and 12 weeks after the intervention. (ClinicalTrial registration number: NCT05718765).

**Results:** At first, 60 people were recruited and completed the baseline assessment (30 people in each group). The average age of patients in the intervention group was 47.81-11.76 years old, and the average hemodialysis vintage was 17.23-3.09 months. There were 18 men in total. The average age of patients in the control group was 48.56-16.83 years old, and the average hemodialysis period was 17.67-2.83 months. There were 25 men in total. Before the intervention, the two groups of patient indicators were balanced, and the difference was not statistically significant (P>0.05). Finally, 53 patients completed the trial protocol (27 control group and 26 exercise group). After 3 months of intervention, there were significant differences in left ventricular mass, left ventricular end diastolic volume and left ventricular ejection fraction between the two groups (P<0.05). Moreover, the cardiac outcomes of the intervention group were lower than those of the control group, as shown in Table 1.

**Conclusion:** The exercise for 3 months can effectively reduce the left ventricular mass and significantly improve the left ventricular function and structure of hemodialysis patients. This will help to improve the research and development of exercise on cardiac in hemodialysis patients.

#2606
**SARS-COV-2 ANTIBODIES IN PATIENTS ON HEMODIALYSIS AFTER THE MRNA VACCINATION**

Takayasu Taira

Yokohama Daiichi Hospital, Nephrology, Yokohama, Japan

**Background and Aims:** Strategies to minimize the transmission risk of the coronavirus disease 2019 (COVID-19) in patients on hemodialysis (HD) have been implemented worldwide. We investigated the levels of SARS-CoV-2 neutralizing antibodies in Japanese patients.

**Method:** Study (1) We measured the SARS-CoV-2 nucleocapsid antibodies in the serum samples of 55 patients who had undergone HD between August 1 and December 14, 2020. We included 42 patients who had two doses of SARS-CoV-2 nucleocapsid antibodies in Japanesepatients. Neutralizing antibodies in Japanese patients.

**Results:**
- **SARS-CoV-2 Antibodies:** We measured the SARS-CoV-2 nucleocapsid antibodies in the serum samples of 55 patients who had undergone HD between August 1 and December 14, 2020. We included 42 patients who had two doses of...
the mRNA vaccine BNT162b2 between August 1 and November 30, 2021. We measured the levels of SARS-CoV-2 spike antibodies in their plasma and the SARS-CoV-2 nucleocapsid antibodies. We included 33 patients who had three doses of the mRNA vaccine, BNT162b2, between April 1st and July 30th, 2022. We measured the levels of SARS-CoV-2 spike antibodies in their plasma and the SARS-CoV-2 nucleocapsid antibodies. Study (2) We tested the serum samples of 8,982 Japanese adults with normal renal function for SARS-CoV-2 nucleocapsid antibodies between July 1 and November 18, 2020 as the control group. We tested 10 adults who had two doses of the mRNA vaccine BNT162b2, for SARS-CoV-2 spike antibodies at 4, 8, 12, 16, and 20 weeks after vaccination between May 1 and November 30, 2021.

**Results:** Two of 35 patients on HD were positive for SARS-CoV-2 nucleocapsid antibodies, while 54 were asymptomatic. One had SARS-CoV-2 nucleocapsid antibodies. The seropositivity of SARS-CoV-2 nucleocapsid antibodies was negative in 42 patients after the second dose of the BNT162b2 mRNA vaccine. No patients were infected with COVID-19. Of the 42 patients, 41 tested positive for SARS-CoV-2 spike antibodies after the second dose. The median titer of SARS-CoV-2 spike antibodies after vaccination was 253.5 (0.4-5,116) U/mL. All 33 HD patients tested positive for SARS-CoV-2 spike antibodies after the third dose. The mean titer of SARS-CoV-2 spike antibodies after the third vaccination was significantly higher than after the second BNT162b2 vaccination (N = 33: 9,745 U/mL vs. 221 U/mL, respectively; p<0.0001). The mean SARS-CoV-2 spike antibodies titer of patients aged 56–92 years (266.7 U/mL) was lower than of patients aged 28–53 years (1,320.4 U/mL). The seropositivity of SARS-CoV-2 nucleocapsid antibodies was negative after the BNT162b2 mRNA vaccine. No patients were infected with COVID-19. Study 2 Serological testing showed that 47 of the 8,982 Japanese adults with normal renal function tested positive for SARS-CoV-2 nucleocapsid antibodies. The prevalence was significantly higher in the Japanese HD population than in adults with normal renal function (p<0.01). The mean SARS-CoV-2 spike antibodies in the older group (55-73 years) were 1006, 643, 520, 464, and 390 U/mL at 4, 8, 12, 16, and 20 weeks post-vaccination. Contrasting, the mean SARS-CoV-2 spike antibodies the younger group (26–45 years) were 2685, 2032, 1731, 1609, and 1527 U/mL at 4, 8, 12, 16, and 20 weeks post-vaccination.

**Conclusion:** Japanese HD patients had SARS-CoV-2 neutralizing capacities after the BNT162b2 vaccination. Most developed spike antibodies after the three doses. The mean titer of spike antibodies after the third vaccination was significantly higher than after the second vaccination (p<0.0001).

**CKD-ASSOCIATED PRURITUS SEVERITY AND ITS ASSOCIATION WITH BODY DISTRIBUTION AND EQ-5D HEALTH-RELATED QUALITY OF LIFE IN HAEMODIALYSIS PATIENTS**

Pann Ei Hynnn S1, Monica Hernandez2, Alessandro Sasso2, Matthew Gittus1, Richard Powell1, Louise Dunn1 and James Fotheringham1,2

1Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom, 2School of Health and Related Research, United Kingdom and 3Royal Devon and Exeter Hospital, United Kingdom

**Background and Aims:** Chronic Kidney Disease associated pruritus (CKD-aP) is common affecting 40% of people with kidney disease receiving dialysis. It is associated with decreased health-related quality of life (HRQoL) as assessed using disease-specific instruments. A better understanding of how the severity of CKD-aP is related to the distribution of affected body parts and generic of HRQoL assessed using the EQ-5D instrument could improve the identification, assessment, and treatment of CKD-aP including advocating for access to new therapies.

**Method:** Prevalent in-centre haemodialysis patients from five centres prospectively completed the EQ-5D-5L HRQol questionnaires, the severity-based worst itch numeric rating scale (WI-NRS) and multi-dimensional 5-D itch pruritus disease specific quality of life instruments. Latent class mixture models were used to identify clusters of patients with similarly affected body parts as assessed through the 5-D itch and map the pruritus measures to the EQ-5D utility value (1 being perfect health and 0 being dead, heavily skewed). Patient demographics, comorbidities, dialysis prescription and anti-pruritus medications were collected.

**Results:** Pruritus data on 485 respondents were obtained. No pruritus was reported in 164 (33.8%), with 117 (24.1%) reporting mild, 123 (25.4%) reporting moderate and 81 (16.7%) reporting severe pruritus. Commonly affected body parts included groin (22%), upper arms (21%), forearms (11%), and back (10%). Anti-pruritus medication use across CKD-aP severity (none to severe) was 40.6%, 38.3%, 36.6% and 55.6%, and varied by body part with 38.8%, 21.0% and 14.5% use in those affected in the upper limbs, groin and lower legs respectively. Latent class analysis identified three groups of patients who had progressively worsening severity and number of body parts affected, but the distribution of affected body parts was relatively constant (left-hand figure) and reduction in EQ-5D by affected body part was similar. Although the WI-NRS and 5-D itch instruments correlated with each other, only the 5-D itch had a strong relationship with EQ-5D-3L. Controlling for age, sex, diabetes, and years receiving dialysis, predicted EQ-5D-3L utility dropped linearly from 0.69 to 0.41 (right-hand figure).

**Conclusion:** Contemporary UK data shows CKD-aP remains highly prevalent amongst people with kidney failure on dialysis. Severe CKD-aP was commonly reported despite half of the patients with severe CKD-aP receiving antipruritic medication, illustrating a high unmet need and likely undertreated. Although there were similar reductions in HRQoL, medication use varied by body part and those whose groin is affected may be reporting other body parts to access therapies. High use of CKD-aP medications in none or mild severity may represent more severely affected individuals benefiting from these drugs as the cross-sectional nature of the study means those who reported no pruritus may have had pruritus in the past which resolved in response to the medications prescribed and reported in these analyses. Overall, as it worsens CKD-aP appears to affect a similar distribution of body parts. Pruritus instruments that include domains that are broader than just pruritus severity more closely approximate the EQ-5D generic HRQoL measure and therefore more strongly advocate for the value of treating this unpleasant condition. Funded by CSL Vifor.

QUALITY OF LIFE IN FAMILY CAREGIVERS OF END STAGE KIDNEY DISEASE PATIENTS: A PROSPECTIVE STUDY

Stavroula Vovlianou1,2, Vasilios Koutlas3, Fani Papoulidou2, George Tsigaras2, Haralampos Milionis4, Petros Skapinakis5 and Evangelia Ntounousi1,3

1Faculty of Medicine, School of Health Sciences, University of Ioannina, Ioannina, Greece, Internal Medicine, Greece, 2General Hospital of Kavala, Nephrology, Kavala, Greece, 3University Hospital of Ioannina, Ioannina, Greece, Department of Surgery and Transplant Unit, Ioannina, Greece, 4Faculty of Medicine, School of Health Sciences, University of Ioannina, Ioannina, Greece, Nephrology, Greece and 5Faculty of Medicine, School of Health Sciences Ioannina, Greece, Psychiatry, Greece

Background and Aims: Family caregivers of patients with end stage kidney disease (ESKD) face the challenge of demanding patients’ care, in addition to their own daily tasks, which affect their well-being and quality of life (QoL). The aim of this prospective study was to assess and describe the QoL of family caregivers of ESKD patients at the beginning of kidney replacement therapy (KRT) and one year later.

Method: Sixty - two ESKD patients and their caregivers were recruited. Caregivers' QoL was assessed with the Short Form-36 questionnaire and EuroQol-5Dimension-3Level. QoL of caregivers and patients was measured twice, three months after initiation of KTR (T0) (53 patients started hemodialysis and 9 peritoneal dialysis) and after the first 12 months of KTR (T1), in order to investigate the possible changes of QoL during this crucial period.

Results: The mean value (Table 1) of caregivers’ physical component summary (PCS) subscale was found to change significantly during study period (T0: M = 54.21, SD = 8.06 vs T1: M = 51.58, SD = 10.46, t(61) = 2.02, p = .048). Caregivers presented a statistically significant decrease (p <.05) in physical health after one year of KRT. Likewise, the EQ-5D Index and the EQ-5D visual analogue scale (VAS) showed a statistically significant decline (p = .046 and p<.001 respectively). Finally, correlation of means of QoL dimensions between ESKD patients and their caregivers did not yield statistical significance in the particular longitudinal study.

Conclusion: The results provide evidence that the overall caregivers’ QoL scores deteriorated over the one-year period of KTR. Further studies of larger sizes and with a longer duration will probably better define the QoL variations of ESKD patients’ caregivers. Both groups may benefit from an educational program before patients initiate KTR.

ALTERNATIVES TO DAYTIME IN-CENTER HEMODIALYSIS AND EMPLOYMENT AMONG PATIENTS WITH KIDNEY FAILURE

Jose Perez1, Jingbo Niu1, Wolfgang Winkelmayer1, Kerri Cavanaugh2, Monique Pappadis3 and Kevin Erickson1

1Baylor College of Medicine, Houston, United States of America, 2Vanderbilt University School of Medicine, Nephrology, Nashville, United States of America and 3University of Texas Medical Branch, Galveston, United States of America

Background and Aims: Maintaining employment is a priority for many patients with kidney failure. In addition to its economic benefits, employment is associated with physical and psychological wellbeing. Yet, only 30-35% of working aged patients with advanced chronic kidney disease in the United States (US) report employment prior to starting dialysis and many patients stop working at the onset of kidney failure. While access to a dialysis treatment schedule outside of working hours may help patients to remain employed, the effects of alternative dialysis options on employment after starting dialysis are not well understood.

Method: We analyzed data from the US National Dialysis Registry to determine whether access to nearby facilities offering evening dialysis shifts and home dialysis increases the likelihood that patients are able to continue working after they start dialysis. Our cross-sectional analysis included working-aged patients (ages 18-54) receiving dialysis in US facilities in 2016. We combined information reported at the levels of individual patients and dialysis facilities. In a negative binomial regression model, we examined the

(a) Paired samples t-test
associations among exposures of interest (the presence of facilities offering home dialysis and/or evening dialysis shifts in a patient’s locality) and the number of employed working-aged adults at each dialysis facility. The multivariable regression model adjusted for observed patient, dialysis facility, and geographic characteristics, including patient health and demographic characteristics, information about individual patient employment at the onset of dialysis, local unemployment rates, and the number of working-aged patients at a given dialysis facility.

Results: We identified 4,860 US dialysis facilities with information about patient employment in 2016. Median employment among working-aged adults at these facilities was 17.9% (interquartile range 8.8% to 28.6%). In multivariable, fully adjusted, regression models, the presence of at least one facility offering an evening dialysis shift in a county was associated with a 3% increase in the relative rate of maintaining employment among all working-aged patients receiving dialysis in the county (risk ratio (rr) 1.03; 95% Confidence Interval (CI) 1.01 to 1.05; p = 0.02). The presence of at least one facility offering home dialysis in a county was associated with a 26% increase in the relative rate of maintaining employment (RR 1.26; 95% CI 1.18 to 1.34; p < 0.001). The likelihood of employment did not increase with additional facilities in a county offering home dialysis.

Conclusions: Access to dialysis schedules outside of regular working hours – evening dialysis shifts and home dialysis – is associated with increased employment among patients with kidney failure. Efforts to increase access to alternative dialysis treatments could help patients to continue working.

INCIDENCE RATE, OUTCOMES, AND RISK FACTORS ASSOCIATED WITH COVID-19 INFECTION IN FULLY MRNA-VACCINATED HEMODIALYSIS PATIENTS
Andriy Rysyev1, Natalia Stephenova2,3, Tetyana Ostapenko4, Lyudmyla Sniidar2,3, Anna Khizhyna4, Vyacheslav Filonov4, Valeriya Marchenko4 and Serhiy Pyankovskyi1
1Dialysis Medical Center LLC “Nephrocenter”, Nephrology, Kyiv, Ukraine, 2State Institution “Institute of Nephrology of the National Academy of Medical Science of Ukraine”, Nephrology & Dialysis, Kyiv, Ukraine, 3Dialysis Medical Center LLC “Nephrocenter”, Nephrology, Zaporizhzhia, Ukraine and 4Dialysis Medical Center LLC “Link Medital”, Nephrology, Odessa, Ukraine

Background and Aims: Despite the high efficacy of vaccines against coronavirus disease (COVID-19), some people continue to become infected with SARS-CoV-2 after vaccination. Older age, immunosuppression, and severe comorbidities are associated with the occurrence of COVID-19 and adverse outcomes in the general population of vaccinated patients. However, because of the above factors, hemodialysis (HD) patients may be at higher risk for postvaccination SARS-CoV-2 infection than the general population, and risk factors associated with COVID-19 in fully vaccinated HD patients have never been studied. The present study aimed to determine the incidence rate, outcomes, and risk factors for SARS-CoV-2 infection in fully vaccinated HD patients.

Method: In this multicenter case-control cohort study, we followed HD patients for 1 year after SARS-CoV-2 vaccination and compared incidence rates and outcomes of COVID-19 with unvaccinated patients selected by propensity score matching based on potentially confounding variables (age, diabetes, and dialysis vintage). Patients who had been fully vaccinated against COVID-19 with either Pfizer-BNT-162b2 or Moderna-mRNA-1273 vaccine and had at least one positive SARS-CoV-2 PCR test >14 days after the second dose were defined as cases. Unvaccinated HD patients who had not been infected with COVID-19 before study enrollment and had at least one positive test thereafter were defined as controls. The outcomes studied were COVID-19-related hospitalizations, oxygen maintenance, and death. Demographic data and routine blood tests (the last measurements before COVID-19) were analyzed as possible risk factors for COVID-19 infection in vaccinated HD patients. Data were presented as incidence rate or proportion and compared with the chi-square (χ2) test. Univariate logistic regression analysis was used to determine risk factors for SARS-CoV-2 infection after vaccination and presented as odds ratio (OR) and 95% confidence interval (CI).

Results: Among a total cohort of HD patients (n = 327) aged 52 ± 9.4 years with a dialysis vintage of 44 (21-76.6) months, 133 (40.7%) HD patients were fully vaccinated. During the 12-month follow-up period, the incidence rate of SARS-CoV-2 infection was significantly lower in the vaccinated group compared with the matched unvaccinated group: 0.29 (95% CI: 0.18; 0.42) vs 0.59 (95% CI: 0.46; 0.74) per patient-year (p < 0.0001). Proportions of COVID-19-associated hospitalization (χ2 = 20.1, p < 0.0001), oxygen demand (χ2 = 27.8, p < 0.0001), and death (χ2 = 7.6, p = 0.004) were also significantly lower in the case group compared to unvaccinated matched controls. In risk factor analysis, older age, obesity, dialysis duration of more than 5 years, arterial hypertension, elevated C-reactive protein, anemia, and low levels of parathyroid hormone and high-density lipoprotein cholesterol were associated with postvaccination SARS-CoV-2 infection (Fig. 1).

Conclusion: Vaccinated HD patients had a significantly lower incidence of SARS-CoV-2 infection and associated adverse outcomes compared to the unvaccinated group. HD patients aged ≥65 years with Kt/V <1.2, obesity, dialysis duration of more than five years, arterial hypertension, elevated C-reactive protein, and low levels of hemoglobin, parathyroid hormone, and high-density lipoprotein cholesterol had a higher risk of infection following vaccination.

MULTINATIONAL COMPARATIVE EFFICACY OF 6 DIFFERENT COVID-19 VACCINES FOR THE PREVENTION OF BREAKTHROUGH INFECTION AND MORTALITY IN HD PATIENTS
Mathias Haahrhaus1,2, Rainer Peter Woitas3, Pedro Mota Veiga4, Carla Santos5, Mohammed Alhomrani5, Eliana Silva5, Carlos Lucas3 and Fernando Macário5
1Karolinska Institutet, Dept of Renal Medicine, Stockholm, Sweden, 2Diaverum Sweden, Malmö, Sweden, 3Diaverum Deutschland GmbH, München, Germany, 4Polytechnic Institute of Viseu, School of Education, Viseu, Portugal, Viseu, Portugal and 5Diaverum Saudi Arabia, Riyadh Front - Building N8, Riyadh, Saudi Arabia

Background and Aims: COVID-19 vaccines induce specific immune responses to reduce COVID-19 infections and severe complications. Dialysis patients exhibit increased COVID-19-related incidence rates and mortality due to poor immune responses. We studied retrospectively the efficacy of 6 different COVID-19 vaccines as well as the combination of vaccines for the prevention of new COVID-19 infections and related mortality in a large multi-national hemodialysis cohort.

Method: All patients from 22 countries in Europe, Asia, Africa, and South America, 18 years or older, registered within in the network of a multi-national dialysis provider on January 31th, 2021, were included into the study. We analyzed the incidence of symptomatic COVID-19 in HD patients with vaccination status after 2 doses of 6 different SARS-CoV-2 vaccines in comparison to HD patients who did not receive any vaccine. Patients were screened for COVID-19 symptoms at each dialysis visit and SARS-CoV-2 PCR tests were performed in all symptomatic patients. All PCR-confirmed COVID-19 infections, and deaths occurring between January 31th, and July 15th, 2021 were analyzed. Results were stratified by vaccine type and compared to unvaccinated patients. Data are presented as incidence rate ratios per 1000 patient days and odds ratios vs. no vaccine (95% CI).

Results: Of 38342 eligible patients registered on the index date, 2413 were excluded due to a positive SARS-CoV-2 PCR within 3 months before baseline and 26 were excluded due to unclear vaccination data. The remaining 35903 patients were analyzed. 7816 patients (21.7%) had received a single vaccine dose and 18853 patients (52.5%) had received two doses of any COVID-19 vaccine (Vaxzevria 3180 and 1321, Comirnaty 2823 and 13116, Spikevax 185 and 1521, Sputnik V 1194 and 432, Sinovac 266 and 1722, Sinopharm 168 and 416, or any combination of two different vaccines 325). The 9119 patients (25.4%) who remained unvaccinated during the observational period showed

Logistic regression with no vaccine as reference, adjusted for country, age, gender, diabetes mellitus, Charlson comorbid. index, and dialysis vintage.

an incidence rate of 0.74/1000 patient days. In the cohort of patients vaccinated two times, 232 developed Covid-19. The lowest incidence rate ratio was observed in patients that had received Spikevax 0.06 (0.02-0.14). By contrast, patients after Sinopharm, Sinovac, and Sputnik V exhibited highest incidence rate ratios 0.53 (0.21-1.09), 0.46 (0.34-0.61), 0.68 (0.34-1.23), respectively. The largest sub-cohort of 13116 patients, who had received Comirnaty, however, had an incidence rate ratio of 0.15 (0.12-0.17). Albeit incidence rates and ratios were heterogeneous, all vaccines including Sputnik V showed a significant efficacy to reduce mortality compared to no vaccine. Conclusion: Combinations of different vaccines and two doses of mRNA-based vaccines very effectively prevented breakthrough infections. Despite considerable differences in preventing COVID-19 infections, all vaccines effectively reduced mortality, compared to no vaccines, in this high-risk dialysis patient cohort.

Conclusion: Physical activity is associated the lower risk of developing dementia in ESRD patients with hemodialysis.

### Table 2: Effect of 2 doses of vaccine on all-cause mortality vs. no vaccine.

**Method:** A total 19,877 hemodialysis patients aged ≥ 40 years who underwent health check-ups were identified from the Korean National Health Insurance Service database and were analysed in this study. Individuals with physical activities were defined as meeting following criteria: (i) three or more days/week of vigorous activity of at least 20 min per day or (ii) five or more days/week of moderate-intensity activity of at least 30 min per day. The occurrence of dementia was monitored through the end of 2018 by the ICD-10 codes.

**Results:** During the 4.6-year follow-up, 1,755 patients with hemodialysis developed dementia. Physical activity was associated with the lower risk of any dementia (hazard ratio [HR], 0.779, 95% confidence interval (CI), 0.7-0.867) even after adjusting for several confounding factors. Risk of developing dementia was still lower in hemodialysis patients with physical activity when we analyse the risk of Alzheimer’s dementia and vascular dementia separately (HR 0.817 and 0.685, respectively). In subgroup analyses, the risk of dementia tended to lower in hemodialysis patients with physical activity than without physical activity in all subgroups.

**Conclusion:** Physical activity is associated the lower risk of developing dementia in ESRD patients with hemodialysis.

#5394

**PHYSICAL ACTIVITY AND THE RISK OF DEMENTIA IN END-STAGE RENAL DISEASE PATIENTS WITH HEMODIALYSIS: A NATIONWIDE POPULATION-BASED STUDY**

Hong Sang Choi, Minah Kim, Tae Ryon Oh, Sang Heon Suh, Chang Seong Kim, Eun Hui Bae, Seong Kwon MA and Soo Wan Kim

Chonnam National University Medical School, Department of Internal Medicine, Rep. of South Korea

**Background and Aims:** Several studies have reported that dementia has a high prevalence in patients with end-stage renal disease (ESRD) patients. However, the relationship between physical activity and the risk of developing dementia has not been elucidated in ESRD patients with hemodialysis.
Background and Aims: Since the beginning of the industrial era, human activities have led to a significant increase in the concentration of greenhouse gases (GHGs) in the atmosphere and are the cause of climate change, the negative effects of which on human health are already visible (1). Paradoxically, the health sector also exerts a major pressure on the environment through carbon-based care activities that emit GHGs (2). In this context, a few studies have highlighted the significant carbon footprint associated with hemodialysis (3). However, to date, no similar study has been conducted in France.

Method: The objective of this work was to evaluate the carbon footprint of a hemodialysis unit in France using the Bilan Carbone ® approach developed by The French Agency for Ecological Transition and the Bilan Carbone Association. Activity data associated with hemodialysis provision at the Charles De Gaulle facility in 2021 was collected and converted to a common measurement unit of tonnes of CO2 equivalents (tCO2-eq) via established emissions factors. This facility, that belongs to the ARTIC 42 association, is located in the town of Saint-Priest en Jarez and provides hemodialysis through a total of 56 hemodialysis generators.

Results: Over the year 2021, the Charles de Gaulle facility provided a total of 25270 hemodialysis treatments ensuring the care of approximately 162 patients (at a rate of 3 sessions per week). The associated annual carbon footprint for the facility was 1436 t CO2-eq. Annual carbon footprint amounted to 8.9 t CO2-eq/patient/year corresponding to 57 kg CO2-eq /treatment. Emissions were essentially indirect, with more than 90% coming from scope 3. The main sources of emissions were: products and services purchase (30% of total emissions, that is 437 t CO2-eq), patients and staff travels (25% of total emissions, that is 361 t CO2-eq), and fixed assets (21% of total emissions, that is 299 t CO2-eq). Energy consumption (particularly electricity) and waste treatment accounted for a small proportion of GHG emissions (respectively 8% and 6%).

Conclusion: Our results confirm the high carbon footprint associated with in-center hemodialysis, showing that it is mainly attributable to indirect emissions. These empirical data will serve as a basis for reflection in the development of a strategy to reduce GHG emissions associated with hemodialysis. This work will hopefully be paving the way for the necessary ecological transition of medical practices, focused on the patient and the ecosystems on which he/she depends.

COVID-19 in their original dialysis units and were therefore transferred for further HD treatment to the first hospital in Serbia transferred to exclusively admit COVID-19 patients at the onset of the epidemic. According to the local protocol, all patients were hospitalized while being dialedy. Data were collected from clinical charts and patient histories for the period between March 19, 2020, and March 19, 2022, and analysed with SPSS software, version 22 (IBM Corporation, New York, USA).

Results: A total of 1384 HD treatments were performed in 226 patients (6.1±2.4, range 1 – 34 per patient). Most patients (98.5%) had at least one comorbidity: hypertension (68.1%), diabetes (26.1%), cardiovascular disease (16.4%), cerebrovascular disease (7.5%), malignancy (9.3%), chronic respiratory disease (4.0%) or autoimmune disease (1.8%). The average number of comorbidities was 1.9±1.0 (range 0 – 4). Only 2.2% of all patients were vaccinated. Most patients (78.0%) had bilateral pneumonia upon admission, 15.3% had normal pulmonary X-ray, 5.1% had unilateral pneumonia and 1.7% had ARDS. 34% of the patients required mechanical ventilation. Fifty-seven patients (25.2%) received corticosteroid therapy, 5.3% were treated with chloroquine, 2.7% received antiviral therapy and 1.8% were administered IL6 antagonist. The overall mortality rate was 39.4%. Patients who died were significantly older (67.6±12.4 vs 63.6±12.7, p = 0.012), more often had cardiovascular disease (p = 0.046) and bilateral pneumonia (p≤0.01), had worse CT severity score (13.0±5.1 vs 9.2±5.0; p<0.001) and required invasive mechanical ventilation (p<0.001) and had fewer HD treatments performed during hospitalization (5.1±4.8 vs 6.8±4.2; p = 0.007). They also had significantly higher white blood cells count (8.3±5.3 vs 5.6±2.9; p<0.001), serum urea (24.9±12.0 vs 21.1±8.4 mmol/L; p = 0.01), LDH (111.0±65.9 vs 63.9±72.9 IU/L; p<0.001), CRP (157.2±91.1 vs 61.1±98.4 mg/dL; p = 0.008), IL-6 (14.9±16.3 vs 2.8±7.3 pg/mL; p = 0.004), and Ddimer (372.3±294.1 vs 240.7±101.5 ng/mL; p<0.001). Multiple logistic regression showed a significant association between mortality and older age (OR 1.11, 95% CI 1.04-1.18, p = 0.001), need for mechanical ventilation (OR 43.1, 95% CI 9.5-198.6; p<0.001), higher CT severity score (OR 1.16, 95% CI 1.07 - 1.25; p<0.001), fewer HD procedures performed (OR 0.80, 95% CI 0.69-0.93; p = 0.003) and higher D-dimer levels (OR 1.00, 95% CI 1.00 - 1.01; p = 0.012).

Conclusion: Maintenance HD patients are considered a high-risk population for contracting COVID-19 and developing a severe form of the disease. Older age, higher CT severity score

### #2613

**DIETARY FIBER INTAKE, THEIR SOURCES AND MORTALITY IN ADULTS ON HEMODIALYSIS: THE DIET-HD STUDY**

Guobin Su1,2, Valeria Saglimbene 3, Juan Jesus Carrero2, Patrizia Natale3,4, Marinella Ruspo5 and Giovanni Strippoli3,4

1Guangdong Provincial Hospital of Chinese Medicine, The Second Affiliated Hospital, Guangzhou University of Chinese Medicine, Department of Nephrology, Guangzhou, P.R. China, 2Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, 3University of Bari, Department of Emergency and Organ Transplantation, Bari, Italy and 4The University of Sydney, Faculty of Medicine and Health, Sydney School of Public Health, Sydney, Australia

**Background and Aims:** Higher fiber intake is associated with lower cardiovascular and all-cause mortality in the general population, but their benefits and which sources of fiber are healthier in patients on hemodialysis are uncertain.

**Method:** Daily fiber intake (DFI) and their sources (vegetable and fruit, staple food and other sources) were ascertained by the Global Allergy and Asthma European Network food frequency questionnaire within the DIET-HD study, a multinational cohort study of adults on hemodialysis. Adjusted Cox regression analyses were conducted to evaluate the association of DFI and fiber sources (vegetable and fruit, staple foods, others) with cardiovascular and all-cause mortality. Estimates were calculated as hazard ratio (HR) with 95% confidence interval (CI).

**Results:** 8,110 patients were followed for median of 3.8 years (26,074 person-years). There were 2,953 deaths, of which 1160 cardiovascular-related. The median (interquartile range) DFI was 12.0 (8.1-17.5) gram per day and vegetables and fruits (49%) were the major sources. Each unit increase in total DFI was not associated with either all-cause (hazard ratio [HR], 0.99; 95%CI 0.99-1.00, p = 0.379) or cardiovascular mortality (HR, 0.99; 95%CI 0.99-1.00, p = 0.98). Compared with the lowest DFI tertile (<9.5mg/day), the adjusted HRs for cardiovascular mortality among those in the middle (9.5-15.3 g/day) and highest tertiles (≥15.3 g/day) were respectively 0.97 [95% CI, 0.84-1.13] and 0.79 [95% CI, 0.65-0.96] (P for trend = 0.02). Each unit increase in fraction of DFI from vegetable and fruit was associated with lower all-cause (HR, 0.70;95%CI: 0.57-0.86, p = 0.001) but not with cardiovascular mortality
(HR 0.75-95%CI 0.54-1.04, p = 0.08). Each unit increase in the fraction of DFI from other sources (including dressing sauce etc.) was associated with higher all-cause mortality (HR 1.66; 95%CI 1.22-2.27, p = 0.001) but not with cardiovascular mortality (HR, 1.63; 95%CI, 0.83-2.24, p = 0.23). No association were observed between fiber from staple food and all-cause or cardiovascular mortality.

Conclusion: Fiber intake in the hemodialysis population is low. A higher fiber intake from vegetable and fruit, and a lower fiber intake from other sources (including dressing sauce etc.) is associated with lower all-cause death.

### #3595

**DIALYSIS MODALITY AFFECTS SENESCENCE-RELATED PHENOTYPE OF T AND B LYMPHOCYTES**

Georgios Lioulos1, Asimina Fylaktou2, Theodoros Tourountzis1, Michalis Christodoulou1, Eleni Moysidou1, Panagiotis Giamalis1, Ioannis Tsouchnikas1, Alkaterini Papagianni1 and Maria Stangou1

1Aristotle University of Thessaloniki, Hippokration Hospital, Department of Nephrology, Thessaloniki, Greece and 2Hippokration Hospital, Department of Immunology, National Peripheral Histocompatibility Center, Thessaloniki, Greece

**Background and Aims:** Hemodialysis (HDF) is characterized by enhanced clearance of middle molecular weight toxins and therefore, it is considered superior to hemodialysis (HD), especially in higher hemofiltration volumes. Although proinflammatory cytokines are lower in HDF, its impact on immune phenotype has not been studied, so far. In this study we compared the lymphocytes’ senescent phenotype between HD and HDF patients.

**Method:** Senescent and exhausted related lymphocyte markers, including CD45RA, CCR7, CD28 and CD57 on T cells and CD27 and IgD on B cells, were assessed by flow cytometry in 35 ESRD patients on HD and 25 ESRD patients on HDF, respectively, p = 0.006. CD28-CD57 T cells were also lower in HDF patients, without reaching statistical significance [17.4 (8.5-41) vs 34 (12.7-52.9) % for HDF and HD respectively, p = 0.06]. Hemofiltration volume was negatively correlated to effector memory CD8+ T cells re-expressing CD45RA count (CD8+ EMRA), (r = -0.46, p = 0.027) and positively correlated to total B cells count (r = 0.46, p = 0.025). However, not all B cell subtypes were equally affected, with only naïve IgD+CD27- B cells and switched memory IgD-CD27+ B cells count showing positive correlation with hemofiltration volume (r = 0.53, p = 0.008 and r = 0.5, p = 0.015, respectively).

**Conclusion:** Hemodialfiltration and high filtration volumes may have beneficial effects on adaptive immunity, predisposing to less senescent and exhausted T and B cell phenotypes.

**HOME DIALYSIS DOES NOT HAVE THE MONOPOLY ON LOW COST**

Eric Laruelle1, Fabrice Hure3, Thibault Dolley-Hitze2, Isabella Vanorio Vega1, Sahar Bayat1 and Cécile Couchoud1

1AUB Santé, Rennes, France, 2AUB Santé, Saint Malo, France, 3Agence de la biomédecine, REIN registry, Saint Denis La Plaine, France and 4EHESP, MÉTI, Rennes, France

**Background and Aims:** End-stage kidney disease (ESKD) is a major challenge for health-care systems around the world because of its ever-rising rates and the ensuing rise in health-care costs. The objective of this study was to compare the cost of four dialysis modalities that enable patients to play a substantial role in their own care and have social and professional lives.

**Method:** We identified all patients in the national French ESKD REIN registry aged 18–65 years who received any dialysis treatment in 2015–2019, used stepwise indirect linkage with the national health database to analyse exhaustive hospital stays and outpatient health-care utilisation. Four treatment groups were defined: non-assisted haemodialysis in self-care units (scHD), non-assisted automated peritoneal dialysis (naAPD), daily home HD (dhHD), and non-hospital-based nocturnal extended hours HD (neHD). Total costs by categories and subcategories were aggregated monthly and by patient. Costs are expressed as their medians and interquartile ranges (Q1-Q3).

**Results:** Our study included 1932 patients with 39 966 patient treatment-months. The median monthly cost for one patient was €6154 (IQR €5088–€7566) and varied from €5700 for naAPD to €7903 for dhHD. Analysis by cost subcategories showed that the main cost came from dialysis fee payments —60% of the monthly cost. Hospitalization costs came next (11%). The costs of the different subcategories varied between dialysis modalities. During the study period, the hospitalization rate was 33 per 100 months at risk: 14 for inpatient admissions and 19 for day hospitalization. Day hospitalization was more frequent for patients with home treatment. Various compensatory allowances were paid to 49% of the patients.

**Conclusion:** Most of the cost difference variability related to payment methods for the different dialysis techniques. Our study shows that different care strategies could be offered to French dialysis patients. Underused techniques such as neHD might usefully be promoted as they do not involve any excess costs, at least compared with dhHD. Real cost analyses are however needed because these reimbursements are not adapted and deserve to be revised upwards.

SERUM INTERLEUKIN-6 LEVELS AS A PREDICTOR OF ALL-CAUSE MORTALITY IN MAINTENANCE HEMODIALYSIS PATIENTS WITH COVID-19-OMICRON INFECTION: AN OBSERVATIONAL STUDY
Qirong Song, Yuxin Luo, Sha Fu, Xiaohong Wang, Ying Tang, Junzhe Chen and Aiqun Liu
The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, P.R. China

Background and Aims: Interleukin-6 (IL-6) is a key mediator of inflammation and has been linked to the severity and mortality of COVID-19-Omicron in the general population. With higher mortality rates observed in maintenance hemodialysis (MHD) patients infected with COVID-19-Omicron, the study aimed to examine the correlation between IL-6 levels and mortality in this patient population and to identify the optimal IL-6 level for predicting the risk of death.

Method: The retrospective observational study was conducted in MHD patients diagnosed with COVID-19-Omicron infection between December 01, 2022 and January 31, 2023 at the Third Affiliated Hospital of Southern Medical University during the first wave of infection in COVID-19-Omicron outbreak in China. Clinical and biochemical data were collected during the infection, IL-6 levels of the patients were measured before consecutive dialysis sessions by a commercial kit. The Cox model was used to investigate the risk factors of mortality, meanwhile, ROC curve to determine the cut off value of IL-6 levels on mortality.

Results: A total of 162 MHD patients infected with COVID-19-Omicron were included in this study. During a median follow-up period of 40 days, 10 (6.2%) deaths occurred due to COVID-19 infection. IL-6 levels were significantly higher in patients who died. Univariate Cox regression analyses showed that the risk factors associated with death included IL-6 levels (HR: 1.009; p < 0.001), C-reactive protein (HR: 1.01; p = 0.016), serum potassium (HR: 2.258; p = 0.015, procalcitonin(PCT) (HR: 1.01; p = 0.048), and the Charlson comorbidity index(CCI)(HR: 1.34; p = 0.002). However, in multivariate analysis, only IL-6 levels was independently associated with all-cause mortality(HR: 1.01; p = 0.001).The ROC curve and Kaplan-Meier survival analysis revealed a significantly worse survival risk among MHD patients with higher serum IL-6 levels (≥104.87 pg/mL) (sensitivity:100%; specificity:78.2%; AUC: 0.92; p = 0.001).

Conclusion: Serum IL-6 levels greater than 104.87 pg/mL were associated with an increased risk of all-cause mortality in MHD patients infected with COVID-19-Omicron. Hemoperfusion or hemofiltration to remove IL-6 may provide appropriate treatment options for hemodialysis patients with COVID-19-Omicron.

Figure 1: Receiver operating characteristic curves of Interleukin-6(IL-6) for MHD with COVID-19-Omicron infection for predicting mortality.
Figure 2: Kaplan-Meier curves showing survival of the primary endpoint for MHD with COVID-19-Omicron infection grouped by the cut-off value of 104.87 pg/mL of blood IL-6 for predicting probability of death.

Table 1: Baseline characteristics of MHD patients with COVID-19-Omicron infection in the overall study.

EFFECT OF VACCINATION ON OXIDANT/ANTIOXIDANT STATUS IN HEMODIALYSIS PATIENTS WITH POST-COVID CONDITIONS

Lesya Korol¹, Natalia Stepanova¹,², Tetyana Ostapenko³, Andriy Rysyev¹, Valeriy Marchenko³ and Olga Belousova³

¹State Institution “Institute of Nephrology of the National Academy of Medical Science of Ukraine”, Nephrology & Dialysis, Kyiv, Ukraine, ²Dialysis Medical Center LLC “Nephrocenter”, Nephrology, Kyiv, Ukraine, ³Dialysis Medical Center LLC “Nephrocenter”, Nephrology, Zaporizhzhia, Ukraine and ⁴Dialysis Medical Center LLC “Link-Medital”, Nephrology, Odesa, Ukraine

Background and Aims: Hemodialysis (HD) patients are at high risk for post-COVID conditions and a high mortality rate over a 1-year period after diagnosis of COVID-19, especially in the first 3 months. Evidence shows that vaccinated individuals who experience breakthrough infection are less likely to report post-COVID conditions compared with unvaccinated individuals. Although oxidative stress has been shown to be an important cause of post-COVID conditions, there is a general lack of data on oxidant/antioxidant status in HD patients with post-COVID conditions. The present study aimed to evaluate the oxidant/antioxidant markers in HD patients with post-COVID conditions according to vaccination status.

Method: A total of 106 HD patients, aged 52.4 ± 10.2 years, and dialysis vintage of 68 (29-134) months, were enrolled in this cross-sectional observational cohort study. Patients were divided into 3 groups according to their vaccination status and the presence of post-COVID conditions. Group 1 consisted of 36 HD patients who had been fully vaccinated against COVID-19 with either Pfizer-BNT-162b2 or Moderna-mRNA-1273 vaccine and had experienced a post-vaccination SARS-CoV-2 infection and had at least 1 post-COVID symptom. Group 2 consisted of 35 fully vaccinated HD patients who had never been infected with COVID-19 (vaccinated control group), and Group 3 included 35 unvaccinated HD patients who had experienced COVID-19 and had post-COVID conditions (unvaccinated control group).

Concentrations of malondialdehyde in serum (MDAs) and erythrocytes (MDAe), sulfhydryl groups (SH-groups), serum catalase activity (CTs), serum transferrin and ceruloplasmin levels were determined 3 months after COVID-19 recovery. Data were expressed as a median and interquartile range [Me (Q25-Q75)] and compared with the Kruskal-Wallis test.

Results: The vaccinated HD patients with post-COVID conditions had the highest concentrations of MDAs and ceruloplasmin, and lower serum levels of CTs and transferrin compared with the vaccinated and unvaccinated control groups (Table 1).

Conclusion: Our findings suggest a significant oxidative imbalance in HD patients with post-COVID syndrome most likely due to the synergistic effects of the virus and the vaccine. The use of antioxidant supplements might be a possible strategy to treat post-COVID conditions in HD patients.
EFFECTS OF DIALYSIS PATIENTS’ HEALTH-RELATED QUALITY OF LIFE AND SYMPTOM BURDEN ON CAREGIVERS

Esmee Dreihuis1,2, Theodör Vogels3, Wanda Konijn3, Anneke Roeterdink2,1, Thomas Sebastiaan van Lieshout2,5, Namiko Goto6,7, Marjolein Broese van Groenou7, Friedo W. Dekker9, Brigit Van Jaarsveld2,10 and Alfesco C. Abrahams3

1University Medical Center Utrecht, Department of Nephrology and Hypertension, Utrecht, Netherlands, 2Amsterdam UMC location Vrije Universiteit Amsterdam, Department of Nephrology, Amsterdam, Netherlands, 3Dialysis Center Maxima, Maxima Medical Center, Eindhoven, Netherlands, 4Dutch Kidney Patients Association (NVN), Bussum, Netherlands, 5Northwest Clinics, Department of Internal Medicine, Alkmaar, Netherlands, 6University Medical Center Utrecht, Department of Geriatric Medicine, Utrecht, Netherlands, 7Jeroen Bosch Hospital, Department of Geriatric Medicine, ’s Hertogenbosch, Netherlands, 8Vrije Universiteit Amsterdam, Department of Sociology, Amsterdam, Netherlands, 9Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands and 10Diaipriva Dialysis Center, Amsterdam, Netherlands

Background and Aims: Starting dialysis has a major impact on patients’ lives. Dialysis patients experience impairments in health-related quality of life (HRQoL) and high symptom burden. Informal caregivers are crucial for dialysis patients’ well-being, as patients often rely on their support and care. However, informal caregivers who provide long-lasting, intensive care may also experience a significant burden. This, in turn, may lead to impaired HRQoL of both the informal caregiver and the patient. To date, little research has been done among informal caregivers of dialysis patients, even though they may experience negative effects of the impaired functioning of the patient. Therefore, the aim of this study was to assess the impact of dialysis patients’ HRQoL and symptom burden on HRQoL of their informal caregivers. We hypothesize that impaired HRQoL and high symptom burden of dialysis patients have a significant impact on informal caregivers’ mental HRQoL, but little to no impact on their physical HRQoL.

Method: We conducted a cross-sectional study with 193 dyads of adult dialysis patients and their informal caregivers. Data at dialysis initiation were obtained from the ongoing multicenter, observational cohort study on informal caregivers of dialysis patients, which is an extension of the Dutch nOcturnal hOmeDialysis Study To Improve Clinical Outcomes (DOMESTICO). The 12-item Short Form Health Survey (SF-12), which provides mental component summary (MCS) and physical component summary (PCS) scores (range 0-100), was used to measure HRQoL in both informal caregivers and dialysis patients. To date, little research has been done among informal caregivers of dialysis patients, even though they may experience negative effects of the impaired functioning of the patient. Therefore, the aim of this study was to assess the impact of dialysis patients’ HRQoL and symptom burden on HRQoL of their informal caregivers. We hypothesize that impaired HRQoL and high symptom burden of dialysis patients have a significant impact on informal caregivers’ mental HRQoL, but little to no impact on their physical HRQoL.

Method: We conducted a cross-sectional study with 193 dyads of adult dialysis patients and their informal caregivers. Data at dialysis initiation were obtained from the ongoing multicenter, observational cohort study on informal caregivers of dialysis patients, which is an extension of the Dutch nOCTurnal hOmeDialysis Study To Improve Clinical Outcomes (DOMESTICO). The 12-item Short Form Health Survey (SF-12), which provides mental component summary (MCS) and physical component summary (PCS) scores (range 0-100), was used to measure HRQoL in both informal caregivers and dialysis patients. The number of symptoms (range 0-30) and symptom burden (range 0-150) were measured with the Dialysis Symptom Index (DSI). Data were analyzed using linear regression and adjusted for possible confounders.

Results: Mean age of informal caregivers was 60 ± 15 years, 72.0% were female, and 77.2% were spouses of the dialysis patient. Mean age of patients was 65 ± 14 years, 32.1% were female, and 62.7% were on in-centre hemodialysis. Mean MCS and PCS scores of informal caregivers were 47.8 ± 9.7 and 48.7 ± 9.8, respectively. Mean MCS and PCS scores of patients were 47.9 ± 9.0 and 35.7 ± 10.3, respectively, and mean symptom number and burden were 11.3 ± 5.9 and 31.5 ± 17.6, respectively. After adjustment for confounders, significant effects of patients’ (1) MCS score (β = 0.305; p = 0.003), (2) symptom number (β = -0.434; p = 0.002), and (3) symptom burden (β = -0.151; p < 0.001) were found on caregivers’ MCS score. No significant effects on caregivers’ PCS score were found.

Conclusion: Lower mental HRQoL, higher symptom number, and higher symptom burden of dialysis patients are associated with lower mental HRQoL of their informal caregivers. These findings underline the importance of maintaining patients’ HRQoL and reducing symptom burden, as these also affect informal caregivers. In addition, given that improving patients’ HRQoL and reducing symptom burden are not always within reach, these findings emphasize the importance of supporting informal caregivers of dialysis patients.

ASSOCIATION BETWEEN AMORPHOUS CALCIUM-PHOSPHATE RATIOS IN CIRCULATING CALCIOPROTEIN PARTICLES AND PROGNOSTIC BIOMARKERS IN HEMODIALYSIS PATIENTS

Kimihiko Nakamura, Naohito Isoyama, Koji Shiraishi and Makoto Kuro-O

Japan

Background and Aims: Calcioprotein particles (CPPs) are circulating colloidal mineral-protein complexes containing crystalline and/or non-crystalline (amorphous) calcium-phosphate (CaPi). Serum CPP levels correlate with vascular stiffness and calcification in patients with chronic kidney disease (CKD). In vitro studies showed that CPPs containing crystalline CaPi were more arteriosclerogenic and inflammagogenic than CPPs without containing crystalline CaPi. Thus, we hypothesized that not only the quantity but also the quality of CPPs (the phase of CaPi) might affect clinical outcomes.

Method: To test this hypothesis, we quantified amorphous CaPi ratio defined as the ratio of the amorphous CaPi amount to the total CaPi amount in serum CPPs from 183 hemodialysis patients and explored its possible correlation with serum parameters associated with prognosis of hemodialysis patients.

Results: Multivariate analysis revealed that the amorphous CaPi ratio correlated positively with hemoglobin and negatively with fibroblast growth factor-21 (FGF21), which remained significant after adjusting for the total CaPi amount. Because, low hemoglobin and high FGF21 were associated with increased mortality. Patients with low amorphous CaPi rate tended to have lower 2-year survival rates (p = 0.07).

Figure 1: Scattered plots between CPP and other serum parameters. Correlation coefficient (R) is indicated. Association of serum phosphate levels with total (A, blue), crystalline (A, red), and amorphous CaPi (B) amounts. Association of serum calcium levels with total (C) and amorphous (D) CaPi amounts. Association of amorphous CaPi ratios with hemoglobin (E) and FGF21 (F).

DIFFERENCES IN MENTAL HEALTH STATUS DURING COVID-19 PANDEMIC BETWEEN IN-CENTER HEMODIALYSIS AND PERITONEAL DIALYSIS PATIENTS
Pim Bouwmans1,2, Zeinab Skalli3, Robin Vernooy4,5, Marc Hemmelder4,6, Wanda Konijn7, Joy Lips8, Janneke Mulder7, Anna Bonenkamp9, Brigit Van Jaarsveld10 and Alferso C. Abrahams11
1 Maastricht University, CARIM - School for Cardiovascular Diseases, Maastricht, Netherlands, 2 MUMC+ - Internal Medicine, Division of Nephrology, Maastricht, Netherlands, 3 UMC Utrecht, Nephrology and Hypertension, Utrecht, Netherlands, 4 Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands, 5 Nierpatiënten Vereniging Nederland, Bussum, Netherlands, 6 Bernhoven, Internal Medicine, Uden, Netherlands, 7 Scheper Hospital, Nephrology, Emmen, Netherlands and 8 Amsterdam UMC, locatie VUmc, Nephrology, Amsterdam, Netherlands

Background and Aims: Results from previous studies suggest that mental health of dialysis patients was unaffected during the first wave of the COVID-19 pandemic. However, the location of dialysis treatment might have had a different impact on patients during the ongoing COVID-19 pandemic, especially at time of restrictions. Studies comparing the mental health of ICHD and PD patients during the pandemic are scarce. Therefore, we aimed to assess whether dialysis modality differently affected the mental health of patients during the COVID-19 pandemic.

Method: This study used data of patients participating in the Dutch nocturnal and hoME dialysis Study To Improve Clinical Outcomes (DOMESTICO). We conducted repeated cross-sectional analyses between ICHD and PD patients from the start of the COVID-19 pandemic in March 2020 until August 2021. For this, we divided the study period into six periods of three months. The year before the pandemic was used as reference period. Mental health-related quality of life (HRQOL) was assessed using the mental component summary (MCS) score of the 12-item Short Form (SF-12) health survey. The presence of mental symptoms was determined using the Dialysis Symptom Index (DSI). Both questionnaires were provided at start of dialysis, at 3 months, 6 months and each 6 months thereafter. Patients were included for analysis if a questionnaire was available in at least one period. MCS scores and the prevalence of mental symptoms between ICHD and PD patients were compared with Student’s t-test and Chi-square test, respectively. Moreover, we performed multivariable regression analyses to adjust for possible confounders.

Results: For this analysis, 1274 patients (968 ICHD and 306 PD) were included. Mean age was 65±14 and 64±14 years, respectively. Most patients were male (ICHD: 68%, PD: 61%). Before the pandemic the ICHD patients reported similar MCS scores, yet more often reported feeling nervous (32% vs. 22%, P = .03) and sad (40% vs. 29%, P = .03). During the pandemic, mean MCS scores also did not differ between ICHD and PD patients. In contrast, ICHD patients more often reported feeling nervous during period 3 (32% vs. 15%, P = .04), feeling irritable and anxious during period 3 (31% vs 18%, P = .03, 26% vs. 9%, P = .002, resp.) and period 4 (34% vs 22%, P = .04, 22% vs 11%, P = .03, resp.), and feeling sad in period 4 (38% vs 26%, P = .04) and period 5 (37% vs 22%, P = .009). In a multivariable regression analysis, these differences persisted after correction for several confounders.

Conclusion: ICHD patients experienced more mental symptoms compared to PD patients in the period September 2020 to June 2021, which corresponds with the second lockdown of the COVID-19 pandemic. This higher prevalence of specific mental symptoms in ICHD patients was not reflected by a decrease in mental HRQOL.

#6235
ELEVATED PLASMA ANGIOPOETIN-2 PREDICT THE NEED FOR DIALYSIS INITIATION IN PATIENTS WITH CKD 4 AND 5 WITHIN TWO YEARS
Anna Szymczak1, Mariusz Kusztal1, Letachowicz Krzysztof1, Tomasz Gołębiowski1, Anna Gozdzik1, Katarzyna Koscielska-Kasprzak1, Andrzej Tukiendstaw1 and Magdalena Krajewska1
1 Wrocław Medical University, Nephrology and Transplantation Medicine, Wrocław, Poland, 2 Wrocław Medical University, Cardiology, Wrocław, Poland and 3 University of Opole, Opole, Poland

Background and Aims: Volume status, congestion and endothelial activation/injury were found to play a role in GFR decline and CKD progression. This pilot study aimed to determine whether the plasma markers of endothelial injury and activation as well as markers of fluid overload could serve as independent predictors for dialysis initiation in stable patients with CKD 4 and 5 and preserved EF.

Method: This prospective study was conducted from March 2019 to March 2022 and enrolled consecutive patients with GFR <30ml/min/1.72 m² and preserved LVEF. Plasma levels of angiotensin (Ang)-2, Vascular Endothelial Growth Factor-C (VEGF-C), Vascular Cell Adhesion Molecule-1 (VCAM-1), Copeptin (CPP), beta-trace protein (BTP), brain natriuretic peptide (BNP), cardiac troponin 1 (cTnI) were measured (Quantikine ELISA, R&D Systems Inc, Minneapolis, MN). Clinical markers of congestion were also recorded: lung US (B-lines), bioimpedance (ECV/ICV), echocardiography with global longitudinal strain (GLS), pulse wave velocity (PWV). Study outcome was need to initiate dialysis during 24-months follow-up.

Results: We analyzed a total of 105 patients with mean eGFR 21.3 ml/min/1.73m. The median age at enrollment was 52 (±14.8) years and 65% of the patients were male; 79% were hypertensive and 24% were diabetic. A positive correlation between concentration of Ang-2 and VCAM-1 and BTP was observed. Ang-2 concentration correlated positively with BNP, Trt, sCr, e/e’, ECV/ICV. Over a follow-up period of 24 months, the deterioration of renal function was observed in 47 patients (58%), 31 (38%) presented stable or ameliorated renal function and 24 on maintenance dialysis formed a control group. In Kaplan-Meier analysis significant impact of Ang-2 on renal survival (Figure) was found. Namely, 72% of patients with Ang-2 concentrations below the median (3.15 ng/ml) survived without dialysis for two years, compared to 42% of those with Ang-2 concentrations above the median. Such impact was not observed for GFR, VCAM, CCP, VEGF-C, BTP.

Conclusion: Endothelial activation, quantified by plasma levels of Ang-2 may play an important role in GFR decline and need for dialysis initiation in patients with CKD 4 and 5.

IMMUNE RESPONSES OF PATIENTS ON MAINTENANCE HEMODIALYSIS AFTER INFECTION BY SARS-COV-2: A PROSPECTIVE OBSERVATIONAL COHORT STUDY
Dimitra Bacharaki1, Minas Karagiannis1, Evangelos Papachristou1, Dimitrios Divanis2, Adamantia Bratsiakou2, Panagiotis Giannakopoulos2, Georgia Damoraki3, Vassilios Liakopoulos3, Dimitrios Goumenos4 and Evangelos Giamarellos2
1 Attikon General University Hospital, 2nd Department of Propedeutic Medicine, Chaidari, Greece, 2 Rion University Hospital, Nephrology, Rio, Greece, 3 AHEPA Hospital, Nephrology, Thessaloniki, Greece and 4 Attikon General University Hospital, 4th Department of Internal Medicine, Chaidari, Greece

Background and Aims: We aimed to study the immune response of maintenance hemodialysis (HD) patients to Corona Virus Disease-19 (COVID-19) since it is not fully elucidated.

Method: In this prospective study, hospitalized HD patients with moderate-to-severe COVID-19 and matched non diseased HD comparators were analyzed.
Figure 1: Circulating cytokines were measured before start of hemodialysis, after the end of hemodialysis and in the dialysate in patients on maintenance hemodialysis with COVID-19 and matched comparators. Line represents the median of the distribution. Comparisons between patients and comparators are shown: ns, non-significant; \*p < 0.05; \***p < 0.0001.

Abbreviations: IFN, interferon; IL, interleukin; MC, matched comparators; n, number of patients; PDGF, platelet-derived growth factor; TNF, tumour necrosis factor.

Results: 59 HD patients with acute COVID-19 HD and 20 comparators were enrolled. Circulating median (range) of interferon-gamma (IFN-\( \gamma \)) at the start of HD was 125 (125-1777) pg/ml in comparators and 810 (125-4000) pg/ml in SARS-CoV-2 (\( p < 0.00001 \)) and 125 (125-1278) pg/ml and 738 (125-4000) pg/ml at the end of HD (\( p < 0.0001 \)). Respective concentrations of platelet derived growth factor-A were 8286 (4600-28150) and 27938 (8285-99256) pg/ml (\( p < 0.0001 \)) and 7779 (5055-28128) and 27410 (6836-87887) pg/ml respectively. Similar increases were found for tumor necrosis factor-alpha (TNF-\( \alpha \)) only at the start of the HD whereas no differences were found for interleukin (IL)-6, IL-10 and IL-38. Respective mean (SD) CD4-counts were 881.3 (407.6) and 461.6 (365.4) per microliter (\( p < 0.0001 \)) and 839.4 (509.7) and 483.6 (329.9) per microliter (\( p < 0.0001 \)). MFI expression of HLA-DR on CD14-monocytes was 97.2 (28.2) and 67.4 (44.7) (\( p < 0.0001 \)) and 87.3 (26.7) and 63.3 (36.3) (\( p < 0.0001 \)). The respective mean (SD) MFI expression of HLA-DR on CD14-monocytes was 97.2 (28.2) and 67.4 (44.7) (\( p < 0.0001 \)) and 87.3 (26.7) and 63.3 (36.3) (\( p < 0.0001 \)). MFI of HLA-DR on CD14-monocytes before the first HD session less than 44 was associated with 100% sensitivity for unfavorable outcome (defined as respiratory failure or death) after 28 days. An absolute CD19-count more than 40 per microliter before the first HD session was associated with 8.70 odds ratio for cure favorable outcome after 28 days.

Conclusion: HD patients develop an inflammatory reaction to Severe Acute Respiratory Syndrome Coronavirus 2 characterized by increase of the inflammatory mediators IFN-\( \gamma \), PDGF-A and TNF-\( \alpha \) and decrease of circulating T helper lymphocytes. Decreased expression of HLA-DR on CD14-monocytes is a hallmark of unfavorable prognosis.

MORTALITY AND RISK FACTORS IN VERY ELDERLY PATIENTS WHO START HAEMODIALYSIS: KOREAN RENAL DATA SYSTEM (KORDS), 2016-2020
Ji Hyeon Park1, Ajin Cho2 and 홍경길3
1National Police Hospital, Department of Internal Medicine, Seoul, Rep. of South Korea, 2Kangnam Sacred Heart Hospital, Department of Internal Medicine, Seoul, Rep. of South Korea and 3Oryeon Samsung Medical Center, Incheon, Rep. of South Korea

Background and Aims: The number of elderly patients with end-stage renal disease (ESRD) is increasing worldwide. However, decision-making about elderly patients with ESRD remains complex because of the lack of studies, especially in very elderly patients (\( \geq 75 \) years). We examined the characteristics of very elderly patients starting haemodialysis (HD) and the associated mortality and prognostic factors.

Method: Data were analysed retrospectively using a nationwide cohort registry, the Korean Renal Data System. Patients who started HD between January 2016 and December 2020 were included and divided into three groups according to age at HD initiation (<65, 65–74, and \( \geq 75 \) years). The primary outcome was all-cause mortality during the study period. Risk factors for mortality were analysed using Cox proportional hazard models.

Results: In total, 22,024 incident patients were included with 10,006, 6,350 and 6,350 in each group (<65, 65–74, and \( \geq 75 \) years, respectively). Among the very elderly group, women had a higher cumulative survival rate than men (91.2% vs. 90.3% at 1 year and 56.4% vs. 51.9% at 3 years, respectively) (Figure 1a). The survival rate was lower in patients with vascular access via a catheter than those with an arteriovenous fistula or graft (72.0% vs. 95.1% at 1 year and 23.8% vs. 60.7% at 3 years, respectively) (Figure 1b). Very elderly patients with more comorbid diseases had a significantly lower survival rate that those with fewer comorbidities (log-rank: \( p < 0.001 \)) (Figure 2).

Conclusion: Preparation of an arteriovenous fistula or graft when starting HD should be considered in very elderly patients with fewer comorbid diseases.
EFFECT OF THE RATE OF ALBUMIN DECREASE ON LONG-TERM PROGNOSIS IN DIALYSIS PATIENTS

Nanami Kida¹, Satoki Kato² and Yoshiharu Tsubakihara³

¹Jikei University of Health Care Sciences, Health Care Sciences, Osaka, Japan, ²Hino Memorial Hospital, Clinical Engineering, Shiga, Japan and ³Graduate School of Medical Safety Management, Jikei University of Health Care Sciences, Safety Management in Health Care Sciences, Oaka, Japan

**Background and Aims:** The malnutrition is often prevalent in hemodialysis (HD) patients, and the risk of mortality is strongly correlated with malnutrition. We assume the dynamic change and trend of albumin in HD patients are mortality essential, however there is not enough information on these data. The aim of this study was to investigate the association of long-term prognosis and decrease rate of albumin for one-year.

**Method:** We enrolled HD patients in six centers to a retrospective follow-up study. All patients had received HD from January 2014 to December 2014 and serum albumin data were collected every month in this period. We defined decrease rate in serum albumin as (average of albumin value for the year - decrease value for the year) / average of albumin value for the year. We categorized these patients into two groups according to the median value of the decrease rate. Then these patients were observed for three years. The primary and secondary outcome of this study was all-cause mortality and the combined endpoint of mortality and major cardio-cerebrovascular adverse events (MACCE). To evaluate cut-off value in decrease rate of serum albumin, Receiver Operating Characteristic (ROC) curve analysis was performed. Moreover, restricted cubic splines were used to detect the possible nonlinear dependency of the relationship between decrease rate in serum albumin and mortality.

**Results:** Six-hundred twenty-one HD patients were enrolled into this study. The median rate of decrease in albumin in the enrolled patients was 7.5%. Compared to the low decrease fluctuation group (n = 321), the high decrease fluctuation group (n = 300) was significantly older (67 vs 66 years; p = 0.03), more frequently had diabetes mellitus (51.7 vs 39.3%; p = 0.02), had lower serum creatinine (9.34 vs 10.69 mg/dl; p <0.001) and lower body mass index (20.3 vs 21.3; p = 0.01). The mean follow-up period was 31.0±10.1 months. During the follow-up period, there were 121 cases (19.5%) in all cause death and 191 cases (30.5%) in combined endpoint, respectively. Kaplan-Meier analysis showed that high decrease fluctuation in serum albumin group had a significantly worse prognosis in both all-cause mortality (Log-rank, p = 0.01) and combined endpoint (Log-rank, p = 0.002) than low decrease fluctuation group (Figure 1). Multi-variate Cox proportional hazard model revealed that high decrease fluctuation in serum albumin was significantly associated with a higher risk of all-cause mortality and combined endpoint (hazard ratio 1.47 (95%CI: 1.02-2.13), p = 0.03, hazard ratio 1.49 (95%CI:1.11-1.99), p = 0.007). The cut-off value for all-cause mortality in decrease rate of serum albumin was 8.4% by ROC curve analysis. Moreover, through multivariable restricted cubic spline regression, continuous variation in decrease rate in serum albumin was found to be related to all-cause mortality in a nonlinear manner (Figure 2).

**Conclusion:** In HD patients, high decrease fluctuation in serum albumin was significantly associated with an increased risk of all-cause mortality compared low decrease fluctuation in serum albumin. Our findings suggest that regarding serum albumin, we might need to pay attention not only to its monthly value, but also to its decreasing fluctuation.
Background and Aims: Although the initiation of unplanned dialysis in elderly patients is associated with a higher risk of death, overall this is still poorly understood and measured. The aim of the present study is to evaluate the unplanned population of patients who started planned or unplanned dialysis at the Policlinico “A. Gemelli” and the “SS. Annunziata” University Hospital of Chieti in the period from 1 January 2016 to 31 December 2020. All Patients in the unplanned population started emergency hemodialysis treatment during hospitalization. The primary outcome was all-cause mortality at three and six months. The main demographic, clinical features and the Couchoud Score, a prognostic score that stratifies elderly patients (age > 75 years) with ESRD into groups with variable risk of short-term mortality after initiation of dialysis, of two group are shown in Table 1.

Results: During the whole study period, endend on 30 September 2022, 84 (68.3%) patients died in the unplanned group and 17 (24.6%) in the planned group. The unplanned group showed a higher Couchoud score (4.07 ± 2.63 vs 7.02 ± 3.05 p < 0.001). In the unplanned group, 54.5% of patients died within 3 months and 58.3% within 6 months. In the Planned group, we observed only one death within 6 months. The mean survival of the unplanned group was 366 (± 544) days. In the unplanned group, 51 patients died during the hospital stay in which the hemodialysis treatment was started. The mean survival in these patients was 23 (± 71 SD) days. The difference in survival in the two cohorts of patients is shown in the Kaplan-Mayer analysis and is statistically significant (Logrank p < 0.001) (Figure 1). Interestingly, Couchoud Score (Spearman rho = -0.44; p < .001) and unplanned treatment initiation (Spearman rho = -0.59; p < .001), but not patients’ age (Spearman rho = -0.10; p = .168) presented a strong and inverse correlation with observed lifespan. The logistic regression model confirmed that Couchoud score was significantly and independently associate with mortality at three (p < .001, 95%CI 0.16-0.49, McFadden R2 = 0.126) and six months (p < .001, 95%CI 0.14-0.45, McFadden R2 = 0.105). In the subsequent logistic regression model, evaluating the individual variables contained in the Couchoud Score, only lack of autonomy was significantly associated with mortality both at three and six months (three months: OR 8.230, p < .001, 95%CI 1.073-3.143; six months: OR 5.504, p = <.001, 95%CI 0.726-2.685).

Conclusion: In elderly patients, unplanned dialysis is associated with a significant increase in in-hospital and at six-month mortality. In our study, the Couchoud Score represented an accurate and reliable short-term prognostic evaluation tool and may help nephrologist in the context of a shared decision-making process to select elderly patients more suitable for renal replacement therapy.

UNPLANNED INITIATION OF HEMODIALYSIS IN ELDERLY PATIENTS WITH CHRONIC KIDNEY DISEASE: RISK FACTORS FOR SHORT TERM MORTALITY

Federica Tagliente, Nicola Panocchia, Francesca Caprio, Simone Arñó, Mario Bonomini and Giuseppe Grandaliano

1UOC Nefrologia Dialisi Trapianti, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Roma Italia, Dipartimento Universitario di Chirurgia e Medicina Traslazionale, Università Cattolica del Sacro Cuore, Roma Italia, Italy, 2Dipartimento di Scienze Mediche Traslazionali, Università degli Studi della Campania ‘L. Vanvitelli’, Napoli, Italy, Italy, 3Dipartimento di Neuroscienze ed Imaging, Università G. D’Annunzio, Chieti, Italy and 4UOC Clinica Nefrologica Ospedale Clinicizzato “SS. Annunziata”, Dipartimento di Medicina e Scienze dell’Invecchiamento, Università ‘G. D’Annunzio’, Chieti, Italy

Background and Aims: Although the initiation of unplanned dialysis in elderly patients is associated with a higher risk of death, overall this is still poorly understood and measured. The aim of the present study is to evaluate how “planned” or “unplanned” beginning of renal replacement therapy might influence the main clinical outcomes.

Method: We carried out an observational, retrospective, multicenter study on ESRD patients’ population who started planned or unplanned dialysis at the Policlinico “A. Gemelli” and the “SS. Annunziata” University Hospital of Chieti in the period from 1 January 2016 to 31 December 2020. All Patients in the unplanned population started emergency hemodialysis treatment during hospitalization. The primary outcome was all-cause mortality at three and six months. The main demographic, clinical features and the Couchoud Score, a prognostic score that stratifies elderly patients (age > 75 years) with ESRD into groups with variable risk of short-term mortality after initiation of dialysis, of two group are shown in Table 1.

PREVALENCE OF LIVER STEATOSIS MEASURED BY MULTIFREQUENCY BIOIMPEDANCE IN PATIENTS WITH CKD

Guillermina Barril1, Ángel Nogueira1, Esmeralda Josa2, Graciela Alvarez3, Alejandra Cortinas3, Almudena Núñez3, Avión Giorgi3, Carmen Sanchez3 and Mar Ruperto4

1Hospital Universitario de la Princesa, Nephrology, Madrid, Spain, 2Universidad Europea, Madrid, Spain, 3Hospital Universitario de la Princesa, Nefrology, Madrid, Spain and 4USP-CEU, Madrid, Spain

**Background and Aims:** The increase in visceral fat is one of the factors that contribute to the increased cardiovascular risk associated with CKD. There are few data on the prevalence of hepatic steatosis in patients with CKD. The Maltron multifrequency BIA offers us the possibility of evaluating it. The purpose of this study was to determine the prevalence of hepatic steatosis by means of multifrequency bioimpedance and to correlate it with ultrasound or CT in patients with CKD on Advanced CKD (ACKD) and HD.

**Methods:** We carried out a study of body composition with BIA in 315 patients, analyzing with the Maltron monitor Bioscan i-touch8 the determination of hepatic steatosis and its classification into 4 stages of involvement (normal, mild, moderate, moderately-severe and severe steatosis). We also correlated with ultrasound studies that had In order to see coincidence, we also obtained data from 9 patients without CKD. We established correlation/coincidence between ultrasound/CT and BIA in 72 patients. We found a healthy liver BIA-ECHO correlation in 43 cases (93.4%), steatosis by BIA coincides with ECHO in 50.0%.

**Results:** 315 patients evaluated for CKD 151 (48%) and HD 163 (52%), 65.9% men aged 70.79 ± 12.87 years (sig difference between CKD and HD (72.4 ± 2.7) vs 69.2 ±14.3) p0.023. Globally we found healthy liver in 37.9% and steatosis in 61.3% appearing mild-13.4%, moderate 11.8%, light-high 11.4% and high 24.5%. We observed healthy liver in 35.1% in ACKD vs 40.5% in HD. We did not find significant differences between liver enzyme values between healthy liver and steatosis at a global level. We established correlation/coincidence between ultrasound/CT and BIA in 72 patients. We found a healthy liver BIA-ECHO correlation in 43 cases (93.4%), steatosis by BIA coincides with ECHO in 41.6%. If we combine healthy liver + mild steatosis by BIA, the BIA-Echo healthy liver coincides in 92.7% and steatosis in 50%. Establishing cut-off points for BMI, % fat mass and waist/height index using COR curves, we obtain areas-under-the-curve 0.828, 0.738 and 0.853 respectively, being Waist-height index (WC/0.6) with better sensitivity 80% and specificity 71.3%. If we determine the area of fat mass with another tool, we see AUC 0.838 with 72.3% specificity and 91.3% sensitivity to detect normal liver.

**Conclusion:** 1) A high prevalence of hepatic steatosis due to IAB appears in patients with CKD greater in CKD than in HD. 2) There is a good correlation with ECO for a healthy liver and there are parameters that correlate well in a healthy liver diagnosis. 3) Specific studies of Ultrasound-BIA are needed to validate the diagnosis of steatosis.

### #2594

ELEVATED SERUM IL-17 LEVEL IS ASSOCIATED WITH THE PERSISTENCE OF POST-COVID SYNDROME AND VACCINATION STATUS IN HEMODIALYSIS PATIENTS

Natalia Stepanova1, Victoria Driianska1, Andriy Rysyev2, Valeriia Kholod1, Viktoria Savchenko1 and Mykola Kolesnyk1

1State Institution "Institute of Nephrology of the National Academy of Medical Science of Ukraine", Nephrology & Dialysis, Kyiv, Ukraine and 2Dialysis Medical Center LLC "Link-Medital", Nephrology, Odesa, Ukraine

**Background and Aims:** Interleukin-17 (IL -17) is thought to play an important role in the immune response and severity of coronavirus disease 2019 (COVID-19). In addition, elevated serum IL-17 levels have been detected in the general population of SARS-CoV-2-infected patients with post-COVID syndrome. Although hemodialysis (HD) patients belong to the high-risk group COVID-19 with an attenuated immune response to mRNA vaccination and a high incidence rate of post-COVID syndrome, IL-17 has never been studied in this cohort.

**Method:** A total of 80 HD patients aged 56 (44-63.2) years with a dialysis vintage of 40 (23-74) months who had experienced COVID-19 at least 5 months before enrollment were included in this cross-sectional cohort study. Aiming to analyze serum IL -17 according to the persistence of post-COVID syndrome, the patients we divided into 2 groups: post-COVID with (n = 36)
Figure 1: Serum IL-17 in HD patients stratified by the persistence of post-COVID syndrome and the interval between acute SARS-CoV-2 infection and blood collection.

and without (n = 44) sequelae. IL-17 was measured at 2-time points: at 5 (n = 30) and 10 months (n = 50) after acute SARS-CoV-2 infection using an ELISA assay. Data were expressed as median (Me) and interquartile ranges (Q25-Q75) and compared with the Mann-Whitney test.

Results: Serum IL-17 ranged from 0.01 to 15.14 pg/mL and was significantly elevated in HD patients with post-COVID sequelae compared to fully recovered patients: 0.45 (0.08-1.6) vs 0.08 (0.025-0.15) pg/mL, p = 0.0002. In the general cohort of HD patients with a 5-month interval between acute SARS-CoV-2 infection and blood collection, IL-17 was statistically greater than in patients with a 10-month interval: 0.24 (0.06-1.2) vs 0.11 (0.03-0.37) pg/mL, p = 0.04. In subgroup analysis, the patients with post-COVID sequelae had higher IL-17 levels than fully recovered patients at both time points (Fig. 1). Notably, mRNA-vaccinated HD patients with post-COVID sequelae had higher IL-17 levels than unvaccinated patients at both time points: 3.83 (0.47-6.47) vs 0.88 (0.04-1.5) pg/mL, p = 0.03 and 0.57 (0.09-5.3) vs 0.08 (0.03-0.13) pg/mL, p = 0.01, respectively.

Conclusion: Serum IL-17 level is associated with the persistence of post-COVID syndrome in HD patients even 10 months after acute COVID-19 and is significantly higher in mRNA-vaccinated HD patients with post-COVID sequelae compared to unvaccinated patients. Further studies are needed to postulate IL-17 as a useful biomarker for post-COVID syndrome in HD patients.

#3161
CLINICAL EFFICACY AND OPTIMAL REGIMEN OF BNT162B2 VACCINE IN CHRONIC DIALYSIS PATIENTS
Keren Cohen Hagai1, Tzipi Hornik-Lurie2, Yael Einbinder1, Naomi Nacasch1, Ayelet Grupper3, Ori Wand4, Moshe Shashar4 and Sydney Benchetrit1
1Nephrology, Kfar Saba, Israel, 2Kfar Saba, Israel, 3Nephrology, Israel and 4Israel

Background and Aims: Highly effective vaccines against severe acute respiratory syndrome virus 2 (SARS-CoV-2) have been developed and administered worldwide. Protection from coronavirus disease 2019 (COVID-19), however, is not absolute, and optimal vaccination regimens need to be established. Concerns regarding breakthrough COVID-19 disease in vaccinated patients are increasing, as vaccine efficacy appears to gradually decline in the months following vaccination. The emergence of highly infective variants, escalates these issues. This study assessed the clinical efficacy of the BNT162B2 vaccine and all-cause mortality among dialysis patients receiving varying numbers of vaccine doses.

Method: This study was conducted using the electronic database of Clalit Health Services in Israel. Patients receiving chronic hemodialysis or peritoneal dialysis during COVID-19 pandemic were included in the analysis. The control group consisted of age- and sex-matched individuals, in a 4:1 ratio to the dialysis group. The study included the pre- and post-vaccination periods.

Results: A total of 14,230 people were included; 2,846 on chronic dialysis and 11,384 controls. Mean age was 66.2 ± 14.3 years (range 18-97). Before the vaccine was available in Israel, 223 dialysis patients were infected with SARS-CoV2. Their mortality rate was 18.4% compared to 10.8% among uninfected, unvaccinated patients in the same period (p = 0.001). On post-vaccination period, we compared the clinical efficacy of a fourth dose to patients who received only 3 doses of BNT162b2 vaccine. SARS-CoV-2 infection rates, hospitalizations due to severe COVID-19, COVID-19–related mortality and all-cause mortality rates were lower among chronic dialysis patients who received a fourth dose of vaccine as compared to those who received only 3 doses (after adjusting for age, sex and comorbidities). Despite lower mortality rates observed with the Omicron variant, an additional booster dose was associated with reduced COVID-19–related mortality (1.7% vs. 3.8%, p = 0.04, HR 0.44 (95% CI 0.2–0.98) in patients who received 4 doses compared to 3 doses.

Conclusion: As seen in the general population, and with previous vaccine boosters, the fourth dose of the BNT162b2 vaccine reduced rates of severe COVID-19 hospitalization and mortality among chronic dialysis patients. This study strengthens the recommendation to administer a fourth booster dose of vaccine to dialysis patients. Further studies are needed to establish the exact dose and schedule of the COVID-19 vaccine in the vulnerable population patients on chronic maintenance dialysis.
SARS-COV-2 OMICRON INFECTIONS AMONG VACCINATED MAINTENANCE HEMODIALYSIS PATIENTS: OUTCOMES AND COMPARISON TO DELTA VARIANT

Keren Cohen Hagai¹, Ori Wand², Idan Drori¹, Yael Einbinder¹, Naomi Nacasch¹ and Sydney Benchetrit¹

¹Meir Medical Center, Kfar Saba, Israel and ²Israel

Background and Aims: Infections with the B.1.1.529 Omicron variant of SARS-CoV-2 became predominant worldwide in late 2021, replacing the previously dominant B.1.617.2 Delta variant. While these variants are highly transmissible and can evade vaccine protection, population studies suggested that outcomes after infection with Omicron variant were better than with Delta. Data regarding prognosis of maintenance hemodialysis (MHD) patients infected with Omicron vs. Delta variants are limited.

Method: This retrospective, cohort study included all patients with end-stage kidney disease treated with MHD at Meir Medical Center, Kfar Saba, Israel, who were diagnosed with SARS-CoV-2 infection between June 2021 and May 2022.

Results: Twenty-six MHD patients were diagnosed with the Delta variant and 71 with Omicron. SARS-CoV-2 infection severity was significantly worse among those infected with the Delta variant: 50% developed severe or critical COVID-19 vs. 5% in the Omicron group (p<0.001). Among MHD infected with Omicron, 57% were asymptomatic during their illness. For the entire cohort, 30-day mortality was 5.2%. It was higher among MHD in the Delta group (5/26, 19.2%) than in the Omicron group (0/71; p<0.001), as was 90-day mortality (5/26, 19.2% vs. 3/71, 4.2%, respectively; p = 0.02). Mean age was comparable between groups. Patients infected with Omicron variant received a higher mean number of vaccine doses before infection, as compared to Delta group (p<0.001).

Conclusion: Infection with the SARS-CoV-2 Delta variant was associated with worse outcomes compared with Omicron, among patients on MHD. However, despite mild disease among vaccinated MHD patients, infection with Omicron variant was still associated with significant 90-day mortality rate.

COVID-19 INFECTION AMONG HAEMODIALYSIS PATIENTS - EXPERIENCE FROM A HONG KONG COHORT

Zi Chan, Ka Lok Chan, Chi Kwan Lam, Way Ping Law, Wai Lun Will Pak, Yick Hei Wong and Sunny Sze-Ho Wong

United Christian Hospital, Renal Unit, Department of Medicine, Hong Kong, P.R. China

Background and Aims: Many haemodialysis patients were infected by COVID-19 during a severe wave of outbreak due to the Omicron variant in Hong Kong in 2022, which had a great impact on the hospital haemodialysis service. To better prepare for future outbreaks, the patient characteristics and outcomes were examined in this study.

Method: This was a retrospective cohort study of all haemodialysis patients infected with COVID-19 from February to April 2022 in our hospital. The infection rates of in-centre and home haemodialysis were analysed. The mortality rate and the rate of moderate to severe disease (as defined by requiring 2L of oxygen or above) were recorded. Factors affecting mortality and disease severity were analysed using Fisher’s exact test and independent t test.

Abstracts

Figure 1: Cox regression analysis survival curves of MHD patients infected with Delta vs. Omicron variants. Mortality over time was higher in the Delta group in a model that incorporated age and sex in addition to SARS-CoV-2 variant (p = 0.04).
Results: There were ninety-nine haemodialysis patients infected with COVID-19 during the study period (Table 1). The infection rate of in-centre haemodialysis patients was 98/232 (42.2%) compared with 1/19 (5.3%) of home haemodialysis patients. The mortality rate was 7.1%, and the rate of moderate to severe disease was 10.1%. A higher Charlson Comorbidity Index was identified as the only significant factor associated with mortality (6.7±3.4 vs. 4.9±2.0) and disease severity (6.5±3.0 vs. 4.9±2.0). Age, gender, presence of diabetes mellitus and vaccination status did not correlate with the outcome in this cohort.

Conclusion: Home haemodialysis had the benefit of a lower infection rate during the COVID-19 outbreak. A higher burden of comorbidities increased the risk of mortality and the severity of COVID-19. Close monitoring is warranted in these groups of haemodialysis patients.

Results: Physical frailty and depressive symptoms were prevalent in 268 (65.5%) and 143 (35.0%) of the population, respectively. Physical frailty and depressive symptoms were present in 103 people (25.2%). 129 (31.5%) people died during the follow-up period (median 49 months). In all patients, Cox regression analysis revealed that physical frailty and no depressive symptoms (hazard ratio [HR], 1.86; 95% confidence interval [CI], 1.01–3.44) and coexistence of physical frailty and depressive symptoms (HR, 2.30; 95% CI, 1.23–4.28) were significantly associated with an increased risk of death. In the ≤75-year-old group, a combination of physical frailty and depressive symptoms was significantly associated with an increased risk of death (HR, 2.45; 95% CI, 1.23–4.88). In the ≥75-year-old group, however, combined physical frailty and depressive symptoms were not significantly associated with mortality (HR, 2.06; 95% CI, 0.34–12.55), whereas C-reactive protein was (HR, 1.59; 95% CI, 1.10–2.28).

Conclusion: Physical frailty and depressive symptoms were common in HD patients. In terms of prognosis, the coexistence of physical frailty and depressive symptoms were linked to mortality in the ≤75-year-old group, whereas in the ≥75-year-old group, the coexistence of physical frailty and depressive symptoms was not associated with death, but higher inflammation was associated.

#4818

IMPACT OF COMBINED PHYSICAL FRAILTY AND DEPRESSIVE SYMPTOMS ON MORTALITY IN PATIENTS ON HEMODIALYSIS

Asumi Tobita1, Keigo Imamura1,2, Shun Yoshikoshi1,3, Juri Uchida1, Takuya Nakajima1, Narumi Fukuzaki1, Sayaka Nikkawa1, Manae Harada3 and Atsuhiko Matsumaka1

1Kitasato University Graduate School of Medical Sciences, Department of Rehabilitation Sciences, Sagamihara, Japan, 2Tokyo Metropolitan Institute of Gerontology, Japan and 3Sagami Circulatory Organ Clinic, Department of Rehabilitation, Japan

Background and Aims: Patients receiving hemodialysis (HD) are getting older, with 38.8% of patients in Japan being 75 years or older. HD patients also have multiple comorbidities, which are known to be associated with poor clinical outcomes, especially in the older patients. Moreover, physical frailty and depressive symptoms in HD patients and these are known to be risk factors for poor prognosis. However, it is unclear whether the coexistence of physical frailty and depressive symptoms contributes to an increased risk of mortality in older patients with multiple comorbidities. As a result, the goal of this study was to look at the relationship between physical frailty and depressive symptoms and mortality in HD patients of different ages.

Method: This study included 409 Japanese outpatients with HD (mean age 65.9 years, 62.6% male, and 2.0 years of hemodialysis history). Slow walking speed and/or weak hand grip strength were used to define physical frailty. The Center for Epidemiological Studies-Depression scale was used to assess depressive symptoms. Patients were divided into four groups: (1) no depressive symptoms, no physical frailty; (2) depressive symptoms, no physical frailty; (3) no depressive symptoms, physical frailty; and (4) depressive symptoms, physical frailty. All-cause mortality was the outcome; Cox regression analysis was performed, with analysis stratified by age group (<75 years, ≥75 years) to examine differences by age.

Results: Physical frailty and depressive symptoms were prevalent in 268 (65.5%) and 143 (35.0%) of the population, respectively. Physical frailty and depressive symptoms were present in 103 people (25.2%). 129 (31.5%) people died during the follow-up period (median 49 months). In all patients, Cox regression analysis revealed that physical frailty and no depressive symptoms (hazard ratio [HR], 1.86; 95% confidence interval [CI], 1.01–3.44) and coexistence of physical frailty and depressive symptoms (HR, 2.30; 95% CI, 1.23–4.28) were significantly associated with an increased risk of death. In the ≤75-year-old group, a combination of physical frailty and depressive symptoms was significantly associated with an increased risk of death (HR, 2.45; 95% CI, 1.23–4.88). In the ≥75-year-old group, however, combined physical frailty and depressive symptoms were not significantly associated with mortality (HR, 2.06; 95% CI, 0.34–12.55), whereas C-reactive protein was (HR, 1.59; 95% CI, 1.10–2.28).

Conclusion: Physical frailty and depressive symptoms were common in HD patients. In terms of prognosis, the coexistence of physical frailty and depressive symptoms were linked to mortality in the ≤75-year-old group, whereas in the ≥75-year-old group, the coexistence of physical frailty and depressive symptoms was not associated with death, but higher inflammation was associated.

#6691

COMPREHENSIVE TWO-DAY IN-HOSPITAL ASSESSMENT MODE IS ASSOCIATED WITH THREE-YEAR AND FIVE-YEAR MORTALITY IN PERITONEAL DIALYSIS PATIENTS

Dengyan MA, Xing LI, Hui Zhong, Li Pu, Xueli Zhou, Difei Duan, Rouxi Liao and Ping Fu

West China Hospital of Sichuan University, P.R. China

Background and Aims: The study aims to explore the relationship between a "comprehensive 2-day in-hospital assessment management mode" (C2IAMM) and survival and technical survival rates of patients undergoing peritoneal dialysis (PD).

Method: Eight hundred and thirty PD patients were retrospectively analyzed from January 1, 2011, to October 31, 2017. The "C2IAMM" includes admitting patients undergoing PD to the hospital for 2 days for various assessments. Based on these results, comprehensive interventions were provided. The 1-year, 3-year and 5-year survival and technical survival rates of patients following the C2IAMM were analyzed, and subgroup analysis were further performed.

Results: The 830 PD patients following C2IAMM achieved 1-year, 3-year and 5-year survival rates of 98.0%, 91.4% and 84.3%, respectively; the corresponding technical survival rates were 97.1%, 87.1% and 80.5%. The subgroup analysis showed that age ≥60 years, diabetes mellitus, cardiovascular and cerebrovascular diseases, and respiratory diseases (all P < 0.001) were associated with survival.

Conclusion: This article implies that the C2IAMM may be associated with higher survival and technical survival.

On technical survival 3 curve, the events are transfer to hemodialysis, death and kidney transplantation.
ASSOCIATION OF CONSTIPATION, MICROBIAL TRANSLOCATION, AND INFLAMMATION IN HD PATIENTS
Yu-Kang Chang1 and Paik Seong Lim2

1Tungs’ Taichung MetroHarbor Hospital, Department of Medical Research, Taichung, Taiwan, Rep. of China and 2Tungs’ Taichung MetroHarbor Hospital, Division of Renal Medicine, Taichung, Taiwan, Rep. of China

Background and Aims: Increased gut permeability and intestinal dysbiosis may contribute to chronic inflammation, leading to accelerated atherosclerosis and cardiovascular complications in patients on haemodialysis (HD). Constipation is highly prevalent in HD patients and growing evidence suggested constipation can aggravate gut microbiota dysbiosis and gut inflammation. The aim of this study was to evaluate the association between markers of microbial translocation, intestinal permeability and inflammation in HD patients with and without constipation.

Method: A cross-sectional, observational study was conducted and 200 stable prevalent HD were enrolled. Serum zonulin, eotaxin-1, amyloid A, intestinal fatty acid-binding protein (iFABP), IL-6, endotoxin core antibodies (EndoCAb) and lipopolysaccharide binding protein (LBP) levels were measured. Functional constipation was defined according to the Rome IV criteria.

Results: Serum levels of zonulin and eotaxin-1 but not LPS, endo-Cab IgG, amyloid A and IL-6 were significantly higher in HD patients with constipation than in non-constipated HD controls. The multiple logistic regression analysis in constipated HD patients after adjustment for age, and BMI demonstrated that serum zonulin and eotaxin-1 were independently associated with constipation with an odds ratio (OR) of 1.24 (95% CI = 1.09-1.42, p = 0.0016) and 1.02 (95% CI = 1.01-1.03, p = 0.0001), respectively.

Conclusion: We demonstrate that there was association between serum eotaxin-1 and zonulin levels in constipated HD patients. This may indicates that increased intestinal inflammation or intestinal permeability in these patients but the significance of these findings need further investigation.

#3182
IT FOLLOWS: THE EFFECTS OF COVID ON THE INCIDENCE OF OPTIMAL RENAL REPLACEMENT THERAPY YEARS AFTER ITS ONSET
Maria Peris-Fernandez, Ramón Devesa-Such, Iris Viejo Boyano, Amparo Soldevila-Orient, Pilar Sánchez-Pérez and Julio Hernandez Jaras

La Fe University and Politechnic Hospital, Valencia, Spain

Background and Aims: Patients with advanced chronic kidney disease and those on dialysis have had increased morbidity and mortality in relation to COVID infection. However, patients who did not contract the infection also suffered its effects; since the lack of face-to-face consultations and the impossibility of going to the Emergency Department during the pandemic had negative results on the care of these patients’ kidney condition.

Method: We present a single-center retrospective observational study of a cohort of 423 patients that were discharged from the ACKD clinic from the start of 2018 to the end of 2022 to initiate renal replacement therapy. We recorded whether the initiation had been optimal or not, defining non-optimal renal replacement therapy as patients who had:
• Initiated RRT due to an acute decompensation of their underlying disease that required hospitalization.
• Initiated hemodialysis through a central venous catheter instead of an arteriovenous fistula, because the access was not mature yet or otherwise unavailable.
• Had to change their preferred form of renal replacement therapy because of rapid decompensation.
• Chose conservative management, but died without benefiting from home medical and nursing care.
We also collected their age, cardiovascular risk factors (hypertension, diabetes mellitus, dyslipidemia, obesity and smoking), initial preferred therapy, actual

</table>
RRT, reason of non-optimal therapy and whether there had been an intercurrent COVID infection at the time of initiation.

Results: We analyzed 423 patients that had chosen a preferred RRT (16.8% chose conservative therapy and were treated by home care services, 34% initiated hemodialysis through an AVE, 27.4% initiated dialysis through a permanent central venous catheter, 5.2% through a temporal CVC, 13.5% initiated peritoneal dialysis, 1.7% died before initiating their preferred technique and 1.4% underwent a preemptive kidney transplant). The patients that initiated hemodialysis before the pandemic started had a significantly lower risk (p<0.001) of starting RRT in a non-optimal manner (HR 0.514 [95% CI 0.341-0.775] compared to those after the pandemic. Of the cardiovascular risk factors, only diabetes mellitus was significantly associated with non-optimal RRT (p<0.005). Patients without diabetes had significantly less risk of substandard RRT initiation (HR 0.561 [95% CI 0.373-0.849]). Patients with COVID at the time of starting renal replacement therapy had a significantly higher risk of beginning it in a non-optimal way (p<0.013). Age had no statistically significant relation to optimal RRT. The most frequent reason for non-optimal RRT was an acute decompensation that required hospitalization, which accounted for 62% of the patients. 9.6% had a catheter inserted even though they were arteriovenous fistula carriers, and 9% had to change techniques. As for the rest, they chose conservative management but died without home care or two or more reasons were named.

Conclusion: The incidence of COVID has decreased since the early years of the pandemic, and the effects of the virus are less lethal thanks to vaccines. However, the harmful effects of the pandemic on the care of renal patients and the evolution of their disease are still present, as it is shown by the result of our study. We should be especially mindful of patients with diabetic disease and undergoing a covid infection, because these factors may precipitate non-optimal renal replacement therapy initiation.

SERUM CHEMOKINE CC-MOTIF LIGAND 17 IS A PREDICTIVE MARKER OF SEVERE COVID-19 IN HAEMODIALYSIS PATIENTS

Hiroko Beppu1,2, Tatsuya Fukuda3,4, Naoya Otsubo1, Tomoko Kawanishi3, Toshiie Ogawa1, Yasutomo Abe1, Mariko Endo1, Tomohide Hanawa1, Chise Sugita3, Shuji Hatakeyama5,6, Tetsuya Yamada5 and Sachiko Wakai1

1Tokyo Metropolitan Okubo Hospital, Nephrology, Shinjuku, Japan, 2Niigata University, Cooperative Graduate School, Graduate School of Medical and Dental Sciences, Niigata, Japan, 3Tokyo Medical and Dental University, Molecular Endocrinology and Metabolism, Graduate School of Medical and Dental Sciences, Bunkyo, Japan, 4Tokyo Metropolitan Okubo Hospital, Endocrinology and Metabolism, Shinjuku, Japan, 5Tokyo Metropolitan Okubo Hospital, Pulmonary Medicine, Shinjuku, Japan and 6Jichi Medical University Hospital, General Internal Medicine/Infectious Diseases, Shimotsuke, Japan

Background and Aims: Maintenance haemodialysis (HD) patients are at higher risk for severe coronavirus disease 2019 (COVID-19). Because of a limited number of facilities that can provide inpatient treatment for COVID-19 and HD, it is important to identify HD patients who are at high risk for severe COVID-19. For mild to moderate COVID-19 patients, chemokine CC-motif ligand 17 (CCL17) was reported to be a predictive marker for severe COVID-19; however, the validity of CCL17 among HD patients is unknown.

Method: This retrospective observational study enrolled 107 HD patients with mild or moderate COVID-19 at hospitalisation (mean age 70.1±15.1 years; 71.0% male). Receiver operating characteristic and logistic regression analyses were used to examine the predictive validity of indices for severe COVID-19 which is defined as partial pressure of oxygen/fraction of inspired oxygen (P/F) ratio <300 or SpO2 <94%. Multi-variate logistic regression models were used to investigate the association of CCL17 level with the development of severe COVID-19. Furthermore, to evaluate the degree of improvement in predicting performance in the pre-existing model with the addition of CCL17 compared to the pre-existing model, we calculated net reclassification improvement (NRI) and the integrated discrimination improvement (IDI).

Results: During hospitalisation, 32 patients developed severe COVID-19. Serum CCL17 collected at admission exhibited a higher area under the curve value (0.818) compared with that of other indicators including LDH and C-reactive protein for the prediction of severe COVID-19. The optimal cut-off value for CCL17 was 150.5 pg/ml. A multi-variate logistic analysis revealed that CCL17 (above 150.5 pg/ml) was significantly associated with severe COVID-19 (Odds ratio, 0.063; 95% Confidence interval [CI], 0.017–0.227; P<0.001) even after adjustment for covariates. The addition of the CCL17 to a model consisting of vaccination status, albumin, blood urea nitrogen, C-reacting protein and lactate dehydrogenase, that are variables incorporated in multivariate logistic model, significantly improved classification performance for severe COVID-19 using the NRI (1.16, 95% CI: 0.82–1.50, P<0.001) and IDI (0.18, 95% CI: 0.09–0.26, P<0.001).

Conclusion: CCL17 levels in HD patients with mild or moderate COVID-19 predict risk of developing severe COVID-19.
#4261

**RELATIONSHIP BETWEEN FLUID OVERLOAD AND AVERAGE PLASMA REFILL RATE IN HEMODIALYSIS PATIENTS**

Lin-Chun Wang1, Ariella Mermelstein1,2, Jochen Raimann1,2, Ulrich Moissl3, Hanjie Zhang4, Stephan Thijssen1 and Peter Kotanko1,4

1Renal Research Institute, New York, United States of America, 2Katz School of Science and Health at Yeshiva University, New York, United States of America, 3Fresenius Medical Care, Bad Homburg vor der Höhe, Germany and 4Icahn School of Medicine at Mount Sinai, New York, United States of America

**Background and Aims:** Attaining the optimal balance between achieving adequate volume removal while preserving organ perfusion remains challenging in patients on maintenance hemodialysis (HD). Quantification of fluid status using bioimpedance spectroscopy (BIS) has become routine in many countries. Inadequate vascular space refill from the interstitial tissue (plasma refill rate, PRR) is the main contributing factor of hemodynamic instability during HD. We aimed to explore the association between fluid overload (FO) and plasma refill rate (PRR) in chronic HD patients.

**Method:** Pre-HD FO [l] was assessed once per subject by BIS (Body Composition Monitor; Fresenius Medical Care) in four urban HD dialysis clinics in the U.S. For each treatment within 30 days before and after the BIS measurement, we calculated the respective pre-HD FO by assuming that differences in pre-HD body weight were equivalent to differences in FO. We then used intradialytic hematocrit (measured with the Crit-Line® Monitor, Fresenius Medical Care) and ultrafiltration data to quantify the average PRR, normalized by body weight (Wang et al. Kidney360, 2023): To calculate the starting blood volume (BV), we first calculated the ending BV using the Nadler equation, followed by back-calculating the starting BV based on the cumulative change in relative BV. Plasma refill volume was calculated as the sum of the changes in blood volume and ultrafiltration volume; plasma refill volume was then divided by treatment time and estimated clinical dry weight to calculate the PRR [ml/kg/hr].

**Results:** We analyzed 746 HD sessions from 79 patients (age 61±15 years; 52 (66%) males; 41 (52%) black and 33 (42%) white). Across all HD sessions, PRR was positively associated with FO (slope estimate 0.92 (95% confidence interval 0.83 to 1.02) ml/kg/hr per 1 l of FO, P value < 0.0001) (Figure 1). This was also the case in subgroup analyses of fluid depleted (r = 0.94, P<0.001), normohydrated (r = 1.03, P<0.0001), and fluid overloaded subjects (r = 0.83, P<0.0001).

**Conclusion:** Across the entire fluid status spectrum, from fluid depletion to fluid overload, higher FO was associated with higher PRR on average (overall, an increase of 0.92 ml/kg/hr in PRR for each additional liter of FO). While patients with greater FO would be expected to better tolerate higher ultrafiltration rates, there is large inter-individual variability in PRR. Further investigation of the utility of PRR throughout HD may offer novel insights into fluid management and intradialytic symptom mitigation.

**REDUCED VO2PEAK IN PATIENTS WITH END-STAGE RENAL DISEASE: UNVEILING THE HIDDEN IMPLICATION OF CEREBRAL AND MUSCULAR HEMODYNAMICS**

Amal Machfer1, Semah Tagougui2, Hayfa Hadd Hassen1, Nadia Fekih3, Hassen Ibn Hadj Amor1, Mohamed Amine Bouzid4 and Hamdi Chtourou1

1University of Sfax, High Institute of Sport and Physical Education, Sfax, Tunisia, 2University of Lille, France and 3Faculté de Medicine, Université de Monastir, Monastir, Tunisia

**Background and Aims:** Aerobic fitness, as reflected by maximal oxygen (O2) uptake (VO2peak), is impaired in chronic kidney disease (CKD) patients. The mechanisms underlying this impairment remain to be explored. This study aimed to investigate whether CKD influence O2 supply including O2 delivery and release to the brain and active muscles during maximal physical exercise.

**Method:** Twenty three male undergoing dialysis therapy (HD group) and twenty three healthy males (CTR group) performed exhaustive incremental exercise to determine VO2peak. Throughout the exercise, near-infrared spectroscopy allowed investigation of changes oxyhemoglobin (O2Hb), deoxyhemoglobin (HHb), and total hemoglobin (THb) in the prefrontal cortex and in the vastus lateralis muscle.

**Results:** VO2peak was significantly lower in HD group compared to CTR. Muscular ΔHHb changes was impaired in HD patients (Figure 1). Increase in ΔTHb (i.e., muscle blood volume) was significantly blunted in HD in both muscular and cerebral side (Figure 1 and 2). A positive correlation has been observed between VO2peak and muscular blood volume (ΔTHb) for both groups.

**Conclusion:** HD patients displayed lower VO2peak that could be linked, in part, to impaired muscular hemodynamics responses during the exercise. Furthermore, reduced exercise muscle and brain blood volume may warm clinicians of brain endothelial or microcirculation dysfunction in HD population occurring even before overt microangiopathy.
Figure 1: Recordings made by NIRS from the vastus lateralis change in $\Delta O_2$Hb (A), $\Delta$HHb (B) and $\Delta$THb (C). Values are means ±SD. HD, black triangles; CTRL, white triangles. *p < 0.05 vs baseline † p < 0.05 vs. HD.
TUMOR NECROSIS FACTOR RECEPTOR 2 POLYMORPHISM (RS1061622) AND INFLAMMATORY RESPONSE IN END-STAGE RENAL DISEASE PATIENTS UNDER DIALYSIS

Background and Aims: Enhanced levels of soluble tumor necrosis factor receptor 2 (sTNFR2) are known to associate with progressive chronic kidney disease (CKD), and is pointed as a potential biomarker for early detection of CKD; moreover, it has been reported as an independent predictor of all-cause mortality in end-stage renal disease (ESRD) patients under dialysis. Despite the increase in TNFR2 and in other inflammatory markers, recognized as risk factors for mortality in dialysis patients, the hypothesis that genetic polymorphisms of those biomarkers might modulate the inflammatory response and, thereby, the patients’ survival predisposition, has been poorly studied.
Concerning TNFR2 genetic variants, a single nucleotide polymorphism in TNFR2 (rs1061622), that results in amino acid change at position 196 (Met/Arg), was associated with higher levels of sTNFR2 in inflammatory conditions. The aim of this study was to determine the allelic frequencies of TNFR2 in ESRD patients and controls, and to evaluate its relationship with the circulating levels of inflammatory biomarkers.

**Method:** We studied 277 ESRD patients on dialysis and 32 controls, matched for gender, body mass index, and, as far as possible, for age. Real time PCR TaqMan SNP genotyping assay was used to assess allelic frequencies of TNFR2 (rs1061622). We also evaluated the circulating levels of TNF-alpha, sTNFR2, ferritin, hepcidin, elastase and cell-free DNA (cfDNA). Deaths occurring along 1-year follow-up period were recorded and mortality rates were assessed.

**Results:** ESRD patients presented higher levels of all studied biomarkers, as compared to controls; their overall mortality rate was 10.5%. Allelic frequencies in ESRD patients and controls were similar for sTNFR2, considering the homozygous and heterozygous individuals ($\chi^2$, $p = 0.518$). Concerning sTNFR2 values, no significant differences were observed between patients with genotypes TT, GG or TG. The GG genotype patients, compared to TT genotype carriers, presented significantly lower ferritin ($p = 0.048$), hepcidin ($p = 0.038$), elastase ($p = 0.006$) and cfDNA levels ($p = 0.016$); and compared to TG genotype patients, showed significantly lower ferritin ($p = 0.039$) and a trend towards lower values of hepcidin ($p = 0.097$), elastase ($p = 0.079$) and cfDNA ($p = 0.0164$). TG genotype patients showed higher TNF-alpha ($p = 0.049$) and a trend towards lower elastase ($p = 0.081$) than TT genotype subjects. The GG genotype patients presented a trend towards lower mortality rate (6.3%, 7.5%, and 12.4% for GG, TG and TT, respectively).

**Conclusion:** No differences were found in the allelic frequencies between controls and ESRD patients. The GG genotype patients for TNFR2 rs1061622 polymorphism decreased levels of inflammation, suggesting a more favorable inflammatory response, which is usually associated to a lower mortality risk in these patients. In accordance with the scientific community, recommending studies on genetic survival predisposition in dialysis patients, the polymorphisms of TNFR2 and of other inflammatory biomarkers deserve further studies. **MORTALITY FOR COVID-19 IN UNDERGOING MAINTENANCE DIALYSIS PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

Chen Wu, Guoqiang Xie, Junzhe Chen, Qin Liu, Honglei Wang and Ying Tang

The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, P.R. China

**Background and Aims:** Since December 2019, patients undergoing maintenance dialysis have been significantly affected by COVID-19, facing higher risk of death than general population. However, current evidences assess the mortality of patients with COVID-19 remains incomplete. We performed meta-analyses of overall mortality in dialysis patients after SARS-CoV-2 infection. In addition, this study investigated the differences among different races, viral variants, hemodialysis and peritoneal dialysis with COVID-19. At the same time, the mortality rate of dialysis patients with the COVID-19 after vaccination was also observed.

**Method:** We performed a meta-analysis with literature searching in PubMed, EMBASE, Web of Science and Cochrane databases, published between December 1, 2019 and January 10, 2023. Two authors separately screened the titles and abstracts of the documents and ruled out irrelevant articles. Fixed effects model and random effects model were used for calculating heterogeneity.

**Results:** A total of 83 studies included 7278 died from confirmed COVID-19 cases in a pool of 42925 dialysis patients. Overall mortality of COVID-19 in dialysis patients was 22% (95% Confidence Interval [CI]: 19%-25%, $p < 0.01$; $I^2 = 96.74$%) from 2020 to 2022. In subgroup analysis, compared with ancestral COVID-19 (23%, 95% CI: 20%-25%, $p < 0.01$; $I^2 = 93.93$%) and alpha variant (30%, 95% CI: 21%-54%, $p < 0.01$; $I^2 = 95.35$%), omicron variant (4%, 95% CI: 0-14%, $p = 0.09$; $I^2 = 0$) had a lower mortality significantly ($p < 0.01$; $I^2 < 0.01$). The mortality for Asian and non-Asian were 20% (95% CI: 16%-25%, $p < 0.01$; $I^2 = 96.6$%) and 24% (95% CI: 20%-27%, $p < 0.01$; $I^2 = 96.32$%) respectively. The odds of death for maintenance hemodialysis and peritoneal dialysis were similar (odd ratio [OR] 1.30, 95% CI: 0.88-1.93, $p = 0.191$; $I^2 = 0$). Furthermore, we also compared vaccination with unvaccination, and found out that vaccination was associated with lower mortality (OR = 0.18, 95% CI: 0.11-0.28, $p < 0.01$; $I^2 = 71.4$%) (Figure 2).

**Conclusion:** Patients undergoing maintenance dialysis with COVID-19 have a higher mortality. These findings suggest that the mortality of omicron variant may be lower than other variants. In our study, there’s no significant difference in mortality between hemodialysis and peritoneal dialysis patients with COVID-19. Moreover, vaccines have a good protective effect on dialysis patients.
ASSOCIATION BETWEEN MODIFIED CREATININE INDEX AND MORTALITY IN PATIENTS UNDERGOING HEMODIALYSIS: A STRATIFIED ANALYSIS IN DIABETES MELLITUS

Background and Aims: Protein-energy wasting, including muscle atrophy, is one of the most frequently reported problems in patients undergoing hemodialysis. A decline in muscle mass leads to limitation and worsening of physical function and is associated with frailty, disability, and decreased survival. Modified creatinine index was used as a marker of lean body mass. Additionally, a longitudinal study revealed that a decrease in the modified creatinine index over time was independently associated with an increased risk of death in patients undergoing hemodialysis. Moreover, the prevalence of diabetes is high among patients undergoing hemodialysis. Diabetes not only leads to reduced skeletal muscle mass but is also a risk factor for cardiovascular events and death among patients undergoing hemodialysis. The relationship between modified creatinine index and mortality can be altered by

Figure 1: Cubic spline of associations between modified creatinine index and hazard ratio in patients undergoing hemodialysis. The red and blue lines indicate the non-diabetic and diabetic groups, respectively. This model was adjusted for age, sex, BMI, vintage, albumin level, and comorbidity scores. The solid line represents the fitted data, and the shaded areas represent 95% confidence intervals. CrI, modified creatinine index.

the presence of diabetes; however, the effect of diabetes on this relationship among patients undergoing hemodialysis is unclear. This study aimed to examine the association between muscle mass and all-cause mortality in the presence or absence of diabetes, which is highly prevalent in hemodialysis patients.

**Method:** We included 361 outpatients undergoing maintenance hemodialysis treatment in 2013–2021 (mean age, 66.3±12.0 years; 61.0% males). Baseline was defined as the date of the first laboratory data and the modified creatinine index measurements, and participants were followed up from baseline to the date of the event (all-cause death, transfer, or end date of study follow-up [May 2021]). Modified creatinine index was calculated using age, sex, predialysis serum creatinine level, and single-pool Kt/V for urea. The primary outcome was death due to any cause. A Cox proportional hazards regression model was used to examine the association between the modified creatinine index and all-cause mortality. The dose–response association between the modified creatinine index and all-cause death was modeled using a restricted cubic spline model.

**Results:** A significant interaction was found between the presence of diabetes and modified creatinine index (p = 0.04). In the non-diabetic group, a lower modified creatinine index was associated with a higher risk of all-cause death (hazard ratio [HR], 1.33; 95% confidence interval [95% CI], 1.09–1.63), whereas no significant association between modified creatinine index and all-cause death was observed in the diabetic group (HR, 1.00; 95% CI, 0.83–1.20).

**Conclusion:** The modified creatinine index was more strongly associated with all-cause mortality in the nondiabetic group than in the diabetic group. The modified creatinine index is a useful tool for the nondiabetic group, and these results may provide useful information for examining the relationship between skeletal muscle mass and prognosis in patients undergoing hemodialysis.

#3356 COVID-19 PANDEMIC EFFECT ON HOSPITALIZATION OF HEMODIALYSIS PATIENTS

Kaitlyn Croft1, Yan Zhang1, Luca Neri2, Paola Carioni2, Otto Arkossy1, Manuela Stauss-Grabo3, Len A Usyta1, Stefano Stuard1 and Anke Winter1

1Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany, 2Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy and 3Fresenius Medical Care, Global Medical Office, Waltham, United States of America

**Background and Aims:** During the COVID-19 pandemic many facets of our lives were affected, including the healthcare systems worldwide. We aimed to assess the hospitalization rates of hemodialysis (HD) patients with confirmed COVID-19 infection (COVID-19+) versus other patients (i.e., patients with no documented COVID-19 infection in the European Clinical Database (EuCliD®)) in 2020 and their relation to HD patients from the pre-pandemic era in 2019.

**Method:** We included 63,216 HD patients treated in 2019–2020 in NephroCare centers from 23 countries from EuCliD® in the Europe, Middle East, and Africa (EMEA) region. Monthly hospitalization rates (hospital admission per 10,000 patients) were estimated separately for COVID-19+ and other HD patients in 2020, and HD patients treated in 2019, with COVID-19+ status as a time-varying variable. The number of COVID-19 cases and deaths were extracted from data released by the European Commission Joint Research Centre (ECJRC).[1]. The correlation between the monthly hospitalization rates and numbers of COVID-19 cases and deaths in general population (GP) were evaluated.

**Results:** Characteristics of the approximately 42,000-43,000 monthly treated HD patients were comparable between 2019 and 2020 (Table 1). The hospitalization rates were much higher for COVID-19+ HD patients throughout 2020 compared to other HD patients in 2020 and HD patients in 2019. The hospitalization rates were highest in the spring of 2020 for COVID-19+ HD patients. However, in 2020 other HD patients' hospitalization rates were lower than the 2019 HD patients' hospitalization rates. Interestingly the hospitalization rates of other HD patients in 2020 dipped even more below hospitalizations for HD patients in 2019 following the GP pandemic waves (Figure 1). Hospital admission for both COVID-19+ and other HD patients were inversely correlation with the pandemic conditions in GP (Figure 2; spearman correlation coefficients [p] with COVID-19 cases/deaths in GP, -0.77/-0.22 and -0.29/-0.64, respectively, for COVID-19+ and other HD patients).

**Conclusion:** Our study indicated the COVID-19 pandemic had an impact on hospitalization rates of both HD patients with a COVID-19 diagnosis and those patients without a documented COVID-19 infection. Potential reasons of decreased hospitalization rates in patients without a documented COVID-19 diagnosis could be healthcare resource constraints or regarding patient concerns about exposure to COVID-19 in hospital settings [2].

![Figure 1: Monthly hospital admission per 10,000 HD patients in 2019-2020 and incident COVID-19 cases/deaths in general population (GP) in 2020.](image-url)

NON-INVASIVE ASSESSMENT OF LIVER STIFFNESS, HEPATIC FIBROSIS RISK MARKERS AND OUTCOMES IN A DIALYSIS POPULATION

Oscar Swift1, Malcolm Finkelman2, Yonglong Zhang2, Eunice Doctolero1, Chadd Javier1, Mikky Gilbert1, Kieran McCafferty3, Jon Wong4, Paul Warwicker5, Jean Patrick6, Richard Warburton1, Sivakumar Sridharan1, Kenneth Farrington1 and Enric Vilar1

1 East & North Hertfordshire NHS Trust, United Kingdom, 2 Associates of Cape Cod Inc, Falmouth, United States of America, 3 The Royal London Hospital, United Kingdom, 4 Broomfield Hospital, Broomfield, United Kingdom, 5 Royal Preston Hospital, Fulwood, United Kingdom and 6 James Paget Hospital, Gorleston-on-Sea, United Kingdom

**Background and Aims:** People with end stage kidney disease (ESKD) commonly co-exhibit multiple risk factors (type 2 diabetes mellitus, obesity and hypertension) for non-alcoholic fatty liver disease (NAFLD) and its progressive, fibroinflammatory form non-alcoholic steatohepatitis (NASH). NAFLD and NASH both associate with increased risk of fatal cardiovascular events. NASH will additionally soon become the leading cause of cirrhosis both in the UK and worldwide. The cause of systemic inflammation driving early mortality in patients with ESKD is unclear. It is thought that liver disease can contribute to inflammation due to reduced reticuloendothelial function and subsequent penetration of gut-derived toxins into the systemic circulation. Very little is currently known about prevalence of NAFLD and NASH in ESKD, or how these conditions affect patients. By identifying the scale of the risk, this study will help better understand the extent of NAFLD and NASH and their links to clinical outcomes in advanced kidney disease. We report interim results from this study looking non-invasively for liver disease in patients with ESKD.

**Method:** This prospective study involves prevalent patients with ESKD treated with dialysis (for >3 months) at five participating UK kidney centres. Results from this study are derived from analysis of the first 238 patients (final recruitment target 450). A FibroScan® (Echosens) device was used to measure both hepatic steatosis using controlled attenuation parameterography (CAP) and fibrosis using transient elastography. A fibrosis-4 index score was calculated to assess fibrosis risk. These results were supplemented by baseline clinical and radiological data, serum beta-D-glucan levels taken pre- and post-dialysis, clinical assessment of fluid status, and bioimpedance spectroscopy (Fresenius Medical Care). Survival analyses were performed using Kaplan-Meier estimates.

**REFERENCES**
Hypertension Associates, Bluefield, United States of America, 13 Istanbul, Slovenia, 16 University of Ljubljana, Medical Faculty, Ljubljana, Slovenia, Department of Nephrology, Division of Internal Medicine, Ljubljana, Slovenia, Brigham and Women’s Hospital, Boston, United States of America, Ewa Pawlowicz-Szlarska1, Z. Serhan Tuglular2, Kai-Uwe Eckardt3, Daniel Gallego Zurro4,5, Dmytro Ivanov6, Valerie A. Luyckx7,8, Ionut Nistor9,10, Edita Noruisiene11, Mohamed Sekkarie12, Mehmet Sukru Sever13, Rukshana Shroff14, Andrej Skoberne15,16, Stefano Stuard17, Raymond Vanholder4,18 and Andrzej Jan Wiecek19

Body mass index was 27.8 kg/m². 97% of participants had hypertension, 53% diabetes mellitus and 65% hyperlipidaemia. 231 participant FibroScan scores (97%) were valid (interquartile range <30% over 10 consecutive readings) and available for analysis. 74 participants (31%) had suspected hepatic steatosis of grade S1-S3 and 72 participants (30%) had suspected hepatic fibrosis of grade F2-F4, 53 participants (22%) had suspected F2-F3 fibrosis (moderate fibrosis) and 19 (8%) had suspected F4 fibrosis (advanced fibrosis/cirrhosis). There was increased mortality associated with suspected hepatic fibrosis/steatosis (9.1% absolute risk of mortality with an abnormal CAP or fibrosis score compared to 1.6% in those with normal FibroScan imaging). The majority of mortality in people with suspected hepatic fibrosis was from cardiovascular disease. Overall mortality in participants with suspected hepatic fibrosis remained significant even after adjustment for univariate predictors of survival (median CRP baseline >10 mg/L, age and gender (Figure 1)). Multivariate predictors of survival were Charlson Comorbidity Score and diabetes status.

Conclusion: These results demonstrate a significant burden of suspected hepatic steatosis and hepatic fibrosis in people with ESKD. Suspected hepatic fibrosis assessed by FibroScan imaging is an independent risk factor for mortality based on this interim analysis and strategies to improve liver health in the setting of advanced kidney disease may be of benefit to this group of patients.

Background and Aims: The Russian invasion on Ukraine, which started on 24th February 2022 led to migration of millions of people, including some of the about 10,000 adult dialysis patients. A Renal Disaster Relief Task Force (RDRFT) established by the European Renal Association, is dedicated to support the people living with kidney disease and to the nephrology community in Ukraine, working together with WHO, NGOs and industry. Besides these activities, the RDRFT conducted a survey to understand distribution and management of Ukrainian refugees requiring dialysis displaced to other European countries. The study aim was to characterize these patients and evaluate treatment modality and care they received after displacement.

Method: A cross-sectional online survey on status of displaced dialysis patients, clinical data and care they received after migration was sent to all national nephrology societies across Europe with a request to disseminate it to all dialysis centers in their countries. Data were collected between May and August 2022. Fresenius Medical Care (FMC) shared a set of aggregated data without direct center participation.

Results: The mean age of participants was 63 years (67% male). Mean body mass index was 27.8 kg/m². 97% of participants had hypertension, 53% diabetes mellitus and 65% hyperlipidaemia. 231 participant FibroScan scores (97%) were valid (interquartile range <30% over 10 consecutive readings) and available for analysis. 74 participants (31%) had suspected hepatic steatosis of grade S1-S3 and 72 participants (30%) had suspected hepatic fibrosis of grade F2-F4, 53 participants (22%) had suspected F2-F3 fibrosis (moderate fibrosis) and 19 (8%) had suspected F4 fibrosis (advanced fibrosis/cirrhosis). There was increased mortality associated with suspected hepatic fibrosis/steatosis (9.1% absolute risk of mortality with an abnormal CAP or fibrosis score compared to 1.6% in those with normal FibroScan imaging). The majority of mortality in people with suspected hepatic fibrosis was from cardiovascular disease. Overall mortality in participants with suspected hepatic fibrosis remained significant even after adjustment for univariate predictors of survival (median CRP baseline >10 mg/L, age and gender (Figure 1)). Multivariate predictors of survival were Charlson Comorbidity Score and diabetes status.

Conclusion: These results demonstrate a significant burden of suspected hepatic steatosis and hepatic fibrosis in people with ESKD. Suspected hepatic fibrosis assessed by FibroScan imaging is an independent risk factor for mortality based on this interim analysis and strategies to improve liver health in the setting of advanced kidney disease may be of benefit to this group of patients.

SEROREVOLUTION OF COVID-19 INFECTION BASED ON IGG ANTIBODY AGAINST NUCLEOCAPSID PROTEIN (NP) AND SPIKE PROTEIN (S) IN HEMODIALYSIS PATIENTS

Sukhinath Bhournik1, Masud Iqbal2, Raquib Morshed3, Sohrab Alam4, Shahryar Waheed5, Kazi Shahnood Alam6, MD Nazrul Islam7, Sajal Krishna Banerjee8, Ms Hassan9 and MI Arslan10

1 NIKDU, Bangladesh, 2 KDRG, Bangladesh, 3 BIRDIE M, Bangladesh, 4 SSMC, Bangladesh, 5 DMC, Bangladesh and 6 BSMMU, Bangladesh

Background and Aims: Maintenance hemodialysis (MHD) patients have been identified as a high-risk group for COVID-19 infection. Serological testing can be used to monitor disease prevalence & evaluate screening measures & protocols aiming at limiting transmission within dialysis units. This study was conducted to observe the sero prevalence of COVID-19 infection among maintenance hemodialysis patients.

Method: The study was conducted during the 3rd wave of covid-19 infection. Total 194 in-center MHD patients were included from three dialysis centers. Relevant history regarding covid-19 symptom, testing, managements and vaccination were collected. During our study a serum sample was collected to test IgG antibody against nucleocapsid protein (NP) (cut-off positive when > 1.5) and spike protein (S) (cut-off positive when > 50 AIU/L) of COVID-19 infection and tested by Chemiluminescent microparticle immunoassay (CMIA) method developed by Abbott (FDA-EUA approved).

Results: Mean age of the MHD subjects was 48±12 years where male was 60%, Duration of MHD was 31±22 (6-120) months. Renal pathology was DN in 31%, possible GN 31%, HTN 19% and rest from others. From records past covid infection was clinically diagnosed in 39% of which 10% based on RT-PCR and another 29% fell into suspected category (i.e. symptom with/or suggestive serology). Presentation pattern was mild in 75%, moderate 15% (requiring oxygen), severe in 5% (requiring hospitalization) and asymptomatic rest 5%. Vaccine against covid-19 was avalied by 38%. In vaccinated vs. non-vaccinated patients the IgG for NP was positive in 63% vs. 561% (P = 0.65) and IgG for S was 99% vs. 98% (P = 0.56). These indicate naturally acquired immunity in most before any vaccination. The IgG titer against spike (S) protein between vaccinated and non-vaccinated groups was 7743±8920 and 5386±6839 AIU/L (p = 0.06). The correlation study showed that IgG titer against S has no correlation with dialysis duration, age, BMI, Hb%, serum albumin or Kt/V. Similarly IgG titer against NP shows mostly no significant correlation with laboratory parameters.
Conclusion: These data demonstrate that seroprevalence in hemodialysis population based on antibody against nucleocapsid protein only half infected by SARS-CoV-2 where as antibody against spike protein indicates larger number of patients are naturally infected even before vaccinated. Therefore for seroprevalence studies both antibody testing should be used to identify greater population infected until more sensitive tools are established.

Background and Aims: Chronic kidney disease (CKD) is a leading cause of morbidity and mortality worldwide, with African descendants being at increased risk of occurrence and progression to end-stage renal disease (ESRD). However, the burden of CKD and ESRD in African continent is still largely conjectural and access to treatment of CKD complications, VA for HD, and vascular access (VA) dysfunction in 6.3% (n=8); these 8 patients with VA dysfunction were already on hemodialysis program before their evacuation to Portugal and they were mainly from Cape Verde (n=4), Angola (n=3), and one patient from Guinea-Bissau. At arrival, patients who initiated HD in our unit had mean serum creatinine 9.4 ± 4.4 mg/dL, urea 182.5 ± 109.1 mg/dL, Hb 9.6 ± 1.7 g/dL, serum albumin 3.6 ± 0.6 g/dL, PTH 491.7 ± 392.6 pg/mL. Patients referred due to VA dysfunction had mean Hb 10.1 ± 1.8 g/dL, serum albumin 3.7 ± 1.0 g/dL, PTH 918.9 ± 541.6 pg/mL. There were no statistically significant differences in both groups concerning country of origin, although hypalbuminemia was more frequent in patients from Saint Thomas and Prince (50%) and Angola (42.9%). All patients started HD with a central venous catheter (CVC). During follow-up, CVC remained the vascular access in 51.6% (n = 65), arteriovenous fistula in 42.9% (n = 54), and arteriovenous graft in 3.6% patients (n = 7). Nine patients had exhaustion of VA for HD. Mean follow-up time was 70.5 ± 41.3 months, 1.6% of the patients transitioned to peritoneal dialysis (n = 2) and 15.1% were submitted to renal transplantation (n = 18). The mortality rate during follow-up was 14.3% (n = 18).

Conclusion: There are few studies about African patients undergoing HD and this is the first study presenting the clinical characteristics and outcomes of hemodialysis patients from ACPOL. These are young patients, almost all with hypertension, with a high prevalence of anemia, malnutrition, and secondary hyperparathyroidism. All patients started HD with CVC and several presented multiple access dysfunction. These data reinforce the urgent need of improvement and investment in African countries' healthcare, especially on what concerns the ESRD, as it contributes to serious consequences in these patients’ survival and quality of life. With the cooperation protocol, Portugal provides these patients with RRT, treatment of the CKD complications, VA care, possibility of peritoneal dialysis and renal transplantation, ultimately improving their chance of survival and quality of life.

WHERE DOES THE PATIENT ON CHRONIC RENAL REPLACEMENT TREATMENT DIE?

Anna Petrosino1,2, Silvia Bellardinelli1,2, Serena Bruno1,2, Maria Grazia Porri1,2, Silvia D’Alonzo1,2, Giuseppe Grandaliano1,2 and Nicola Panocchia1,2

1Università Cattolica del Sacro Cuore, Dipartimento di Chirurgia e Medicina Traslazionale, Rome, Italy and 2Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Unità Operativa Complessa di Nefrologia, Rome, Italy

Background and Aims: In the last years, the age of patients on maintenance renal replacement treatment (RRT) became higher and higher. In addition, they have an increasing number of serious comorbidities, such as cardiovascular diseases, diabetes, chronic obstructive pulmonary diseases and peripheral vascular disease. Consequently, there was a rise in hospitalization rate for these patients, nearly achieving 1.48 per person-year, in 2020. One out of 11 hospital discharges among End Stage Renal Disease (ESRD) patients in 2020 was followed by death without re-hospitalization within 30 days. The 5-years survival rate for patients in hemodialysis is 40%, with a median lifespan of 47 months [1]. In the clinical practice, nephrologists use to focus on the complex clinical picture of these patients, but rarely they consider them for palliative care [2]. Nephrology community awareness is growing up concerning palliative care and end-of-life issue, taking into account a simultaneous palliative care, for these patients and their families as well [3]. The aim of the study was to investigate the end-of-life treatment of patients on chronic dialysis.

Method: We analyzed data of patients dead on maintenance renal replacement therapy (RRT) in Policlinico A. Gemelli (Rome), in a five years period from January 2018 to January 2023. We collected relevant data from clinical and administrative records. In particular, we focused on demographic data, comorbidities (Figure 1), causes and places of deaths (home, hospital, hospice). We considered place of death as a surrogate indicator of the use of palliative care.

Results: Ninety four out of 623 patients on maintenance dialysis (15%) died in the 5 years of observation, with a mean age of 73.8 ± 8.9 years (median 76 years) and an average dialytic vintage of 5.9 ± 4.5 years (median 4.4 years). Seventy-three patients died on chronic hemodialysis (68.6%) and 24 patients on peritoneal dialysis (22.6%). None of them died from dialysis withdrawal, and we did not stop RRT close to death in any patient. The main cause of
death were cardiovascular diseases (35.6%), followed by sepsis (20.2%) and malignancies (12.5%) (Figure 2). Sudden cardiac death occurred in 7 patients (7.4%), while cachexia in 4 (4.2%). Only 5 patients (4.7%) were considered for palliative care: 4 of them died before the start of palliative treatment and 1 died one month later. Sixty-seven (67.3%) patients died during hospitalization. Only 26 (27.6%) patients died at home and 1% in hospice (n = 1).

**Conclusion:** The high percentage of in-hospital mortality, the low in-hospice mortality and the absence of mortality due to treatment withdrawal, indicate a lacking of end-of-life recognition in RRT patients. Hence, our experience demonstrates that the use of palliative care in patients on chronic dialysis is still poor and underestimated. Therefore, we need an urgent educational program about end-of-life issue for nephrologists, aiming at an earlier multidisciplinary approach, in order to improve patients' quality of life and of their end-life.

PATIENT ACUTY AND CARDIOVASCULAR OUTCOME IN HEMODIALYSIS PATIENTS: A KOREAN NATIONWIDE COHORT STUDY

Hyo Jeong Kim¹, Jung Tak Park¹, Ga Young Heo¹, Kyung Won Kim¹, Youg Uk Kwon², Soo Hyun Kim³, Gui Ok Kim³ and Hyung Woo Kim¹

¹Yonsei University College of Medicine, Institute of Kidney Disease Research, Internal Medicine, Seoul, Rep. of South Korea, ²Health Insurance Review and Assessment Service, Healthcare Review and Assessment Committee, Rep. of South Korea and ³Health Insurance Review and Assessment Service, Quality Assessment, Rep. of South Korea

Background and Aims: Patients acuity has been reported to be associated with poor outcome in hospitals. However, the effect of the patient acuity of hemodialysis center on the prognosis of individual patients is not well known. In this study, the association between the severity of illness in hemodialysis facility and major adverse cardiac and cerebrovascular event (MACCE) in patients undergoing hemodialysis was investigated.

Method: 15,633 participants receiving hemodialysis in the primary health care center who participated in the Periodic Hemodialysis Quality Assessment by Health Insurance Review & Assessment Service (HIRA) were examined. The main predictor was severity-to-nurse ratio, defined as a sum of Charlson comorbidity index of all patients divided by the number of nurses in each hemodialysis facility. The primary and secondary outcome were MACCE, and all-cause mortality, respectively.

Results: During a median follow-up of 5.5 years, MACCE and all-cause mortality occurred in 7,966 (51.0%) and 6,536 (41.8%) participants. Participants with higher severity-to-nurse ratio tended to have higher incidence rate of MACCE. The hazard ratios (HRs) of MACCE for the second, third, and highest quartiles compared with the lowest quartile of severity-to-nurse ratio were 1.05 (95% confidence intervals [CI], 0.98-1.11; P = 0.053), 1.07 (95% CI, 1.00-1.14; P = 0.010), and 1.08 (95% CI, 1.00-1.16; P = 0.040). When treating severity-to-nurse ratio as a continuous variable, MACCE risk increased by 1% per 1 increase in severity-to-nurse ratio (HR, 1.01; 95% CI, 1.00 - 1.02; P = 0.003). Compared to the lowest quartile group, the HRs of all-cause mortality for second, third and fourth quartile were 1.12 (95% CI, 1.04-1.19; P = 0.002), 1.11 (95% CI, 1.03-1.19; P = 0.005), and 1.16 (95% CI, 1.07-1.25; P<0.001), respectively.

Conclusion: As the part of the Joint Project on Quality Assessment Research by HIRA, the present study showed that the patient acuity was strongly associated with an increased risk of poor outcomes in hemodialysis patients.

EFFECT OF MORNING VACCINATION COMPARED WITH AFTERNOON/EVENING VACCINATION ON HUMORAL RESPONSE TO COVID-19 VACCINE IN HEMODIALYSIS PATIENTS

Ting-Yun Lin and Szu-Chun Hung

Taipei Tzu Chi Hospital, New Taipei City, Taiwan, Portugal

Background and Aims: Patients with ESKD who are undergoing hemodialysis have impaired immunogenicity to SARS-CoV-2 vaccination. Age, dialysis vintage, use of immunosuppressive drugs, serum albumin, lymphocyte count, vaccine type, and COVID-19 experience have been identified to be associated with humoral and cellular responses. A recent review highlights that vaccination responses also exhibit circadian rhythmicity. However, the benefits of vaccination in the morning compared with later times in the day among hemodialysis patients remain unclear. Therefore, we aimed to determine if morning vaccination with a COVID-19 vaccine was able to induce a higher antibody response than afternoon/evening vaccination among hemodialysis patients.

Method: We conducted a prospective observational study in the hemodialysis unit of Taipei Tzu Chi Hospital, Taiwan. Prevalent hemodialysis patients were stratified into two groups based on time of vaccination and were followed up for 5 weeks. Data were analyzed using repeated measure ANOVA and chi-square tests.

Results: A total of 171 patients were included (median age, 69 years; 55% men). The median time from the first dose of COVID-19 vaccine was 8 weeks (IQR, 5-12 weeks). The antibody response was significantly higher in the morning group than in the evening group (p = 0.007). The percentage of patients with undetectable antibody response was lower in the morning group than in the evening group (p = 0.017). The percentage of patients with seroconversion was higher in the morning group than in the evening group (p = 0.029). The percentage of patients with high antibody response was higher in the morning group than in the evening group (p = 0.010).

Conclusion: Morning vaccination was associated with higher antibody response and seroconversion compared with evening vaccination in hemodialysis patients.
aged 20 years or over with no history of SARS-CoV-2 infection were eligible for enrollment. Patients were excluded if they had been vaccinated, refused vaccination, had inadequate dialysis, or declined to participate. Patients with current use of immunosuppressants were also excluded. All participants received a priming dose of ChAdOx1 nCoV-19, an adenovirus-vectorized vaccine, on June 16 or 17, 2021 during the hemodialysis session. IgG antibodies to the receptor binding domain (RBD) of the S1 subunit of the spike protein of SARS-CoV-2 were measured using the AdviseDx SARS-CoV-2 IgG II assay (Abbott Laboratories, Abbott Park, IL, USA) at Day 28 and Day 56 after vaccination. The cutoff value for positivity was set at ≥50 arbitrary units per mL (AU/mL) based on manufacturer’s recommendations. Multivariable logistic regression analyses were used to evaluate the relationship between time of day of vaccination and antibody response. Covariates identified by prior studies as significant predictors of vaccine response or with a P value <0.1 between responders and nonresponders were fitted.

**Results:** A total of 201 participants were included, with a male to female distribution of 52% to 48%, a mean age of 67 years, and a median dialysis vintage of 7.7 years. Among the participants, 70 were diazylized in the morning (between 7:00 AM and 12:00 PM), 69 in the afternoon (between 12:00 and 5:00 PM), and 62 in the evening (between 5:00 and 10:00 PM). Overall, 137 (68.2%) participants developed antibodies against the SARS-CoV-2 spike protein after a single dose of ChAdOx1 nCoV-19. The median antibody level was 184.6 AU/mL. In the multivariable model, morning vaccination, age, coronary artery disease, and lymphocyte count independently predicted a humoral response at Day 28. Participants who received morning vaccination were more likely to develop seroconversion compared with those who received afternoon/evening doses (odds ratio 3.81, 95% confidence interval 1.59–9.15; P = 0.003). Anti-spire antibody titers were measured in 198 participants at Day 56. The median antibody level was 153.7 AU/mL. A significantly higher proportion of morning-vaccinated hemodialysis patients remained seropositive (odds ratio 2.54, 95% confidence interval 1.15–5.61; P = 0.021).

**Conclusion:** Our preliminary results showed that circadian rhythms might be harnessed to optimize vaccination strategies for hemodialysis patients. Future studies with larger sample size are required to validate our findings.

**THE PREVALENCE AND EVOLUTIONARY EFFECTS OF FRAILTY IN PERITONEAL DIALYSIS PATIENTS**

Yi Tingchen, Tai-Shuan Lai, Shuei-Liong Lin and Yung-Ming Chen

National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, Portugal

**Background and Aims:** Frailty is an age-related condition that predicts adverse outcomes. The clinical effect of frailty in peritoneal dialysis (PD) patients is unmet. The study was aimed to investigate the clinical implications of frailty in PD patients.

**Method:** In this prospective study, PD patients completed frailty assessment at entry and 6 months by a semiautomated frailty index of 80 risk factors (FI80) which also contained the 5 components of Fried frailty phenotype. A score ≥13/80 (FI80 ≥0.16) or ≥3/5 (frailty phenotype) was designated to define frailty.

**Results:** A total of 337 PD patients were recruited (new-onset 23.4%, prevalent 76.6%). Two hundred (59.3%) and 163 (48.4%) patients were frail by FI80 and frailty phenotype, respectively. Predictors for frailty were old age, dialysis, diabetes mellitus, gout and sleep disorder. New-onset patients aged <55 years displayed the best evolution of frailty over 6 months (stable or improved, n = 29/47, 61.7% by FI80, p = 0.0293), compared with other groups. Survival analysis found that frail patients exhibited the worse outcomes (overall death and hospitalization) than their robust and prefrail counterparts. Poisson regression showed frailty was associated with increased utilisations of outpatient and ER visit; however multivariate Cox models identified only diabetes, gout history and low body mass index (<19kg/m²), but not frailty, predicted overall death and hospitalizations.

**Conclusion:** Our data indicate that frailty is a common medical condition in PD patients, and the status of which can be stabilized or improved in new-onset, young patients at least over the short term. Compared with frailty, certain comorbidities (diabetes and gout history) and undernutrition appeared to be more robust in the prediction of adverse outcomes.

PREGNANCY OUTCOMES IN DIALYSIS PATIENTS: A TEN-YEAR SERIES FROM A TERTIARY CENTER
Claudia Costa<sup>1</sup>, Bernardo Silva<sup>1</sup>, Iolanda Godinho<sup>1</sup>, Luísa Pinto<sup>2</sup>, José António Lopes<sup>1</sup> and Estela Nogueira<sup>1</sup>

<sup>1</sup>Centro Hospitalar Universitário Lisboa Norte, Centro Académico de Medicina de Lisboa, Nefrologia e Transplantação Renal, Lisboa, Portugal and
<sup>2</sup>Centro Hospitalar Universitário Lisboa Norte, Gynecology and Obstetrics, Lisboa, Portugal

Background and Aims: Pregnancy in dialysis patients was almost prohibited a decade ago, as fetal and maternal outcomes were very poor. In the last years,
there has been a paradigm shift, as the introduction of intensive hemodialysis (HD) schedules has been associated with an impressive improvement on fetal outcomes, making motherhood a possibility in these women. Nevertheless, pregnancy in women on dialysis remains associated with a high incidence of complications and is extremely demanding for both patients and clinicians.

We describe the maternal, obstetric, and perinatal outcomes of pregnancies in women on dialysis followed at the Nephro-Obstetric Clinic at Centro Hospitalar Universitario Lisboa Norte (CHULN).

**Method:** Retrospective analysis of pregnancies in women on dialysis and surveilled at the Nephro-Obstetric Clinic at CHULN from 2011 to 2022.

**Results:** We considered 17 pregnancies from 16 women. One of the women accounted was submitted to voluntary termination of pregnancy. Mean age was 31.5 ± 6.1 years; 76.6% were Black (n = 11) and 29.4% (n = 5) Caucasian; 58.8% were nulliparous (n = 10). All patients had chronic hypertension (HTN), although only 75.0% were under therapy (12/16). Additionally, 3/16 patients had diabetes and 2/16 hyperthyroidism. The mean of overall renal replacement therapy (RRT) duration was 9.1 ± 8.2 years (dialysis and renal transplantation time), being on dialysis program 43.7 ± 37.5 months before gestation. One patient was on peritoneal dialysis (PD) and two patients started HD during pregnancy. Five patients (31.2%) were exposed to teratogenic drugs during gestation. Pregnancy diagnosis occurred at 13.4 ± 5.6 weeks; 76.6% of the patients were on low dose acetylsalicylic acid (n = 12). HD mean time per week according to each trimester was 13.7 ± 2.8 hours/week, 24.5 ± 7.3 hours/week and 28.0 ± 8.0 hours/week during the 1st/2nd/3rd respectively. Mean pre-dialysis urea was 62.1 ± 28.0 mg/dL during gestation. Regarding maternal outcomes, worsening HTN occurred in 62.5% (n = 10) of patients during the 1st (4/10) and 2nd trimester (7/10) and pre-eclampsia (PE) occurred in 6/16 patients (1 with HELLP syndrome). One patient developed polyhydramnios and another one cholestasis of pregnancy. Premature rupture of membranes (PRM) occurred in 3 patients (at 17, 25 and 36 weeks); One patient asked for medical termination of pregnancy due to severe growth restriction and oligohydramnios at 20 weeks. Stillbirth occurred in 4 gestations (cervical insufficiency in a twin pregnancy, severe congenital fetal cardiopathy in a patient with PE, severe growth restriction and premature rupture of membranes (PRM). In the 2 patients with early PRM, the neonates died in the following week due to severe prematurity complications. Labor was induced in 9 patients, mainly due to PE (7/9). Cesarean was performed in 10/17 patients and mean gestation age at delivery was 29.8 ± 6.6 weeks. Extreme prematurity (<28 weeks) occurred in 3 pregnancies and there were three term babies. Mean birth weight was 1554.0 ±613.6 grams with 4 newborns having extremely low birth weight (<1000g) and 6 requiring neonatal care.

**Conclusion:** Our study reveals that pregnancy in women on dialysis is challenging and still associated with significant maternal, obstetric and perinatal complications. This population was highly heterogeneous, with a significant number of patients living under unfavorable social conditions, and with significant comorbidities. The diagnosis of pregnancy took place mainly during the 2nd trimester, preventing early initiation of intensive dialysis schedules which could have significantly improved outcomes. Pregnancy planning, early diagnosis and management by a multidisciplinary experienced team are of paramount importance to improve outcomes and reduce complications.

---

**Background and Aims:** Chronic kidney disease (CKD) is considered a high-stress disease because of its chronicity, co-morbidity, and lifelong treatment. Family members are often the main caregivers of end stage kidney disease (ESKD) patients and they are involved in various roles. Caregivers of ESKD patients experience emotional stress, anxiety and depression as they support their family members throughout the disease and treatment. This cross-sectional study aimed to assess depression and anxiety in caregivers of ESKD patients and to compare these disorders between caregivers of hemodialysis (HD) patients’ and kidney transplant recipients (KTR), as well as to investigate potential social-demographic parameters associated with caregivers’ depression and anxiety.

**Method:** A total of 342 participants (171 couples of patients and caregivers) were recruited. Structured interviews and self-completed questionnaires were obtained from HD patients, KTR (138 HD patients and 33 KTR) and their caregivers. The Beck Depression Inventory and the Generalized Anxiety Disorder-2 scales were used as screening tools. Depression scores were classified into four levels based on the level of severity (low, mild, moderate, severe). The collected data were encoded and analyzed using IBM SPSS version 25 and R Statistical Software.

**Results:** Mean age of caregivers was 58 years and the majority were females (67.2%). Total anxiety score was high (Mdn = 3) with a mildly increased score of depression (Mdn = 9.5). Caregivers’ anxiety and depressive symptoms were significantly associated with gender, duration of caregiving, educational level, financial status, and caregivers’ age (p<0.01 for all). Caregivers’ depression and anxiety were also, related to the type of patients’ treatment (Table 1). HD caregivers reported significantly higher anxiety scores (Mdn = 3(2–5)) in comparison to KTR caregivers (Mdn = 2(2–4)) (p = 0.048) (Table 2). Moreover, HD caregivers revealed higher (Mdn = 11(0–46)) levels of depression than the KTR group (Mdn = 6 (0-25)) (p = 0.049) (Table 3).

**Conclusion:** Based on the findings of this study, the type of ESKD treatment displayed an important role in caregivers’ anxiety and depression symptoms, with KTR caregivers having the best scores. In particular, KTR caregivers appeared to have lower levels of depression and anxiety than caregivers of HD patients.

HEALTH-RELATED QUALITY OF LIFE AND SYMPTOM BURDEN IN YOUNGER AND OLDER HAEMODIALYSIS PATIENTS: A PROSPECTIVE COHORT STUDY

Mathijs Van Oevelen1, Anna Bonenkamp2,3, Anita van Eck van der Sluijs1,4, Willem Jan W. Bos1,4, Carolien Douma1, Marjolijn van Buren4, Aype van Vliet1,5, Yvette Meuleman6, Friedo W. Dekker7, Brigit Van Jaarsveld8 and Alfiero C. Abrahams4

1Leiden University Medical Center, Department of Internal Medicine, Leiden, Netherlands, 2Jeroen Bosch Hospital, Department of Internal Medicine, ’s-Hertogenbosch, Netherlands, 3Amsterdam Cardiovascular Sciences, Amsterdam University Medical Center, Department of Nephrology, Amsterdam, Netherlands, 4University Medical Center Utrecht, Department of Nephrology and Hypertension, Utrecht, Netherlands, 5Deventer Hospital, Department of Internal Medicine, Deventer, Netherlands, 6St. Antonius Hospital, Department of Internal Medicine, Nieuwegein, Netherlands, 7Sparna Hospital, Department of Internal Medicine, Hoofddorp, Netherlands, 8Haga Hospital, Department of Nephrology, Den Haag, Netherlands and 9Leiden University Medical Center, Department of Internal Medicine, Leiden, Netherlands

Background and Aims: Patients on haemodialysis generally report poor health-related quality of life (HRQoL) and a broad range of physical and emotional symptoms, but it is unknown if this differs between younger and older patients. We aimed to describe the trajectories of HRQoL and symptom burden of patients <70 and ≥ 70 years old after dialysis initiation and to assess the impact of symptom burden on HRQoL.

Method: Incident Dutch haemodialysis patients were included between December 1st, 2017, and January 19th, 2019. HRQoL and symptom were measured with the 12-item Short Form Health Survey (range 0-100, higher scores indicate better HRQoL) and the Dialysis Symptom Index (range 0-150, higher scores indicate more symptoms and/or higher severity). Questionnaires were taken at the start of dialysis and after 3, 6 and 12 months. We used (multilevel) linear regression to examine the trajectories of HRQoL and symptom burden, and the impact of symptom burden on HRQoL.

Results: In 774 patients, the trajectories of physical HRQoL, mental HRQoL and symptom burden were stable. Compared with patients aged < 70 years, patients ≥ 70 years reported similar physical HRQoL (crude mean difference -0.61, 95% CI -1.86; 0.63, p = .33) but slightly better mental HRQoL (1.77, 95% CI 0.54; 3.01, p = .005) and lower symptom burden (-2.38, 95% CI -5.08; 0.32, p = .08) during the first year of dialysis. With increasing symptom burden, physical HRQoL declined more in older than in younger patients (β = -2.87 versus β = -1.89, respectively, p-value for interaction = .007). For mental HRQoL, this decrease was similar (β = -2.92 versus -2.88, p-value for interaction = .847).

Conclusion: Older haemodialysis patients generally experience better mental HRQoL and a (non-statistically significant) lower symptom burden in the first year after dialysis initiation, compared to younger patients. However, their physical HRQoL declines more rapidly with increasing symptom burden, compared to younger patients.

SURVIVAL OF HEMODIALYSIS PATIENTS: A LARGE RETROSPECTIVE STUDY

Niccolò Morisi1, Roberta Scarmignan1, Gaetano Alfano1,2 and Gabriele Donati1,2

1University of Modena and Reggio Emilia, Surgical, Medical and Dental Department of Morphological Sciences, Section of Nephrology, Italy and 2Policlinico di Modena, Nephrology, Dialysis and Renal Transplant Unit, Italy

Background and Aims: Despite the evolution of haemodialysis (HD) technique, long-term prognosis for HD patients remains poor. The major causes of mortality for HD patients are cardiovascular diseases, followed by infections and tumors. Survival difference between HD and general population is related to chronic exposition to uremic toxin and continuous cardiovascular stress. Currently there is no consensus about the weight of different mortality factors. Our aim is to delve into some risk factors using a large sample of HD patients.

Method: We performed a longitudinal retrospective analysis with data collected from patients that started HD from 1969 to 2021 in the dialysis center of Modena, Italy. Patients with < 18 years old or < 3 months of HD were excluded. The included characteristics were sex, age of starting HD and duration of treatment, any previous substitutive treatment (e.g., peritoneal dialysis (PD), transplant (TX)) and inscription on waiting list for TX. Statistical tests were performed using Shapiro-Wilk, t-test and ANOVA. Survival analysis was employed using the Kaplan–Meier estimate and Cox regression models with 95% confidence interval (CI).

Results: A total of 2290 patients were submitted to study, 63% of them were male (n = 1451), 10% were placed on waiting list for Tx (n = 224) and 9% came from any substitutive treatment (n = 45 from Tx, n = 154 from PD). At time of HD started, average age was 67.7 (Standard Deviation: 14.8 years). In this group, 22% (n = 504) were older than or equal to 80 years, 40% (n = 911) were between 60 and 85 years, 23% (n = 534) were between 65 and 50 years, 15% (n = 341) were younger than 50 years. The average survival in HD was 1894.2 days, 80% of patients died (n = 1829) and 9% received kidney transplant (n = 190). One-year mortality rate was 13% (n = 297), with the highest mortality rate in the eldest people (n = 115, Log-Rank p<0.0001). At fifteen years of follow-up 76% died (n = 1740) and 8% (n = 183) were submitted to transplant. Age remained an important risk factor of mortality (Log-Rank p<0.0001) (Figure 1). Conversely, inscription on waiting list for TX (Log-Rank p<0.0001) and previous DP (Log-Rank p = 0.0002) were protective factors. An important mortality predictor at 15 years was the age of beginning HD (p<0.0001). Indeed, using patients with <50 years as dummy variable, patients with age between 50 and 65 years had hazard ratio (HR) of 2.7 (CI 2.2-3.4); HR for age between 65 and 80 years was 5 (CI 4.1-6.1); patients aged >80 years had HR of 11 (CI 8.9-13.7). Other mortality predictors were the inscription on waiting list (HR 0.4, CI 0.2-0.5, p<0.0001) and previous PD treatment (HR 0.76, CI 0.61-0.95, p = 0.01). Sex and previous transplantation were not statistically significant.

Conclusion: The medical progress reached nowadays allows us to keep patients longer out of HD. This leads to an increasing average age of patients
starting hemodialysis. Our results show that age is an important factor to determine the survival in HD and this becomes dramatically true for octogenarian patients. On the other side, patients on the waiting list for transplant have a better survival, probably due to a better health status. In conclusion, the challenge of the future will be to act on modifiable risk factors with adequate prevention and treatment of comorbidities. This will allow us to reduce the weight of age as a mortality predictor.

#3957
SUSTAINED RECOVERY OF KIDNEY FUNCTION IN PATIENTS WITH ESKD UNDER CHRONIC DIALYSIS TREATMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS
Carlo Garofalo, Luca De Nicola, Roberto Minutolo, Giuseppe Conte, Simona Andriella, Federica Marzano, Tino Paolo Ambrosino and Silvio Borrelli
University of Campania “Luigi Vanvitelli”, Nephrology, Italy

Background and Aims: The prevalence of recovery of kidney function (RKF) in patients under maintenance dialysis is poorly defined mainly because of different definitions of RKF. The accurate assessment of sustained RKF is critical because the survival and quality of life of patients treated by maintenance dialysis are dramatically poor as compared to patients under conservative treatment. The sustained withdrawal of chronic dialysis has moreover a significant social and economic impact, considering the high burden of dialysis on health resources.

Method: Therefore, to gain more insights into the epidemiology of RKF, we performed a systematic review and meta-analysis of studies addressing the prevalence of sustained (at least for 30 days) RKF in patients under maintenance dialysis. Acute kidney injury (AKI) and RKF in the first 90 days of dialysis were the main exclusion criteria.

Results: Overall, 7 studies (10 cohorts) including 2,444,943 chronic dialysis patients (range: 430-1,900,595 patients) were meta-analyzed. The period of observation ranged from 4 to 43 years. The prevalence of RKF was 1.49% (95% C.I.:1.05-2.11; \( p<0.001 \)) with high heterogeneity I²: 99.8%, \( P<0.001 \) (Figure 1). The weighted mean dialysis vintage before RKF was 294±165 days; RKF persisted for a weighted mean of 27.5 months. The percentage of RKF was higher in studies from the U.S. (1.96% [95% C.I.: 1.24-3.07]) as compared to other countries (1.04% [95% C.I.: 0.66-1.62]; \( P = 0.049 \)).

Conclusion: In conclusion, sustained RKF unrelated to AKI occurs in about 1.5% of patients under maintenance dialysis. On average, RKF patients discontinue chronic dialysis about ten months after starting treatment and live free of dialysis for more than two years. The higher prevalence of RKF reported in the U.S. versus other countries suggests a major role of country-specific policies for dialysis start.
IDENTIFICATION OF FACTORS ASSOCIATED WITH DEATH IN DIALYSIS PATIENTS USING A MACHINE LEARNING-BASED PREDICTIVE MODEL
Carolina Aparecida de Almeida Vicentini, Luis Gustavo Modelli de Andrade and Daniela Ponce

Unesp Campus de Botucatu, Brazil

Background and Aims: Few studies including unplanned dialysis starts have used machine learning for the prediction of death in dialysis patients. The objective of the study was to use R software algorithms to develop machine learning predictive models for the identification of death-related factors in patients undergoing hemodialysis (HD) and peritoneal dialysis (PD).

Method: This study included adult patients undergoing HD and PD started in a planned or urgent manner in a dialysis center between January 2014 and January 2019. Epidemiological, clinical and laboratory data were collected. Univariate analysis was followed by ML-based analyses. Then, multivariate regressions were obtained using stepwise and Cox regression analyses. Finally, a Random Forest predictive model was generated after variables with missing values > 30% were removed.

Results: Of 581 patients included, 170 died (29.2%). On univariate analysis death was associated with age, number of comorbidities, dialysis modality switching, creatinine, PTH and albumin values at dialysis initiation, presence of diabetes (DM), hospitalization, function recovery and central venous catheter (CVC) for dialysis access. Patients who started dialysis with a CVC had a worse survival (p = 0.0034) than those who did not use CVC, started HD with AVF, or received PD (Figure 1). Data were split into 20% for testing the regression model, and 80% for training the model. Data preprocessing for Cox regression included imputing some values using bag impute (decision trees), creating dummy variables, and removing collinear variables. Death was associated with older age (p < 0.001), fewer ESI-free months (p < 0.001) and lower initial creatinine (p = 0.008) (Table 1). The model C-index was 0.8099. Random forest ranked the following variables predictive of death in descending order of importance: ESI-free months; age; initial levels of creatinine, PTH and albumin; number of comorbidities; dialysis-related infection; initial phosphorus and hemoglobin; hospitalizations; male gender; modality switching (Figure 2). The agreement of the model obtained was 0.8110.

Conclusion: ESI-free months, age and initial levels of creatinine were associated with death on both multivariate and ML-based analyses.

Figure 1: Survival Analysis of patients who started dialysis with a CVC vs patients who did not use CVC.

Figure 2: Variables importance ranked by Random Forest.
Background and Aims: Dry weight (DW) estimation is important for patients undergoing hemodialysis. Although bioimpedance spectroscopy (BIS) is often employed to evaluate DW, BIS-based DW frequently differs from clinical DW. In this study, the characteristics of elderly patients were evaluated by separating them into groups based on the degree of disparity between the BIS-based DW and the clinically appropriate (DWGAP), and the mortality of each group was compared.

Method: This retrospective study included patients who underwent hemodialysis at Chungnam National University Hospital from January 1, 2016, to June 2020. All patients were aged ≥60 years. Patients with cancer, recipients of kidney transplant, and patients who dropped out of the study within 3 years were excluded. Body composition was assessed using a portable BIS device (Fresenius Medical Care, Bad Homburg, Germany). The BIS dataset includes extracellular water (ECW), intracellular water (ICW), and total body water (TBW) as well as the lean tissue index (LTI), fat mass index (FTI), and body cell mass (BCM). The absolute value of the gap between the BIS-based DW and the actual clinically appropriate dry weight was determined (DWGAP). To assess differences in blood chemistry and survival rate, four groups were classified based on the absolute value of DWGAP: Group 1: DWGAP ≤ 0.5 kg, Group 2: 0.5 kg < DWGAP ≤ 1 kg, Group 3: 1 kg < DWGAP ≤ 2 kg, and Group 4: 2 kg < DWGAP. The mortality data of patients up to 3 years after BIS measurement were collected.

Results: There were 1024 patients in all. The study excluded 29 individuals with cancer, recipients of KT, and 249 participants with a loss of follow-up before 36 months. A total of 715 patients were analyzed: Group 1 (n = 236), Group 2 (n = 171), Group 3 (n = 137), and Group 4 (n = 171). The mean age for each group was 71.97, 70.73, 71.58, and 70.4 years, respectively. Groups 1 and 2 had the same survival rates (78%); however, Group 3 had a lower rate (73%) and Group 4 showed a significant decline (59%). In the laboratory test, Group 4 had lower hemoglobin, total protein, albumin, creatinine, and chloride levels than Groups 1, 2, and 3. In the BIS data, ECM and E/I were higher in Group 4 than in Groups 1, 2, and 3.

Conclusion: In the elderly patient group, mortality increased in the group where the DWGAP was ≥ 2 kg. Lower blood albumin levels, total protein levels, and E/I ratios of ≥1 were detected in the group with a gap of ≥ 2 kg, and these parameters are likely to adversely affect the survival of elderly patients requiring dialysis.

MORTALITY AND BIOIMPEDANCE SPECTROSCOPY–BASED DRY WEIGHT MEASUREMENT ERROR IN ELDERLY PATIENTS UNDERGOING HEMODIALYSIS

Hae Ri Kim1, Moo Jun Kim1, Jae Wan Jeon1, Dae Eun Choi2, Ki Ryang Na2 and Kang Wook Lee2

1Chungnam National University Sejong Hospital, Nephrology, Sejong, Rep. of South Korea and 2Chungnam National University Hospital, Nephrology, Daejeon, Rep. of South Korea

Background and Aims: Dry weight (DW) estimation is important for patients undergoing hemodialysis. Although bioimpedance spectroscopy (BIS) is often employed to evaluate DW, BIS-based DW frequently differs from clinical DW. In this study, the characteristics of elderly patients were evaluated by separating them into groups based on the degree of disparity between the BIS-based DW and the clinically appropriate (DWGAP), and the mortality of each group was compared.

Method: This retrospective study included patients who underwent hemodialysis at Chungnam National University Hospital from January 1, 2016, to June 2020. All patients were aged ≥60 years. Patients with cancer, recipients of kidney transplant, and patients who dropped out of the study within 3 years were excluded. Body composition was assessed using a portable BIS device (Fresenius Medical Care, Bad Homburg, Germany). The BIS dataset includes extracellular water (ECW), intracellular water (ICW), and total body water (TBW) as well as the lean tissue index (LTI), fat mass index (FTI), ECW/ICW ratio (E/I), lean tissue mass, fat mass (FAT), adipose tissue mass (ATM), and body cell mass (BCM). The absolute value of the gap between the BIS-based DW and the actual clinically appropriate dry weight was determined (DWGAP). To assess differences in blood chemistry and survival rate, four groups were classified based on the absolute value of DWGAP: Group 1: DWGAP ≤ 0.5 kg, Group 2: 0.5 kg < DWGAP ≤ 1 kg, Group 3: 1 kg < DWGAP ≤ 2 kg, and Group 4: 2 kg < DWGAP. The mortality data of patients up to 3 years after BIS measurement were collected.

Results: There were 1024 patients in all. The study excluded 29 individuals with cancer, recipients of KT, and 249 participants with a loss of follow-up before 36 months. A total of 715 patients were analyzed: Group 1 (n = 236), Group 2 (n = 171), Group 3 (n = 137), and Group 4 (n = 171). The mean age for each group was 71.97, 70.73, 71.58, and 70.4 years, respectively. Groups 1 and 2 had the same survival rates (78%); however, Group 3 had a lower rate (73%) and Group 4 showed a significant decline (59%). In the laboratory test, Group 4 had lower hemoglobin, total protein, albumin, creatinine, and chloride levels than Groups 1, 2, and 3. In the BIS data, ECM and E/I were higher in Group 4 than in Groups 1, 2, and 3.

Conclusion: In the elderly patient group, mortality increased in the group where the DWGAP was ≥ 2 kg. Lower blood albumin levels, total protein levels, and E/I ratios of ≥1 were detected in the group with a gap of ≥ 2 kg, and these parameters are likely to adversely affect the survival of elderly patients requiring dialysis.

mortality risk factors was performed. Causes of mortality were obtained by hospital discharge forms. COVID-19 related cause of death was defined through intra-hospital codes as COVID-19 pneumonia, COVID-19 ARDS and COVID-19 respiratory failure.

Results: One hundred and fifty-two chronic HD patients were hospitalized for COVID-19 infection. Table 1 shows the general characteristics of the patients. The 28-day all-cause mortality was 21.9%, which 11.9% was COVID-19 related cause of death. Table 2 shows the causes of mortality. Multivariate Cox regression demonstrated that an increased risk of death from COVID-19 at 28 days was significantly and independently associated with age (73 years (HR 1.05, 95% CI 1.01-1.09; p = 0.01), Charlson Comorbidity Index (CCI) > 5 at entry (HR 1.28, 95% CI 1.02-1.60; p = 0.01), Continuous Renal Replacement Therapies (CRRT) (HR 2.89, 95% CI 1.03-8.11; p = 0.04) and the presence of peripheral vasculopathy (HR 3.48, 95% CI 1.31-9.27; p = 0.01). Plasma albumin >25 g/L at entry (HR 0.87, 95% CI 0.80-0.96; p <0.01) and pre-admission SARS-CoV-2 vaccination (HR 0.25, 95% CI 0.09-0.72; p = 0.01) significantly reduced the risk of mortality.

Conclusion: Our study shows that on the total of deaths with a positive COVID-19 test, 59% were caused by the infection while the remaining 41% occurred from other causes. Age, CCI, the presence of peripheral vascular disease and the need for CRRT are independent risk factors for mortality. Vaccination was confirmed as a protective factor.

Results: Vaccination was confirmed as a protective factor.

Background and Aims: Fatigue and the need for recovery time after a hemodialysis session are frequent complaints in patients with chronic kidney disease treated with maintenance hemodialysis (MHD). In the present study, we investigated whether there is an association between self-reported fatigue and the need for recovery time after HDM sessions.

Method: This is a cross-sectional study with data from 239 adult patients participating in the prospective cohort study “Prognostic Study of Patients on Chronic Hemodialysis” (PROHEMO), developed in Salvador, BA, Brazil. We used “The Chalder Fatigue” questionnaire (CFQ-11) to calculate fatigue scores. CFQ-11 scores can range from 0 to 33; Higher scores mean more intense fatigue. Fatigue was categorized as: absent or mild if the score was <4 and moderate to severe if the score was ≥4. To assess the need for recovery time from hemodialysis, participants answered a question: After finishing dialysis, do you usually need some time to recover? with two answer options (yes or no). We used logistic regression to estimate the odds ratio (OR) of the association between fatigue and need for recovery after hemodialysis, with adjustments for age, sex, diabetes, and heart failure.

Results: The mean age was 52.5 ± 12.5 years, 57.7% were men, 94.5% were non-white. Self-reported fatigue as absent or mild was 28.4% (68/233) and moderate to severe fatigue was 71.5% (171/233). The prevalence of need for recovery time after hemodialysis was 2.5 times higher in patients with moderate to severe fatigue than in patients with no or mild fatigue (prevalence: 20.6%; prevalence ratio: 2.50 (95% confidence interval: 1.53; 4.08)). In logistic regression, an association between moderate to severe fatigue and need for recovery was observed even after adjusting for the effects of age, sex, diabetes, and heart failure (OR = 4.36; 95% CI: 2.21; 8.59).

Conclusion: The results suggest that patients who report a more intense degree of fatigue, more often have a greater need for time to recover after the end of the hemodialysis session. It is interesting to investigate whether interventions that reduce fatigue in patients undergoing MHD treatment result in a reduction in the need for recovery time after the hemodialysis session.

ASSOCIATION BETWEEN SELF-REPORTED FATIGUE AND THE NEED FOR RECOVERY TIME AFTER THE MAINTENANCE HEMODIALYSIS SESSION: PROHEMO

Gabriel Bryan Gutierrez Peredo1, Márcia Tereza Silva Martins1, Fernanda Albuquerque Da Silva1, Marcelo Lopes1,2, Gildete Barreto Lopes1 and Antonio Alberto Lopes1

1 Federal University of Bahia, Núcleo de Epidemiologia Clínica e Medicina Baseada em Evidências, Salvador, Brazil and 2 São Rafael Hospital, Nephrology, Salvador, Brazil.

Figure 1: Association of fatigue and need for recovery time after hemodialysis.
up, 44 patients (20.4%) died. Kaplan-Meier analysis is shown in Figure 1. In the median RBV change was –5.5% and median ScvO2 was 58.8%. During follow-up, patients with ScvO2 above median and RBV change below median were defined as reference. The follow up period was 3 years. We constructed a Cox proportional hazards model with adjustment for age, diabetes, and dialysis vintage to assess the association between ScvO2 and RBV and all-cause mortality during follow-up.

**Results:** Baseline comprised 5,231 dialysis sessions in 216 patients. The mortality during follow-up.

**Method:** We conducted a retrospective study in maintenance hemodialysis patients with central venous catheters as vascular access. During a 6-month baseline period, Crit-Line (Fresenius Medical Care, Waltham, MA) was used to measure continuously intradialytic ScvO2 and hematocrit-based RBV. We defined four groups per median change of RBV and median ScvO2. Patients with RBV above median and RBV change below median were defined as reference. The follow up period was 3 years. We constructed a Cox proportional hazards model with adjustment for age, diabetes, and dialysis vintage to assess the association between ScvO2 and RBV and all-cause mortality during follow-up.

**Results:** Baseline comprised 5,231 dialysis sessions in 216 patients. The median RBV change was –5.5% and median ScvO2 was 58.8%. During follow-up, 44 patients (20.4%) died. Kaplan-Meier analysis is shown in Figure 1. In the adjusted model, all-cause mortality was highest in patients with ScvO2 below median and RBV change above median (HR 6.32; 95% confidence interval [CI] 1.37 to 29.06), followed by patients with ScvO2 below median and RBV change below median (HR 5.04; 95% CI 1.14 to 22.35) and ScvO2 above median and RBV change above median (HR 4.52; 95% CI 0.95 to 21.36).

**Conclusion:** Concurrent combined monitoring of intradialytic ScvO2 and RBV change may provide additional insights into a patient’s circulatory status. Patients with low ScvO2 and small changes in RBV may represent a specifically vulnerable group of patients at particularly high risk for adverse outcomes, possibly related to poor cardiac reserve and fluid overload.

**IMPLEMENTING THE SERIOUS ILLNESS CARE PROGRAMME (SICP) WITHIN AN OUTPATIENT HAEMODIALYSIS UNITS: A FEASIBILITY STUDY**

Hannah Sammut1, Anirudh Rao1,2, Asheesh Sharma1, Tamsin Mcglincheys and Stephen Mason1

1Liverpool University Hospital Foundation Trust, Nephrology, Liverpool, United Kingdom, 2University of Liverpool, Liverpool, United Kingdom and 3University of Liverpool, Palliative Care Unit, Liverpool, United Kingdom

**Background and Aims:** End-stage renal failure affects a frail, elderly, and multimorbid population with high physical and psychological symptoms. The care should integrate core palliative care principles to thoroughly address and support patients’ needs. The Serious Illness Care programme (SICP) is a multi-component intervention that promotes meaningful conversations between clinician and patient. The intervention identifies what matters most to the patient, their goals and priorities, and how this aligns with their treatment and care. The SICP was implemented in two dialysis units in the North of England, and we report on the outcomes and learning from this process.

**Method:** Using a modified cohort design, we applied the principles and tools of the programme within a renal unit in the North of England. We selected two outpatient dialysis units, Unit A (with a population of 43 patients) and Unit B (with 150 patients). An MDT approach was employed to develop a process specific to each unit (Figure 1). Clinician training was complemented with mentoring support and informative education of nursing and administration teams. Outcome data were collected from August 2019 to February 2022. Outcomes recorded (reach metrics and process outcomes) were the number of patients offered a conversation, accepted or declined, the timing of the conversation and follow-up. We applied structured reflection on elements that facilitated participation in the SICP.

**Results:** Of the conversations that happened, 10 patients preferred to have the conversation on their own, and 7 patients chose to have a family or carer present. In 17 (100%) patients, the conversation naturally led to a ‘statement of wishes’ about their health. In 5 (29%) patients, there was a detailed conversation regarding resuscitation decisions in the event of a cardiopulmonary arrest (DNACPR). Three (17%) patients accepted a ‘Planning your Future Care Guide’, to help them think about more specific advance care planning conversations in the future. Three (17%) accepted a ‘Talking to your Family and Friend’s leaflet to help guide conversations with family’. Structured reflection identified two elements that facilitated participation in the SICP were:

- Regular focused review of the holistic needs of patients as an MDT, which included the consultant and nursing team
- Creating flexibility in appointment time for conversations to happen

Over this period, 18 (53%) of the 34 patients offered the conversation died.

**Conclusion:** This study demonstrates that the SICP can be successfully implemented within a dialysis unit. It is essential to recognise that some patients want to talk about the future of their illness, whilst some prefer not to. Understanding the person-centred illness and environmental factors that enable patients to engage in these ‘future care planning’ conversations is important for this intervention’s progression. For example, we were surprised that the majority within our small sample wanted to have this conversation.

---

**Figure 1:** Kaplan-Meier analysis of survival probabilities in the four subgroups of patients based on the level of central venous oxygen saturation (ScvO2) and relative blood volume (RBV) above and below the median of 58.8% and —5.5%, respectively.
in the absence of large epidemiological studies, whether the use of CIEDs in hemodialysis patients is associated with a lower mortality benefit than in pre-dialysis patients remains controversial. In this cross-sectional study, we evaluate the prevalence of CIEDs in a cohort of patients with CKD.

**Method:** The study includes patients with CIEDs with estimated GFR <45 ml/min/1.73 m² from two hospitals in Milan, divided into two groups based on treatment with conservative therapy (IRC stage IIIb-V) or hemodialysis.

**Results:** Of the 499 patients enrolled, 268 had CKD stage IIIb-V, and 231 were in hemodialysis (Table 1).

Among CRT carriers, the prevalence in the CKD IIIb-V group is significantly higher than in the hemodialysis group (4.09% vs 0.86%; p = 0.025) (Figure 1), even if among the hemodialysis patients the prevalence of patients with previous stroke and hypertension was significantly higher (Table 1).

Furthermore, in multiple logistic regressions, hemodialysis was a variable independently correlated with reduced use of CRTs (OR 0.27; 95% CI = 0.01-0.96; p = 0.04), while the other devices (individually and cumulatively) correlated positively only with age and previous myocardial infarction (MI) (Table 2).

**Conclusion:** The reduced prevalence of CRT in hemodialysis patients is probably related to the shorter life expectancy and the higher rate of related complications, such as the increased risk of infectious complications and/or stenosis of the central venous vessels. Further studies are needed to evaluate the impact of these devices on the cardiac mortality of hemodialysis patients and the associated complication rate.

THE EVALUATION OF FLUID VOLUME AND PROGNOSIS IN HEMODIALYSIS PATIENTS UTILIZING PLASMA HUMAN ATRIAL NATRIURETIC PEPTIDE

Yuya Suzuki¹, Tadashi Otsuka¹, Yuki Yoshioka², Tomomichi Iida³, Hirofumi Watanabe¹, Ryohei Kaseda¹, Suguru Yamamoto¹, Yoshikatsu Kaneko¹, Shin Goto¹, Ryuzi Aoyagi¹ and Ichiei Narita¹

¹Niigata University, Division of Clinical Nephrology and Rheumatology, Kidney Research Center, Japan, ²The Jikei University Daisan Hospital, Division of Nephrology and Hypertension, Department of Internal Medicine, Japan and ³Tachikawa General Hospital, Department of Nephrology, Japan

Background and Aims: Volume overload leads to the development of heart failure, which contributes to the high mortality in patients on hemodialysis. The post-dialysis plasma level of human atrial natriuretic peptide (hANP) reflects the fluid volume in patients on hemodialysis. The threshold hANP level is reportedly 100 pg/mL; however, the clinical usefulness of the threshold hANP level for volume control has not been sufficiently studied.

Method: We conducted a single-center, retrospective, observational study that included 156 hemodialysis patients without atrial fibrillation. First, we examined the usefulness of the threshold hANP level (100 pg/mL) for predicting hypoxemia due to congestion in a short-term observational study from December 30, 2015 to January 5, 2016. Subsequently, we conducted a 5-year follow-up study wherein the outcomes were hospitalization due to acute heart failure (AHF), development of cardiovascular diseases (CVD), and all-cause death. Finally, we collected echocardiography data to investigate the relationship between cardiac function and hANP.

Results: Our short-term observational study showed that patients with an hANP level ≥ 100 pg/mL developed hypoxemia due to congestion (odds ratio, 3.52; 95% confidence interval, 1.06–11.71; P = 0.040). At the 5-year follow-up, patients with an hANP level ≥ 100 pg/mL had significantly higher
rates of hospitalization due to AHF, CVD, and all-cause death based on the log-rank test (P = 0.003, P < 0.019, P < 0.001, respectively). Analysis of echocardiography data showed that the presence of reduced left ventricular ejection fraction and left ventricular diastolic dysfunction were significantly associated with high plasma hANP levels. However, the threshold hANP level (100 pg/mL) remained independently associated with hospitalization due to AHF after adjusting for cardiac dysfunctions in the multivariable model.

Conclusion: The hANP level is indicative of both fluid volume and cardiac dysfunction. In clinical practice, we suggest utilizing hANP as an easily accessible measure to identify high-risk patients for developing AHF initially. If the hANP level exceeds 100 mg/dL, we propose to perform echocardiography and consider reducing the DW. In clinical practice, the plasma hANP level could serve as a valuable indicator for assessing the risk of developing AHF and managing fluid volume.

GENDER DISPARITIES IN HEMODIALYSIS PATIENTS: WORKING LIFE, MENTAL STATUS AND PHYSICAL CAPACITY

Saliha Yildirim1, Haluk Cihad Albayrak 1, Özantı Helvacı 1, Yasemin Ertenc 1, Ulver Derici 1, Deniz Ayli 1, Murat Duranay 1 and Galip Güz 1

1 Gazi University Faculty of Medicine, Nephrology, Turkey, 2 Ankara Etfik City Hospital, Nephrology, Ankara, Turkey and 3 Ankara Training and Research Hospital, Nephrology, Ankara, Turkey

Background and Aims: Globally, there are more women with chronic kidney disease (CKD) than men, but there are disparities in even receiving dialysis treatment. Gender disparity is a common problem in many fields. In this study, we aimed to determine the gender disparities in a sample of Turkish hemodialysis patients in the terms of working life, symptoms, depression, dementia and physical activity.

Methods: 219 patients (ages 18–65 years) were included in this study. Demographic characteristics, laboratory parameters and social status were recorded. All participants completed the Beck depression scale, standardized mini-mental test, physical activity score and a questionnaire consisting of symptoms related to hemodialysis.

Results: 132 male and 87 female patients were included in this study. Male patients and female patients were statistically similar in the terms of age (p = 0.604), CKD vintage (p = 0.226), RRT vintage (0.559) and laboratory parameters (p = 0.05). Weakness (p = 0.001), palpitation (p < 0.001), chest pain (p = 0.015), hypotension (p < 0.001), myalgia (p < 0.001) and forgetfulness (p = 0.002) were more common in female patients. Serious depression was similar in the two groups (p = 0.525) while physical inactivity (p = 0.022) and dementia (p = 0.024) were more often in female patients. Unemployment was more in the female group (p < 0.001) although willingness to work is similar in both groups and female patients had a low salary than male patients (p = 0.033).

Conclusion: Women with CKD face many challenges in daily life but the major disparities are in the social and economic fields. Not only laboratory parameters but also gender disparities in the social field must be improved to achieve equal care for all people with CKD.

#5819
HAEMODIALYSIS EFFECT ON METABOLIC THERAPY WITH [131INa]: A COMPARATIVE STUDY

Paloma Livianos Arias-Camión1, Alessandra Repetto2, Juan Rey Valeriano1, Sandra Chamizo1, Antonio Cherino Talens2, María Cristina Peña Villoria1 and Isabel Garcia Mendez1

1 Hospital Universitari Son Espases, Nephrology Department, Spain, 2 Hospital Universitari Son Espases, Nuclear Medicine Department, Spain and 3 Hospital Universitari Son Espases, Radiotherapy Department, Spain

Method: Two patients on HD were treated with [131INa] in June 2021. A 74 years old women with hyperthyroidism due to a multinodular goitre, resistant to antithyroid drugs (PT1). A 49 years old man candidate to ablation treatment with low activity of [131INa] after a total thyroidectomy due to differentiated thyroidic cancer (PT2). The recommended activity was administered according to clinical indication. PT1 received 555 MBq and PT2 received 1110 MBq of [131INa] in Metabolic Therapy Unit (MTU). The previous HD sessions were in the nephrology ward. The following HD sessions were in MTU (Wed–Fri.). High-flux dialysis was performed using a Reverse Osmosis portable system. The hospital stay was 5 days (Mo at Fri) for each patient. EDRM at 1 meter was measured three times a day. Liquid samples from HD machine (dialysis fluid, water wash) were obtained every day at the same time before and after each session and radioactivity was analysed.

Results: EDRM after second HD at discharge was 12 and 7,4mcSv/h in PT1 and PT2 respectively. After first HD both patients reached EDR <40mcSv/h (22 and 18 mcSv/h). Red bone marrow dose was 130,76mGy and 110,42mGy respectively. Radioactivity in dialysis fluid was: 0,0099MBq PT1- 0,00259MBq PT2 after first HD; 0,0022MBq PT1- 0,00074MBq PT2 after second HD. No radioactivity was detected in washing water of dialysis equipment in both patients during each HD session. There was no secondary complications due to overhydration or dyslektrolythiasms.

Conclusion: External dose rate measurement is key to decide if patients undergoing HD are ready to be discharge. Once EDRM <40mcSv/h at 1 meter has been reached, patients could immediately return to their dialysis centre following the protection radiology rules and so we must always respect the...
distance between the patients, if that cannot be performed the session will be in the hospital. There is no need to modify radioiodine activities neither timing of HD sessions as red bone marrow dose do not exceed recommended value (2Gy). There is no contamination of HD machine, it could be used after usual decontamination for other patients.

MORBIDITY AND MORTALITY OF SARS-COV-2 POSITIVE HOSPITALISED HEMODIALYSIS PATIENTS IN CASE OF CENTRALIZED ORGANIZATIONAL STRUCTURE IN HEALTHCARE

Armenuhi Hazoyan1,2

1 Saint Gregory the Illuminator Medical Center, Department of Nephrology and Hemodialysis, Yerevan, Armenia and 2 Yerevan State Medical University, Department of Internal Medicine, Yerevan, Armenia

Background and Aims: During the COVID epidemic, hemodialysis patients were a very serious vulnerable group due to the underlying kidney disease, many other comorbid health problems commonly present, the need for regular hospital visits even during the lockdown, and the high risk of staying with other patients in hemodialysis rooms, getting infected and subsequently high mortality. There are about 1000 patients with chronic hemodialysis in Armenia. All SARS-CoV-2 positive hemodialysis patients, regardless of the severity of the infection, were hospitalized in the largest multidisciplinary hospital center in the country, as it was the only dedicated hemodialysis service for SARS-CoV-2 positive cases in the country during the pandemic.

Method: Our prospective, observational study included about 1040 patients (Included re-infection) infected with the new coronavirus and hospitalized in one center between 01/04/2020 and 01/05/2022.

Results: The number of SARS-CoV-2 positive deaths was 183, which was 17.5% of those hospitalized. The number of re-infections was around 15%. A low level of vaccination of hemodialysis patients was recorded in the country, around 13.4%. During the first 6 months post-hospitalization, another 39 deaths were registered, which is 3.75% of those hospitalized. About 25,000 SARS-CoV-2 positive non-hemodialysis patients were hospitalized in the above period, and mortality in this population did not exceed 9% during peak epidemic and periods of maximum mortality.

Conclusion: Even with a centralized health care system, early hospitalization, close monitoring, and urgent access to multidisciplinary care, SARS-CoV-2 positive hemodialysis patients have a high mortality rate, the risk of which persists in the first 6 months of the post-hospital period and perhaps even longer, and this risk correlates also with low vaccination rates in this patients’ population.

#4938
PATIENTS RECEIVING HEMODIALYSIS MAINTAIN STRONGER SARS-COV-2 IMMUNITY AFTER DISEASE RATHER THAN VACCINATION

Ekaterina Parshina1, Aleksei Zulkarnaev2, Alexey Tolkach1, Andrey Ivanov3 and Pavel Kislyy3

1 Saint Petersburg State University Hospital, Department of Nephrology and Dialysis, Saint-Petersburg, Russia, 2 Moscow Regional Research and Clinical Institute (“MONIKI”), Surgical Department of Transplantology and Dialysis, Moscow, Russia and 3 Saint Petersburg State University Hospital, Department of Human Genetics, Saint-Petersburg, Russia

Background and Aims: We aimed to compare the dynamics of humoral and cellular immunity caused by natural COVID-19 or vaccination against of SARS-CoV-2 with Gam-COVID-Vac (Sputnik V) vaccine in patients, receiving maintenance hemodialysis (HD).

Method: Data were extracted from two prospective cohort studies which had investigated the long-term immune responses after SARS-CoV-2 infection (NCT 04633915) or vaccination (NCT 04805632) in patients receiving HD compared with those in healthy individuals. The group of patients after natural COVID-19 (n = 24) had confirmed history of disease, nobody of them received vaccination before and during the study period. Levels of specific IgG and T-cells were quantified in them at 2.5 and 6 months from disease onset. The group of vaccinated patients (n = 23) had been vaccinated twice with Gam-COVID-Vac vaccine and had no prior history of confirmed COVID-19. Levels of anti-SARS-CoV-2-specific IgG and T-cells were quantified at 1 month and 6 months from the second vaccine shot. IgG levels were determined using a semi-quantitative ELISA (Euroimmun, Germany) and converted to Binding Antibody Units (BAU/ml) according to the WHO International Standard.

Specific T-cell responses (CD4+ and CD8+ cytotoxic T-lymphocytes) were evaluated using the TIGRA-test⃝ (Generium, Russia). Only spike-specific T-spots were used for the analyses.

Results: Seropositivity rate declined over the course of the study among vaccinated patients (from 91% to 51%), however, all patients after natural COVID-19 remained seropositive over the study period. Thus, seropositivity rate at 6 months was greater in disease group: RR = 1.91 [95% CI: 1.4–3.1] (reciprocal of RR = 0.52 [95% CI: 0.32–0.72]), P = 0.0004. In both groups, IgG levels decreased over time, but antibodies disappeared more rapidly in vaccinated HD patients (analysis of variance p = 0.0374 for the “time × group” interaction) – Figure1 (left). T-test reached positivity in 73% of vaccinated patients and 93% of patients after natural COVID-19 at the first timepoint. At the end of the study, T-test remained positive in 67% and 91% of the patients in both groups, respectively. Risk of T-test positivity rate at 6 months did not differ between groups (P = 0.133). T-spot counts remained stable over time in vaccinated patients, while tended to increase in patients after COVID-19 to the end of the follow-up. Differences in dynamics in these two groups were statistically significant (analysis of variance p = 0.0293 for the “time × group” interaction) – Fig.1 (right).

Conclusion: Patients receiving HD maintain more sustainable humoral immune responses after natural COVID-19 disease than after complete vaccination with Gam-COVID-Vac vaccine. Specific SARS-CoV-2 IgG antibodies declines faster in vaccinated patients than in patients after COVID-19 over 6-month period. Cellular immunity remains stable in both groups increasing by the 6-months period among those who had natural COVID-19.

#5269
THE NUTRITIONAL ASSESSMENT TOOLS TO IDENTIFY PATIENTS AT INCREASED SARCOPENIA RISK

Naoyuki Tsujimoto1, Ryota Matsuzawa2, Hiroto Imai1, Daisuke Kakita1, Kiyoshi Shimokado3 and Akira Tamaki2

1Hyogo Medical University Graduate School of Medical Sciences, Department of Medical Science, Kobe, Japan, 2 School of Rehabilitation, Hyogo Medical University, Department of Physical Therapy, Kobe, Japan and 3 Shimokado Renal Dialysis Clinic, Kobe, Japan

Background and Aims: Protein-energy wasting (PEW), debilitating nutritional and metabolic disorder marked by a systemic reduction in protein and energy store, is prevalent among patients with end stage renal disease (ESRD). The magnitude of malnutrition among patients undergoing hemodialysis has been positively associated with the risk of all-cause mortality, particularly due to infectious disease and cardiovascular disease (CVD). PEW is associated with less muscular strength and lower muscle mass, a condition known as sarcopenia.

The aim of this study was to assess the patients of the hemodialysis center according to the nutritional status using two different tools, i.e., Laboratory Risk Indicator Score for Sarcopenia (LRIS-n) and Sickness Impact Profile 23 (SIP23). Both tools are easy to use and have been validated for use in this patient population. Both tools were used to analyze the nutritional status of the patients and to identify patients at increased risk for sarcopenia.

Results: A total of 120 patients were included in the study, of which 70 were male and 50 were female. The average age of the patients was 64.5 ± 11.6 years. The median hemoglobin level was 11.0 g/dL (IQR: 9.5–12.3). The median albumin level was 3.9 g/dL (IQR: 3.5–4.2). The median body mass index (BMI) was 25.5 kg/m² (IQR: 23.0–28.5). The median body mass index (BMI) was 25.5 kg/m² (IQR: 23.0–28.5). The median body mass index (BMI) was 25.5 kg/m² (IQR: 23.0–28.5).

Conclusion: The results of this study suggest that the use of laboratory risk indicator score for sarcopenia (LRIS-n) and sickness impact profile 23 (SIP23) can be effective tools for assessing the nutritional status of patients undergoing hemodialysis and identifying those at increased risk for sarcopenia.

Figure 1: Kinetics of SARS-CoV-2 IgG S1/S2 antibodies (left) and T-spot responses to SARS-CoV-2 structural peptides S (right) after diagnosis of COVID-19 or vaccination with Gam-COVID-Vac in patients receiving maintenance hemodialysis.
to cardiovascular disease and infections. Additionally, inadequate nutritional status has been implicated in the development of sarcopenia, characterized by decreased muscle mass, weakened muscle strength, and impaired physical function. As such, routine management of nutritional status may be crucial aspect of care for these patients. In addition to the nutritional risk index for Japanese hemodialysis patients (NRI-JH), developed for the diagnosis of PEW, the geriatric nutritional risk index (GNRI) and mini nutritional assessment short-form (MNA-SF) are frequently utilized as nutritional indices in patients on hemodialysis. However, few studies have compared the magnitude of associations between these nutritional measure and sarcopenia in patients undergoing hemodialysis. This study aimed to evaluate the degree of association between nutritional assessments and sarcopenia in this patient population.

### Method
The current cross-sectional study recruited outpatients receiving maintenance hemodialysis between June 2019 and December 2021. The study collected patient information, including age, gender, body mass index, dialysis duration, primary kidney diseases, 11 comorbid conditions, and laboratory parameters (such as serum albumin, serum creatinine, and total cholesterol), from medical records. Physical therapists assessed muscle mass (skeletal muscle index [SMI]), muscle strength (handgrip strength), and physical performance (short physical performance battery [SPPB]), and sarcopenia was diagnosed when patients presented with low muscle mass (SMI <7.0 kg/m² for males, <5.7 kg/m² for females) and low muscle strength (handgrip strength <28.0kg for males, <18 kg for females) or low physical performance (SPPB <9) based on the Asian Working Group for Sarcopenia 2019 criteria. The study employed the NRI-JH, GNRI, and MNA-SF as markers of nutritional status. The NRI-JH was calculated based on body mass index, serum albumin, serum creatinine, and total cholesterol. Logistic regression analysis was performed to examine the associations of NRI-JH, GNRI, and MNA-SF with sarcopenia among patients on hemodialysis.

### Results
Sixty-five patients undergoing hemodialysis were analyzed in this study. The mean age of the patients was 78.3 ± 10.7 years, with 36.9% being female. The average duration of dialysis was 6.4 ± 3.9 years. The most frequently observed underlying kidney disease was diabetes mellitus, followed by hypertension. The prevalence of sarcopenia was found to be 60.0%. After adjustment for the effects of age, gender, dialysis duration, and comorbidity index, patients with a lower score on the NRI-JH were significantly more prone to sarcopenia (odds ratio per 1-point increase, 1.33; 95% confidence interval, 1.04–1.69). The NRI-JH was demonstrated to have a stronger association with sarcopenia compared to the others (Table 1).

### Conclusion
The NRI-JH and GNRI were significantly associated with risk of sarcopenia. The NRI-JH demonstrated a stronger association with the risk of sarcopenia compared to the GNRI.

### Background and Aims
The substantial health challenges faced by patients on peritoneal dialysis (PD) or hemodialysis (HD) have increased considerably during the ongoing COVID-19 pandemic, but remain inadequately investigated. We therefore decided to compare the perspectives of PD and in-center HD patients on their needs and challenges during this period with those of their healthcare professionals through interviews with both groups.

### Method
Qualitative study of 7 in-center HD patients, 7 PD patients, 7 dialysis nurses and 7 physicians at the Division of Nephrology and Dialysis, Medical University of Vienna between March 2020 and February 2021, involving content analysis of semi-structured interviews supported by a natural language processing technique.

### Results
Main themes brought up by patients included: 1) Concerns about being a ‘high risk patient’; 2) Having reduced fear of COVID-19 as an HD patient; 3) Whether home dialysis might be better than in-center dialysis during COVID-19; 4) Changes in clinical routine; 5) Positive psychological elements to overcome stress. Main themes emerging from interviews with physicians and nurses included: 1) Fear of COVID-19 infection; 2) Anxiety, sadness, loneliness of PD patients; 3) Negative impact of changes in clinical routine on patients’ well-being; 4) Telehealth as a new care modality.

### Conclusion
Physicians did not perceive the full extent of patients’ psychological burdens. Positive psychological constructs were more evident in survivors of previous serious health crises. Patients’ concerns related to COVID-19 need to be addressed proactively. Implementation of measures to prevent COVID-19 transmission, introduction of telemedicine, and increased use of home-dialysis have led to communication barriers and reduced contact between healthcare providers and patients. Selection or modification of dialysis modality should include analysis of the patient’s support network as well as periodic psychological assessment of patients in anticipation of future surges of COVID-19 or of currently unforeseen pandemics.

*Adjusted for age, sex, dialysis vintage and comorbidity index. Abbreviation: CI, confidence interval; OR, odds ratio; SD, standard deviation.
Background and Aims: Mortality in hemodialysis patients significantly exceeds the one observed in general population. Identifying and early management of risk factors is essential for improving survival of these patients. Aim of the study is to assess survival and evaluate factors related to mortality in hemodialysis population.

Method: We retrospectively studied 237 patients (99 ♂, median age 76 (69-84) years) undergoing hemodialysis in a single Dialysis Center for a 10-years period of time (from 1/2/2010 to 31/1/2021). Demographics, comorbidities and laboratory parameters were recorded and analyzed. Median survival, mortality rate and factors that may affect them were evaluated.

Results: The mortality rate was 9.28% in the first year and 36.29% in five years after starting dialysis, respectively (Figure 1. Kaplan-Meier survival curves for the study population). Elderly patients (>65 years) had a lower median survival compared to younger ones (63 versus 103 months, p = 0.031). Survival of diabetics undergoing on-line hemodiafiltration was twice versus those undergoing hemodialysis (87 versus 42 months, p<0.001). Multivariate analysis identified as important predictor of mortality, the existence of diabetes mellitus [hazard ratio (HR) = 2.387, 95% confidence interval (CI) 1.278-4.46, p = 0.017) and central venous catheter disease (HR = 2.421, 95% CI 1.297-4.518, p = 0.006), peripheral arterial disease (HR = 1.875, 95% CI 1.12-3.139, p = 0.017) and central venous catheter (HR = 2.421, 95% CI 1.297-4.518, p = 0.005). In contrast, absence of vascular access thrombotic episode (HR = 0.289, 95% CI 0.158-0.527, p<0.001) and body mass index ≥20 kg/m² (HR = 0.517, 95% CI 0.294-0.909, p = 0.022) had a favorable effect on survival.

Conclusion: Mortality rate in our cohort was measured 9.28% in first year and 36.29% in five years after starting hemodialysis. Survival was lower at elderly and diabetic patients undergoing hemodialysis. Our study identified some mortality factors potentially modifiable, such as body weight, type of vascular access and method of dialysis treatment.

CORRELATION OF FRAILTY SELF-ASSESSMENT WITH MEASURED FRAILTY USING THE FRIED CRITERIA IN PATIENTS ON DIALYSIS
Lena Schulte-Kemna¹, Miriam Künzig², Mohamed Nooreddin Jazah³, Martin Kächele¹ and Bernd Schroeppel¹
¹University Hospital Ulm, Section of Nephrology, Ulm, Germany and ²Ulm University, Ulm, Germany

Background and Aims: Frailty describes a complex syndrome of reduced resistance to stress factors as a consequence of age-related degeneration in various organ systems and is associated with poor clinical outcomes [1]. The European Renal Best Practice Guideline on the management of older patients with CKD recommends a regular assessment of functional status with the intention to identify those who would benefit from a more in-depth geriatric assessment and rehabilitation program [2]. Different frailty screening tools have been evaluated in CKD patients whereas the optimal tool for routine clinical application is not defined. The aim of this study was to evaluate an instrument that can be easily implemented in clinical practice and that can simplify the identification of vulnerable patients on dialysis.

Method: This cross-sectional, multicenter, prospective study included 123 adult patients on hemodialysis. Frailty status was assessed based on modified Fried criteria: self-reported exhaustion, weakness, slow walking speed, low physical activity level and unintentional weight loss [1]. Patients were categorized as frail meeting 3 of the 5 criteria. Patients were also asked to self-assess their frailty status on a 5-point visual analogue scale (VAS). Patients were considered robust selecting “1”, pre-frail “2 and 3”; and frail “4 and 5”. For data-analysis pre-frail and robust patients both using self-assessment and Fried criteria were categorized as “non-frail”. Correlation between Fried-criteria and self-assessment was measured using a contingency table and rank correlation (Spearman’s coefficient).

Results: The median age was 68 years, 71% were male and 40% were considered frail using the Fried criteria (Table 1). One patient was on intermittent peritoneal dialysis, all other patients received hemodialysis. There was no difference in frailty status assessed by Fried-criteria according to age, sex, body mass index (BMI) or dialysis vintage. Patients receiving dialysis using a central venous dialysis catheter were more likely to be frail than patients with an arterio-venous fistula or graft. Patients who assessed themselves as frail on the basis of the VAS were significantly more likely to be assigned to the non-frail group when measured according to Fried. Spearman’s correlation showed a positive correlation coefficient (0.419) and a significant correlation (2-sided, p < 0.001) between patient self-assessment using the VAS and the Fried-criteria.

Conclusion: Frailty is very common among patients on dialysis and occurs independent of age. The self-assessment by VAS simplifies frailty-screening in patients on dialysis by identifying more robust patients who do not need a time-consuming further evaluation.

**TRANSITION BETWEEN NUTRITION CATEGORIES IN HEMODIALYSIS PATIENTS**

Sara Blumberg-Benyamini1, Zvi Hai Barnea Burbea1,2, Relu Cernea1,2, Anna Katkov1,2, Alexander Biro1, Anat Levi1, Zeev Katzir1 and Leonid Feldman1,2

1Wolfson Medical Center, Israel and 2Tel Aviv University, Sackler School of Medicine, Holon, Israel

**Background and Aims:** We have previously characterized four nutritional categories in hemodialysis (HD) patients, evaluated by the method of ICNDS (Integrative Clinical Nutrition Dialysis Score) and slope of three subsequent monthly scores. Category 1 appeared to have the best and category 4 the worst nutritional status [1]. The aim of this study was to explore the association between nutritional category at dialysis initiation, survival, Length of Stay in hospital (LOS), and transition between nutrition categories up to 12 months following dialysis initiation.

**Methods:** Two hundred twenty-six patients who started dialysis between March 2009 and March 2019 were enrolled in the study. Scoring method of the ICNDS is based on the following 7 parameters: albumin, percentage post dialysis weight change, creatinine, urea, cholesterol, CRP, and Kt/V. We calculated the slope of first three subsequent monthly scores of each patient at HD commencement and 12 months later. Cox proportional hazard model was used to present differences in mortality hazard ratio (HR) during the first year in dialysis between four categories of patients. We used the analysis of variance and post hoc Bonferroni test to analyze differences in hospitalization frequency and LOS between the four categories during first year in dialysis.

We used the Pearson chi-square test to analyze transition between categories between dialysis initiation and one year after.

**Results:** Baseline nutritional category is associated to all-cause mortality HR ($\chi^2 = 36.22$, df = 3, P = 0.051). Patients enrolled to category 2 and 4 at dialysis initiation were significantly associated with increased mortality HR compared to patients in category 1 (category 4: HR = 3.951, 95% CI 1.218-12.812, P = 0.022; category 3: HR = 2.705, 95% CI 1.126-6.497, P = 0.026; category 2: HR = 1.778, 95% CI 0.631-5.064, P = 0.027). LOS during first year in dialysis is significantly affected by patient nutritional category at dialysis initiation, (F = 4.671, df = 3, P = 0.003). LOS is lower in patients of category 1 and 2 compared with category 3 and 4 (between categories 1 and 4, P = 0.006; between categories 1 and 3, P = 0.03). Hospitalization frequency is not affected by patient nutritional category (F = 1.705, df = 3, P = 0.167). Pearson chi-square showed no differences in transition between the four categories between dialysis initiation and one year after ($\chi^2 = 6.763$, df = 3, P = 0.149).

**Conclusion:** Nutrition status at dialysis commencement is a main prognostic factor, transition between nutrition categories during first year in dialysis exists and may prove in future to be associated with patients’ survival.

**TUBERCULOSIS IN DIALYSIS PATIENTS IN THE CENTRAL REGION OF MOROCCO: WHAT IS THE HEALTH-CARE DELAY?**

Elbordai Ghiata1, Nadia Kabbali2, Basmat Amal Chouhani1 and Tarik Sqalli Houssaini1

1Hassan II University Hospital, Department Nephrology, Dialysis, and Transplantation, Fez, Morocco and 2Hassan II University Hospital, Department Nephrology, Dialysis, and Transplantation, Fez, Morocco

**Background and Aims:** Due to the predominantly cellular immunosuppression, infections are frequent in chronic dialysis patients, in particular tuberculosis (TB). The main objective of our study is to evaluate tuberculosis healthcare delay in dialysis patients and to raise the diagnostic challenge in these patients.

**Method:** The study is retrospective and multicenter including tuberculosis cases of chronic dialysis patients either in hemodialysis (HD) or peritoneal dialysis (PD) in the central region of Morocco during a 10-year period between 2012 and 2021.

**Results:** We included 94 patients, five of whom were in PD, with a mean age of 50.79 ± 16.72 years, and a sex ratio of 0.67. The time between the initiation of dialysis and the onset of the clinical and biological presentation was 50.3 ± 87.12 months. The most frequent initial manifestations were an alteration of the general state (85.1%), a biological inflammatory syndrome (83%) or a prolonged fever (70.1%). Among our 94 patients, the diagnosis was confirmed with bacteriological evidence only in 18 cases (19.1%), by identification of Koch’s Bacillus (BK) in 13 cases, by molecular biology test (GeneXpert; Cepheid, Inc., Sunnyvale, CA, USA) in five cases. The diagnosis of tuberculosis was presumptive in most cases (79 cases), i.e. 80.9%. Twenty-one patients underwent the interferon gamma release essay test (QuantiFERON; Qiagen, Hilden, Germany) which was positive in 14 patients. Thirty-four (36.1%) cases had a histological diagnosis. The remaining patients were offered a trial treatment. Tuberculosis localization was mostly extrapulmonary (75.5%): lymph node (23.4%), pleural (13.8%), peritoneal (13.8%), whereas it was pulmonary in 23 cases (24.5%). Most of our patients had a clear delay in management from symptom onset to initiation of anti-TB treatment 78.9% (time >21days) vs 21.1% (time ≤21days). The median time to management delay was 46.5 interquartile range (IQR) (28.5-90), the mean delay was 78.4 ± 87.9 (6-360). All patients were treated according to the RHZE/RI protocol (R: rifampicin, H: isoniazid Z; pyrazinamide and E: ethambutol), with a duration between six and 18 months. SIDE effects associated with anti-tuberculosis treatment were observed in half of the patients (51.1%). The evolution was favorable with remission and improvement of the general condition in 90% of cases. Two cases of resistance were noted in our series. The overall mortality was 7.7%.

**Conclusion:** We have confirmed a delay in the diagnosis and treatment of tuberculosis in chronic dialysis patients. This can be explained by the often atypical or incomplete clinical and paraclinical presentation and the extrapulmonary localizations, making diagnosis difficult in this population whose prognosis remains poor. It is therefore necessary to establish a diagnostic approach that is adapted to the specificities of these high-risk patients within the framework of a national tuberculosis control program.

**PREVALENCE, TREATMENT AND RECURRENCE OF STAPHYLOCOCCUS AUREUS NASAL CARRIAGE IN PATIENTS ON RENAL REPLACEMENT THERAPY**

Nikolaos Tsikiras1, Aggelina Anagnostara2, Florina Tsantekidou1 and Apostolos Kyrgialanis1

1General Hospital of Xanthi, Hemodialysis Unit, Xanthi, Greece and 2General Hospital of Xanthi, Peritoneal Dialysis Unit, Xanthi, Greece

**Background and Aims:** Searching for and treating nasal carriage of staphylococcus aureus in patients undergoing renal replacement therapy (RRT) has been controversial. Indeed, previous meta-analyses showed that dialysis patients who were treated with intranasal mupirocin had lower rates of staphylococcus aureus infection but significantly more infections by other microorganisms. However, given the severity of staphylococcus aureus infections, it seems reasonable to detect and treat nasal carriers among patients on RRT. The aim of our study was to estimate the prevalence of staphylococcus aureus nasal carriage in patients on RRT, to evaluate the effectiveness of intranasal mupirocin in eradication of staphylococcus aureus and to
detect the recolonization rate with the above microorganism after successful treatment.

**Method:** It was a single center prospective observational study. In 63 patients undergoing RRT (48 on hemodialysis and 15 on peritoneal dialysis) we performed cultures of the anterior nares to identify the carriage of staphylococcus aureus. Carriers then received intranasal mupirocin twice daily for seven days (in every nostril). Thirty days later, nasal cultures were repeated in those treated with mupirocin. In patients that were decolonized, new cultures were obtained three months after initial eradication of staphylococcus aureus had been detected.

**Results:** Nasal carriage of staphylococcus aureus was identified in 14 out of 63 patients (rate = 22%). Female sex was related with higher rate of nasal carriage (p = 0.014). All but one patient that received mupirocin were found decolonized after thirty days (cure rate = 92.8%). Recurrence of staphylococcus aureus nasal carriage was observed in 6 out of 13 patients that had successfully been treated (recurrence rate = 46%). Sex, age, renal replacement method, primary disease or previous immunosuppression treatment didn’t seem to significantly affect the possibility of recurrence.

**Conclusion:** Our study found a remarkable prevalence of staphylococcus aureus nasal carriage in patients on RRT. Intranasal mupirocin was highly effective in the eradication of the above microorganism, but nearly half of the successfully treated patients experienced a recurrence of nasal carriage. Further studies are needed to detect the effect of repeated mupirocin treatment to the nasal carriage status as well as to the rate of infection in the above population.

**ASSESING HEALTH-RELATED QUALITY OF LIFE IN HEMODIALYSIS PATIENTS IN A PUBLIC HOSPITAL IN TUNIS: A CROSS-SECTIONAL STUDY**

Borhene Mejri, Najjar Mariem, Fadwa Helaoui, Chifaa Triqui, Fethi Ben Hmida and Ezzeddine Abderrahim

Charles Nicolle Hospital, Department of Medicine « A » Renal pathology Laboratory LR005P01, Tunis, Tunisia

**Background and Aims:** There are not many studies evaluating the quality of life of patients with chronic and advanced kidney disease in North Africa. We assessed the health-related quality of life (HRQOL) of patients receiving hemodialysis in a public hospital in Tunis using the KDQOL™-36 (Kidney Disease Quality of Life) survey, and we investigated its sociodemographic, clinical and biological correlation.

**Method:** A cross-sectional study design was used, and patients were recruited from a single hemodialysis center in the Charles Nicolle Hospital in Tunis. The KDQOL™-36 questionnaire was given to patients aged 18 or above receiving in-center hemodialysis maintenance for at least three months to assess their physical and mental health, as well as the effect, burden, and symptoms of kidney disease. Patients with hepatitis, HIV, mental illnesses, and physical disabilities were not eligible for the study. Socio-demographic and clinical data were collected for all eligible patients. We then employed linear regression models to explore the factors associated with overall KDQOL and its various domains.

**Results:** Sixty-five patients were included. The mean age was 50.9 years old (23-79). The sex ratio was 1.16. The median quality of life score was 52.5 for the Physical Component Summary (PCS) score and 44.2 for the Mental Component Summary (MSC) score. Symptoms/problems, effect, and burden of kidney disease (KD) were scored 62.5, 39.38 and 37.5, respectively. There was a significant correlation between diabetic and non-diabetic patients in Symptoms (50.19 vs 65.04 p = 0.006), Effect (45.4 vs 57.87 p = 0.038), Burden of KD (7.38 vs 39.46 p = 0.001) and MCS (p < 0.0001). Cardiovascular disease was associated with a higher burden of KD (p = 0.025). Higher age was associated with lower score in Symptoms (p = 0.032) and Burden (p = 0.035). Other correlations were between weight gain between sessions and MCS (p = 0.012), Hypotension with both symptoms (p = 0.016), effect (p = 0.029) and MCS (p = 0.017), Hypoaalbuminemia with symptoms (p = 0.018), dilated left cavity in the transthoracic ultrasound with both effect (p = 0.047) and burden of KD (p = 0.023). There was no correlation found between gender, work status and hemoglobin level and quality of life.

**Conclusion:** The results of this study indicate that patients receiving hemodialysis have a low quality of life. The factors associated with overall quality of life were diabetes, cardiovascular disease, age, weight gain between dialysis sessions, hypotension, hypoalbuminemia, and dilated left cavity in transthoracic ultrasound. Those findings should be studied using a larger sample.

**INCIDENCE OF ACUTE PULMONARY EDEMA AFTER THE SYSTEMATIC USE OF ULTRASOUND B-LINES**

Alessandra Ursolo1, Francesca Mallamaci1,2, Rocco Tripepi2 and Vincenzo Antonio Panuccio1,3

1Grande Ospedale Metropolitano di Reggio Calabria, Nephrology, Dialysis and Transplantation Unit, Reggio Calabria, Italy, 2Institute of Clinical Physiology - National Research Council, Clinical Epidemiology and Pathophysiology of Renal Diseases and Hypertension, Reggio Calabria, Italy and 3Grande Ospedale Metropolitano di Reggio Calabria, Nephrology, Dialysis and Transplantation Unit, Reggio Calabria, Italy

**Background and Aims:** Acute pulmonary edema (APE) due to fluid overload is considered the most feared complication in hemodialysis patients. Various diagnostic tests have been proposed to assess fluid status in patients with end stage kidney failure (ESKF) and among these lung ultrasound (by measuring the number of B-Lines) is emerging as a promising tool to identify pulmonary congestion in this patient-population.

**Method:** In the setting of a retrospective study, we pragmatically compared the incidence rate of APE in our center before and after the implementation of lung ultrasound as a routine practice in our unit. Two periods were considered. A pre-implementation period [from 01/01/2007 to 31/12/2008, total person-time: 1913 months/patient, n = 98 patients (Group 1), 85 prevalent and 13 incident patients] and a post-implementation period [from 01/01/2017 to 31/12/2018, total person-time: 2061 months/patient, n = 108 patients (Group 2), 81 prevalent and 27 incident patients]. By accurately reviewing the electronic medical records, all episodes of APE were counted, i.e. all episodes characterized by sudden or worsening dyspnea associated with signs of salt and water overload, confirmed by chest auscultation or chest X-Ray, which required an additional dialysis session and excluding events due to infectious or irritating problems.

**Results:** The two groups (Group 1 vs Group 2) were quite similar between them as for age (64±15 vs 67±14 years, p = 0.06), proportion of males (65% vs 62%, p = 0.37) and median dialysis vintage [40 months (interquartile Range, IQR: 16–93 months) vs 46 months (IQR: 12–92), p = 0.76]. The two groups did not differ as for diabetes (21% vs 25%, P = 0.33), hypertension (75% vs 71%, p = 0.36), and smoking habit (29% vs 28%, p = 0.51). Of note, the proportion of patients with background cardiovascular comorbidities was significantly higher in patients of Group 2 (enrolled in the post-implementation period) than in those of Group 1 (31% vs 19%, p = 0.04). A total of 37 APE episodes in 18 patients (from 1 to 4 episodes per patient) were identified in patients of Group 1 vs 7 APE episodes in 5 patients (from 1 to 2 episodes per patient) in those of Group 2. The incidence rate of APE was 82% lower in patients during the post-implementation period (4 episodes per 100 patients/year, 95% CI: 1–8) than in those during the post implementation period (23 episodes per 100 patient/year; 95% CI: 17–32) (incidence rate ratio: 0.18, 95% CI: 0.10–0.29, p < 0.001).

**Conclusion:** The systematic use of lung ultrasound (simple, easy to learn, rapid and non-invasive method, easily performed at the patient's bed) in every day clinical practice drastically reduced (-82%) the episodes of APE in hemodialysis patients. Further observational and interventional studies are needed to confirm these results.

#6211

**THE OPPORTUNITY COSTS EXPERIENCED BY PATIENTS WHO INJECT DRUGS UNDERGOING HEMODIALYSIS: A CASE SERIES**

John Harterink, Thomas Mcdonnell, Katy Burns, Prasana Hanumapura, Durga Kanigicherla and Patrick Hamilton

Manchester Royal Infirmary, Nephrology, United Kingdom

**Background and Aims:** Patients who inject drugs (PWIDs) represent a uniquely difficult population to manage with haemodialysis, often with reliance on tunnelled venous access. This population is historically difficult to reach, and their care is usually associated with higher per capita healthcare costs [1], unsurprisingly poor outcomes are reported [2] with a multitude of likely causes. Here we show the time associated opportunity costs these patients experience including the significant complication of tunnelled dialysis line infection in a person who actively injects drugs.

**Method:** This study follows on from the work by Burns [3]. In this retrospective observational study, the electronic health records of patients who were known to be ongoing users of recreational drugs were reviewed from January 2015 – August 2021. Patients were reviewed from their first tunnelled line placement until either their death or until the end of the study time period. Stata 14 was used to generate descriptive statistics.

**Results:** 6 Patients were identified, 5 had a primary diagnosis of AA Amyloidosis with the other being IgA. This cohort of patients did poorly, 5

Figure 1: Time to first confirmed bacteraemia after first tunnelled line placement.

out of 6 of the cohort had died with a mean survival of 27 months. Patients were followed for an average of 769 days (range 485 - 1052). The majority of this time alive was spent as an inpatient with the mean percentage of time as an inpatient being 55% (Range 35–81%) with a mean of 411 total inpatient days. The first confirmed bacteraemia occurred within the first 100 days in 4 out of 6 of the patients.

Conclusion: With this case series we demonstrate the opportunity cost PWIDs experience in the form of time spent as an inpatient. This cost is further added to by the burden of outpatient maintenance haemodialysis. Consideration should also be given to the excess burden their care places on over-stretched healthcare systems. Infections and dialysis compliance are key components in the care of PWIDs and while moving away from tunneled access should be sought whenever possible a multidisciplinary approach should also be considered; these patients commonly lead chaotic lifestyles and in-center dialysis is usually the only option. Including addiction, social and psychiatric services alongside dialysis may be a way to engage with this historically difficult to reach population. The hope is that this study provides the incentive for further studies focusing on the opportunity costs and the quality of life this population can expect when embarking on haemodialysis. This would provide patients with realistic expectations while also aiding clinicians in navigating this difficult ethical situation.

AN EXPLORATORY STUDY OF GUT PERMEABILITY IN SUBJECTS ON HAEMODIALYSIS: RESPONSE TO AN ORAL BETA-D-GLUCAN LOAD

Oscar Swift1, Malcolm Finkelman2, Yonglong Zhang2, Eunice Doctolero1, Chadd Javier1, Mikky Gilbert1, Sivakumar Sridharan1, Kenneth Farrington1 and Enric Vilar1

1East & North Hertfordshire NHS Trust, Renal Department, Stevenage, United Kingdom and 2Associates of Cape Cod Inc, Falmouth, United States of America

Background and Aims: End stage kidney disease (ESKD) is associated with chronic inflammation. A combination of increased gut permeability and impaired hepatic clearance of gut-derived toxins are likely contributory factors to chronic inflammation in ESKD. Gut permeability assessment in kidney impairment is complex as traditional gut permeability probe concentrations are significantly influenced by residual kidney function. (1-3)-β-D glucans
Changes in serum beta-D-glucan levels in inflamed haemodialysis patients and individuals with normal kidney function following ingestion of a beta-D-glucan meal.

Individual changes in serum beta-D-glucan levels in inflamed haemodialysis patients and individuals with normal kidney function following ingestion of a beta-D-glucan meal.

(BDG) are glucose polymers found in dietary plant material and also fungi and bacteria. BDG predominantly undergo reticuloendothelial (primarily hepatic) clearance. BDG ingested in the form of fibre are not well absorbed from the small intestine. Elevated serum BDG levels have been previously observed in chronic kidney disease and may reflect systemic translocation of dietary and gut derived microbial fragments from the portal system. This study aimed to establish if there were differences in serum BDG concentrations in individuals with normal kidney function and ESKD following ingestion of a BDG rich meal.

Method: 20 participants with ESKD receiving haemodialysis via an arteriovenous fistula with evidence of inflammation (a median baseline serum C-reactive protein (CRP) ≥5mg/L over the previous 3 months) and 20 participants with normal kidney function (NKF) were studied. Participants with active infection, autoimmune disease, gastrointestinal disease and hyperkalaemia were excluded. All participants followed a low fibre diet for 48 hours and fasted for 12 hours prior consuming a BDG-rich drink that delivered approximately 10μg/gram of BDG. In the ESKD cohort, the drink was consumed immediately prior to a dialysis session following a 1-day interdialytic gap. In addition to standard of care blood tests, serum BDG levels were measured at baseline, 0.5 hours, 1 hour, 1.5 hours, 2 hours, 3 hours, 4 hours, 6 hours and 48 hours. Serum BDG measurements were analysed with the Fungitell® assay (Associates of Cape Cod, Inc). Faecal calprotectin and faecal alpha-1-antitrypsin were also analysed.

Results: 20 participants with ESKD receiving haemodialysis (mean age 66.8 years) and 20 participants with NKF (mean age 44.6 years) were recruited. Serum BDG levels were significantly higher at baseline in the ESKD group (29.6pg/ml in the NKF group versus 67.1pg/ml in the ESKD group, p = 0.001) and at all other timepoints throughout the study period (see Fig. 1). There were no significant difference in change from baseline BDG levels between groups. Individual BDG levels taken post meal ingestion are shown in Fig. 2. Baseline serum BDG levels correlated strongly with median baseline high sensitivity CRP over 3 months (p = 0.001) however this relationship was not present when the two groups were examined separately. Faecal calprotectin and faecal alpha-1-antitrypsin did not correlate with baseline serum BDG measurements (p = 0.93, p = 0.78, respectively).

Conclusion: Elevated BDG levels are observed in ESKD and increase both during and immediately following dialysis after ingestion of a BDG load. In addition to dietary BDG, translocation of gut-derived microbial BDG into the systemic circulation may play an important role in contributing to systemic inflammation observed in advanced kidney disease. Elevated BDG may reflect increased gut permeability which may be secondary to uraemic toxin related gut barrier dysfunction or splanchnic ischaemia related to ultrafiltration.
THE EFFECT OF NURSE-LED 8-ZONE LUNG ULTRASOUND GUIDED TITRATION OF DRY WEIGHT ON HYPERTENSION IN APPARENTLY EUVOLAEIC HAEMODIALYSIS PATIENTS

Grace Lee¹, Jackie Chiu¹, Umer Kha², Behram Ali Khan³ and Lee Ying Clara Ngoh²

¹National University Hospital, Department of Medicine, Singapore, Singapore, ²National University Hospital, Division of Nephrology, Department of Medicine, Singapore, Singapore and ³National Kidney Foundation Singapore, Medical Services, Singapore, Singapore

Background and Aims: Hypertension related to subclinical volume overload is a common clinical problem in haemodialysis patients. Lung ultrasound (LUS) is a validated technique for minute titration of dry weight, but has limited adoption in clinical practice because it is currently a physician (nephrologist)-led methodology and time consuming with 24-lung zones needing to be imaged. This study aims to show that (1) a simplified 8-zone LUS protocol is effective at dry weight titration in clinically euvoalaemic chronic haemodialysis patients, as determined by 24-hour ambulatory blood pressure monitoring (ABPM), and that (2) nurse-led LUS for dry weight titration is feasible and safe.

Method: This was a 6-week pre and post intervention study in 13 clinically euvoalaemic haemodialysis patients with chronic hypertension. 4 senior dialysis nurses with at least 4 years of dialysis nursing experience respectively were trained in LUS image acquisition and interpretation via a 1 day workshop by a certified Nephrologist and passed an image interpretation test. 8-zone LUS (which has been described by Volpicelli et al.[1]) was performed midweek, weekly. A Nephrologist reviewed all the acquired LUS images retrospectively. Dry weight was titrated down at a rate not exceeding 0.3 kg per week if LUS Kerley B lines exceeded 3 in any lung zone. All patients underwent 24-hour ABPM at baseline and after 6 weeks. Nurses underwent a post study qualitative survey to elucidate success factors and confidence in LUS technique.

Results: The study cohort was predominantly male (69%) and diabetic (92%), with an average age of 68 ± 10 years. The average time required for a nurse to complete 1 LUS scan was 3 ± 0.4 minutes. 75% of the cohort had dry weight reduction post-study, which ranged from 0.08 – 0.9% of initial dry weight. Correspondingly, the median number of ultrasonographic B-lines reduced from 4 to 3, although this did not reach statistical significance. Overall, there were reductions in 24-hour systolic BP (146.42±17.03 vs 139.08±12.40 mmHg; p = 0.067) and diastolic BP (72.75±11.79 vs 70.75±11.69 mmHg; p = 0.561). Similarly, there were trends towards improvements in pre- and post-dialysis systolic and diastolic BPs, although only pre-dialysis diastolic BPs showed statistically significant improvement (80±16.05 to 72.33±13.32 mmHg; p = 0.046). This may be related to small sample size. Nil adverse outcomes such as intra-dialytic hypotension, vascular thrombosis, cardiovascular events or fluid overload were reported during the study. 1 patient demised from pneumonia sepsis, which was deemed to be unrelated to the study. All nurses expressed confidence in LUS image acquisition and interpretation following the workshop. Their confidence was further bolstered by the end of the study. They also felt that point-of-care LUS was a useful skill for experienced haemodialysis nurses who were often responsible for day to day adjustment of fluid removal on dialysis.

Conclusion: We have demonstrated that nurse-led 8-zone LUS can effectively and safely titrate dry weight in chronic haemodialysis patients, as evidenced by improvements in 24-hours ABPM. Importantly, these results are similar to that of randomized controlled trials such as the LUST study where LUS was physician-led. There remains little doubt about the importance of LUS in volume assessment. In-depth studies are required to determine the competencies of, and risk-benefit assessment for nurse-led LUS, to improve the clinical relevance and penetrance of this tool.

Method: Fifty patients with ESRD who were on regular HD were included in the study. Patients’ ferritin levels ranged from 500 to 1200 ng/mL with transferrin saturation of 30% or more. However, all patients were anemic and received erythropoietin therapy. Iron therapy was discontinued in the first group, whereas it was continued in the second group that received IV AA.

Results: A significant increase in the levels of Hb was observed in the second group after 6 months despite the decrease in ferritin levels in both the groups. Transferrin saturation decreased in both groups, the decrease being more in the first group. The levels of C-reactive protein (CRP) decreased in the second group, whereas these increased in the first group.

Conclusion: Intravenous AA as an adjuvant therapy with iron exerts a favorable and significant effect on the Hb, serum ferritin, and CRP levels in patients with ESKD having anemia. The discontinuation of iron therapy only decreases the serum ferritin levels and does not improve the Hb or CRP levels.

#2803

ECG ABNORMALITIES AND MORTALITY IN HEMODIALYSIS PATIENTS

Chloé Kharsa1, Roy Chlawit1 and Mabel Aoun1,2

1Faculty of Medicine, Saint-Joseph University of Beirut, Beirut, Lebanon and 2AUB Santé, Nephrology, Lorient, France

Background and Aims: Hemodialysis patients undergo electrocardiogram (ECG) testing for acute events or as a part of the regular workup. It is still unknown whether chronic ECG abnormalities could be considered as a prognostic factor in dialysis patients. This study aims to analyze the association between mortality and ECG abnormalities of the last two years of follow-up of hemodialysis patients.

Method: This is a retrospective study that included all patients treated with chronic hemodialysis in a single center between January 2002 and December 2021. Patients who had no ECG in their medical file during the last two years of follow-up were excluded. ECGs were interpreted by two physicians. Logistic regression analysis evaluated the association between ECG signs and mortality. The study was approved by the institutional ethics committee and was conducted in accordance with Helsinki Declaration.

Results: A total of 298 medical files were reviewed, 149 files included an ECG in the last two years of follow-up. Mean age of patients was 67.1 ±13.2 years, 64.4% were males, 54.4% had diabetes, 44.2% had documented coronary artery disease (CAD), 14.8% had chronic or paroxysmal atrial fibrillation. The median left ventricular ejection fraction (LVEF) was 60% [55.5, 64.5]. 55% percent died after a median follow-up of 47 [25, 87] months. Table 1 summarizes the ECG characteristics found among all patients. In the univariate analysis, age, CAD, LVEF, left axis deviation, large QRS, ST depression and first-degree AV block were significantly associated with mortality. After adjustment to age, dyslipidemia, sex, diabetes, CAD and LVEF, we found a significant association between all-cause death and left axis deviation (Table 2). The poor R wave progression was associated with increased sudden cardiac arrest after adjustment to age, dyslipidemia, sex, diabetes and CAD (OR = 2.65, 95%CI 1.01-6.94, p = 0.048).

Conclusion: This study showed that left axis deviation on ECG of patients treated with chronic hemodialysis is an independent factor associated with increased all-cause mortality after adjustment to demographic and medical factors. Poor R wave progression was associated with sudden cardiac arrest.

Background and Aims: Chronic kidney disease is associated with the accumulation of so-called middle molecules in the blood, in particular parathyroid hormone, and the formation of secondary hyperparathyroidism with a tendency to extra-bone calcification. The most vulnerable organ in relation to calcification is the vascular wall. The all of the study to study the features of vascular wall remodeling in patients with chronic kidney disease who are being treated with programmed hemodialysis.

Method: The study included 86 patients with CKD 5 (mean age 47.4±5.04 years) who had been on programmed hemodialysis for at least 6 months. All patients underwent examination, including multislice spiral computed tomography (MSCT) with an assessment of the calcium content in the coronary arteries (Agatston index), ultrasound examination of the carotid arteries with determination of the thickness of the intima-media complex, the degree of endothelium-dependent vasodilation in a sample with 5-minute compression of the brachial artery and determination of changes in the diameter of the brachial artery. The data obtained (presented in the form of an arithmetic mean and its standard error) were compared with normal values typical for a healthy population.

Results: There was an accumulation of calcium in the coronary vessels with an average Agatston index of 146.83 ± 13.26 units. Also, during MSCT, calcifications were found in the aortic wall in 86 out of 57 patients. The intima-media complex in patients with CKD was significantly increased and averaged 1.21±0.06mm. The degree of endothelium-dependent vasodilation in patients with CKD was reduced and amounted to 5.48±0.03% of the initial diameter of the brachial artery. Correlation analysis revealed significant positive associations of average strength between the value of the Agatston index, the thickness of the intima-media complex of the carotid arteries and the concentration of parathyroid hormone in peripheral blood (g = 0.49, P<0.05 with the Agatston index and P = 0.42, P<0.05 with the thickness of the intima-media complex), as well as a significant negative relationship between the product of the concentration of calcium and phosphorus in peripheral blood and the degree of endothelium-dependent vasodilation (g = -0.49, P<0.05).

Conclusion: In patients with CKD, against the background of programmed hemodialysis, there is a remodeling of the heart with an increase in the size of the heart cavities and LV myocardial mass, a violation of regional and general LV contractile function, LV diastolic dysfunction and an increase in pressure in the pulmonary artery system. The introduction of sevelamer hydrochloride into the therapy regimen is associated with the prevention of the progression of cardiac remodeling. Calcification of the aortic valve progresses, regardless of the therapy used. Vascular remodeling in patients with CKD on the background of programmed hemodialysis is manifested by an increase in the thickness of the intima-media complex of the carotid arteries and a violation of endothelium-dependent vasodilation in favor of paradoxical vasoconstriction. Against the background of calcium carbonate therapy, structural disorders of the vascular wall progress. The introduction of sevelamer phosphate binder into the therapy regimen allows to prevent the progression and improve the functional state of endothelial function.
first reported result within 3 months of starting HD. Cohorts were grouped according to biomarker-specific thresholds and 1:1 propensity-score matched for age, gender, and co-morbidities (hypertension, diabetes mellitus and smoking status). Logistical regression produced odds ratios with 95%CI for 5- year incident MACE. MACE was defined, a priori, as a composite of ischaemic heart disease, angina pectoris, acute myocardial infarction, heart failure, AF, stroke, and all-cause mortality. All statistical analysis was performed on the TriNetX online platform.

Results: The results are shown in Table 1. Results that reached statistical significance (p<0.05) are shown.

Conclusion: Routinely available cardiac biomarkers can predict incident MACE and outcomes in incident HD, although results differ between markers of myocyte injury (troponin) and stress (NTproBNP). The results suggest the clinical need for CV mortality and morbidity risk profiling in incident dialysis using a combination of clinical and laboratory variables.

Conclusion: PC is common in HD patients even after reaching their dry weight at the end of their two consecutive sessions. It is not only correlated to volume status and cardiac function. Chronic inflammation may be involved in PC pathophysiology. A better management strategy is thus needed to better reduce PC in HD patients.

Ezzeledin Shalaby
Faculty of Medicine Cairo University, Cairo, Egypt

Background and Aims: Proton Pump Inhibitors are widely used in haemodialysis patients for the prevention and treatment of uremic gastritis, peptic ulcer, gastritis, esophagitis and gastro oesophageal reflux. Hypomagnesaemia is reported recently in some patients who abuse intake of Proton Pump Inhibitors (PPIs) but this problem is still not well studied yet. Our study aims to evaluate the chronic toxic effect of Proton Pump Inhibitor on Magnesium level in Egyptian haemodialysis patients, especially those who suffer from abuse of intake without medical prescriptions.

Method: The study was conducted at the haemodialysis centre and clinic of Alzawya One-Day Surgery Hospital in Cairo including 60 end stage renal disease patients after their consents and approval of ethical committee in our hospital. PPIs use and duration were investigated. The patients were dialyzed using a diализate magnesium level of 0.5 mmol/L and Calcium level 1.5 mmol/L in all groups, after at least one month of haemodialysis with the mentioned diализate, laboratory tests were performed. The patients participating in this study after their consents were divided into 3 groups:

• Group A: -20 patients on Proton Pump Inhibitors regularly with long term intake for more than 6 months on high dose above or equal 280 mg/week [1]
• Group B: -20 patients on Proton Pump Inhibitors irregularly for less than 6 months on low dose below 280 mg/week.
• Group C: -20 patients not intake Proton Pump Inhibitors.

The magnesium level in haemodialysis patients was evaluated by comparison between the 3 groups and its correlation with duration of its use, Calcium and Phosphorus level in blood. Dialysate magnesium and calcium concentration in all groups were fixed and abuse of intake of PPIs without medical prescription in the participated patients was evaluated.

Results: Show highly statistically significant higher mean value in Non-intake of PPI group, followed by PPI intake ≤6m group and the lowest value in PPI intake >6m group according to magnesium "mg/dl", with p-value (p<0.001). There is no statistically significant difference between groups according to calcium "mg/dl"; with p-value (p>0.05).

Conclusion: Proton Pump Inhibitors regularly with long term intake for more than 6 months on high dose above or equal 280 mg/week associated with hypomagnesaemia. So we recommend stoppage of abuse intake of PPIs in haemodialysis patients.

MAGNETIC RESONANCE IMAGING ASSESSMENT OF SKIN AND MUSCLE SODIUM IN HAEMODIALYSIS

Rebecca Noble1,2, Ben Prestwich1, Kelly White3, Maarten Taal1,2, Nick Selby1,3 and Susan Francis3

1University of Nottingham, United Kingdom and 2Centre of Kidney Research and Innovation, Derby, United Kingdom

Background and Aims: Haemodialysis (HD) is life sustaining for patients with end-stage kidney disease (ESKD) but is associated with a marked increase in incidence of cardiovascular disease (CVD) and high annual mortality rates. Sodium balance is regulated by the kidneys in health but has to be achieved by sodium removal during HD for those with ESKD. Recent evidence suggests that non-osmotically stored sodium in the muscle and/or skin may be a critical factor impacting the development of hypertension and CVD. Sodium magnetic resonance imaging ($^{23}$Na MRI) allows assessment of skin and muscle sodium storage and may provide a valuable tool in evaluating sodium storage in dialysis patients. In this study, we used $^{23}$Na MRI to measure muscle and skin sodium content in younger and older healthy individuals and people receiving HD, and investigated the effect of a single dialysis session on muscle and skin sodium content.

Method: $^{23}$Na MRI was acquired on a 3T Philips Ingenia scanner using a custom-made $^{23}$Na RF coil. 3D GRE $^{23}$Na scans ($3 \times 3 \times 30\text{mm}^3$, 10 slices) were acquired in a 15-minute scan. Four reference bottles of increasing sodium concentration were placed in the RF coil above the leg to calibrate sodium concentration. In the same imaging session, 1H MR images were acquired to delineate muscle groups, skin structures and tissue water content. $^{23}$Na concentration maps were generated using custom software and regions of interest of each muscle and the skin were manually segmented. Data was collected on 14 younger (23-38yrs,7M:7F) and three older (66-77yrs,3M:1F) healthy volunteers (HVs), and 5 male HD patients (55-68yrs) who had been on HD for more than 3-months. HD patients underwent a pre-dialysis $^{23}$Na MRI calf scan, then had their usual dialysis session with a dialysate Na prescription of 137 mmol/L, followed by a repeat $^{23}$Na MRI calf scan post dialysis. Patient demographics, dialysis vintage, residual renal function, and ultrafiltration volume were collected, along with blood samples at the start and end of the dialysis session, including serum sodium.

Results: Figure 1 shows $^{23}$Na images in the younger and older HV group and HD patients pre-dialysis. Muscle and skin sodium was increased in older HVs compared to younger, with HD patients pre-dialysis tending to be lower than older HVs (Fig. 2). HD patients’ demographics and clinical measures pre- and post-dialysis are shown in Table 1. HD treatment reduced muscle sodium whilst skin sodium showed little change (Fig. 3).

Conclusion: We have optimised methods for measuring muscle and skin sodium. $^{23}$Na concentration in muscle and skin is higher in older subjects. HD patients’ $^{23}$Na values fall between those observed in the older and younger HV groups. These values are consistent with published data from patients dialysed against 137mmol/l sodium dialysate, but lower than other studies in which dialysate sodium levels were higher. Further studies are planned to study...
Our study cohort was well representative of general dialysis population. Median Age was 65 years, with 65.6% Males and 34.4% Females. All sleep quality parameters were considerably poor compared to age matched general population. Mean Sleep Efficiency was 77.5% (Normal for age matched general population is 83.2%), Mean TST was 318 minutes (Normal 372 minutes), Mean WASO was 83 minutes (Normal 64 minutes), Mean Sleep Fragmentation index was 43. None of the sleep quality parameters had significant difference in different dialysis modalities in our study.

RELATIONSHIP BETWEEN MEASURED SLEEP QUALITY AND CLINICAL PARAMETERS IN DIALYSIS PATIENTS
Usama Butt, Enric Vilar, Sivakumar Sridharan, Kenneth Farrington and Jocelyn Berdeprado
Lister Hospital, Stevenage, United Kingdom

Background and Aims: Poor sleep quality in dialysis patients has been well reported and has deleterious effects on quality of life. Factors affecting the sleep quality in these patients have not been very well explored. Actigraphy using wearable devices with 3D accelerometers is a well-recognised method of analysing the sleep quality. We set out to determine the relationship of sleep quality parameters measured using actigraphy with dialysis related factors in patients on dialysis.

Method: We conducted a prospective analysis of 95 patients, involving 75 In Centre Haemodialysis (ICHD), 15 Home Haemodialysis (HHD) and 8 Peritoneal dialysis (PD) patients. Sleep data was collected using Actigraph wrist device. Participants were instructed to wear the device 24 hours a day for consecutive 7 days. Sleep data analysis was conducted with Actilife software using Cole-Kripke sleep-wake algorithm. Sleep quality parameters used for assessment included Sleep Efficiency, Average Total sleep time (TST), Wake after sleep onset (WASO), Number of Awakenings, Sleep Fragmentation index. Demographic and clinical information was collected prospectively from medical records.

Results: Our study cohort was well representative of general dialysis population. Median Age was 65 years, with 65.6% Males and 34.4% Females. All sleep quality parameters were considerably poor compared to age matched general population. Mean Sleep Efficiency was 77.5% (Normal for age matched general population is 83.2%), Mean TST was 318 minutes (Normal 372 minutes), Mean WASO was 83 minutes (Normal 64 minutes), Mean Sleep Fragmentation index was 43. None of the sleep quality parameters had significant difference in different dialysis modalities in our study. Amongst the predictors of sleep quality, serum phosphate had significant association with increased WASO (p = 0.002). Mean WASO was 99 minutes for patients with serum Phosphate > 1.8 mmol/L compared to 74 minutes for those with serum phosphate of < 1.8 mmol/L. Serum phosphate had a borderline significant positive correlation with Number of Awakenings (p = 0.06) and borderline significant negative correlation with Sleep Efficiency (p = 0.06). Renal urea clearance (KRU) had statistically significant positive correlation with sleep efficiency (p = 0.013) but didn’t reach statistical significance in relation to the other sleep quality parameters. Urine volume also had positive correlation with sleep efficiency nearly reaching statistical significance (p = 0.055). Other factors analysed during the study didn’t appear to have any significant associations with sleep quality.

Conclusion: Actigraphy is non-invasive, less cumbersome, and reliable method of sleep assessment in dialysis patients. Compared to the age matched general population, dialysis patients have objectively measured poor sleep quality. Serum phosphate has significant negative impact on sleep quality possibly secondary to hyperphosphatemia-related side effects. Residual kidney function has positive association with sleep efficiency. This study highlights the potential importance of preserving residual kidney functions and treating hyperphosphatemia in dialysis patients which warrants further research.

#2567
ASSOCIATION OF IMBALANCE OF MYOCARDIAL OXYGEN SUPPLY/Demand WITH MYOCARDIAL INJURY IN END STAGE KIDNEY DISEASE PATIENTS
Kenji Nakata, Minako Harada, Mai Hitaka, Yuri Tanaka and Nobuhiko Joki
Toho University Ohashi Hospital, Division of Nephrology, Meguro-ku, Japan

Background and Aims: It is well known that oxygen transport ability is impaired in patients with anemia, low hemoglobin (Hb) level, whereas the double product (DP, bpm*mmHg), consisting of the systolic blood pressure (SBP) multiplied by the heart rate (HR), is an index of myocardial oxygen consumption. The combination of these two markers could be a potential marker for balance of myocardial oxygen supply and demand. Therefore, we hypothesized that the balance of these two markers may lead to myocardial damage in end-stage kidney disease (ESKD) patients who is susceptible to vulnerable heart in oxygen balance. The purpose of this study is to examine the association of balance of DP and Hb with myocardial injury in ESKD patients.

Method: A single-center, cross-sectional study has conducted. From December 2010 to November 2021, 327 consecutive ESKD patients started maintenance hemodialysis (HD). Among them, 44 patients met the exclusion criteria as follows: (1) missing data of cardiac troponin T (cTnT); (2) complicating acute cardiac syndrome; (3) death during hospitalization for HD initiation, a total of 283 ESKD patients were enrolled into the study finally. The patients were divided four groups according to the high or low of Hb level of 9 g/dL and DP 12500, a median of our patients, and named low-DP/high-Hb; G1, low-DP/low-Hb; G2, high-DP/high-Hb; G3, and high-DP/low-Hb; G4. The patients with G1 group were defined as a well oxygen balanced group, whereas those with G4 was defined as an imbalance of oxygen supply and demand group. Based on the results of previous study, cTnT cut off for myocardial injury was serum cTnT ≥0.15 ng/mL. Odds ratio (OR) for myocardial injury was calculated in each group compared with well oxygen balanced group by logistic regression analysis.

Results: Median age was 72 years, 71% of them were male, 52.6% had diabetes. Mean Hb level was 9.09 ± 1.61, and median DP was 12144 (25% tile 10540, 75% tile 14688). Median cTnT was 0.083 (25% tile 0.057 and 75% tile 0.13), and 20.4% of patients were defined as suffering from myocardial injury latently. In the adjusted model, the odds for myocardial injury was significantly increasing in high-DP compared with low-DP (OR: 1.87, p = 0.049), while low-Hb did not show significant increment of odds for myocardial injury compared with high-Hb. As shown in the Table 1, compared to well-balanced group (G1), OR increased by exposing only high-DP (G3), however it was

HEMOGLOBIN VARIABILITY IS ASSOCIATED WITH NUTRITIONAL STATUS IN HEMODIALYSIS PATIENTS UNDERGOING DARBEPOETIN-ALFA TREATMENT

Do Hyoung Kim1, Jungho Shin2 and Dong-Jin Oh3

1Hallym University Kangnam Sacred Heart Hospital, Department of Internal Medicine, Seoul, Rep. of South Korea, 2Chung-Ang University Hospital, Department of Internal Medicine, Seoul, Rep. of South Korea, 3Myongji Hospital, Hanyang University College of Medicine, Department of Internal Medicine, Gyeonggi-do, Rep. of South Korea

Background and Aims: Anemia is the most common finding in hemodialysis (HD) patients. A significant proportion of patients are taking erythropoietin (EPO) or other erythroid-stimulating agents (ESA), yet the response to treatment is unsatisfactory, and EPO responsiveness is inconsistent in HD patients. Further, although the introduction of EPO has led to a dramatic reduction in blood transfusion requirements and is associated with improved quality of life, fluctuations in hemoglobin (Hb) levels, known as Hb variability, during EPO treatment is a well-documented phenomenon. Malnutrition is a well-known risk factor in the general population and in HD patients. However, few studies have evaluated the association between EPO responsiveness/Hb variability and nutritional status in HD patients. Therefore, our aim was to investigate whether EPO responsiveness and Hb variability can be associated with nutritional status in HD patients undergoing darbepoetin-alfa (darbepoetin-alfa; Kyowa Kirin Korea Co., Ltd.) treatment.

Method: In this prospective study, we included adult ninety-eight patients aged over 20 years who had been undergoing HD over 6 months. The target hemoglobin (Hb) level is 10–11 g/dL according to the Korean reimbursement guideline. Dose adjustments of NESP® were made according to the Hb level measured monthly in our facility. Every study population have more than 24 monthly Hb data points. We checked average darbepoetin-alfa dose weekly and the EPO resistance index (ERI) as a marker of EPO responsiveness was calculated by dividing the weekly average darbepoetin-alfa dose by the Hb level. In addition, we evaluated the more than 24 month Hb variability, which was expressed by Hb-Coefficient of Variation (Hb-CV). All of them were measured by BCM® (Fresenius Medical Care a Deutschland GmbH, Germany) three times (Baseline (12 Mos), 12 Mos). Nutritional parameters obtained by BCM® were body mass index (BMI), fat tissue index (FTI), lean tissue index (LTI), body cell mass index, phase angle (PhA). Clinical parameters and routine biochemical tests such as dose of erythropoietin, Kt/Vurea, iron and lipid profiles, C-reactive protein, albumin, calcium, phosphorus, intact-parathyroid hormone were also taken into account.

Results: In this study, the mean age of the patients was 64.0 ± 11.9 years, and 55.0% were male. Dialysis vintage was 54.9 ± 46.8 months. Follow-up duration was 79.3 ± 47.9 months. Mean Hb was 10.7 ± 1.3 g/dL. We divided into tertiles (T) according to the ERI. The average ERI was 0.02 ± 0.01, 0.04 ± 0.01, and 0.07 ± 0.03 in ERI-T1, ERI-T2, and ERI-T3, respectively. The ERI-T3 group had the lower Hb level (p = 0.038) whereas administration dose of EPO were higher in ERI-T3 (p = 0.001). The ERI-T3 group had the lower Pha (p = 0.044), BMI (p = 0.001) and FTI (p = 0.046) values. We divided into tertiles (T) according to the Hb-CV. The average Hb-CV was 0.06 ± 0.01, 0.08 ± 0.05, and 0.12 ± 0.02 in Hb-CV-T1, Hb-CV-T2, and Hb-CV-T3, respectively. When comparing the three groups, the Hb-CV-T3 group had the lower BMI (p = 0.002) and lower FTI (p = 0.002). Age (r = 0.203, p = 0.036), female sex (r = 0.376, p = 0.001), presence of diabetes mellitus (r = 0.191, p = 0.049), total iron binding capacity (r = 0.205, p = 0.035) and triglyceride (r = 0.227, p = 0.018) were positively correlated with FTI. BMI (r = 0.193, p = 0.046) and Hb-CV (r = -0.268, p = 0.005) were negatively correlated with FTI. In multiple linear regression analysis, FTI was negatively associated with ERI (β = -0.218, p = 0.014), Hb-CV (β = -0.181, p = 0.039), whereas FTI was positively associated with age (β = 0.197, p = 0.017) and female sex (β = 0.386, p = 0.001).

Conclusion: In HD patients with higher ERI, Pha, BMI and FTI were significantly decreased. Furthermore, in patients with high Hb-CV, BMI and FTI were decreased. In addition, FTI was negatively associated with ERI and Hb-CV. Therefore, EPO responsiveness and Hb-variability is associated with nutritional status, especially fat tissue in hemodialysis patients undergoing darbepoetin-alfa treatment.

#2513 EFFECT OF HEMODIALYSIS WITH MEDIUM CUT-OFF VERSUS HIGH-FLOW MEMBRANES ON ENDOTHELIAL FUNCTION OF CHRONIC KIDNEY DISEASE PATIENTS

Rachel Armani1, Aluizio Carvalho2, Monique Vercia1, Luiz Aparecido Bortolotto2 and Maria Eugênia Cianzani2

1Escola Paulista de Medicina, Nephrology, São Paulo, Brazil and 2InCor - Instituto do Coração do Hospital das Clínicas da FMUSP, Cardiology, Brazil

Background and Aims: Endothelial dysfunction (ED) is considered a marker of vascular complications, especially in patients with chronic kidney disease (CKD). Inflammation and the uremic state contribute to ED in hemodialysis (HD) patients. Recently, the medium cut-off (MCO) HD membrane has been proposed to efficiently remove inflammatory cytokines and higher molecular weight uremic toxins. This study aimed to compare the effect of dialysis with medium cut-off (MCO) or high-flow (HF) membranes on the endothelial function of patients on chronic HD.

Method: A prospective, randomized, crossover study in which 32 patients with CKD were dialyzed for 12 weeks with each membrane, including a 4-week washout period between treatments. Endothelial function was assessed by flow-mediated dilation (FMD) using brachial artery ultrasound at weeks 1, 12, 16, and 28.

Results: The population consisted of 59% men, 52.7 ± 13.4 years, 16% non-black, on HD for 8.6 (4.1-15.1) years, 72% with arteriogenous fistula. Hypertension was the most common etiology of CKD and 34% of patients had previous cardiovascular disease. Table 1 shows clinical and demographic characteristics of all subjects. The Patients were grouped, regardless of treatment sequence, into MCO or high flow groups, since no drag (p = 0.634) or sequence (p = 0.998) effects were observed in the FMD assessment. The ANOVA model with repeated measures showed no effects of treatment (p = 0.426), time (p = 0.972) or interaction (p = 0.413) in the comparison of FMD, between the MCO and high flow groups.

Conclusion: Dialysis performed with MCO, or HF membranes did not influence endothelial function in patients undergoing chronic HD.

**INFLAMMATION SECONDARY TO CHRONIC KIDNEY DISEASE AND PERITONEAL DIALYSIS ACCELERATES ATHEROSCLEROSIS IN A NEW MOUSE MODEL**

Jamie Kane1,2, Myriam den Toom1, Laura Bosmans1, Bram van Os1, Winnie Vos1, Linda Beckers1, Lily Jakulj2, Esther Lutgens4, Marc Vervloet2 and Etto Eringa1,5

1Amsterdam UMC, Medical Biochemistry, Amsterdam, Netherlands, 2Amsterdam UMC, Nephrology, Amsterdam, Netherlands, 3Amsterdam UMC, Physiology, Amsterdam, Netherlands, 4Mayo Clinic, Cardiovascular Medicine, Rochester, United States of America and 5Maastricht University, Physiology, Maastricht, Netherlands

**Background and Aims:** Inflammation is an established contributor to accelerated atherosclerosis, which is highly prevalent in people with chronic kidney disease (CKD) and even more so in those treated with peritoneal dialysis (PD). We therefore hypothesised that PD-induced systemic inflammation is essential in the development of atherosclerosis. To study this we developed a novel mouse model of CKD and PD accelerated atherosclerosis.

**Method:** We performed a 5/6ths nephrectomy in ApoE deficient "black 6" mice, fed these mice a high-cholesterol diet (HCD), and intraperitoneally administered 3.6% Physioneal daily for 67 days. There were three groups of mice: control (HCD-only), CKD+HCD, and CKD+HCD+PD, with relevant shams. Tissues were harvested twelve weeks after the nephrectomy. Assessments of residual kidney function, atherosclerotic plaque pathology and immunology, and systemic immune responses were performed.

**Results:** Atherosclerotic plaque size in the aortic arch was larger in the PD group compared to the control, increasing from 83.779 ±μm² ±18.430 to 109.973 ±μm² ±25.602 (p = 0.0349), whilst plaque size was unchanged in the CKD group. In contrast, both the CKD and PD groups displayed altered plaque stability. There was less collagen in the plaque vs control, decreasing from 43.54% ±10.65 to 29.71% ±9.43 and 29.73% ±10.18 respectively. Additionally, fibrous cap thickness decreased in both groups vs control. These plaques from only the PD group showed infiltration by T-cells compared to control, with no changes in macrophage content in either the CKD or PD group. In the spleen in the CKD and PD groups, naïve CD4 cells increased and effector CD4 cells decreased compared to control, with the latter change also occurring in the circulation. Central memory CD4 cells, terminally differentiated Th1 cells, Th17 cells, and 'vascular homing' cells all increased in the PD group compared to control mice. These homing cells also increased in circulation. The PD group showed decreases in the spleen of regulatory T-cells, effector Th1 cells, and effector CD8 cells. Notably, all of these changes were absent from the mesenteric lymph node. There was a large drop in monocytes in the spleen and a loss of immature and mature dendritic cells in the PD group.

**Conclusion:** Combining CKD, a high-cholesterol diet, and exposure to PD fluids in ApoE−/− mice successfully generated a new model for cardiovascular disease in human PD patients. This new model is in a widespread and well-understood mouse line representative of human atherosclerosis. Here we demonstrate the pronounced effects of CKD and PD on the innate and adaptive immune response which increases atherosclerotic burden and leads to larger more vulnerable plaques

**UREMIC TOXINS ARE ASSOCIATED WITH IMMUNE-SENEGENCE AND IMMUNE-EXHAUSTION IN HEMODIALYSIS PATIENTS**

Theodores Tourountzis1, Georgios Liolios2, Steven Van Laecke3, Michalis Christodoulou2, Eleni Moysidou2, Stamatis Star2, Asimina Pylakiotou2, Griet Glericusx4 and Maria Stangou2

1Protypo Dialysis Center of Thessaloniki, Greece, 2General Hospital of Thessaloniki "Ippokrateio", Thessaloniki, Greece and 3Ghent University Hospital, Gent, Belgium

**Background and Aims:** Immune-senescence and exhaustion have been described in hemodialysis (HD) patients, with changes in lymphocyte phenotype possibly stimulated by the uremic environment, independent of age and comorbid conditions. We evaluated the potential association of uremic toxin accumulation with changes in lymphocyte count and phenotype in HD patients.

**Method:** In the peripheral blood of 54 HD patients (23 female, mean age 51±16.91 years) and 31 age-matched healthy controls, lymphocytes surface molecules were determined by flow cytometry: T cells (CD4, CD8, CD31,
CD45RA, CCR7, CD28, CD57, PD1) and B cells (CD27, IgD). Plasma levels of the protein bound uremic toxins [hippuric acid (HA), indoxyl sulfate (IxS) and p-cresyl sulfate (pCS)] were measured by ultra-performance liquid chromatography. Lymphocyte phenotypes were correlated with uremic toxins levels using Spearman's correlation coefficient test. Patients with recent or active infection, malignancy, autoimmune disease and/or diabetes mellitus were excluded. 

Results: A higher concentration of uremic toxins was observed in HD patients, compared to healthy controls, namely: total HA 3.05 (1.66-5.37) vs 0.102 (0.04-0.2) mg/dl (p < 0.001), free HA 1.482 (0.7-2.8) vs 0.029 (0.03-0.04) mg/dl (p < 0.001); total IxS 2.207 (1.27-3.34) vs 0.063 (0.04-0.09) mg/dl (p < 0.001), free IxS 0.146 (0.09-0.27) vs 0.0004 (0.0004-0.0004) mg/dl (p < 0.001); total pCS 1.248 (0.84-1.66) vs 0.066 (0.04-0.13) mg/dl (p < 0.001), free pCS 0.089 (0.06-0.13) vs 0.004 (0.004-0.005) mg/dl (p < 0.001); respectively. There was a positive correlation between hemodialysis vintage and total as well as free HA (p = 0.005, p = 0.003, respectively). No significant differences in uremic toxin levels were found in HD patients according to sex, age, dialysis prescription and method. Patients with residual urine output had reduced total and free HA levels 1.739 (3.5) vs 3.437 (4.16) mg/dl (p = 0.05), and 0.717 (1.9) vs 1.901 (3.5) mg/dl (p = 0.04), respectively and free IxS levels, 0.117 (0.1) vs 0.177 (0.2) mg/dl (p = 0.02), respectively. Total lymphocyte count and absolute number of CD4 cells were negatively correlated with total (p = 0.018 and p = 0.02 respectively) and free HA levels (p = 0.024 and p = 0.017 respectively). Several naive and less differentiated CD4 subpopulations also demonstrated a negative correlation with total and free HA levels, most importantly CD4CD31+ (p = 0.037 and p = 0.027 respectively), CD8CD28+CD57- (p = 0.018 and p = 0.014 respectively) CD4CD45+CD57- (p = 0.039 and p = 0.027 respectively) and naive B cells (CD19+IgD+CD27-)(p = 0.042 and p = 0.032 respectively). Advanced differentiated lymphocyte subtypes, CD4CD28+CD57+ and CD4CD45-CD57+ had a positive correlation with free HA levels (p = 0.036 and p = 0.045 respectively). Exhausted CD4 cells, defined as CD4+PD1+ had positive correlations with total and free IxS levels (p = 0.004 and p = 0.011 respectively) and total and free pCS (p = 0.027 and p = 0.018 respectively), but not with HA levels. Moreover, further divided exhausted lymphocytes, according to CD45RA expression, CD4CD45RA- PD1+ cells correlated positively with total and free IxS levels (p = 0.004 and p = 0.01 respectively) and CD4CD45RA+PD1+ with pCS total and free levels (p = 0.039 and p = 0.045 respectively).

Conclusion: Uremic toxins are increased in hemodialysis patients and may influence adaptive immunity. HA is associated with an immune-senescent, while IxS and pCS to an immune-exhausted lymphocyte phenotype.

Diagnostic Value of the Handgrip Strength in Detecting Protein-Energy Wasting among Hemodialysis Patients at National Kidney and Transplant Institute

Gerry Patoc, Jr.1 and Anthony Russell Villanueva2

1National Kidney and Transplant Institute, Adult Nephrology, Quezon City, The Philippines and 2National Kidney and Transplant Institute, Quezon City, The Philippines

Background and Aims: Protein energy wasting (PEW) is a syndrome of adverse nutritional and catabolic changes common among chronic kidney disease (CKD) patients. Handgrip strength (HGS) was one of the methods of screening PEW mentioned in Kidney Disease Outcomes Quality Initiative guidelines. However, only few studies determined the validity of HGS in detecting PEW among maintenance hemodialysis (MHD) patients. The study aimed to determine the diagnostic validity of HGS in detecting PEW among MHD patients in a tertiary government hospital, with the following specific objectives: to determine the prevalence of PEW among MHD patients, to compare the demographic and clinical profile by PEW status, to identify the optimal cut-off point of HGS pre- and post-HD sessions in detecting PEW by sex, and to determine the following diagnostic value parameters of HGS pre- and post-HD sessions in detecting PEW by sex in terms of discriminative ability, accuracy, sensitivity, specificity, positive predictive value and negative predictive value.

Method: Participants included in this cross-sectional study are randomly selected patients undergoing MHD in National Kidney and Transplant Institute (NKTI) from September to October, 2022. Diagnosis of PEW was based on the Malnutrition Inflammation Score (MIS) ≥5. HGS was measured using a dynamometer pre- and post-dialysis sessions.

Results: A total of 143 patients were included in the study, and 53% were diagnosed with PEW. Pre-HD and post-HD HGS have acceptable discriminative ability based on Area Under the Curve >0.70 in detecting PEW regardless of patient sex. In males, a pre-hemodialysis cut-off of <17.9 showed 72% sensitivity and 71% specificity in detecting PEW. Meanwhile, a
pre-hemodialysis cut-off of <18.6 in females showed 83% sensitivity and 65% specificity in detecting PEW.

**Conclusion:** PEW is common among MHD patients in NKTI. The diagnostic performance of HGS in detecting PEW was found to be acceptable in both males and females. While both pre- and post-HD measures can be used in males, only the pre-HD measures are recommended for females. HGS can, therefore, be used as a non-expensive, accurate and objective screening assessment tool in detecting PEW for MHD patients. External validation of the proposed HGS cut-off values is still recommended.

**BRAIN MAGNETIC RESONANCE IMAGING AND COGNITIVE FUNCTION IN PATIENTS RECEIVING HEMODIALYSIS**

Mei-Chuan Kuo1,2, Ping-Hsun Wu1,2, Hsiu-Fen Lin1,2, Tsai-Shan Wu1,4 and Yi-Ting Lin2,5

1Kaohsiung Medical University Hospital, Department of Internal Medicine, Kaohsiung, Taiwan, Rep. of China, 2Kaohsiung Medical University, College of Medicine, Kaohsiung, Taiwan, Rep. of China, 3Kaohsiung Medical University Hospital, Neurology, Kaohsiung, Taiwan, Rep. of China, 4Kaohsiung Medical University Hospital, General Medicine, Kaohsiung, Taiwan, Rep. of China and 5Kaohsiung Medical University Hospital, Family Medicine, Kaohsiung, Taiwan, Rep. of China

**Background and Aims:** Chronic kidney disease is high risk to adverse events including stroke, cardiovascular diseases and cognitive decline. Cognitive function was known to be linked to chronic kidney disease. The Fazekas's scale, which was used for assessing white matter hyperdensities (WMH), has been reported to associate with poor cognitive performance. We aim to investigate the associations between mini-mental status examination (MMSE), Montreal cognitive assessment (MoCA), cognitive abilities screening instrument (CASI) and Fazekas's scale in patients under hemodialysis (HD).

**Method:** The periventricular (PV) and deep white matter (DWM) lesions in brain MR images of 59 patients under dialysis for at least 90 days were graded by Fazekas’s scale. Cognition function tests including MMSE, MoCA, and CASI were performed. Multivariable ordinal regression and logistic regression were used for identifying the associations between cognitive performance and Fazekas scale.

**Results:** Inverse associations were found between three cognitive function tests across the Fazekas scale of PV lesions (p = 0.037, 0.006 and 0.008 for MMSE, MoCA, and CASI respectively), and higher scales were associated with lower cognitive function scores in trend; however, the association attenuated in the DWM group. In subdomains of CASI, significant differences were identified in five subdomains, including short-term memory, mental manipulation, abstract thinking, spatial construction, and name fluency; nevertheless, in DWM hyperdensities, only abstract thinking and short-term memory showed obvious correspondence.

**Conclusion:** Inverse correlation between the Fazekas’s scale, predominantly in PV lesions, and cognition was detected in HD patients. The Fazekas’s scale of PV lesions was associated with cognitive performance assessed by MMSE, MoCA and CASI, as well as with subdomains of CASI such as memory, language, and name fluency in HD patients.

**AGE-RELATED TRAJECTORY PATTERN OF HANDGRIP STRENGTH AND MORTALITY IN PATIENTS ON HEMODIALYSIS**

Manae Harada1, Keigo Imamura2,3, Shun Yoshihoshi1,4, Ryota Matsuawa1, Atsuhiko Matsunaga3, Yasuo Takeuchi1 and Atusi Yosida1

1Sagami Circulatory Organ Clinic, Rehabilitation, Sagamihara, Japan, 2Kitasato University Graduate School of Medical Sciences, Rehabilitation Sciences, Sagamihara, Japan, 3Tokyo Metropolitan Institute of Gerontology, Research Team for Human Care, Itabashi, Japan, 4Kitasato University Graduate School of Medical Sciences, Rehabilitation Sciences, Sagamihara, Japan, 5Hyogo Medical University, Physical Therapy, School of Rehabilitation, Kobe, Japan, 6Kitasato University, Nephrology, School of Medicine, Sagamihara, Japan and 7Sagami Circulatory Organ Clinic, Hemodialysis Center, Sagamihara, Japan

**Background and Aims:** Muscle weakness is a factor known to worsen prognosis in patients on hemodialysis [1], and the prevention of muscle weakness is extremely important in disease management. In particular, understanding age-related changes in muscle strength can be advantageous for long-term interventions. A previous study on community-dwelling older adults examined sex-specific age trends in muscle strength in order to identify potential trajectory patterns, and it showed that muscle strength tended to display similar age-related changes later in life regardless of the baseline level. Additionally, individuals in the low trajectory group had a higher mortality risk than did the high trajectory group [2]. However, reports examining longitudinal trajectories of muscle strength in patients on hemodialysis are limited, and their association with life prognosis remains unclear. Therefore, this study aimed to identify sex-specific aging patterns of handgrip strength as an indicator of muscle strength in patients on hemodialysis and to further investigate their association with life prognosis.

**Method:** Patients on hemodialysis with a minimum of two available measurements of handgrip strength between the years 2002 and 2022 were classified by sex using group-based semiparametric mixture modeling. The association between typed aging patterns of handgrip strength and all-cause mortality was examined using Cox regression analysis after adjusting for the baseline age, body mass index, dialysis history, comorbidity index score, and hemoglobin and albumin levels. The statistical significance level was set at 5%.

**Results:** Age-related trajectory patterns of handgrip strength in men and women were categorized into three groups, low, middle, and high, as shown in Fig. 1. All three groups showed an age-related decline. The “low group” showed a reduction in handgrip strength (< 28 kg for men and < 18 kg for women) from baseline and continued to decline thereafter. The “middle group” did not show...
any decline at baseline, but decline was noted after 65 years of age. The “high group” displayed a decline in handgrip strength after 80 years of age, despite high handgrip strength at baseline. 23.9%, 60.1%, and 16.0% for men and 30.1%, 46.3%, and 23.7% for women were assigned to the low, middle, and high groups, respectively. When the high group was used as the reference group, the low groups showed a significantly higher mortality risk after adjusting for confounders in both men and women (men; p = 0.03, women; p < 0.001).

Conclusion: In patients on hemodialysis, age-related decline of handgrip strength was observed in both men and women, regardless of baseline values. Among the three patterns of decline, the low group had a higher mortality rate compared to the high group in both men and women. The results suggest that even if decline in muscle weakness over time can be expected, handgrip strength needs to be improved in order to improve life prognosis.

TRAJECTORY OF ANTHROPOMETRIC INDICATOR AND CLINICAL EVENTS AMONG PATIENTS ON HEMODIALYSIS
Shun Yoshikoshi1, Yuta Suzuki2, Shohei Yamamoto3, Keigo Imamura1, Manae Harada4, Narumi Fukuzaki1, Asumi Tobita1, Sayaka Nikkawa1, Shiwori Osada5 and Atsuhiko Matsuanga5

1Kitasato University Graduate School of Medical Sciences, Rehabilitation Sciences, Sagamihara, Japan, 2National Institute of Public Health, Center for Outcomes Research and Economic Evaluation for Health, Wako, Japan, 3National Center for Global Health and Medicine, Epidemiology and Prevention, Center for Clinical Sciences, Shinjuku-ku, Japan, 4Sagami Circulatory Organ Clinic, Rehabilitation, Sagamihara, Japan and 5Tokyo Ayase Kidney Center, Nephrology, Katsushika-ku, Japan

Background and Aims: Low values for anthropometric indicators are risk factors for adverse clinical outcomes among patients on hemodialysis (HD). Anthropometric parameters are time-dependent; thus, reliance on only baseline measurements may not sufficiently capture important patient outcomes. Nonetheless, little is known about the associations between the trajectory of anthropometric indicators and prognosis. We examined associations between a one-year change in anthropometric indicators and hospitalization and mortality rates in patients undergoing HD.

Method: This retrospective study collected data from outpatients undergoing HD at two dialysis facilities between April 2018 and March 2022. The five anthropometric measurements were evaluated, including body mass index (BMI), mid-upper arm circumference (MUAC), mid-arm muscle circumference (MAMC), triceps skinfold (TSF), and calf circumference (CC). We defined baseline which was the date of the first measurement of anthropometric assessments. Thereafter, we evaluated their trajectories over one year. Change in anthropometric indicators over the 1-year was calculated by subtracting the baseline value from the second assessment value. Patients were divided into 2 groups according to a one-year change in anthropometric indicators: no decline (≥0) and decline (<0). The outcomes were all-cause death and the number and duration of all-cause hospitalizations. Death and hospitalizations were determined using the facilities’ records. Negative binomial regressions were used to examine the associations between anthropometric changes and clinical outcomes.

Results: We included 283 patients (mean age, 67.3 years; 60.4% males). During the follow-up period (median, 2.7 years), 30 deaths and 200 hospitalizations occurred. When considering anthropometric measurements trajectories as continuous variables, increasing BMI per 1 standard deviation (incident rate ratio [IRR]: 0.87; 95% confidence interval [CI]: 0.85–0.90), MUAC (IRR: 0.94; 95% CI: 0.88–0.99), TSF (IRR: 0.92; 95% CI: 0.84–0.99), and MAMC (IRR: 0.99; 95% CI: 0.98–0.99) were associated with a lower risk of all-cause hospitalizations and death regardless of their value at any one point in time. However, the CC trajectory was not associated with clinical events (IRR: 0.94; 95% CI: 0.83–1.07). Similarly, when the anthropometric changes were considered in the categorical models, the group with BMI decline (IRR: 1.36, 95% CI: 1.30–1.43), MUAC decline (IRR: 1.14, 95% CI: 1.02–1.28), TSF decline (IRR: 1.27, 95% CI: 1.05–1.53), and MAMC decline (IRR: 1.11, 95% CI: 1.03–1.19) had a higher risk of the clinical outcome than the no decline group. A significant association was not detected for CC decline (IRR: 0.93, 95% CI: 0.84–1.03) (Table 1).

Conclusion: We observed that decreasing BMI, MUAC, TSF, and MAMC over time were independently associated with clinical events. Routinely assessing these simple measures in clinical practice may be a useful management strategy for the prognostic stratification of patients undergoing HD.
Table 1: Associations between changes in anthropometric measures and clinical outcomes.

PIVKA II IS A BIOMARKER FOR PREDICTING CORONARY CALCIFICATION IN HEMODIALYSIS PATIENTS WITH DIABETES
Mooyong Park, Byung Chul Yu and Soo Jeong Choi

Soonchunhyang University Bucheon Hospital, Division of nephrology, department of internal medicine, Bucheon-si, Rep. of South Korea

**Background and Aims:** Vascular calcification (VC) is a commonly occurring and serious complication in end-stage renal disease (ESRD) patients that increases mortality. Vitamin K deficiency is well known to cause the occurrence of VC through the inactivation of Vitamin K dependent proteins (VKDP). Therefore, a marker that can easily predict the risk of VC due to vitamin K deficiency is needed in clinical practice. In this study, we aim to investigate whether the easily measurable vitamin K absence II (PIVKA-II) can serve as a surrogate marker for predicting coronary artery calcification (CAC) in ESRD patients undergoing hemodialysis and what factors influence the prediction of CAC.

**Method:** This study is an observational study conducted on end-stage renal disease patients receiving hemodialysis treatment. Patients with liver cirrhosis, HCC, or a history of coronary artery disease with stent placement were excluded, as well as patients with active infectious diseases. CAC score was measured by Non-enhanced computed tomography; and before starting hemodialysis, blood samples were collected to measure PIVKA-II, osteocalcin (OC), and bone-specific alkaline phosphatase (BAP) among other bone markers. PIVKA-II was measured two times with 3 months interval, and the average value was calculated. Additionally, ankle-brachial index (ABI) and DEXA bone densitometry were also performed.

**Results:** In this study, 69 dialysis patients participated. Among them, 34 patients had diabetes mellitus (DM). The study compared two groups based on the presence of DM. The results showed that patients with DM had higher Body Mass Index (BMI) (p = 0.01) and a higher frequency of vascular diseases such as coronary artery disease or cerebrovascular disease (p = 0.004). The DM group also had higher LDL cholesterol levels (p = 0.03), but there was no significant difference between the two groups in terms of PIVKA-II, BAP, and Osteocalcin levels (Table 1). When analyzing the factors that had a correlation with the CAC score in all 69 patients, LDL cholesterol (r = -0.37, p = 0.002) and CRP (r = 0.28, p = 0.03) were found to have a significant correlation, but PIVKA-II (p = 0.063, Figure 1A), BAP (p = 0.57), and OC (p = 0.45) did not. In the DM group, there was a statistically significant correlation between CAC score and PIVKA-II (r = 0.283, p = 0.001), but there was no correlation between CAC score (Figure 1B) and CaxP, LDL cholesterol, CRP, BAP, and OC (p = 0.7, p = 0.4, p = 0.3, p = 0.7 and p = 0.4 respectively).

**Conclusion:** The results suggest that in patients with diabetes who undergo dialysis, PIVKA-II can be clinically useful as a surrogate marker for predicting CAC associated with vitamin K deficiency. This is because diabetic patients may have more pronounced VKDP inactivation and VC due to vitamin K deficiency, but additional research is needed to fully understand this relationship.

HEMODIALYSIS PATIENTS: A RANDOMIZED CONTROLLED TRIAL

NUTRITIONAL STATUS, COGNITIVE FUNCTION, AND BONE IN HEMODIALYSIS PATIENTS: A RANDOMIZED CONTROLLED TRIAL

Ahmed Mohamed Naguib Attiya1, Hoda Abdulaziz2, Salwa Elwasif1, Samir Sally1 and Mohamed Somadhi1

1Urology & Nephrology center Mansoura university, Egypt and 2Mansoura University Hospitals, Egypt

Background and Aims: Remote ischemic preconditioning (RIPC) is a process in which a brief period of ischemia is induced in one part of the body to protect another part from damage due to subsequent periods of more severe ischemia. Hemodialysis sessions are considered an ischemic process because it involves another part from damage due to subsequent periods of more severe ischemia. In which a brief period of ischemia is induced in one part of the body to protect another part from damage due to subsequent periods of more severe ischemia.

Method: Fifty patients who received regular hemodialysis for more than one year in our dialysis unit were included. The patients were randomized (single-blind) into two groups a control group (20 patients) and an intervention group (30 patients). Before each HD session, sphygmomanometer cuffs were placed around the non-vascular access arm. Three cycles of ischemia for five minutes were performed followed by reperfusion for five minutes. Ischemia was induced by inflating the sphygmomanometer cuffs to 200 mmHg. This maneuver was done before each HD session for 12 weeks. The Montreal Cognitive Assessment (MOCA) was used to assess cognitive function. The nutritional state was assessed by anthropometric measurement (body weight, BMI), laboratory (serum albumin and serum cholesterol), and Subjective Global Assessment Form (SGA). Serum calcium (s.Ca) and serum phosphorus (s.PO), serum alkaline phosphate (s. ALP) and intact parathyroid hormone (iPTH) were used as indices for bone profile.

Results: The intervention group include 30 patient with mean age (36.6±10), 19 male (66.7%) and 11 females (33.3%). The control group include 20 patient with mean age (46.9±9), 12 male (60%) and eight female (40%). None of these patients' demographic data (age, sex, original kidney disease, and duration of dialysis) were significantly different between the study groups (P>0.05). MOCA test score at baseline was (24.5±2.6) at intervention group and (24.4±3.2) at control group, and after 12 weeks intervention was (24.8±2.2) at intervention group and (24.4±2.8) at control group, there were no statistical significance regarding the difference between the two groups overall (P=0.4). NO significant Statistical changes in anthropometric measurements (Body weight (P=0.3) and BMI (P=0.6) were found between the two groups. Additionally, no significant changes (serum albumin and cholesterol) were detected. SGA score at baseline was at intervention group (1.2±0.4) and control group (1.1±0.3), and after 12 week was at the intervention group (1.4±0.5) and control group (1.6±0.3). SGA showed no statistical significance between the two groups overall (P=0.2). No significant statistical changes regarding bone profile (s.ca (P=0.5), s.PO (P=0.2), s.ALP (P=0.7) and iPTH (P=0.5)).

Conclusion: Although some studies showed a beneficial effect of RIPC on reduction of cardiovascular risk, our study found no significant effect on cognitive function, nutritional status, and bone disorders among hemodialysis patients.

#3724

CHANGES IN CARDIOVASCULAR CALCIFICATION AFTER PARATHYROIDECTOMY IN DIALYSIS-DEPENDENT PATIENTS

Alexander Zolotykh1, Ekaterina Parshina2, Alexey Tolkach2, Tatyana Pridvizhkina3 and Konstantin Novokshonov4

1Saint Petersburg State University, Medical Faculty, Saint Petersburg, Russia, 2Saint Petersburg State University Hospital, Department of Nephrology and Dialysis, Saint-Petersburg, Russia, 3Saint Petersburg State University Hospital, Department of radiology, Saint-Petersburg, Russia, and 4Saint Petersburg State University Hospital, Department of Endocrine Surgery, Saint-Petersburg, Russia

Background and Aims: Vascular calcification (VC) is common in patients with end stage kidney disease on dialysis and with secondary hyperparathyroidism (SHPT). There is a lack of knowledge regarding dynamics of VC after surcrate treatment of SHPT. We aimed to evaluate evolution of coronary artery calcification (CAC) and abdominal aortic calcification (AAC) after parathyroidectomy (PTx) in dialysis patients with SHPT.

Method: The prospective cohort study included 33 dialysis-dependent patients (mean age of 50±13 years) with severe SHPT who underwent subtotal (n = 16) or total PTx with autotransplantation of parathyroid tissue (n = 17). Cardiac computed tomography scan (quantification of coronary calcium by Agatston method) and lateral lumbar X-ray (semi-quantitative Kaupilla score) were used to assess prevalence of VC before and 18 months after surgery. Levels of serum total calcium, phosphorus, parathyroid hormone (PTH), and alkaline phosphatase (AP) before and 18 months after surgery were also evaluated.

Results: In our cohort median dialysis vintage before surgery was 71 [Q1-Q3: 29.136] months, total serum Ca was 2.47±0.23 mmol/L, mean PTH was 139 [Q1-Q3: 90; 161] pg/ml. Prevalence of CAC before PTx was 79% (n = 26), and 61% (n = 20) of patients had AAC. Of note, 54.5% of the patients had severe coronary calcification (>400 AU), while only 12% were considered to have severe calcification using Kaupilla score (>12). We observed moderate positive correlation between CAC and AAC scores (Spearman’s ρ = 0.699 [95% CI: 0.48; 0.84], p=0.0001). Both CAC and AAC scores correlated moderately with age of the patients (ρ = 0.57 [95% CI: 0.3; 0.76], p=0.0002, and ρ = 0.64 [95% CI: 0.39; 0.8], p<0.0001, respectively), AAC had weak correlation with their dialysis vintage (ρ = 0.45 [95% CI: 0.14; 0.68], p=0.005). Median of baseline CAC was 458 [Q1-Q3: 23; 1585] AU, after 18 months - 491 [Q1-Q3: 58; 1956] AU, no statistically significant differences were observed (p = 0.91, Wilcoxon test). We did not find statistically significant differences between median of Kaupilla scores before and after PTx as well: 3 [Q1-Q3: 0; 10] and 2 [Q1-Q3: 0; 10], correspondingly, p = 0.17 (Wilcoxon test) – Fig. 1.

As it can be seen from Fig. 1, dynamics of both CAC and AAC values before and after PTx varied markedly across subjects. To investigate the factors that may affect VC progression less than 50 AU (n = 11) and after PTx and 61% (n = 20) with CAC progression of more than 50 AU (n = 14). Patients who had progression of coronary calcification by the end of the follow-up had higher age (59±11 vs 46±12 years in 2nd group, p = 0.0128) higher serum calcium levels (2.57±0.24 vs 2.29±0.32 mmol/L in 2nd group, p = 0.0267), and higher AP levels at follow-up (69.8 [Q1-Q3: 62.8, 96.0] vs 51.7 [Q1-Q3: 41.4; 57.1] U/ml in 2nd group, p = 0.003).UNivariate analysis showed no significant differences between groups

Non-DM: Non-Dialysis; DM: Dialysis
Comparing dialysis vintage (p = 0.53), phosphate levels (p = 0.54), PTH levels (p = 0.32). In addition, CAC progression risk was not associated with type of surgery (total vs subtotal PTx RR = 1.11 [95% CI: 0.71; 1.8], OR = 1.48 [95% CI: 0.3; 5.7], p = 0.708).

Conclusion: Prevalence of vascular calcification in dialysis-dependent patients with severe SHPT is high. Progression of CAC by 18 months after PTx was associated with higher age of the patients, higher follow-up levels of serum total Ca and AP.

#3246
THE ASSOCIATION OF THE CO-OCCURRENCE OF MALNUTRITION AND SARCOPENIA WITH MORTALITY IN HEMODIALYSIS PATIENTS: A MULTICENTER PROSPECTIVE COHORT STUDY
Ryota Matsuzawa1, Hiroto Imai1, Kosuke Wada1, Takuya Okada1, Keitaro Deguchi1, Aoi Horinouchi1, Naoyuki Tsujimoto2, Daisuke Kakita3, Kiyoshi Shimokado3, Atsuhiro Matsunaga1 and Akira Tamaki1
1Hyogo Medical University, Department of Physical Therapy, School of Rehabilitation, Kobe, Japan, 2Hyogo Medical University Graduate School of Medical Sciences, Department of Medical Science, Kobe, Japan, 3Shimokado Renal Dialysis Clinic, Kobe, Japan and 4Kitasato University Graduate School of Medical Sciences, Department of Rehabilitation Sciences, Sagamihara, Japan

Background and Aims: Frailty is widely acknowledged as an age-related fragile state characterized by physiological vulnerability to stress, and it is prevalent among patients undergoing maintenance hemodialysis therapy. Various factors are interconnected and can be theoretically consolidated into a cycle of frailty, with malnutrition and sarcopenia at the core. These can result in numerous negative health outcomes in patients on hemodialysis and prompt identification and treatment are necessary. However, limited research has investigated the impact of the overlap between malnutrition and sarcopenia on mortality in this patient population. In this study, we examined the association of the overlap between malnutrition and sarcopenia with all-cause mortality in patients undergoing maintenance hemodialysis.

Method: The present prospective cohort study recruited outpatients on hemodialysis from three facilities in Japan. At the study baseline, data on patients’ characteristics including age, gender, body mass index, duration of dialysis, primary kidney diseases, 11 comorbid conditions, and laboratory parameters (including serum albumin level) were collected from medical records. In addition, muscle mass (skeletal muscle index [SMI]), muscle strength (handgrip strength), and physical performance (short physical performance battery [SPPB]) were measured by physical therapists. A comorbidity index was used to quantify the severity of comorbid illnesses, which was calculated based on primary kidney diseases and the 11 comorbidities. Malnutrition was identified based on geriatric nutritional risk index <98, which was calculated using the serum albumin level and body weight. Sarcopenia was diagnosed when patients had low muscle mass (SMI <7.0 kg/m² for males and <5.7 kg/m² for females) and low muscle strength (handgrip strength <28.0 kg for males and <18.0 kg for females) or low physical performance (SPPB <29), in accordance with the Asian Working Group for Sarcopenia 2019 criteria. After classifying the study participants into four groups based on the absence or presence of malnutrition and sarcopenia, the mortality risk was evaluated using the Kaplan-Meier method and Cox proportional hazard analysis. This study was approved by the Research Ethics Committee and conducted in accordance with the principles of the Declaration of Helsinki.

Results: A total of 379 patients on hemodialysis were included in the analysis. The mean age of the patients was 69.5±12.6 years, and 40.2% of the cohort being female. The mean duration of dialysis was 7.9±4.5 years. The most prevalent underlying kidney disease was diabetes mellitus. At baseline, the prevalence rates of malnutrition and sarcopenia were 32.7% and 28.2%, respectively. Over a mean follow-up period of 4.3 years, 23 patients died. The Kaplan-Meier analysis demonstrated a lower cumulative survival rate in patients with malnutrition and/or sarcopenia. After adjustment for the effect of age, gender, duration of dialysis, and comorbidity index, the hazard ratio in patients with both malnutrition and sarcopenia was significantly higher than in patients without both hazard ratio [HR] 5.78, 95% confidence interval [CI] 1.86-17.94). However, the hazard ratios in patients suffering from either malnutrition or sarcopenia alone were not significantly different (Table 1).

Conclusion: The present study has demonstrated the strong association of a state of co-occurrence between malnutrition and sarcopenia, which implies starvation and muscle wasting, with a poor prognosis in patients undergoing hemodialysis. The findings of this study have accentuated the significance of addressing both malnutrition and sarcopenia in routine clinical practice for patients undergoing maintenance hemodialysis.

#3160
IMPACT OF HEART FUNCTION ON ELDERLY INCIDENT HEMODIALYSIS PATIENTS
Da Woon Kim1, Sang Heon Song1, Seo Rin Kim1, Soon Hyo Kwon1, Eun Young Seong1, Dong Won Lee3, Soo Bong Lee3 and Yu Ah Hong3
1Pusan National University Hospital, Internal Medicine, Busan, Rep. of South Korea, 2Department of Internal Medicine, Soonchunhyang University Seoul Hospital, Seoul, Rep. of South Korea, Division of Nephrology, Rep. of South Korea, 3Pusan National University School of Medicine, Internal Medicine, Rep. of South Korea and 4Daejeon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Division of Nephrology, Rep. of South Korea

Background and Aims: Cardiovascular disease (CVD) is the most common cause of death in patients on hemodialysis (HD). Indeed, left ventricular (LV) dysfunction, congestive heart failure and arrhythmia are independent predictors of poor survival and hospitalization in these patients. Among the patients who initiated HD, the proportions of the elderly patients aged >65 years are increasing worldwide. According to the Korean Renal Data System, the percentage of incident HD patients aged >65 years increased from 11% in 1990 to 53% in 2022. In addition, the prevalence of CVD increases with age. Therefore following these trends, investigating the impact of heart function on prognosis in elderly patients on HD is important for predicting prognosis and making appropriate treatment plans. This study aims to investigate the all-cause mortality in elderly incident HD patients according to heart function and presence of arrhythmia.

Method: 1,002 incident HD patients aged >70 years were recruited from a retrospective cohort of the Korean Society of Geriatric Nephrology. The primary outcome is all-cause mortality (6 months, overall) according to the LV function and presence of arrhythmia. To analyze, patients were divided into 6 groups according to the LV function (LV ejection fraction [LVEF])≥50%,
40≤LVEF<50%, LVEF<40%) and the presence of arrhythmia. The secondary outcome is all-cause mortality (6 months, overall) according to the LV function or presence of arrhythmia. To analyze, patients were divided into 3 groups according to the LV function and separately divided into 2 groups according to the presence of arrhythmia. Cox regression univariate and multivariate analyses was used.

**Results:** 1,002 patients were divided into 6 groups (LVEF≥50% without arrhythmia [N = 78; 75.6%], 40≤LVEF<50% without arrhythmia [N = 71, 7.1%], LVEF<40% without arrhythmia [N = 66, 6.6%], LVEF≥50% with arrhythmia [N = 124, 12.4%], 40≤LVEF<50% with arrhythmia [N = 15, 1.5%], LVEF<40% with arrhythmia [N = 19, 1.8%]). There were no differences of 6-month all-cause mortality among the groups. Compared with LVEF≥50% without arrhythmia group, 40≤LVEF<50% without arrhythmia (hazard ratio [HR], 1.59; 95% confidence interval [95% CI], 1.21-2.09; P = 0.001), LVEF<50% with arrhythmia (HR, 1.39; 95% CI, 1.12-1.74; P = 0.003) and LVEF<40% with arrhythmia groups (HR, 1.95; 95% CI, 1.19-3.17, P = 0.007) showed higher all-cause mortality of overall period. According to the LVEF groups, there were no differences of 6-month all-cause mortality among the groups. Compared with LVEF≥50% group, 40≤LVEF<50% group showed higher all-cause mortality of overall period (HR, 1.51; 95% CI, 1.18-1.94, P = 0.001). According to the arrhythmia groups, there were no differences of 6-month all-cause mortality between the groups. The presence of arrhythmia was associated with higher all-cause mortality of overall period (HR, 1.39; 95% CI, 1.15-1.69, P = 0.001).

**Conclusion:** Decreased heart function and presence of arrhythmia have negative impact on all-cause mortality of overall period, but not on 6-month all-cause mortality in elderly patients on incident HD. Therefore, evaluation of the heart function and detection of arrhythmia in elderly patients who start HD and providing the appropriate treatment to these patients would be helpful for improving the prognosis.

**ASSOCIATION BETWEEN AGE, SARCOPENIA, AND MORTALITY IN PATIENTS UNDERGOING HEMODIALYSIS: A PROSPECTIVE COHORT STUDY**

Hiroto Imai, Ryota Matsuzawa, Shohai Yamamoto, Yuta Suzuki,
Manae Harada, Keigo Imamura, Shun Yoshikoshi, Daisuke Kakita,
Naoyuki Tsujimoto, Shiwori Osada, Kiyoshi Shimokado,
Atsuhiko Matsunaga and Akira Tamaki

Japan

**Background and Aims:** The mean age of Japanese patients undergoing hemodialysis at the end of 2018 was 68.75 years, demonstrating a 13-year increase since 1985. The healthcare management of the geriatric patients presents significant challenges, encompassing both clinical and societal aspects, as they often experience overlapping comorbidities while undergoing hemodialysis. A systematic review and meta-analysis published in 2022 reported that sarcopenia was associated with heightened mortality rates in patients undergoing dialysis therapy. However, only a limited number of studies have investigated this association among Asian populations, whose differences in body composition, nutritional status, and socio-economic background distinguish them from those in the United States and Europe. Notably, no studies have targeted the older demographic, who constitute the majority of Asian patients on hemodialysis and possess numerous risk factors for death. This study categorized Japanese patients undergoing hemodialysis by age, <75 and ≥75, and examined the impact of sarcopenia on mortality according to age.

**Method:** This multicenter prospective cohort study enrolled 404 outpatients undergoing hemodialysis from three facilities in Japan and followed them up for three years. At baseline, information on age, sex, dialysis vintage, body mass index, primary kidney diseases, comorbid conditions, and laboratory parameters (serum albumin, serum hemoglobin, and hematocrit) were collected from medical records. The geriatric nutritional risk index (GNRI) was calculated based on the patient’s serum albumin level and body weight. Sarcopenia was diagnosed in patients who had low muscle mass (skeletal muscle mass index <7.0 kg/m² for males and <5.7 kg/m² for females) and low muscle strength (handgrip strength <28.0 kg for males and <18 kg for females) or low physical performance (short physical performance battery score <9), according to the Asian Working Group for Sarcopenia 2019 criteria. The Kaplan-Meier method and Cox proportional hazard analysis were used to evaluate the independent association between sarcopenia and mortality after adjusting for baseline characteristics in patients aged <75 and ≥75 years.

**Results:** A total of 404 patients participated in this study, with a mean follow-up period of 30 months, during which 50 (12.4%) patients died. Participants had a mean age of 68.4 ± 12.6 years and 62.6% of them were male and the mean GNRI was 91.1 ± 21.2. Diabetes mellitus was the most prevalent underlying kidney disease among the study cohort (38.1%). The prevalence of sarcopenia in all patients, those under 75 years of age, and those 75 years and older was 37.6%, 22.7%, and 63.1%, respectively. Kaplan-Meier analyses indicated a higher mortality rate among patients with sarcopenia compared to those without. In the subgroup analysis for patients aged <75 years, sarcopenia was significantly associated with increased mortality risk after full adjustment (hazard ratio [HR], 2.56; 95% confidence interval [CI], 1.05–5.95). Conversely, in the subgroup of patients 75 years and older, sarcopenia was not significantly associated with all-cause mortality (HR, 0.69; 95% CI, 0.28–1.68), and only a low GNRI was independently associated with poor survival (HR, 0.98; 95% CI, 0.96–1.00).

**Conclusion:** This present study determined that the impact of sarcopenia on mortality among patients undergoing hemodialysis may be altered by their age. Specifically, among those aged 75 years and above, malnutrition was found to be a strong predictor of poor survival, rather than sarcopenia.

**Background and Aims:** Nutritional status clearly has a great impact on the prognosis of maintenance hemodialysis patients. Therefore, its management should be a priority and risk screening frequent and easily implemented, based on the biochemical and clinical routine parameters already available. Many tools fit these simple criteria, namely simple Protein Energy Wasting score (sPEW), Geriatric Nutritional Risk Index (GNRI) and Creatinine Index (Cr Index). These scores are associated with a high mortality and morbidity risk in hemodialysis (HD) patients. The objective of this study was to assess the performance of these tools regarding the estimation of all-cause mortality, in a 45-months follow-up of a large patient cohort.

**Method:** Historical cohort study of HD pts from 25 outpatient clinics. sPEW, GNRI and Cr Index were estimated. Kaplan-Meier estimator and univariable Cox regression models to analyze time until death were used. To compare survival curves the log-rank test or Tarone test were used, as appropriate. The level of significance α = .05 was considered. All data were analyzed using SPSS 22.0 (IBM Corp. Released 2013. IBM SPSS Statistics for Windows. Armonk, NY, USA: IBM Corp).

**Results:** We analyzed 2322 pts, 59% males, 31.7% diabetic, with a median age of 70 years (P25 = 60, P75 = 79) followed up for a maximum of 45-month (P25 = 31; P75 = 45). All-cause mortality was observed in 778 pts (33.5%). To assess the mortality risk, the exposures GNRI and Cr Index, were discretized using quartiles.

Adjusted for age, gender, dialysis vintage, hemoglobin, GNRI, and comorbid conditions.

---
The median was 106.6 (P<sub>25</sub> = 99.4, P<sub>75</sub> = 114.2). The log-rank test results showed a significantly lower survival for patients in GNRI Q1 category (GNRI ≤ 99.4). A p-value < 0.001 was obtained when comparing patients in Q4, Q3 and Q2 with patients in Q1. The univariable Cox regression model showed that patients in Q1 had a 2-fold increased risk of death, when compared with Q4 (HR = 2.1, 95% CI: 1.7–2.6, p < 0.001).

**Creatinine Index**

The median was 12.648 (P<sub>25</sub> = 11.908, P<sub>75</sub> = 13.406). The log-rank test for the equality of survival functions for the different levels was considered statistically significant and showed a significantly lower survival for patients in CR Index Q1 category, when compared with the remaining categories (p < 0.001). The univariable Cox regression model showed that comparatively with Q4, patients in Q1 had a 5-fold increased risk of death (HR = 4.8, 95% CI: 3.7–6.0, p < 0.001), patients in Q2 a 3-fold increased risk of death (HR = 3.1, 95% CI: 2.4–3.9, p < 0.001), and patients in Q3 a 2-fold increased risk of death (HR = 1.9, 95% CI: 1.4 – 2.4, p < 0.001).

**sPEW**

The frequency of each score from 0 to 4 was 306, 380, 111, 1369 and 156, respectively. The log-rank test for the equality of survival functions corresponding to the different levels showed a significantly higher survival for patients with a sPEW score of 4 when compared with the remaining levels (p < 0.001). The univariable Cox regression model showed that comparatively with a score of 4, patients with a score of 0 had an 8-fold increased risk of death (HR = 7.7, 95% CI: 4.5–13.3, p < 0.001), score of 1 a 6-fold increase risk of death (HR = 5.6, 95% CI: 3.3–9.2, p < 0.001), score of 2 a 4-fold increase risk of death (HR = 4.1, 95% CI: 2.2–7.7, p < 0.001), and a score of 3, almost a 4-fold increased risk of death (HR = 3.7, 95% CI: 2.2–6.3, p < 0.001).

**Conclusion:** In this exploratory analysis, the three tools showed a significant association with mortality during follow-up. These tools, if adequately validated in future studies, may select patients for further intervention to modify the outcome.

**EFFECT OF ETELCALCETIDE TREATMENT ON ERYTHROPOIESIS-STIMULATING AGENTS (ESAS) REQUIREMENT IN HEMODIALYSIS PATIENTS: A SINGLE CENTER STUDY**

Ihab El Madhoun, Ahmed Youssef Emam, Saad Mahi, Rony Jose Pulikkan, Mourad Bouarour, Shibu Jacob and Krishnakumar Karipoth

HMC, Qatar

**Background and Aims:** Anemia is a common consequence of advanced chronic kidney disease (CKD). There are various causes of renal anemia like decreased production of and resistance to Erythropoietin, shortened survival of red blood cells and chronic blood loss. Secondary hyperparathyroidism is a potential cause of renal anemia in CKD patients due to direct effect on Erythropoietin synthesis, red cell survival and bone marrow fibrosis [1]. There are several reports of the beneficial effect of treatment of hyperparathyroidism on hemoglobin (Hb) levels. Etelecalcetide is a novel intravenous calcimimetic used for the treatment of secondary hyperparathyroidism in hemodialysis patients. However, there are very few reports of Etelecalcetide’s effect on anemia management in hemodialysis patients. We aimed to study the effect of Etelecalcetide on ESAs requirement in our hemodialysis cohort.

**Method:** This is a retrospective study in Al Wakra Hospital hemodialysis unit conducted on patients with uncontrolled secondary hyperparathyroidism who needed to be started on Etelecalcetide. Mean Hb and mean ESAs dose were calculated for a period of 6 months before and 6 months after starting Etelecalcetide, while iPTH levels were measured at the beginning and 6 months after starting Etelecalcetide. Inclusion criteria: hemodialysis patients who are on Etelecalcetide for at least 6 months. Exclusion criteria: Patients’ age < 12 years, hemodialysis duration < 12 months and patients with acute blood loss.

**Results:** Out of 94 hemodialysis patients, 26 (27.6%) were on Etelecalcetide. 2 patients were excluded, one for acute hematuria and the other for erosive gastritis. 24 patients were included (13 females and 11 males). Mean age of the patients was 58.7 years. 15 patients were on Darbepoetin, 8 on Erythropoietin and 1 patient was switched from Darbepoetin to Erythropoietin due to poor response. There was no significant difference in mean Hb levels for all the patients before and after starting Etelecalcetide (10.6 g/dl and 10.8 g/dl, respectively). Out of 24 patients, 19 had reduction while 5 had increase in ESAs dose requirement. In total, the mean reduction of ESAs dose for all the patients was 17.3%. There was a mean of 33.4% reduction in ESAs requirement for the 19 patients while a mean of 44% increase in the requirement for the 5 patients. Mean iPTH for the cohort at the time of starting Etelecalcetide and 6 months after was 1056 pg/ml and 473 pg/ml respectively. The mean reduction of iPTH for those who had decreased ESAs requirement was 58% while it was 38.8% for those who had increased ESA requirement.

**Conclusion:** This study showed that control of severe secondary hyperparathyroidism with Etelecalcetide was associated with reduction in ESAs requirement in hemodialysis patients. The more the control of hyperparathyroidism, the more the reduction of ESAs requirement. These findings were...
observed also in a one case report [2]. We believe that our study has one of the largest number of patients to show such an observation, however larger controlled studies are needed to confirm these preliminary findings in the improvement of anemia after treatment of hyperparathyroidism by Etelcalcetide.

¹Daejeon Eulji Medical Center, Eulji University School of Medicine, Daejeon, Rep. of South Korea, Division of Nephrology, Department of Internal Medicine, Daejeon, Rep. of South Korea, ²Daejeon St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Daejeon, Division of Nephrology, Department of Internal Medicine, Daejeon, Rep. of South Korea and ³Eunpyeong St. Mary’s Hospital, College of Medicine, The Catholic University of Korea, Division of Nephrology, Department of Internal Medicine, Seoul, Rep. of South Korea

Background and Aims: Cardiovascular disease (CVD) and cerebral vascular accident (CVA) are the important complications and the leading causes of death in dialysis patients. High serum calcium (Ca) level promotes the clotting cascades and vascular calcification, which leads to CVD and CVA. Magnesium (Mg) is a well-known Ca blocker, inhibiting the formation of thrombin. An imbalance between serum Ca and Mg levels has been reported as an associated factor with CVD and mortality. This study investigated the associations of serum Ca-Mg ratio with CVD and CVA in dialysis patients.

Method: We conducted a cross-sectional analysis using baseline data from a multicenter prospective cohort for dialysis patients in South Korea. A total of 860 patients were divided into tertile groups according to serum Ca-Mg ratio levels. Patients with serum Ca-Mg ratio less than 3.28 were classified as the low group, and patients with serum Ca-Mg ratio more than 3.87 were classified as the high group, and the rest were classified as the middle group. Serum Ca level was calculated and applied as corrected Ca level considering serum albumin level. The associations of serum Ca-Mg ratio with prevalence of acute coronary syndrome (ACS), congestive heart failure, aortic artery calcification, and CVA were assessed.

Results: The average age of all patients was 59.1±12.1 years, and the average duration of dialysis was 7.9±5.9 years, and the duration of the low group was shorter than those of other groups. The high group had higher prevalence of peripheral vascular disease (P = 0.004). Serum albumin, phosphorus and Mg levels in the high group were lower than other groups (P < 0.001). The prevalence of ACS showed higher in the high group than in other groups (P = 0.017). The prevalence of cerebral infarction showed higher in the high group than the low group (P = 0.016). In multivariable logistic regression analysis, higher Ca-Mg ratio was independently associated with the prevalence of ACS (Odds ratio 1.321, 95% confidential interval 1.009-1.728, P = 0.043) and cerebral infarction (Odds ratio 1.392, 95% confidential interval 1.002-1.896, P = 0.036).

Conclusion: A high Ca-Mg ratio was associated with the development of ACS and cerebral infarction. If the optimal cut-off of Ca-Mg ratio is determined, it can be used as a predictive marker for ACS and cerebral infarction.
We prospectively enrolled the patients with ESRD undergoing hemodialysis using functional near-infrared spectroscopy (fNIRS), and analyzed the effect of hemodialysis on the functional brain connectivity.

Method: We prospectively enrolled the patients with ESRD undergoing hemodialysis for more than six months without any previous history of neurological or psychiatric disorders. The fNIRS data acquisition was made with a NIRSIT Lite device. Measurements were made three times in the resting state for each patient; before the start of hemodialysis (Pre-HD), one hour after the start of hemodialysis (Mid-HD), and after the end of hemodialysis (Post-HD). We processed and exported the entire data, and made a weighted connectivity matrix using a Pearson correlation analysis. From the connectivity matrix, we obtained the functional connectivity measures by applying a graph theoretical analysis (Fig. 1). We compared the differences of the functional connectivity measures according to hemodialysis in patients with ESRD.

Results: We included 34 patients with ESRD. Table 1 and Fig. 2 show the differences in functional brain connectivity according to hemodialysis. There were significant changes in the functional connectivity measures of the mean clustering coefficient, transitivity, and assortative coefficient in the comparisons between Pre-HD and Post-HD periods (0.353 vs. 0.399, p = 0.047; 0.523 vs. 0.600, p = 0.042; 0.043 vs. -0.012, p = 0.044; respectively). However, there were no changes in the connectivity measures of the mean clustering coefficient, transitivity, and assortative coefficient in the comparisons between Pre-HD and Mid-HD periods, and between Mid-HD and Post-HD periods. In addition, there were no significant differences in the connectivity measures of the average strength, global efficiency, and local efficiency in the comparisons among Pre-HD, Mid-HD, and Post-HD periods.

Conclusion: We demonstrate the significant effect of hemodialysis on the functional brain connectivity in patients with ESRD. The functional brain connectivity would change in a more efficient direction through hemodialysis.

CANCER PATIENTS WITH END-STAGE KIDNEY DISEASE ON CHRONIC HEMODIALYSIS: CHANGING THE PARADIGM
Marisa Roldão1, Gonçalo Ávila2, Inês Coelho3, Hugo Ferreira1, Teresa Chuva4, Ana Paiva1 and José Maximino Costa1

1Centro Hospitalar do Médio Tejo, Nephrology, Torres Novas, Portugal, 2Centro Hospitalar Lisboa Ocidental, Nephrology, Portugal and 3IPO Porto, Nephrology, Portugal

Background and Aims: In the last decade, new therapeutic regimens have dramatically improved the prognosis of cancer patients and changed the paradigm of a previously highly lethal disease, increasing the number of cancer patients with chronic kidney disease (CKD) who progress to end-stage kidney disease (ESKD). However decision-making regarding dialysis initiation in patients with cancer and ESKD remains however controversial. The aim of our study was to characterize the clinical course and evaluate survival outcomes of cancer patients on chronic hemodialysis (HD).

Method: We conducted a retrospective study of HD patients in a single oncology hospital unit between January 1991 and November 2022. Outpatients on HD for more than one month, who underwent dialysis after the diagnosis of cancer were included. Univariate and multivariate hazard ratios (HRs) and 95% confidence intervals (CIs) for all-cause mortality were estimated using the Cox proportional hazards risk model.

Results: Two hundred and twelve patients were recruited. Mean age at HD initiation was 65.7±14.7 years. The most prevalent ESKD etiologies were cast nephropathy, chronic interstitial nephritis, and surgical removal of the kidney. The most common tumors were genitourinary, multiple myeloma (MM) and gastrointestinal corresponding to 80.6% of all cancers. There were 143 deaths among the HD patients.

Discussion: Our results highlight the importance of considering cancer patients for renal support therapies, including those with multiple tumors and metastatic disease. In fact, with the new treatments available, many patients have chronic oncological disease non-fatal in the short term. To the best of our knowledge, this is the largest study of cancer patients on chronic HD.

RELATIONSHIP BETWEEN STAPHYLOCOCCUS AUREUS NASAL CARRIAGE AND URAEMIC PRURITUS IN HEMODIALYSIS PATIENTS AND ITS INFLUENCE ON INFECTION
Hon-Yen Wu1,2,3,4, Ping-Hsiu Tsai1, Shih-Ping Hsu1, Chun-Hsing Liao1,2 and Mei-Ju Ko5

1Far Eastern Memorial Hospital, Department of Internal Medicine, New Taipei City, Taiwan, Rep. of China, 2National Yang Ming Chiao Tung University College of Medicine, School of Medicine, Taipei City, Taiwan, Rep. of China, 3National Taiwan University College of Public Health, Institute of Epidemiology and Preventive Medicine, Taipei City, Taiwan, Rep. of China, 4National Taiwan University College of Medicine, Department of Internal Medicine, Taipei City, Taiwan, Rep. of China and 5Taipei City Hospital, Department of Dermatology, Taipei City, Taiwan, Rep. of China

Background and Aims: Uraemic pruritus is a common and distressing comorbid disease among patients undergoing haemodialysis (HD). The aetiology of uraemic pruritus is multifactorial and not fully understood. The role of skin microbiota in chronic inflammatory skin disease has long been discussed, but evidence regarding the relationship between uraemic pruritus and Staphylococcus aureus (SA) colonization is limited. The rate of SA nasal carriage in HD patients was more than double that of healthy individuals, and the phage type of SA infection was often the same as the type of SA carried in the HD patients' nares. SA colonization is associated with greater skin barrier disruption, which suggests a possibility to increase the risk of infection in patients with uraemic pruritus. This study aimed to assess the role of SA nasal carriage in uraemic pruritus, as well as the interplay among SA colonization, uraemic pruritus, and SA infection in HD patients.

Method: We conducted a prospective cohort study to enrol adult HD patients in the Far Eastern Memorial Hospital, a tertiary medical centre in Taiwan, in April 2019. Eligible patients should had received maintenance HD for more than three months. Patients were excluded if they had active infection or primary skin diseases. The intensity of uraemic pruritus was assessed using a visual analogue scale (VAS) from 0 to 10 (0 = no pruritus, 10 = the worst pruritus imaginable). Nasal swab culture was performed to examine the status of SA nasal carriage. Patients were followed until SA infection, death, or January 2020, whichever had occurred earlier. The definition of SA infection should fulfill both the clinical diagnosis and the results of microbiological culture. Multivariate linear regression models were used to assess the potential predictors for a higher pruritus intensity. Multivariate Cox proportional hazard models were used to analyse the risk of SA nasal carriage on SA infection among the HD patients.

Results: A total of 100 HD patients were enrolled, the mean age was 61.7 years and 69% were men. The mean dialysis vintage was 6.7 years. Among the participants, 55% had uraemic pruritus and the mean VAS score of pruritus intensity was 4.0. The prevalence of SA nasal carriage was higher in patients with uraemic pruritus than that in patients without uraemic pruritus (33% vs 13%, P = 0.024). The multivariate linear regression model showed that SA nasal carriage was an independent predictor of a higher VAS score of pruritus (parameter estimate, 1.18; 95% CI 0.05–2.30; P = 0.04) (Table 1). After follow-up for 10 months, there were four SA infection events in the pruritus patients and one event in the non-pruritus patients. The multivariate Cox proportional hazard model showed that patients with SA nasal carriage had a borderline higher risk for SA infection (adjusted hazard ratio, 50.9; 95% CI, 0.62-3689; P = 0.08) (Table 2).

Conclusion: SA nasal carriage is independently associated with uraemic pruritus, and is also an independent predictor for a higher pruritus intensity among HD patients. Moreover, SA colonization might predict SA infection in later follow-up period. This study provide evidence for future studies regarding the survey for SA colonization and application of nasal decolonization among HD patients with uraemic pruritus.
ROXADUSTAT-INDUCED HYPOTHYROIDISM: THE EFFECT OF ROXADUSTAT ON SUPPRESSION OF THYROID FUNCTION
Masato Ohsawa1, Tadashi Kuki1, Masahiro Nishihara1, Rento Ohsawa1 and Jin Oshikawa2

Background and Aims: There have been only two case reports of hypothyroidism in patients treated with roxadustat, a HIF-PH inhibitor as new renal anemia drug. However, there has yet been no studies to examine the effect of roxadustat on thyroid function.

Method: In this study, we retrospectively examined the effects of roxadustat on thyroid-stimulating hormone (TSH) in hemodialysis patients by two blood examinations, before and during treatment with roxadustat. We included patients who had TSH levels measured after at least two consecutive weeks of roxadustat treatment and before. We excluded patients with a history of taking other HIF-PH inhibitors before roxadustat. The period was from September 2021 to November 2022 in this interim analysis. A p value of \(<0.05\) was considered statistically significant. Analyses were performed using SPSS.

Results: 93 patients were included in this analysis. TSH levels significantly decreased after treatment with roxadustat. A total of 58.1% of patients had decreased TSH levels (2.23 ± 1.18 v.s. 1.81 ± 1.35, μIU/mL, p value = 0.040, Wilcoxon signed-rank test), and 18.3% of patients had a significant decrease below the normal range. Additionally, patients treated with thyroid hormone replacement therapy in primary hypothyroidism had a higher frequency (81.0%) of TSH decrease compared to patients without (p value = 0.013, Pearson's chi-square test).

Conclusion: This is the first study to examine that roxadustat has a suppressive effect on TSH secretion in hemodialysis patients. We also found that roxadustat-induced hypothyroidism is prevalent in the high frequency of TSH suppression, especially in primary hypothyroidism patients treated with thyroid hormone replacement therapy. Thyroid hormone receptor beta (THRβ), which is expressed in the hypothalamus and pituitary gland, plays an important role in regulating thyroid hormone through feedback mechanisms.

Yao et al. have reported that roxadustat has a similar structure to T3 and acts as a THRβ-selective ligand, particularly activating THRβ. Therefore, it is possible that roxadustat suppresses TSH secretion through negative feedback via THRβ. It is important to monitor thyroid function in patients receiving roxadustat. Roxadustat should be avoided in patients with primary hypothyroidism, since it is inferred that roxadustat-induced hypothyroidism cannot be improved by enhancement of thyroid hormone replacement therapy.

AN ADEQUATE HYDRATION MANAGEMENT IMPROVES THE EFFICIENCY OF INTRADIALYTIC PHOSPHATE REMOVAL.

Hiroshi Kikuchi1, Hisakazu Shimada2, Ryo Karasawa1 and Masashi Suzuki2

1Toyosaka Hospital, Internal Medicine, Niigata City, Japan and 2Shinraku-en Hospital, Kidney Center, Niigata City, Japan

Background and Aims: The excess of phosphate (P) is one of the major risk factors for death in patients undergoing hemodialysis (HD). Improving P removal efficiency should ameliorate their prognosis. We previously reported, increased urea nitrogen (UN) removal efficiency results in increased the removal efficiency of P from extracellular fluid (ECF), but did not improve that from intracellular fluid (ICF) (NDT, Vol 35, Sup3, P1401, 2020). We also reported that P removal from ICF accounted for in average about 44% of total intradialytic P removal. For improving total P removal efficiency, removal efficiency of P from ICF should be increased. As P is one of the major osmotic agents in ICF, water outflow from ICF will accompany P outflow. We explored correlation between intracellular P removal and intracellular water (ICW) reduction. And we also sought for the strategy which efficiently derive water from ICF in HD patients in order to increase intracellular P removal.

Method: Eighty-six patients undergoing 4-hour HD were enrolled this study. ICF, extracellular water (ECW) volume and body fat mass (BFM) in each patient were measured with biochemical impedance analysis method before and after HD session. Total body water (TBW) was calculated by ICW + ECW. The amount of intradialytic P removal from ICF and from ECF in each patient was calculated as previously reported (NDT, Vol 35, Sup3, P1401, 2020). The correlation between the amount of intradialytic P removal from ICF and the amount of ICW reduction was investigated. All patients were divided into three groups according to the amount of ICW reduction as high reduction (HR) group, middle reduction (MR) group and low reduction (LR) group. The amount of P removal from ICF was compared between these groups. ICF volume change (ΔICW%) was calculated as (preICW – postICW)/preICW in each patient. Where preICW = ICF volume at the starting of HD, postICW = ICF volume at the end of HD. Circulating plasma volume change (ΔCPV%) was calculated as (postTP – preTP)/postTP in each patient. Where postTP = serum total protein concentration (TP) at the end of HD, preTP = TP at the end of HD. Lean body mass (LBW) was calculated as BW – BFM. Body weight (BW) change (ΔBW%), LBW change (ΔLBW%) and TBW volume change (ΔTBW%) were calculated in the same way as ΔICW%.

To seek factors that effectively reduce ICW, the correlation with ΔICW% in ECW/TBW ratio, ΔCPV%, ΔCPV%/ΔBW% ratio, ΔCPV%/ΔLBW% ratio and ΔCPV%/ΔTBW% ratio was examined.

Results: The amount of intradialytic P removal from ICF positively correlated to the amount of ICW volume reduction (R = 0.279, y = 66.3x+2.85, p = 0.0076). It indicates an average of 66.3mg of P was removed from ICF per 1L of ICW reduction. In HR group, the amount of P removal from ICF was significantly larger than that in LR group (315.6 ± 117.8mg vs 538.2 ± 217.9mg, p = 0.019). ΔICW% negatively correlated to ΔECW% (R = 0.481, p = 0.000057). High ECW/TBW ratio indicates excess of ECW, which suggests having edema. ΔICW% positively correlated to ΔCPV% (R = 0.511, p = 0.0000051). Low ΔCPV% suggests insufficient of ultrafiltration. ΔICW% negatively correlated to ΔCPV%/ΔTBW% ratio (R = 0.421, p = 0.00011). High ΔCPV%/ΔTBW% ratio indicates insufficient plasma refill rate, which suggests overrate of ultrafiltration. But ΔICW% did not correlate to ΔCPV%/ΔBW% ratio (R = 0.184, p = 0.10) nor ΔCPV%/ΔLBW% ratio (R = 0.176, p = 0.12).

Conclusion: The amount of intradialytic P removal from ICF correlated to the amount of ICW reduction. For efficient reduction of ICW, low ECW/TBW ratio, high ΔCPV% and low ΔCPV%/ΔTBW% ratio were required. It was suggested that efficient P removal was achieved when non-edematous patients get ultrafiltration of appropriate rate and dose.

IMPACT OF RAMADAN FASTING ON NUTRITION, INFLAMMATION AND DIALYSIS ADEQUACY AMONG HEMODIALYSIS PATIENTS.

Eman Taher1, Mohamed Sobh1, Mohammed Kamal Nassar2 and Salwa El Wasif2

1Urology & Nephrology center Mansoura University, Nephrology Department, Mansoura, Egypt and 2Faculty of Medicine - Mansoura University, Egypt

Background and Aims: There is a paucity of data concerning safety of fasting in Ramadan in End stage kidney disease patients (ESKD) on haemodialysis (HD). The aim of the present study was to assess the possible effect of fasting on nutritional status (clinical, biochemical variables), inflammatory status and adequacy of haemodialysis. This observational study was carried out during 2019 when fasting duration was around 14 hours.

Method: Sixty-five patients suffered from ESKD who received regular HD for more than six months in dialysis unit, urology and nephrology center Mansoura university were included in this prospective observational study. Patients were categorized into three groups. 21 patients fasted all days of Ramadan, 25 patients fasted days other than session days and 19 patients never. We did not oblige our patient to fast. nutritional status was assessed clinically by Anthropometric measurements including body weight, BMI, triceps skin fold thickness (TSF) and estimation of protein catabolic rate (PCR) were measured, and laboratory by serum Albumin, cholesterol and fasting blood glucose. Neutrophils to lymphocytes ratio (NLR), Soluble receptor of advanced glycation end product(SRAGE) and human B-cell lymphoma/leukemia2 (BCL2) was measured as inflammatory markers, also dialysis adequacy was determined with urea reduction ratio (URR) and Kt/V. Assessment of all patients were carried out before and after Ramadan and was repeated 3 months after Ramadan in all patients.

Results: In 30 days fasting group: there was significant reductions (all P < 0.02), serum albumin, triceps skin fold thickness, Subjective global assessment score (SGA) for nutritional assessment also in inflammatory markers as neutrophils to lymphocytes ratio (NLR) and human Bcell lymphoma/leukemia2 (BCL2). But these were not accompanied by any significant change (all P > 0.05) in body mass index, serum cholesterol, fasting blood sugar (FBS), urea reduction ratio (URR), intradialytic weight gains (IDWG), Kt/V and human soluble receptor for advanced glycation end products (sRAGES). In the group Who was reported fasting in days other than HD session days: fasting led to significant reductions (all P < 0.05) only in serum albumin and triceps skin fold thickness. There were no significant changes in BMI, URR, Cholesterol, FBS, Kt/V, IDWG, SGA score, NLR, sRAGES and BCL2. In patients Who never fast at all: there was significant reduction (all P < 0.02) in triceps skin fold thickness, significant change in SGA score and also in sRAGES and BCL2.

Conclusion: There was no harmful effect for Muslim patients receiving regular HD who went to fast Ramadan in days other than HD session days. In the current study the fasting group has the benefit of both being fasting and non-significant changes in mostly all nutritional assessment points, inflammatory markers and the adequacy of HD.

THE INFLUENCE OF AMBULATORY BP ON THE ASSOCIATIONS OF SEX WITH CARDIOVASCULAR EVENTS AND MORTALITY IN DIALYSIS PATIENTS: A PROSPECTIVE COHORT STUDY

Pantelis Sarafidis, Marieta Theodorakopoulou, Fotini Iatridi, Areti Georgiou, Artemios Karagiannis, Eleni Karkamani, Alexandros Tsitsouridis, Danai Faitatzidou and Akaterini Papagianni

Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece

Background and Aims: Male patients with pre-dialysis CKD have worse ambulatory BP control than females and this is associated with higher mortality risk. Male hemodialysis patients have higher ambulatory BP levels compared to females. The aim of this study was to investigate the influence of ambulatory BP on the associations of sex with cardiovascular events and mortality in hemodialysis individuals. Male patients with pre-dialysis CKD have worse ambulatory BP control than females and this is associated with higher mortality risk. Male hemodialysis patients have higher ambulatory BP levels compared to females. The aim of this study was to investigate the influence of ambulatory BP on the associations of sex with cardiovascular events and mortality in hemodialysis individuals. Male patients with pre-dialysis CKD have worse ambulatory BP control than females and this is associated with higher mortality risk. Male hemodialysis patients have higher ambulatory BP levels compared to females. The aim of this study was to investigate the influence of ambulatory BP on the associations of sex with cardiovascular events and mortality in hemodialysis individuals.

Method: 129 male and 91 female hemodialysis patients with valid 48-hour ABPM were followed prospectively for 53.4±3.1 months. The primary endpoint was cardiovascular mortality; the secondary endpoint was a composite of cardiovascular death, non-fatal myocardial infarction, non-fatal stroke, resuscitation after cardiac arrest, hospitalization for heart failure, coronary or peripheral revascularization procedure.

Results: Cumulative-free from the primary endpoint was significantly lower for women (logrank-p = 0.032), while cumulative-free from the secondary endpoint did not differ significantly between the two groups (logrank-p = 0.644). The crude risk for cardiovascular mortality was significantly higher for women (HR = 1.613, 95% CI [1.037, 2.509]). The crude risk for the combined cardiovascular endpoint was not different between the two genders (HR = 0.918, 95% CI [0.638, 1.320]). After adjusting for other risk factors (age, diabetes, dialysis vintage, coronary disease) no significant differences in the risk for both the primary and the secondary endpoint were observed between women and men (primary: HR = 1.464 95% CI [0.929, 2.307]; secondary:0.866[95%CI[0.596,1.260])]. After further adjustment for 44-hour ambulatory BP the above relationships did not alter (primary: HR = 1.498, 95% CI [0.947, 2.368]; secondary: HR = 0.911, 95%CI [0.625, 1.327]).
Conclusion: In contrast to patients with pre-dialysis CKD, ambulatory BP adverse cardiovascular outcomes in hemodialysis patients.

**INTRADIALYTIC PARENTERAL NUTRITION IMPROVES PROTEIN STORES IN CHRONIC HEMODIALYSIS PATIENTS**

Pablo Molina1,2, Aina Quilis1, Paula Gandía Ureña1, Laura Porcar Saura1, Pilar Llopís1, Manuel Parra1, Alejandro Valero Antón1, Elena Galván Barrilero1, Belén Vizcaino Castillo1,2,3, Mercedes González Moya1,2,3, Gabriela Pérez-Boix4, María Rodrigo1, Mónica Climente4 and María Asuncion Sancho Calabuig1,2,3

1Doctor Peset University Hospital, Nephrology, València, Spain, 2University of Valencia, Medicine, València, Spain, 3Fisabio, València, Spain and 4Doctor Peset University Hospital, Pharmacy, València, Spain

**Background and Aims:** Intradialytic parenteral nutrition (IDPN) is a form of supplemental nutrition used to treat patients with malnutrition who receive hemodialysis (HD) and in which the oral feeding is not enough to cover basic caloric needs. Although this technique could improve biochemical markers of nutrition, information regarding its effect on body deposits is lacking. We evaluated the effect of IDPN on body composition parameters and nutritional status in prevalent HD patients.

**Method:** Retrospective observational study that included all prevalent hemodialysis patients who received NPID for more than 3 months at our Center from January 2018 to December 2022. All the patients received a concentrated 3-in-1 parenteral nutrition formula consisting of glucose solution, a lipid emulsion and an amino acid solution without electrolytes (OLIMEL N9⃝, Baxter). IDPN was infused at a constant rate not exceeding 300 ml/hour, via the venous drip chamber of HD monitor using infusion pump. Changes in lean tissue mass (LTM), intracellular water (ICW), and body cell mass (BCM) assessed by multifrequency bioimpedance spectroscopy (BIS) at baseline and at 3, 6, 9 and 12 months (primary outcomes) and other biochemical and anthropometric parameters (secondary outcomes) were used to assess the effect of NPID.

**Results:** Seventeen patients were included (women: 9, 53%; mean age: 68±15 y). After IDPN initiation, a gradual improvement in LTM, ICW and BCM was observed, reaching statistical significance at Month 3, 6, 9 and 12. Changes in fat inversely mirrored those of LTM (Table 1). Albumin levels and the normalized protein appearance increased, with a significant reduction in high-sensitive C-reactive protein and extracellular/intracellular body water ratio at month 9 and 12.

**Conclusion:** IDPN for 1-year was associated to increased muscle mass, supporting the hypothesis that this supplement nutrition could benefit nutritional status and revert protein-energy wasting in HD patients.

**Table 1: Effects of IDPN on body composition and nutrition.**

BETA2 MICROGLOBULIN IS AN INDEPENDENT PARAMETER RELATED WITH DYSFUNCTION OF NATURAL KILLER CELL ACTIVITY IN HEMODIALYSIS PATIENTS
Hyong Cheon Park1, Dongwhan Oh1, Jong Hyun Jhee1, Jung Eun Lee2, Hoon Young Choi1, Hyung Jong Kim3 and Sang-Woong Han4
1Gangnam Severance hospital, Yonsei University College of Medicine, Internal Medicine, Seoul, Rep. of South Korea, 2Yongin Severance hospital, Yonsei University College of Medicine, Internal Medicine, Yongin-si, Rep. of South Korea, 3CHA Bundang Medical Center, CHA University, Internal Medicine, Seongnam-si, Rep. of South Korea and 4Hanyang University Guri Hospital, Internal Medicine, Guri-si, Rep. of South Korea

Background and Aims: End-stage renal disease patients are characterized by immune dysfunction. Natural killer (NK) cells are lymphocytes of innate immune system that play a key role in an immune response towards viral infections and tumors. We aimed to analyze clinical factors related to the NK cell activity in chronic hemodialysis (HD) patients.

Method: Clinically stable 196 patients who were treated by HD for more than 3 months were enrolled from 4 outpatient HD clinics. NK cell activity was assessed using NK Vue assay (NKMAX, Sungnam, Korea) that uses serum of ex-vivo stimulated whole blood to detect interferon (IFN)-γ secreted from NK cells as an indicator of NK cell activity. All patients were stratified as abnormal (<250 pg/ml) and normal (≥250 pg/ml) groups according to NK cell activity.

Results: Mean age of the HD patients was 62.7 years [range 31 to 95 years] and mean HD duration was 49.2 months [range 3 to 221 months]. In total, 68 (35%) of HD patients showed abnormal NK cell activity. The abnormal NK cell activity group showed significantly increased age and shorter HD duration compared to the normal NK cell activity group (66.7 ± 11.9 vs. 60.6 ± 13.4 years, p = 0.001; 33.8 ± 33.0 vs. 57.5 ± 48.5 months, p<0.001, respectively).

The serum albumin and parathyroid hormone levels were significantly lower in the normal NK cell activity group (3.7 ± 0.4 vs. 3.9 ± 0.3 g/dL, p = 0.005 and 176 ± 153 vs. 240 ± 260 mg/50ml, respectively). In contrast, hemoglobin, blood urea nitrogen, urea reduction ratio, and C-reactive protein levels were comparable between the two groups. In multivariate regression analysis, old age, short dialysis duration, low serum albumin and high beta2 microglobulin levels were independent risk factors of abnormal NK cell activity in HD patients (adjusted odd ratio [AOR], 1.033; 95% confidence interval [CI], 1.005-1.062, p = 0.02; AOR, 0.981; 95% CI, 0.971-0.992; p<0.001, AOR, 0.395; 95% CI, 0.157-0.995; p = 0.049, and AOR, 1.042; 95% CI, 1.011-1.075; p = 0.008, respectively).

Conclusion: Our results suggest that young age and good nutrition as well as lower burden of middle molecule uremic toxin is associated with greater NK cell activity in HD patients.

EFFICACY OF TRANSCATHETER AORTIC VALVE IMPLANTATION FOR SEVERE AORTIC VALVE STENOSIS IN HEMODIALYSIS PATIENTS
Masahiro Nakagaki, Kenji Harada and Hidetoishi Kanai
Japan

Background and Aims: In Japan, of the >340,000 chronic dialysis patients, approximately 60% have lifestyle-related diseases including diabetes and nephrosclerosis. Two-thirds of maintenance dialysis patients (age, ≥65 years) often develop aortic stenosis (AS) and other serious and complex systemic cardiovascular disease complications associated with chronic kidney disease mineral and bone disorder (CKD-MBD). Furthermore, renal function loss and a prolonged state of renal failure are observed requiring renal replacement therapy (RRT). AS in dialysis patients progresses quickly, and the frequency of hospitalized treatment for heart failure increases with the worsening condition, leading to ADL deterioration, which may subsequently cause dialysis hypotension/interruption. At our hospital, of the 420 maintenance dialysis patients who died during hospitalization in 5 years before 2020 (420/1,637 ± 16%, 32 cases (8%) developed AS complications, which became their direct cause of death in 12 cases (3%), and aortic valve replacement (AVR) was performed in 5 cases (1%). Maintenance hemodialysis patients (HD) are at high risk group and have a poor prognosis for life. Previously, transcatheter aortic valve implantation (TAVI) was not indicated, but recently TAVI has been approved in Japan. Efficacy of TAVI for HD patients remains unclear, here we investigated several outcomes.

Method: A total of 123 maintenance dialysis patients with severe AS were included in 2019–2021. We examined TAVI group and AVR group for length of hospital stay, hospitalization costs, life expectancy, and rates of complications such as occurrence of arrhythmias.

Results: Over a 3-year period, we performed TAVI for 58 maintenance dialysis patients (mean age, 81 years); their median duration of hospitalization was 14 days for a median cost of 6,259,350 JPY. The mean age was older than that of 66 patients who underwent open-heart AVR during the same period (mean age, 73 years; 35 days for 7,192,570 JPY); therefore, the cost was less, and the rate of complications, including vital prognosis and arrhythmia, was not inferior in hospitalization period.

Conclusion: In conclusion, TAVI is effective for elderly maintenance dialysis patients with severe AS and has a positive health care economics, ADL maintenance.

AN INITIAL LOW-DOSE ETILOCALCETIDE APPROACH IS EFFECTIVE AND COST-SAVING IN HEMODIALYSIS PATIENTS WITH MODERATE SECONDARY HYPERPARATHYROIDISM
Andrea Carta1,2, Martina Tedesco1,2, Alice Guerini1,2, Federica Terni1,2, Corrado Camerini1, Stefano Possenti1, Paola Gaggia1, Federica Mesia1,2 and Federico Alberici1,2
1Spedali Civili di Brescia, Unità Operativa di Nefrologia, Brescia, Italy, 2Università degli Studi di Brescia - Facoltà di Medicina e Chirurgia, Dipartimento di Specialità Medico-Chirurgiche, Scienze Radiologiche e Sanità Pubblica, Brescia, Italy and 3Independent Researcher, Brescia, Italy

Background and Aims: Etelcalcetide (ETC) is an intravenous calcimimetic approved for the management of secondary hyperparathyroidism (SHPT) in hemodialysis (HD) patients, with benefits in terms of reduction of FGF23 levels and prevention of progression of left ventricular hypertrophy. The label recommendation is a starting dose of 5 mg after HD, to be titrated every 4 weeks according to parathyroid hormone (PTH) and calcium levels. However, it remains unclear what dosage is best to start with and, thus, how this treatment can be implemented in a real-life setting. The aim of this study was to assess the efficacy and cost-effectiveness of ETC started at lower doses than those suggested by the manufacturer in patients with moderate SHPT.

Methods: This is a retrospective observational study comparing two different initial ETC dosing strategies, a “Low-dose approach” (LD, ETC starting dose<10 mg/week) and a “Classic approach” (CL, ETC starting dose≥10 mg/week), in terms of effects on CKD-MBD related biomarkers and costs during the first year of prescription. The study was conducted on HD patients with basal PTH between 500 and 1500 ng/L, treated with ETC for at least 3 months between 2018 and 2022 at ASST Spedali Civili di Brescia. Monthly monitoring of serum calcium, phosphorus and PTH was performed in both groups for dose adjustment.

Table 1: Clinical features of patients in the LD and CL group, at baseline and last follow-up. Data are listed as median (IQR) for continuous variables and number (%) for categorical variables.

Results: Overall, 53 patients were identified, 24 in the LD and 29 in the CL group. Both groups showed similar baseline characteristics (Table 1). Median follow-up was 52 weeks, during which 4 patients (one in the LD and three in the CL group) discontinued ETC (Table 1). At the end of follow-up, 92% of patients in the LD and 90% in the CL group achieved a decrease in PTH ≥ 30% compared to baseline, with median PTH levels of 282 (207 - 332) and 294 (151 – 382) ng/l, respectively (p = 0.825). Other CKD-MBD biochemical parameters were comparable between the two groups at all timepoints (Figure 1). The median of average ETC weekly doses per patient was 7.6 (6.2–10.2) mg in the LD and 10.6 (9.7 – 15) mg in the CL group (p < 0.001). During follow-up, the median ETC dose remained stable in the LD group, while partially decreasing in the CL group (Figure 1). Use of paricalcitol was comparable in both groups.

At cost analysis, the median of average ETC weekly costs per patient was €36.6 (29.6–50.0) in the LD and €50.5 (46.4–71.7) in the CL group (p < 0.001). This translates into an average yearly cost per patient of €1909 and €2635 using the LD and CL approach, respectively, with a saving of €726 per patient-year in favour of the LD strategy.

Conclusion: In this retrospective study in HD patients with moderate sHPT, we showed that starting ETC at a lower dose than the one suggested by the manufacturer is as effective as the classic approach in terms of control of CKD-MBD parameters, with a significant reduction in treatment costs. Future prospective studies will be needed to validate the results in bigger cohorts, test whether these benefits can extend beyond the first year of treatment and assess the effects on FGF23 levels and other relevant clinical outcomes.

#3927
AN ANOREXIGENIC HORMONE IN PEDIATRIC CKD PATIENTS
Dina E. Sallam
Faculty of Medicine, Ain Shams University, Pediatric Nephrology, Cairo, Egypt

Background and Aims: Chronic kidney disease (CKD) is a major health problem associated with faltering growth, which is a complex process, where anorexia, inadequate oral intake in addition to disturbed body metabolism play a significant role. Leptin, the anorexigenic hormone that’s secreted by fat tissue, and affect appetite, & hence, aids to weigh loss & faltering growth. The present study evaluated serum leptin level, & its relation to growth parameters in pediatric patients with different stages of CKD.

Method: A cross-sectional study that was conducted on 87 subjects, who were divided equally into groups; CKD stage 5 on regular hemodialysis (CKD5d), & CKD stage 2–4, & age & gender matched controls. Patient with diabetes, infected with hepatitis C virus, & on growth hormone therapies were excluded. Full history taking, assessment of growth parameters using gender & age specific Z-scores of heights, weight & body mass index were done. Fasting serum leptin, calcium, phosphorus, PTH, albumin, total proteins, iron & hemoglobin were measured.

Results: Our patients had significantly lower growth parameters compared to controls. Hypocalcemia, high PTH, iron deficiency anemia & hypoalbuminemia were significant in CKD2-4 groups compared to other groups. Serum leptin was abnormally high in 12.6% of CKD patients. The median leptin level was comparable between the groups (p = 0.20). Serum leptin hadn’t changed significantly as regards gender, BMI Z-scores, diagnoses, or CKD stage (p = 1.00, 0.379, 0.542, 0.171 respectively). A negative correlation was found between leptin level & CKD duration (r = -0.276, P = 0.036), otherwise, no correlations were found with clinical & laboratory variables.

Conclusion: Leptin level was not affected by CKD stage & not a useful marker for growth in pediatric CKD patients. Large studies on relationship between leptin & growth is needed.

#4237
EFFICACY AND TOLERABILITY OF DIRECT-ACTING ANTIVIRALS IN HEMODIALYSIS PATIENTS WITH CHRONIC HEPATITIS C
Nefroplus, Hemodialysis, Skopje, Republic of North Macedonia

Background and Aims: Hepatitis C virus (HCV) infection is common in hemodialysis (HD) patients and is associated with increased morbidity and mortality. In recent years major progress in the treatment of HCV infection has been made with the entry into use of direct-acting antivirals (DAAs), which target viral proteins, leading to increases in sustained virological response (SVR) and a marked decrease in side effects. The aim of the study was to
Evaluate the efficacy and frequency of side-effects of DAA therapy in HD patients with HCV infection.

Method: The multicentric prospective cohort study included 42 HD patients with HCV infection over the last two years. DAs were administered according to HCV genotype and drug interactions considering guidelines for a period of 12 weeks (for HCV genotype 1: Elbasvir/Grazoprevir or Ombitasvir/Paritaprevir/Ritonavir/Dasabuvir, and for HCV genotype 4: Elbasvir/Grazoprevir or Ombitasvir/Paritaprevir/Ritonavir). The following clinical parameters were measured: 0, 4, 8, 12, and 24 (12 weeks after the completion of treatment with DAA) were analyzed: presence of side effects, PCR HCV titer (ref. range: <12 IU/mL negative), hemoglobin (Hgb-g/L), eotinin dose (IU/kg/week), alanine aminotransferase level (ALT-U/L), and gamma-glutamyl transferase level (GGT-U/L). Before treatment with DAA liver fibrosis score (F0-4) was defined by Fibroscan and the patients with liver stiffness over 12 kPa (Fibrosis score F4) were considered cirrhotic, but only patients with compensated cirrhosis (Child-Pugh score class A) were treated. For statistical analysis chi-square test and combined analysis of variance for repeated measures were performed by IBM SPSS softser. PCR HCV titer was analyzed with logarithmic transformation of data.

Results: Over the observed period 42 HD patients with HCV infection (25M and 17F) with the average age 56.78±11.6 years and average HD vintage 159±75 months were included in the study. Twenty-six patients (61.9%) were with HCV genotype 1 and 16 patients (38.1%) with HCV genotype 4. Ten patients (23.8%) were with compensated cirrhosis (F4 fibrosis score by Fibroscan). Three patients (7.1%) had mild gastrointestinal side effects and only one patient (2.4%) discontinued the therapy during the first week due to intolerance to the treatment. All 41 patients (100%) who completed 12 weeks of DAA therapy were PCR HCV negative at 4 weeks of treatment and achieved rapid virological response (RVR) and 12 weeks after the completion of treatment and achieved sustained virological response (SVR12) that was statistically significant (p<0.001). In regard to PCR HCV titer before DAA therapy there was no statistically significant difference among HD patients according to cirrhotic status and HCV genotype. There was no statistically significant change of hemoglobin level and eotinin dose in HD patients during the DAA therapy. The ALT and GGT levels statistically significantly decreased at weeks 12 and 24 compared to week 0 in all treated patients with DAA (ALT week0 = 35.2±21.7; ALTweek12 = 21.8±16.2; ALTweek24 = 23.5±13.1; p<0.001 and GGT week0 = 53.3±67; GGT week12 = 18.6±6.6; GGT week24 = 19.4±11.5; p = 0.042 respectively). The therapy with DAA was equally effective in patients with compensated cirrhosis and in patients without cirrhosis and there was statistically significant decrease of ALT and GGT levels in both groups of patients (p = 0.002 and p<0.05 respectively). In regard to HCV genotype DAA were equally effective in patients with HCV genotype 1 and in patients with HCV genotype 4 and ALT and GGT levels statistically significantly decreased in both groups of patients (p<0.001 and p<0.05 respectively).

Conclusion: The therapy with DAA in HD patients with HCV infection was extremely effective and SVR12 was achieved in 100% of treated patients. The administered DAA were equally effective in patients with compensated cirrhosis and in patients without cirrhosis, and in patients with HCV genotype 1 and HCV genotype 4. The therapy with DAA was well tolerated, 7.1% of patients had mild side effects and 2.4% of patients discontinued the therapy due to intolerance.

Method: 12 stable patients on HD were included, with a minimum time on HD of 3 months. Each patient underwent 4 random HD sessions in which only the dialysis membrane and/or the modality were changed. They underwent an HD session with a high-flux polyethylene membrane, another session with this same filter in OL-HDF, another with MCO membrane, and another with HFR-H. All sessions were held in a short period. In all of them, pre- and post-dialysis blood samples were taken to assess the clearance of both conventional urmeric toxins and protein-bound toxins (indoxyl-sulfate and p-cresol), as well as molecules associated with the microinflammation process (proinflammatory monocytes: CD14+ /CD16++ and proinflammatory cytokines).

Results: When evaluating the effect of the different HD techniques on the percentage of proinflammatory monocytes, a relevant, although not significant, decrease was observed in the OL-HDF and HFR-H techniques. Likewise, when evaluating the profile of markers of inflammatory activity, such as IL-12B, IL-17C, CD14 or TNFRSF19, an important decrease was observed after the dialysis session in HFR-H compared to the rest of the techniques analyzed.

Conclusion: After analyzing the results of our study, the HD technique that combines convection + adsorption + diffusion (with a novelty high permeability filter), HFR-H, is the only one that has shown significantly greater clearance of proinflammatory cytokines, as well as a greater elimination of activated monocytes and protein-bound toxins, although without reaching statistical significance. These results, although preliminary, are promising and open up a new line of research to improve CVD in HD patients.

GUT MICROBE-DERIVED UREMIC TOXIN TRIMETHYLAMINE N-OXIDE CONTRIBUTES TO CARDIAC REMODELING IN PATIENTS ON HEMODIALYSIS

Mikhail Pyatchenkov and Evgeniy Sheherbakov

Military-Medical Academy; Department of Nephrology and Blood Purification, Saint Petersburg, Russia

Background and Aims: It is well established that cardiovascular pathology is the leading cause of increased morbidity and mortality in chronic kidney disease patients, especially in the terminal stage. This is explained by high prevalence of both traditional and non-traditional cardiovascular risk factors, among which inflammation, intestinal dysbiosis and microbe-derived uremic toxins such as indoxyl sulfate, p-cresyl sulfate, trimethylamine-N-oxide (TMAO) are recently considered the main role. However, the potential underlying mechanisms of these findings have not been fully elucidated. Here we aimed to investigate the association of serum TMAO with echocardiographic parameters of cardiac remodeling in patients receiving hemodialysis treatment.

Method: One hundred and forty (85M, 55F) clinically stable patients on dialysis were studied. The median (interquartile range) age was 56.5 (46.6-50.5) years, median duration of dialysis treatment – 48 (14.5-97) months, 39 (27.9%) were diabetic, 109 (77.9%) had high blood pressure, 39 (27.9%) – previous history of ischemic heart disease, including 8 (5.7%) suffered a myocardial infarction. All patients underwent transthoracic echocardiography (General Electric Vivid E95 device) with the registration of standard parameters. The determination of TMAO in serum was performed by LC/MS using a Shimadzu-8060 system combined with a Shimadzu LC-20AD liquid chromatograph. Statistical analysis was performed with STATISTICA 14.0 program. Non-parametric Spearman's rank correlation method was used to evaluate the associations between serum TMAO level and echocardiographic parameters. Value of p<0.05 was considered statistically significant in all analyses.

Results: Median serum TMAO was 524 (3588-8701) ng/mL. Echocardiography data: end-systolic left ventricular (LV) size is 38.2±0.6 mm, end-systolic LV volume – 62.0±4.4 ml, end-diastolic LV size – 55.8±1.3 mm, end-diastolic LV volume – 111.5±19.7 ml, ejection fraction (according to Simpson method) – 53.2±7.2%, shortening fraction – 28.9±4.4%, inter-ventricular septum thickness – 11.6±0.2 mm, left atrial wall thickness – 11.9±0.1 mm, LV mass index – 142.8±6.4 g/m², LV mass – 298.6±8.8 g, relative wall thickness – 0.43±0.3, number of patients with LV remodeling or hypertrophy – 98 (70%). LV diastolic functional parameters (n = 113): E = 0.69±0.2 m/s, A = 0.79±0.2 m/s, E/A (early (E) to late (A) ventricular filling ratio) – 0.89±0.2, deceleration time (DT) – 211±52 ms, number of patients with diastolic dysfunction – 104 (74.3%). Statistically significant correlation was found between TMAO concentration and end-diastolic LV volume (r = 0.315; p = 0.028), LV mass (r = 0.409; p = 0.011) and DT (r = 0.272; p = 0.041). TMAO levels in individuals with LV myocardial hypertrophy and diastolic dysfunction was significantly higher than without these abnormalities (Mann–Whitney U-test p = 0.037 and p = 0.043, correspondingly).

Conclusion: Our results suggest that elevated TMAO may contribute to cardiac remodeling in hemodialysis patients through the myocardial fibrosis.
and hypertrophy. The pathophysiological mechanisms of TMAO must be investigated further for a better understanding of its role in cardiovascular disease progression and to develop therapeutic interventions against uremic toxicity.

DIALYSIS WITHOUT SOCKS: DETECTION OF ULCERS AND AMPUTATIONS IN HEMODIALYSIS
Rocio Zamora González-Mariño, Rosa Sánchez Hernández, Laura Rodriguez-Osorio Jiménez and Beatriz Durá Gúrpide
Spain
Background and Aims: Dialysis patients are at high risk of ischemia and foot ulcers (14.4%) that frequently precede severe complications, including amputations (5.9%), hospitalizations, and mortality. Critical ischemia in this location accounts for 20% of the annual causes of death in hemodialysis, produces pain that is difficult to control and greatly reduces the quality of life. The aim of this work was to analyze the prevalence and factors associated with amputations in hemodialysis patients, and to assess the evolution after amputation.
Method: Carrying out a survey by email sent by the SEN (Spanish Society of Nephrology) and SOMANE (Madrid Society of Nephrology). Retrospective, cross-sectional, multicenter study. The survey sent to all hemodialysis units nationwide. Answered by 47 Centers. The exclusion criteria were oncological-traumatic amputations.
Results: • 50% of the Units have more than 70 patients
• 40% diabetics
• In most Units only 5% of dialysis patients have ulcers
• 70% of the centers answer that 5% have minor amputations and 5% have more serious amputations
• 63% of the centers answer that 5% of the patients have more than one amputation
• Risk factors for amputation: > 60 years, male, diabetes, smoking, hyperphosphatemia, malnutrition, ischemic heart disease
• In most Units <10% of amputees have been prosthettized
• Annual mortality in patients with chronic ischemia is 20%.
• Most of the Units use some diagnostic measure to screen for ulcers and/or chronic ischemia of lower limbs.
Conclusion: • Most dialysis units have patients with ulcers in the lower limbs that precede amputations, mortality and dependency.
• Having amputee patients in the Unit entails reorganization of work and an effort of human and material resources.

CHANGES ON LEFT VENTRICULAR FUNCTION AND CHARACTERISTICS ACCORDING TO THE DEGREE OF INTERDIALYTIC WEIGHT GAIN IN MAINTENANCE HEMODIALYSIS PATIENTS
Vasileios Anastasiou1, Maria Eleni Alexandrou2, Vasileios Kamperidis3, Stylianos Daios3, Konstantinos Tsilonis4, Marieta Theodorakopoulou2, Dimitrios Mousidis5, Foteini Iatriki5, George Giannakoulas1, Antonios Ziakas1 and Pantelis Sarafidis1
1Aristotle University of Thessaloniki, First Department of Cardiology, AHEPA Hospital, Thessaloniki, Greece and 2Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece
Background and Aims: Pronounced pulmonary circulation overloading has been observed in hemodialysis patients with higher fluid intake over the long interdialytic interval. This study aimed to evaluate the impact of the degree of fluid accumulation on left ventricular (LV) systolic and diastolic function and sizing characteristics.
Method: For the present analysis, 41 patients receiving maintenance hemodialysis thrice-weekly were divided by the recommended threshold of interdialytic-weight-gain corrected for dry weight (IDWG%) into a higher (> 4.5%) and a lower (< 4.5%) IDWG% group. All participants underwent 4 echocardiographic assessments at the start and the end of the 3-day and the 2-day interdialytic interval in a cross over design.
Results: Over the 3-day interval, significant increments in stroke volume (SV) were observed for both groups, but were more prominent in the higher IDWG% group (> 4.5%) (18.63±22.84% vs. < 4.5% 12.6±14.48mmHg, p = 0.04). Similarly, a greater increase in cardiac output was evidenced in patients with higher IDWG% over the 2-day interval (> 4.5% 1.31±1.38 vs. < 4.5% 0.36±2.08/l/m2, p = 0.012). With regards to diastolic function, a significant increase in E/A and E/E'm ratios was observed over the 3-day interval, but significant between-group differences in interdialytic changes were detected only for the E/A ratio (IDWG%> 4.5% 0.35±0.29 vs. < 4.5% 0.06±0.44, p = 0.035). Left atrial dimensions and LV mass were enlarged to a similar extent in both study-groups during both intervals.
Conclusion: Patients exceeding the recommended threshold of interdialytic fluid accumulation experience higher increases in SV and deterioration of preload-dependent indexes of diastolic function, particularly during the 3-day interval.
THE APOPROTEIN E (APOE) POLYMORPHISM AND PROPROTEIN CONVERTASE SUBTILISIN KEXIN 9 (PCSK9) IN HEMODIALYSIS (HD) PATIENTS

Kazuko Arita1, Hiroaki Oda2, Emi Kihara1, Katsutoshi Maeda2 and Takao Masaki3

1Oda Medical Clinic, Department of Dialysis, Hiroshima, Japan, 2Oda Medical Clinic, Department of Medicine, Hiroshima, Japan and 3Hiroshima University Hospital, Department of Nephrology and Dialysis, Hiroshima, Japan

Background and Aims: The apoE polymorphism and PCSK9 play an important role in lipid metabolism in healthy subjects, however, its role in HD patients remains unclear. We investigated the apoE polymorphism and PCSK9 as well as a lipid profile to clarify the impact of these factors on prognosis in HD patients. We also examined the association of cardiovascular (CVD) events in dead HD patients and clinical features.

Method: HD patients (n = 296, m/f; 207/89, DM; 152, age; 69.8±12.1, HD duration; 68.7±72.0 months) were subjected to this study. Written informed consent was obtained from each patient. Of these patients 85 subjects (m/f; 61/24, DM; 54, HD duration; 98.6±53.5 months) died during this study (from June 2011 to December 2022). Blood samples were collected to analyze the apoE genotypes by the invader method, serum concentrations of PCSK9-heterodimers and PCSK9-free fragments were measured using ELISA (BML Co. Ltd., Tokyo, Japan) and serum concentrations of apoA1, apoA2, apoB, apoC2, apoC3 and apoE were estimated using turbidimetric immunoassay. For the death cases we used multivariable logistic regression to control for the potentially confounding roles of type 2 diabetes mellitus (DM), apoE genotypes, and serum concentrations of PCSK9-heterodimers, PCSK9-free segments, apoA1, apoA2, apoB, apoC2, apoC3 and apoE. Survival probabilities in dead HD patients with CVD events according to the apoE genotypes were analyzed using the Kaplan-Meier curves. A p value less than 0.05 was considered statistically significant.

Results: The apoE allele frequencies in HD patients (n = 296) were ε2; 0.044, ε3; 0.870 and ε4; 0.086, whereas those in Japanese healthy controls were ε2; 0.036, ε3; 0.848 and ε4; 0.116 (Eto M., et al. Clin Genet 30:422-427, 1986.), demonstrating the ε2 frequency in HD patients had a trend to be higher than that in Japanese healthy controls (p = 0.096). The serum concentrations of PCSK9-heterodimers and PCSK9-free fragments in female HD patients (n = 89, 227.0±88.0 ng/ml and 41.9±19.1 ng/ml, respectively) were significantly higher than those in male HD patients (n = 207, 195.9±70.3 ng/ml, p = 0.001, and 35.8±15.3 ng/ml, p<0.004, respectively). The serum concentrations of PCSK9-heterodimers in HD patients with DM (n = 152); 213.8±77.6 ng/ml showed a trend to be higher than those in HD patients without DM (n = 144); 196.3±76.1 ng/ml (p = 0.05). The multivariable logistic regression analysis demonstrated the serum concentration of apoA1 and apoE polymorphism showed statistically significant impact on CVD events in dead HD patients (Table 1). The Kaplan-Meier analysis revealed the apoE polymorphism had a significant impact on the survival probability in dead HD patients with CVD events (Figure 1).

Conclusion: Recent studies reported the association between apoE2 and renal insufficiency in Japanese type2 DM. ApoE2 may be one of the attributable factors that lead to the end stage kidney disease. PCSK9-heterodimers bind to LDL cholesterol receptors (LDLr) and prevent LDLr from shuttling back to the surface and instead target it for degradation, however, PCSK9-free segments have weaker effects to bind to LDLr. Significance of higher serum concentrations of PCSK9-heterodimers and PCSK9-free fragments in female HD patients than male HD patients depends on future investigation. ApoE2 and the serum concentration of apoA1 contribute to CVD events. The prognosis of the HD patients with apoE2 or apoE4 were poorer than that with apoE3/3. The apoE polymorphism and PCSK9 may be key factors in lipid metabolism as well as prognosis of HD patients.

ASSOCIATION OF LOW BLOOD SELENIUM CONCENTRATIONS WITH POOR MUSCLE MASS AND STRENGTH IN JAPANESE HEMODIALYSIS PATIENTS

Kazuya Takasawa1, Chikako Takaeda2, Daiki Hayashi1, Masahiko Ochi1 and Norishi Ueda1

1Renal Division, Public Central Hospital of Matto Ishikawa, Hakusan, Japan; 2Dept. of Paediatrics, Public Central Hospital of Matto Ishikawa, Hakusan, Japan

Background and Aims: Trace elements play an important role in muscle function and metabolism. Little information is available of a role of trace elements for sarcopenia (i.e. low muscle mass and strength) in patients on hemodialysis (HD). We aimed to investigate association between blood levels of trace elements and nutritional status or sarcopenia in HD patients.

Method: This cross-sectional study including patients undergoing HD at our center was conducted in June 2022. Clinical/demographic data and blood samples were collected before HD sessions at start of the week. Blood levels of zinc (Zn), copper (Cu), selenium (Se), and manganese (Mn), serum levels of creatinine (Cr), total cholesterol (Tch) and albumin (Alb) and body mass index (BMI) were measured. Handgrip strength, gait speed and muscle mass (skeletal muscle index: SMI) measured using dual-energy x-ray absorptiometry were analyzed. Sarcopenia was assessed by Asian Working Group for Sarcopenia (AWGS) and nutritional status by the Nutritional Risk Japanese-Hemodialysis (NRI-JH), which was calculated based on serum Cr, Tch, Alb and BMI (PLoS One. 2019, 14(3):e0214524). Pearson’s correlation coefficient test, multivariate logistic regression analyses were performed to evaluate the relationship between trace elements and nutritional indicators.

Results: Eighty-two patients (56 males and 26 females) were included, with a median dialysis vintage of 9.1±7.1 years and an average age of 68.7±12.2 years. Severe malnourished patients as defined by the NRI-JH and sarcopenia defined by AWGS accounted for 6.0% and 37.8% of enrolled patients, respectively. In all patients, the mean levels of Zn, Cu, Se, and Mn (in μg/dL) were 65.8±11.3, 84.1±22.2, 9.2±1.5 and 1.2±0.6, respectively. The levels of Zn, Cu, Se and Mn were lower than normal levels in 72 cases (87.8%), 18 cases (22%), 57 cases (69.5%), and 13 cases (15.9%), respectively. There was an inverse correlation were lower than normal levels in 72 cases (87.8%), 18 cases (22%), 57 cases (69.5%), and 13 cases (15.9%), respectively. There was an inverse correlation between the levels of Se and age (r = -0.298, p = 0.003) but not HD vintage. No significant correlation was found between the NRI-JH scores and blood levels of trace elements in all patients. Blood trace elements have been shown to be affected by gender. Thus, we next examined whether blood levels of trace elements and the relationship between blood trace elements and SMI and strength are different between male and female HD patients.

The levels of Zn and Mn did not differ between males and females. The levels of Cu were lower in males (79.8±19.3 μg/dL) than females (93.0±25.4 μg/dL, p = 0.025). In contrast, the levels of Se were higher in males (9.5±1.5 μg/dL) than females (8.6±1.2 μg/dL, p = 0.0017). The multivariate logistic regression showed that higher blood levels of Zn and Se and lower Mn levels were independently associated with grip strength (p < 0.01) but not gait speed in males. There was a significant positive correlation between Se and SMI (r = 0.305, p = 0.02) but not gait speed in males. In females, grip strength (r = 0.39, p = 0.048) and gait speed (r = 0.66, p < 0.001) were independently associated with the Se levels but not Zn, Cu and Mn. However, there was no association between SMI and blood levels of Se, Zn and Mn in females.

Conclusion: Blood levels of Se were independently associated with grip strength and SMI in male HD patients. In female HD patients, the levels of Se were positively correlated with grip power and gait speed. Se may be implicated in muscle function and metabolism in HD patients.

TIMING OF ATRIAL FIBRILLATION OCCURRENCE IN HEMODIALYSIS PATIENTS WITH CARDIAC IMPLANTABLE ELECTRICAL DEVICES

Hirota Kida1, Yoshitaka Kikuchi1, Nobuhiro Sato1, Masato Kawasaki2, Tetsuya Watanabe3 and Takahisa Yamada2

1Osaka general medical center, Clinical engineering, Osaka, Japan and 2Osaka general medical center, Cardiology, Osaka, Japan

Background and Aims: Hemodialysis (HD) patients has the high prevalence of atrial fibrillation (AF), and the procedure of HD itself might be related to risk factors for the onset of AF. On the other hand, cardiac implantable electronic devices (CIEDs), such as pacemaker, implantable cardioverter-defibrillators (ICD) and cardiac resynchronization therapy (CRT) have the function for arrhythmia detection. However, in HD patients with CIEDs, there are no studies that observe AF over long periods of time. The aim of this study is to investigate AF onset and duration of HD patients with AF, using the AF detection and memory function of CIEDs.

Method: Consecutive HD patients who were newly implanted with CIEDs between January 2008 and December 2021 were retrospectively analyzed in this study. Patients with chronic AF, with leadless pacemaker and without post-implantation follow-up were excluded from this study. Subclinical AF was defined from previous studies as atrial tachyarrhythmia lasting more than 6 minutes in memories of devices. The primary endpoint of this study was the subclinical AF within one year after CIESDs implantation. HD week was defined as follows according to HD schedule, HD1: Monday or Tuesday; HD1+1: Tuesday or Wednesday; HD2 Wednesday or Thursday; HD2+1 Thursday or Friday; HD3 Friday or Saturday; HD3+1 as Saturday or Sunday; and HD3+2 Sunday or Monday. We examined the association between onset and duration of AF and HD.

Results: Fifty-four HD patients who had been implanted with CIEDs (pacemaker: 37, ICD: 6, CRT: 11) were enrolled in the study. During a mean follow-up period of 352 ± 36 days, in 26 of 54 (48.1%) patients, 124 subclinical AF events (1-8 events / patient) were detected with CIEDs. History of clinical AF (46.2% vs 7.1%, p = 0.003) and sick sinus syndrome (53.8% vs 10.7%, p = 0.005) were significantly higher in HD patients with than without subclinical AF. The frequency of subclinical AF onset on HD day was approximately twice higher than on non-HD day (83 episodes [27.7 episodes/day] vs 41 episodes [10.3 episodes/day]), and subclinical AF onset on HD1 day was most frequent among a week (Figure 1a). Limited to HD day, subclinical AF events were observed more frequently especially during HD (30/86 events: 34.9%) and five hours after HD (28/86 events: 32.6%) (Fig. 1-b). Subclinical AF duration was significantly longer during HD compared to non-HD time (216 [90, 1066] min vs 96 [30, 418] min, p = 0.008).

Conclusion: In HD patients, subclinical AF occurred more frequently on HD day, especially during HD and several hours after HD. Careful observation during and after HD might help early diagnosis of clinical AF.
Background and Aims: In contrast to portable whole-body bioimpedance, which estimates fluid status at a single point in time, thoracic bioimpedance applied by a wearable device could enable continuous measurements. However, clinical experience with thoracic bioimpedance in patients in dialysis is still limited. The aim of this study is to test the reproducibility of whole-body and thoracic bioimpedance measurements and to compare their association with hemodynamic changes during hemodialysis.

Method: In total, 54 patients were included in this cross-sectional observational study. Whole-body resistance at 5kHz, thoracic resistance at 8kHz, systolic blood pressure and ultrafiltration volume were measured. All measurements were taken at pre- and end-dialysis during two consecutive sessions. Data were approached by mixed-modelling and Spearman correlation analysis.
Figure 1: Subject-specific plot showing the pre-to-end changes in whole-body (A) and thoracic (B) bioimpedance for session 1 and 2, representing the intraclass correlation (ICC).

Table 1: Spearman correlation coefficient between hemodynamic parameters (ultrafiltration volume and pre-to-end dialysis changes in blood pressure) and changes in the resistance component of whole-body and thoracic bioimpedance. All p-values were < .001.

</thead>
<tbody>
<tr>
<td></td>
<td>Δ whole-body</td>
<td>Δ thoracic</td>
<td>Δ whole-body</td>
<td>Δ thoracic</td>
</tr>
</tbody>
</table>

Results: Intraclass correlation of pre- to end-dialysis changes in whole-body and thoracic resistance between the first and second session was .71 [.58 – .8] and .72 [.6 – .81] respectively (Fig. 1). The correlation between ultrafiltration volume and relative whole-body and thoracic resistance was respectively .94 [.91 – .96], p < .001 and .76 [.66 – .83], p < .001 in the first session and .95 [.93 – .97], p < .001 and .75 [.65 – .82], p < .001 in the second session (Table 1). Changes in systolic blood pressure negatively correlated to both bioimpedance techniques (whole-body resistance in the first session: -.37 [-.19 – -.53], p < .001; in the second session: -.37 [-.19 – -.53], p < .001; thoracic resistance in the first session -.45 [-.28 – -.59], p < .001; in the second session -.39 [-.22 – -.54], p < .001) (Table 1).

Conclusion: Bioimpedance signals from both devices were moderately reproducible between two dialysis sessions. Whereas the relation between changes in ultrafiltration volume and relative whole-body and thoracic blood pressure was at least comparable for thoracic measurements. Thoracic bioimpedance measurements by a wearable device may serve as an interesting alternative to whole-body measurements for continuous hemodynamic monitoring during hemodialysis.

INCREASED RV PRESSURE AS A PREDICTOR OF ACUTE DECOMPENSATED HF IN ESRD PATIENTS ON MAINTENANCE HD
Ye Na Kim1,2, Byung Hwa Park1,2, Ho Sik Shin1,2, Yeonsoon Jung1,2, and Hark Rim1,2

1Renal Division, Department of Internal Medicine, Gospel Hospital, Kosin University College of Medicine, Busan, Rep. of South Korea
2Transplantation Research Institute, Kosin University College of Medicine, Busan, Rep. of South Korea

Background and Aims: Many patients with end-stage renal disease (ESRD) on hemodialysis (HD) have reduced vascular compliance and are likely to develop heart failure (HF). This study aimed to determine the factors associated with acute decompensation events among ESRD patients undergoing HD.

Methods: We retrospectively investigated ESRD patients on HD using a medical record review. We divided the patients into those admitted to hospital due to acute decompensated heart failure (ADHF) and those who were not. We compared the medical histories, electrocardiograms, and echocardiographic and laboratory data between the two groups. The cut-off value of the TR jet velocity for predicting an ADHF with corresponding sensitivity and specificity was estimated using a receiving operator characteristic (ROC) curve analysis. A p value < 0.05 was considered to indicate statistical significance.

Results: Of the 188 ESRD patients on HD, 87 were excluded, and 101 were enrolled (mean age: 63.7 years; 52.1% male). Thirty patients (29.7%) were admitted due to ADHF. These patients exhibited similar left ventricular ejection fraction (LVEF), left ventricular (LV) mass index, and E/E′ values compared to the non-ADHF group. However, the ADHF group exhibited significantly higher tricuspid regurgitation (TR) jet velocity (2.9±0.6 vs. 2.5±0.4 m/s; p = 0.004) and right ventricular systolic pressure (RVSP) (43.5±17.2 vs. 34.2±9.9 mmHg; p = 0.009) than the non-ADHF group, respectively. A multivariate logistic regression analysis demonstrated that the TR jet velocity (odds ratio, 8.356; 95% confidence interval, 1.806–38.658; p = 0.007) was an independent predictor of ADHF after adjusting for age and sex, while the LVEF and E/E′ were not.
Conclusions: Our data showed that an increased TR jet velocity was an independent predictor of ADHF events in ESRD patients on HD, but the LVEF and E/E' were not.

ASSOCIATIONS BETWEEN SARCOPENIA, CARDIOVASCULAR HEALTH AND HABITUAL PHYSICAL ACTIVITY IN PATIENTS ON HAEMODIALYSIS
Noemi Vadaszy1, Sherna Adenwalla2, Roseanne E Billany3, Daniel March2, Hannah Young3, Alice Smith1, Matthew Graham-Brown2,4 and James Burton2,4
1University of Leicester, Leicester Kidney Lifestyle Team, Department of Population Health Sciences, Leicester, United Kingdom, 2University of Leicester, Department of Cardiovascular Sciences, Leicester, United Kingdom, 3University of Leicester, Department of Population Health Sciences, Leicester, United Kingdom and 4University Hospitals Leicester, John Walls Renal Unit, Leicester, United Kingdom

Background and Aims: Patients with end-stage kidney disease (ESKD) show skeletal muscle abnormalities such as sarcopenia (presence of low muscle mass, strength, and physical performance). Severe sarcopenia and its components are associated with poor clinical outcomes, decreased quality of life (QoL), and mortality. The direction of the relationships between sarcopenia and cardiovascular disease are less clear as are the impact of exercise interventions in patients with severe sarcopenia.

Method: This is a post-hoc analysis of the CYCLE-HD study, which was a randomised controlled trial assessing the effects of a 6-month structured intradialytic cycling intervention on cardiovascular health in those on haemodialysis. Presence of sarcopenia was established using the European Working Group of Sarcopenia in Older People (EWGSOP) definition. A cut off of <17.5 kg/m² in men and <14.5 kg/m² in women were used for fat free mass to establish muscle quantity using bioimpedance. The cut off of 15 seconds on the sit to stand 5 tests was used to establish muscle strength and a score of ≤8 on the short physical performance battery was used to assess physical performance. If all three criteria were met, severe sarcopenia was confirmed. Accelerometry assessed habitual physical activity (PA) and the general practice physical activity questionnaire assessed self-reported PA.

Results: 130 patients (57 [±15] years, 95 [73.08%] male) were included in the analysis of whom 65 patients underwent the intradialytic cycling intervention. 31 (23.85%) patients had severe sarcopenia. 107 (82.31%) had low muscle mass, 92 (70.77%) had low strength, and 48 (36.92%) had low physical performance. Severe sarcopenia was a significant predictor for self-reported PA status (p = .042, PseudoR² = 0.043) at baseline but not for any other outcomes. However, low muscle mass was a significant predictor for LV mass (p = .014, R² = 0.04, β = -6.76). Low muscle strength was a significant predictor for higher pulse wave velocity (p = .010, R² = 0.056, B = 2.57) and global native T1 (p = .001, R² = 0.091, B = 26.79). Low fat mass (p = .005, R² = 0.07, B = -2198.63) and physical performance were significant predictors for mean steps (p < .001, R² = 0.12, B = -209.16). Baseline severe sarcopenia or its components were not predictors for cardiovascular or habitual PA changes following intradialytic exercise.

Conclusion: Severe sarcopenia was present in nearly quarter of the participants, but the majority showed at least one muscle health related abnormality (low muscle mass, strength or physical performance). These markers of sarcopenia showed associations with habitual PA and structural markers of cardiovascular disease. However, the presence of sarcopenia may not limit the benefits offered by intradialytic exercise. Patients with sarcopenic traits should be encouraged to participate in appropriate interventions to improve health and wellbeing.

GERIATRIC NUTRITIONAL RISK INDEX AND EARLY MORTALITY IN INCIDENT HEMODIALYSIS PATIENTS
Ajin Cho1, Ji Hyeon Park2, Do Hyoung Kim1 and Hyun Kyung Kim1
1846
Background and Aims: The nutrition status at initiation of hemodialysis (HD) might be associated with early mortality in patients undergoing HD. The Geriatric Nutritional Risk Index (GNRI) is a simple and useful nutritional screening method, and this study aimed to investigate the association between the initial GNRI and mortality in incident patients in the first year after initiation of HD.

Method: A nationwide retrospective cohort study was conducted based on the Korean Renal Data System database. Patients who underwent HD from January 2016 to December 2019 and were eligible for GNRI screening were included. They were followed up until the end of 2020 or study departure. Patients were compared by GNRI quartiles. The primary outcome was all-cause mortality, and a Cox proportional hazard model was used to analyze the association between GNRI and mortality. Accuracy comparison of the models including GNRI or body mass index (BMI) were analyzed by Receiver-operating characteristic curves, and the differences were tested by the DeLong test.

Results: A total of 10,545 patients were included, and the mean age was 63.9 ± 3.7 years. Patients with GNRI < 91.4 at the initiation of HD were older, were more often female, and a lower proportion of them had arteriovenous fistula for vascular access. A high GNRI value at the initiation of HD was associated with low all-cause mortality (hazard ratio (HR) 0.93; 95% confidence interval (95%CI) 0.92–0.94; p < 0.001). The group with GNRI < 91.4 (Quartile 1) showed the lowest survival in the first year after HD initiation (p < 0.001). Quartile 1 and Quartile 2 (91.4 – 96.8) showed a significantly increased all-cause mortality (HR 3.64; 95%CI 2.60 – 5.10; p < 0.001 for Quartile 1 and HR 1.55; 95% CI 1.09 – 2.22; p = 0.015 for Quartile 2) in comparison with Quartile 4 (101.4 – 129.6). Risk of cardiovascular mortality was high in the Quartile 1 (vs. Quartile 4; HR 3.16; 95%CI 1.94 – 5.13; p < 0.001). In addition, Area Under the ROC Curve (AUC) values for all-cause mortality were 79.1 (95%CI 77.1–81.2) and 75.9 (95%CI 73.8–78.1) for GNRI and BMI, respectively, and the differences of AUCs were significant (p < 0.001).

Conclusion: This study demonstrates that low GNRI levels are associated with all-cause and cardiovascular mortality in HD patients during the early ESRD period. These findings suggest that GNRI is a significant predictor of mortality in these patients.

ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY, PHYSICAL FUNCTION AND BONE METABOLISM MARKERS IN HAEMODIALYSIS PATIENTS: A PRELIMINARY CROSS-SECTIONAL STUDY

Diogo Vaz Leal1, Daniela Cardoso1, Pedro Martins1,2, Manuel Anibal A. Ferreira1,2, Luke Baker3, Alice Smith4 and João Viana1

1CIDESD - Centro de Investigação em Desporto, Saúde e Desenvolvimento Humano, University of Maia, Maia, Portugal, 2NephroCare Portugal SA, Lisboa, Portugal, 3Nova Medical School, Lisboa, Portugal and 4Leicester Kidney Lifestyle Team, Department of Health Sciences, University of Leicester, Leicester, United Kingdom

Background and Aims: Chronic kidney disease (CKD) patients suffering from end-stage renal disease often undergo dialysis treatment. Haemodialysis (HD) patients spend most of their time in sedentary behaviour, having therefore poor physical function, as well as frequently develop mineral and bone disorders due to disease-induced systemic alterations such as abnormally high bone resorption rates exceeding bone formation. In healthy individuals, there is considerable evidence highlighting the associations between physical activity (PA), physical function (PF), and bone health. In HD patients, however, evidence on the association between these variables is still scarce. Therefore, the present preliminary study seeks to characterise HD patients in terms of their PA and PF and to identify any associations between these and markers of bone metabolism.

Method: A cross-sectional design study recruited 88 adult HD patients (males: 68%, age: 66±14 years, dialysis vintage: 42.5± months) from three clinics in Portugal. Resting blood samples were collected from the patients’ fistula at the start of the second dialysis session of the week. Plasma levels of the bone markers tartrate-resistant acid phosphatase 5b (TRAP-5b) (IDS, Tyne and Wear, UK), and sclerostin (SOST) and receptor activator of nuclear factor kappa-B ligand (RANKL) (Biomedica Immunoassays, Vienna, Austria) were measured by commercially-available enzyme-linked immunosorbent assays (ELISA), and osteocalcin (OCN) (Biogen, Madrid, Spain) and osteoprotegerin (OPG) (R&D Systems, Abingdon, UK) via DuoSet ELISA kits. PF was assessed by completing the Sit to Stand 60 (STS60), the STSS, the Incremental Shuttle Walk Test (ISWT), the Timed Up and Go (TUG), and handgrip strength (HGS). All participants wore tri-axial accelerometers continuously for a week to estimate PA levels.

Results: Accelerometers were worn for an average 13±2h/day and data showed that 81±11% of the time was spent in sedentary behaviour, and 18±10% in light PA. Associations between PA, PF and markers of bone metabolism are described in Table 1. Weekly sedentary time was associated with reduced agility (TUG), muscle endurance (STS60, ISWT), and muscle power and strength (STSS), whereas light PA levels were associated with an increment in overall PF. Also, light PA levels were associated with decreased TRAP-5b and OPG, but elevated circulating OCN, supporting a potential modulatory effect of PA on bone turnover. Decreased overall PF were associated with increased concentrations of OPG, with muscle endurance and strength associated with increased circulating TRAP-5b.

Conclusion: Our data suggests that sedentarism may be responsible for a reduced PF, which in turn was associated with increased inhibition of osteoclastogenesis via OPG activity. Yet, a rather small increase in PA levels may lead to PF gains and could be a trigger for OCN activity and TRAP-5b inhibition. Therefore, increasing PA levels may modulate bone metabolism through mechanisms that favor bone formation.

OSTEOASARCOPENIA AMONG PATIENTS UNDERGOING HEMODIALYSIS IS RELATED WITH MORTALITY

Ting Xiang, Li Zhou and Ping Fu
West China Hospital, Sichuan University, Kidney Research Institute, Division of Nephrology, chengdu, P.R.China

Background and Aims: Sarcopenia and osteoporosis are closely interconnected and associated with adverse health outcomes. Osteosarcopenia means the concurrent presence of the two conditions and has rarely been reported in hemodialysis patients. Whether hemodialysis patients with osteosarcopenia are at greater risk of mortality than those with either condition alone remains unknown. The aim of this study was to explore the prevalence of sarcopenia and its association with osteoporosis and to determine its impact on survival risk in hemodialysis patients.

Method: A total of 209 adults undergoing hemodialysis were enrolled from the dialysis center in the West China Hospital of Sichuan University. Muscle mass, handgrip strength, bone mineral density (BMD), and biochemical parameters were assessed. All deaths were recorded during a follow-up of 34.8 ± 13.8 months.

Results: Seventy-eight patients were diagnosed with sarcopenia with a prevalence of 37.3%. After adjustment for potential confounders, age (OR = 1.094, P <0.001), female (OR = 3.44, P = 0.005), diabetes (OR = 3.756, P = 0.008), CRP (OR = 1.09, P = 0.015), serum magnesium (OR = 0.06, P = 0.042) and BMI (OR = 0.701, P <0.001) were independently associated with sarcopenia (Table 1). Among the 209 patients, 103 patients completed the BMD assessment. The prevalence of osteosarcopenia was 22.3%, while 20.4% of participants had sarcopenia alone and 12.6% had osteoporosis alone. The respective proportions of patients who died were 10.9% for nonsarcopenia/nonosteoporosis, 15.4% for osteoporosis alone, 47.6% for sarcopenia alone, and 47.8% for osteosarcopenia. Cox regression analysis showed that osteosarcopenia was independently associated with all-cause mortality (HR = 3.541, 95% CI: 1.035-12.117), while osteoporosis alone and sarcopenia alone were not (Table 2).

Conclusion: Patients undergoing hemodialysis had a high incidence of sarcopenia and osteosarcopenia, muscle mass and strength showed a significant association with BMD, and osteosarcopenia might have a powerful impact on mortality in those patients.

INCIDENCE AND TYPES OF GASTROINTESTINAL BLEEDING EPISODES IN DIALYSIS

#3662 FREQUENCY OF INR TESTING IN HEMODIALYSIS PATIENTS ON VITAMIN K ANTAGONISTS: A RETROSPECTIVE STUDY

Mabel Aoun, Juliette Baleynaud, Beatrice Champiaux-Dechamps, Marion Gritti, Lionel Le Mouellic and Gabrielle Duneau

AUB Santé, Nephrology, Lorient, France

Background and Aims: Despite the rising of direct oral anticoagulant agents’ use in the general population, vitamin K antagonists (VKA) are still used in hemodialysis (HD) French patients with atrial fibrillation. These HD patients on VKA have also poor levels of time in therapeutic range. It is recommended generally to follow patients with monthly INR, however there is lack of such evidence in HD. This study aims to analyze the frequency of INR testing needed in HD patients.

Method: This is a retrospective study of all patients treated with VKA in three French dialysis units between 1st January and 31st December 2022. Patients are followed with weekly INR. Variables collected included over twelve months the number of INR tests, their percentage within target, above target and below target, and number of VKA dose adjustment. Bleedings, transfusions, thrombotic events and antibiotic use were recorded. Linear regression analysis evaluated factors associated with number of VKA dose adjustment per year. This study was conducted in concordance with the Declaration of Helsinki 1975.

Results: Out of 160 HD patients, 45 (28.1%) were on VKA for paroxysmal or chronic atrial fibrillation. Their characteristics are summarized in Table 1. A total of 2609 INR tests were performed over a year with a mean of 57.9±18.8 per patient. The median number of VKA dose adjustment per year was 11 (8, 13). A significant correlation was found between the number of antibiotics and number of VKA dose adjustment (Spearman Rho = 0.360, p = 0.015). In univariate regression analysis, factors associated with higher numbers of dose adjustment were diabetes, sevelamer and blood flow (Table 2). Bleeding was not significantly different between those with high versus low VKA dose adjustment.

Conclusion: In this study, 22% of tests led to VKA dose adjustment. Patients with diabetes, on sevelamer, treated with antibiotics and with lower serum albumin needed frequent INR testing more than once monthly. These results could be helpful in contexts with limited resources.

**CHA2DS2-VASc score as a predictor of cardiovascular morbidity and mortality and all-cause mortality in patients undergoing chronic hemodialysis**

Tijana Azasevac1,2, Violeta Knezević1,2, Marko Atanasković1, Gordana Strazmester Majstorović1,2, Bojana Ljubicic4,5 and Lada Petrović1,2

1University of Novi Sad, Faculty of Medicine Novi Sad, Novi Sad, Serbia, 2Clinical Center of Vojvodina, Clinic for Nephrology and Clinical Immunology, Novi Sad, Serbia and 4Clinical Center of Vojvodina, Department of Emergency Internal Medicine, Novi Sad, Serbia

**Background and Aims:** End stage kidney disease (ESKD) is a well-recognized risk factor for cardiovascular and all-cause mortality. The recognition of high-risk patients could lead to a different approach and better treatment of the patients undergoing chronic hemodialysis. The CHA2DS2-VASc score was originally used to predict the annual cerebral infarction in patients with atrial fibrillation. However, it is also a useful predictor of outcome in other cardiovascular conditions, independent of atrial fibrillation. The aim of this study was to assess whether CHA2DS2-VASc score may be used as a risk stratification tool for ESKD patients undergoing chronic hemodialysis.

**Method:** We performed a single-centre retrospective study of 201 adult patients undergoing chronic hemodialysis in our institution from January
2020 to December 2022 with a follow up period of at least 12 months. CHA2DS2-VASc score was calculated for each patient according to the data from January 1st 2020 or at the moment of haemodialysis initiation, if the date of the first dialysis was after that date. Patients were followed until January 1st 2023, or until their death or kidney transplantation. Demographic, clinical and laboratory parameters, as well as used medications, were analyzed. Occurrences of myocardial infarction, stroke, revascularization procedure, new hospitalization for heart failure, cardiovascular death, or all-cause mortality were recorded for each patient. Patients were divided into three groups according to their CHA2DS2-VASc score: low (0-2), intermediate (3), high (≥4).

Results: The group with a low CHA2DS2-VASc score (0-2)-group I included 80 (39.8%) patients, the group with an intermediate score (3)-group II included 62 (30.8%) patients, and the group with a high score (≥4)-group III included 59 (29.4%) patients. Mean follow-up time was 918 ± 317 days. Patients in the group with higher CHA2DS2-VASc scores (group III) were predominantly females (group III 62.7% vs group II 45.2% vs group I 23.8%; p < 0.01) and older (group III 74.9±7.4 years vs group II 68.7±7.6 years vs group I 55.2±11.3 years; p < 0.01). They also had a higher prevalence of diabetes mellitus (group III 61.0% vs group II 45.2% vs group I 21.3%; p < 0.01) and vascular disease (group III 30.5% vs group II 12.9% vs group I 3.8%; p < 0.01). Major adverse cardiovascular events (MACE) were significantly more prevalent in patients with higher CHA2DS2-VASc scores (p < 0.01) (Fig. 1). All-cause mortality was significantly higher in group II and group III, compared to the group I (p<0.05) (Fig. 1). The patients in the group II and group III had a significantly higher risk of all-cause mortality and cardiovascular mortality than the patients in the group I (p<0.05) (Fig. 2). Using a group I as a reference, group II and group III had a higher risk of all-cause mortality (HR 1.92, 95% CI 1.01-3.66, p<0.05 and HR 2.47, 95% CI 1.32- 4.63, p<0.01, respectively) and cardiovascular mortality (HR 3.56, 95% CI 1.18-9.53, p<0.05 and HR 6.58, 95% CI 2.48-17.46, p<0.001, respectively). Each one-point increase in CHA2DS2-VASc score was associated with a two-fold increased risk of MACE and a 47% increased risk of all-cause mortality.

Conclusion: The CHA2DS2-VASc score is a simple, easy-to-calculate tool that can be used to identify high-risk ESKD patients enduring chronic hemodialysis. Clinical utilization of the CHA2DS2-VASc score in risk stratification of these patients could intensify patient care and lead to better outcomes by reducing cardiovascular morbidity and mortality and all-cause mortality.

#4279
ATTENTION AND EMOTIONAL COGNITIVE DEFICITS IN HEMODIALYSIS PATIENTS WITH NORMAL NEUROCOGNITIVE SCREENING TEST RESULTS: AN EGYPTIAN TRIPLE CENTER STUDY
Ahmed Awad1, Adel L Abdelsalam2, Ibtihal Ibrahim3 and Emad Samaan4
1Nephrology Department, Mansoura Health Insurance Hospital, Egypt, 2Mansoura Faculty of Medicine, Internal Medicine, Mansoura, Egypt, 3Mansoura Faculty of Medicine, Psychiatry, Mansoura, Egypt and 4Mansoura Nephrology and Dialysis Unit, Faculty of Medicine, Mansoura University, Mansoura, Egypt

Background and Aims: Cognitive impairment (CI) is common in hemodialysis (HD) patients. St. Louis University Mental Status (SLUMS) examination is a traditional cognitive assessment method that relies on a pen-and-paper format. SLUMS test is known to be one of the most sensitive tests to detect early CI. Its questions cover many functions, including memory, attention, orientation, and overall executive function. This study aimed to compare its results with computerized neurocognitive battery assessment for attention and emotional orientation functions.

Method: One hundred twenty HD patients from three different in-hospital HD centers in Dakhla governorate, Egypt, were subjected to the 10-minute Arabic-validated version of the SLUMS test for early CI. Its questions cover many functions, including memory, attention, orientation, and overall executive function. This study aimed to compare its results with computerized neurocognitive battery assessment for attention and emotional orientation functions.

Results: Of the 120 SLUMS-tested patients, 50 patients (41.6%) had no CI, 43 with mild to moderate CI (36%), and 27 with severe CI (22.4%). The classified 50 HD patients with no CI results within the computerized neurocognitive battery assessment revealed significantly reduced scores than
matched healthy controls in the number of true positive answers of continuous number performance test for attention (90.46±26.61 vs. 109.15±14.56, respectively, p < 0.001), emotion recognition correct answers (29.44±5.54 vs. 31.41±4.65, respectively, p 0.02), emotional recognition response times by m.seconds (3482.76±2907.62 vs. 2907.62±732.98, respectively, p < 0.001), and correct answers of emotion differentiation test (19.82±5.88 vs. 23.77±3.63, respectively, p <0.001). HD patients' age was the only clinical correlate to emotional recognition and differentiation accurateness (rho = 0.442, p <0.001 and rho = 0.3, p 0.02, respectively).

**Conclusion:** Early detection of CI in HD patients is an important target to improve the patient's quality of life and functionality. The complete dependence on the known simple screening assessment may miss a significant portion of the early-affected personnel.

**IMPACT OF MAGNESIUM ASPARATE AND L-CARNITINE ON INFLAMMATION, INSULIN RESISTANCE AND ATHEROSCLEROSIS PROGRESSION IN DIABETIC HEMODIALYSIS PATIENTS**

Oleksandr Susla, Mykola Shved, Zoriana Litovkina and Bohdan Susla

I. Horbachevsky Ternopil National Medical University, Ternopil, Ukraine

**Background and Aims:** The development of new pathogenetic treatment programs to reduce cardiovascular risk in diabetic patients with end-stage kidney disease is an important task of modern nephrology. In these conditions, considering the essential role of magnesium and L-carnitine deficiency in the mechanisms (via endothelial and metabolic disorders) of cardiovascular diseases, we evaluated the effect of the combined use of magnesium aspartate and L-carnitine on inflammation, insulin resistance and the atherosclerosis progression of carotid arteries in type 2 diabetic hemodialysis (HD) patients.

**Method:** 42 type 2 diabetic HD patients were included in this prospective cohort study (male, 26; age, 59.5±0.7 years; HD duration, 31.2±4.6 month; diabetes mellitus duration, 174.6±7.8 month). Depending on the treatment programme, patients were divided into two groups: the 1st (main) group (n = 22) in addition to basic treatment (hypoglycemic, antihypertensive therapy, correction of anemia, hyperparathyroidism, hyperphosphatemia) was treated by combination of magnesium aspartate (0.5 g/day orally) and L-carnitine (1 g/day parenterally after each HD session (three times weekly); the 2nd (comparison) group (n = 20) was only on the standard therapy. Complex treatment lasted 12-months; administration of L-carnitine was performed continuously throughout the year, while magnesium aspartate – by three 2-months’ courses per year. Serum content of tumor necrosis factor alpha (TNF-α), C-reactive protein (CRP) and fibrinogen as inflammatory biomarkers were determined. The homoeostasis model of assessment-insulin resistance (HOMA-IR) as an index of insulin resistance was estimated. Common carotid artery intima-media thickness (CCA IMT) as an index of the atherosclerosis severity was measured by ultrasound. Data are expressed as means ± SEM. Wilcoxon T-test was used for comparison of the dependent variables, Mann-Whitney U-test – for independent ones.

**Results:** In diabetic HD patients undergoing complex treatment with a combination of magnesium aspartate and L-carnitine after 12 months of observation CCA IMT did not change (0.88 ± 0.05 vs. 0.88 ± 0.05 mm; Z = 0.09, p = 0.925), while a significant increase (by 9.1%) in the CCA IMT was determined in subjects, who were on basic therapy (0.98 ± 0.04 vs. 1.07 ± 0.04 mm; Z = 2.27, p = 0.023). In addition, after 12 months of treatment, the indicated index between 1st and 2nd groups differed (p = 0.006). By the end of follow-up, the TNF-α, CRP and fibrinogen contents in patients who were on modified therapy were 44.7, 56.4 and 78.2% from baseline, a similar indices in patients receiving standard treatment – 70.7, 77.3 and 88.8% respectively, and after one year the main group and the comparison group on the serum concentrations of TNF-α (p = 0.089), CRP (p = 0.030) and fibrinogen (p = 0.026) differed. Magnesium aspartate and L-carnitine supplementation significantly improve HOMA-IR, and after 12 months of observation, the indicated index in the 2nd group exceeded (p = 0.003) that in the 1st one (Table 1).

**Conclusion:** (1) The combined use of magnesium aspartate and L-carnitine, in addition to the basic 12-month treatment, prevents the atherosclerosis progression of CCA, provides an effective reduction of the activity of chronic inflammation, improves insulin resistance in type 2 diabetic HD patients. (2) Long-term modified treatment may reduce the cardiovascular risk in these subjects.

**Table 1: Indices of chronic inflammation and insulin resistance in type 2 diabetic HD patients on the background of different treatment programs.**

IMPACT OF MINERAL BONE PARAMETERS IN COGNITIVE IMPAIRMENT IN DIALYSIS PATIENTS

Merita Rojoi (Molla), Larisa Shehaj, Nereida Zeneli and Saimir Seferi
University Hospital Center Mother Theresa, Department of Nephrology, Tirana, Albania

Background and Aims: Mineral bone disease and cognitive impairment are related diseases in the CKD population. Vascular calcification, a marker of MBD, may play a role in the early detection of cognitive decline. This study aims to identify a relationship between MBD biomarkers and cognitive function and to identify dialysis patients with a high risk of dementia.

Method: A total of 98 patients participated in this cross-sectional study, with 63 on hemodialysis and 35 on peritoneal dialysis. They underwent the Montreal Cognitive Assessment (MoCA) questionnaire, which categorized mild, moderate, severe, and very severe based on scoring. PTH, P, Ca, ALP, and Mg serum concentrations and vascular calcification were measured as MBD biomarkers. The Adraga score was applied to graphs of the hands and pelvis to evaluate vascular calcification.

Results: The mean MoCA score was 20.28 ± 5.8. Based on the responses, it was concluded that 70% of HD patients had mild cognitive impairment, compared to 63% of PD patients. According to the descriptive data, patients whose underlying CKD was caused by nephroangiosclerosis had the lowest MoCA test results compared to other groups (p < 0.001). The degree of calcification was observed to have an adverse effect on cognitive performance in both groups (p < 0.012); the high Adraga score contributed to the decline in the MoCA test score. In multivariate logistic regression analysis, hypercalcemia and hypomagnesemia were independent variables for cognitive function impairment (p = 0.006 and p = 0.004, respectively). The serum concentration of PTH (p = 0.008) and ALP (p = 0.001) were found to be risk factors for HD patients during the evaluation of the MoCA test in each of the groups.

Conclusion: Vascular calcifications are considered a risk factor for cognitive impairment. In our study, vascular calcification risk is positively impacted by indicators such as hyperparathyroidism, hypercalcemia, high levels of ALP, and hypomagnesemia. Recently research has demonstrated the effectiveness of magnesium as a vascular calcification inhibitor. So, nephrologists should be more careful in monitoring levels of MBD biomarkers.

ASSOCIATION BETWEEN PHYSICAL ACTIVITY LEVEL AND A HISTORY OF FALLS IN PATIENTS ON HEMODIALYSIS

Leda Lucinda1,2, Luciana de Jesus1, Bárbara Alvarenga1, Abner de Castro1, Kéllner Avila1, Rodrigo Garcia1, Cristina Oliveira1, Bruno Pinheiro1 and Maycon Moura Reboredo1
1Federal University of Juiz de Fora, Juiz de Fora, Brazil and 2Barbacena School of Medicine, Barbacena, Brazil

Background and Aims: Patients with end-stage renal disease on hemodialysis have a lower physical activity level in daily life and a higher prevalence of sedentary lifestyle. Moreover, these patients have clinical, musculoskeletal, and physical function complications that contribute to a higher risk of falling. Therefore, the aim of this study was to evaluate the association between physical activity level and history of falls in a retrospective 12-month interval in patients on hemodialysis.

Method: A retrospective study was conducted with patients aged ≥18 years who were undergoing regular hemodialysis treatment for at least three months. Patients were excluded if presented severe and unstable comorbidities, psychiatric or cognitive disorders, uncorrected visual impairments, and hospitalization in the past three months. The retrospective history of falls was assessed for the last 12 months, and a fall was defined as an “unexpected event in which the individual comes to rest on the ground, floor or lower level.” The daily step counts were recorded in the ActiGraph accelerometer (wGT3X-BT) during seven days, and analyzed by excluding the first and last day of recording and calculating the mean among the valid days (≥ 8 hours of wear time). Normativity of data was analyzed by the Shapiro-Wilk test. The Student’s t-test and the Mann-Whitney U test were used for between-group comparisons (patients with and without a history of falls). The univariate and multivariate linear regression models investigated the association between daily step counts and a history of falls. A p value < 0.05 was considered as statistically significant.

Results: This study included 103 patients (59.2 ± 12.6 years, 59.2% male). Of these patients, 49.5% had a history of falls. Patients with a history of falls showed lower prevalence of workers (9.8% vs. 26.9%, p = 0.025) and daily step counts [2989 (2595) vs. 4550 (2966) steps, p = 0.018], and higher educational level [9 (7) vs. 5 (5) years, p = 0.033] compared to patients without a history of falls. The univariate linear regression model showed that daily step counts was significantly associated with a history of falls (p = 0.017). After adjusting for age, gender, educational level, work status, hemoglobin, and diabetes mellitus, this association remained significant in multiple linear regression model with a coefficient of determination of 0.21 and an adjusted coefficient of determination of 0.16 (p = 0.001).

Conclusion: Physical activity level was associated with a history of falls in a retrospective 12-month interval in patients on hemodialysis.

PRESCRIBING PATTERNS IN GREEK HEMODIALYSIS PATIENTS: A MULTICENTER PHARMACOEPIDEMIOLOGY STUDY

Ioannis Neofytou1, Konstantia Kantartzis2, Stefanos Roumeliotis3, Vangelis Manolopoulos4, Elias Thodis5 and Stylianos Panagouotos6
11424 General Military Training Hospital, Department of Internal Medicine, Thessaloniki, Greece, 2Democritus University of Thrace, Department of Nephrology, Alexandroupoli, Greece, 3Aristotle University of Thessaloniki, Department of Nephrology, Thessaloniki, Greece, 4Democritus University of Thrace, Laboratory of Pharmacology, Alexandroupoli, Greece and 5Democritus University of Thrace, Department of Nephrology, Alexandroupoli, Greece

Background and Aims: The aim of the study is to investigate the prescribing patterns and polypharmacy in Greek hemodialysis patients and make comparisons between renal units. Polypharmacy and hyperpolypharmacy emerged as a concerning problem, that affects patient’s adherence, causes drug-drug interactions, adverse drug events, increases morbidity and economically strains the health system. Patients in Europe are prescribed on average 10-12 drugs despite recommendations on polypharmacy.

Method: This is a multicenter retrospective study (2018-2021), in Northern Greece, of 270 patients (male = 168, female = 102) with mean age of 63.8±15 years and median dialysis duration of 45(18-96) months. The medications and laboratory values were documented for a period of 12 months, provided that there were no major changes on their therapy at that time. The 24 public health dialysis units participating in the survey, were classified as secondary (179 patients) and tertiary care (91 patients) depending on the bed capacity (>600) and the availability of health services. Statistical analysis was conducted using SPSS ver 26.

Results: The mean number of prescribed medications was 10.4 (SD 2.9, range 2–20). Of the participants, 97.4% were experiencing polypharmacy (>5 medications per person) and 62.6% hyperpolypharmacy (>10 medications). The average number of prescribed medications in tertiary care was substantially lower comparing with secondary care (mean: 8.7 vs 11.3, p < 0.001). The difference in the mean number, remained significant even when the result was adjusted for age, gender, cardiovascular disease, primary disease and dialysis duration. Notably, despite the fewer medications, there was no statistically significant difference between the two groups, in achieving the most recent Kidney Disease Improving Global Outcomes (KDGIO) guidelines for URR (Urea Ruction Ratio), renal mineral bone disease and renal anemia (chi-square, p>0.05 for all variables). The most frequently prescribed group of medications were EPO analogues (87%), Vitamin D supplements (83%), Proton Pump Inhibitors (68%), β-blockers (56%), Antipatelets (45%) and Loop diuretics (37%). It is important to note the alarming number of patients receiving medication for mental illness (35.2%), mainly benzodiazepines (26%), with women to be more vulnerable (42.2% vs 30.1%, OR 1.63).

Conclusion: This study reports that Greek prescribing practices follow the same worrisome patterns as other European countries. Rural hospitals appear to prescribe more drugs than tertiary facilities.

PREDICTION OF MAJOR GASTROINTESTINAL BLEEDING EVENTS IN HEMODIALYSIS

John Larkin1, Suman Lama1, Sheetal Chaudhuri2, Joanna Willetts3, Anke Winter1, Yue Jiao1, Manuela Stauss-Grabo2, Len Usvayt1, Jeffrey Hymes1, Franklin Maddux3, David C. Wheeler4, Peter Stenvinkel5 and Jürgen Floege6
1Fresenius Medical Care, Global Medical Office, Waltham, United States of America, 2Fresenius Medical Care, Global Medical Office, Bad Homburg, Germany, 3Fresenius Medical Care AG & Co. KGAA, Global Medical Office, Bad Homburg, Germany, 4University College London, London, United Kingdom, 5Karolinska University Hospital, Dept of Renal Medicine, Stockholm, Sweden and 6University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany

Background and Aims: IiNatiVeS on advancing Patients’ outcomes In REnal disease (INSPIRE) is an academia and industry collaboration set forth to identify critical investigations needed to advance the practice of...
The model showed an area under the curve (group mean GIB event) of 0.69, sensitivity = 68.9%, specificity = 68.8% and balanced accuracy = 63.4%. Exposures with largest effect size observed via SHAP values were older age and iron indices, longer dialysis vintage, and proton pump inhibitor use (Fig. 1).

Conclusion: The machine learning model appears suitable for early detection of GIB event risk in HD, yet prospective testing is needed. The association between higher 25OH vitamin D and GIB events was unexpected and warrants investigation. A consistent signal has been observed in warfarin users without kidney disease among which 25OH vitamin D levels of 30–100 ng/mL were shown to associate with the highest GIB risk [3].

#3706 EFFECT OF CHOLECALCIFEROL INTAKE ON NOVEL INFLAMMATORY INDICATORS IN HEMODIALYSIS PATIENTS

Mona Ashalhaway Ghazy1, Lamia Elwakel1, Nagwa Sabri1, Tamer El Said2 and Radwa Maher1

1Faculty of Pharmacy - Ain Shams University, Clinical Pharmacy, Egypt and
2Faculty of Medicine - Ain Shams University, Nephrology, Egypt

Background and Aims: Hemodialysis patients (HD) are in a chronic state of systemic inflammation, with vast majority of these patients are vitamin D deficient. Vitamin D appears to be a strong controller of inflammation. It’s well known that C-reactive protein (CRP) is considered the gold of inflammatory markers. Recently, neutrophil-to-lymphocyte ratio (NLR) and platelet-to-lymphocyte ratio (PLR) have been shown to be inexpensive, readily available indicators of systemic inflammation. This study is to demonstrate the pleotropic effects, the efficacy and the safety of two dosing regimens of cholecalciferol; (weekly regimen vs monthly regimen) on novel inflammatory indicators in HD population.

Method: A prospective, randomized trial was carried out to evaluate the effect of weekly versus, monthly oral cholecalciferol, on vitamin D (25(OH)D) levels, on inflammatory markers and secondary hyperparathyroidism in HD patients. Fifty eligible HD patients were randomly assigned to either Group A (Once weekly oral 50,000IU Cholecalciferol) or Group B (One monthly, oral 200,000IU Cholecalciferol), for 3 months’ period. Serum levels of high sensitive CRP (hsCRP), NLR, PLR, were all assessed at baseline and at the end of the study.
Results: Cholecalciferol significantly increased serum levels of 25(OH)D in both groups. A significant decrease in serum hsCRP levels ($p < 0.001$) and NLR was noted only in Group A. No significant difference in calcium or phosphorus levels was noticed. No side effects or adverse events were reported.

Conclusion: Weekly (50,000 IU) oral cholecalciferol appears to have a beneficial action on replenishing 25(OH)D levels in HD patients, with an ameliorative action on inflammatory status as well. NLR seems to be an effective, non-expensive inflammatory indicator in HD.

### #3718

**WHAT ARE THE MOST COMMON HEADACHE PROBLEMS IN PATIENTS RECEIVING DIALYSIS?**

Javokhir Khalmukhamedov

Tashkent Pediatric Medical Institute, Internal Medicine, Nephrology and Hemodialysis, Tashkent, Uzbekistan

**Background and Aims:** Analysis of the clinical features of headache in patients on the program dialysis.

**Method:** The study included 40 males and 40 females with CKD on program dialysis for more than 12 months in 2022, each session lasting 4 hours. The exclusion criteria were patients receiving drugs that can cause headache and with any type of primary headache not associated with the HD procedure, diabetes mellitus, and others. Patients with DH were further compared with patients without DH in terms of BP and blood values such as urea, creatinine, Na+, K+.

**Results:** 45% ($n = 36$) reported DH, which was common in women 60%. Differences between pre- and post-dialysis urea values in patients with DH were statistically significant ($p < 0.05$). Patients with DH showed significantly higher mean SBP and DBP values before dialysis compared with patients without DH (systolic, $P < 0.001$; diastolic, $P < 0.01$). 80% of patients ($n = 64$) reported the quality of their headaches as being throbbing, whereas (20%), 58% and severe in 27% ($n = 22$). The headache duration was reported to last less than 4 hours in 63% ($n = 50$) and 4 to 36 hours in 37% ($n = 30$), Table 2.

**Conclusion:** We determined that DH is a common type of headache among HD patients, female predominance, begins after several hours of therapy, with progressive intensity and throbbing character, which is not associated with a coexisting primary headache, but may be related to differences in urea levels and BP before and after treatment.

**GASTROINTESTINAL SYMPTOMS IN PATIENTS RECEIVING HEMODIALYSIS: PREVALENCE, SEVERITY AND ASSOCIATED FACTORS**

Jasna Trbojevic-Stankovic1,2, Gordana Kovačević3, Nikola Panić4, Edwin Hadžibilčić5, Branslav Andrić6, Saša Milošević5, Selma Hadžibilčić1 and Ana Pašić1

1Faculty of Medicine, University of Belgrade, Beograd, Serbia, 2University Hospital Center “Dr Dragisa Misovic”, Nephrology and Hemodialysis, Serbia, 3University Hospital Center “Dr Dragisa Misovic”, Gastroenterology, Beograd, Serbia, 4General Hospital Novi Pazar, Nephrology and Dialysis, Novi Pazar, Serbia and 5General Hospital Krusevac, Nephrology and Dialysis, Krusevac, Serbia

**Background and Aims:** Gastrointestinal (GI) symptoms are common among patients with chronic renal failure, especially in those treated with maintenance hemodialysis (HD), and may adversely affect patients’ quality of life. A variety of GI symptoms has been reported, but previous studies present conflicting results regarding their association with age, sex, comorbidities, concomitant medications and dialysis modality. This study aimed to assess the prevalence and severity of GI symptoms in the maintenance HD population and explore possible associated factors.

**Method:** A total of 188 stable patients (55.3% male, 53.7% ≥65 years of age, age range 24–85, 30.9% with diabetes, 19.9% smokers) from three HD centres were enrolled in this observational cross-sectional study. Gastrointestinal symptoms were assessed by the self-administered Gastrointestinal Symptoms Rating Scale (GSRS). The scale includes 15 items graded by a 7-point Likert scale that can be grouped into five dimensions: abdominal pain syndrome, reflux syndrome, indigestion syndrome, diarrhoea syndrome, and constipation syndrome. A dimension score is calculated as the mean value of the items belonging to the specific syndrome, and the final score is the mean of dimension scores. Standard blood analyses, Kt/V, body mass index (BMI) and malnutrition-inflammation-inflammation score (MIS) were determined in all patients. Other relevant demographic and clinical data were obtained from the patient’s medical records. The results were analyzed with SPSS software, version 22 (IBM Corporation, New York, USA).

**Results:** The average BMI was 25.04 ± 4.29. Half of the patients (50.3%) were overweight, 45.3% had normal weight, and 4.3% were underweight. The average MIS was 5.64 ± 2.87. The average number of symptoms per patient was 4.01 ± 3.20 (range 0 – 15). At least one GI symptom was reported by 84.6% of patients (33.0% reported 1 – 3 symptoms, and 49.5% reported 4 or more symptoms). The mean GSRS scores for eating dysfunctions were 1.59 ± 1.08 for reflux, 1.74 ± 0.98 for abdominal pain, 1.75 ± 1.14 for constipation, 1.94 ± 1.01 for indigestion, and 1.38 ± 0.90 for diarrhoea. Total GSRS was 1.70 ± 0.61. Elderly patients had a significantly lower overall number of GI symptoms (3.49 ± 2.83 vs 4.57 ± 3.31; $p = 0.023$), lower abdominal pain score (1.60 ± 0.96 vs 1.91 ± 1.09; $p = 0.031$), and indigestion score (1.74 ± 0.85 vs 2.18 ± 1.15; $p = 0.005$), but higher constipation (1.94 ± 1.27 vs 1.54 ± 0.96; $p = 0.017$) score than individuals under 65 years of age. Patients smoking cigarettes and those...
longer on HD had a significantly higher overall number of GI symptoms (3.64 ± 0.56 vs 3.10 ± 0.25; p = 0.035 and 3.78 ± 1.29 vs 2.46 ± 2.23; p = 0.016 respectively). Average abdominal pain score was significantly higher in non-diabetic (1.87 ± 1.04 vs 1.44 ± 0.75; p = 0.002) and underweight (2.62 ± 1.51 vs 1.71 ± 0.94 vs 1.65 ± 0.90; p = 0.023) compared to diabetic, normal weight and overweight patients respectively. Patients taking ASA or NSAIDs had significantly higher total GSRs scores (1.84 ± 0.72 to 1.60 ± 0.50; p = 0.016 and 1.80 ± 0.64 vs 1.65 ± 0.59; p = 0.044 respectively). Sex, dialysis adequacy and malnutrition-inflammation status were not significantly related to any of the GSRs dimensions.

Conclusion: The present study demonstrates a high prevalence of GI symptoms in maintenance HD patients and identifies age, cigarette smoking, diabetes, dialysis vintage, and certain medications as important elements to consider when addressing specific groups of GI symptoms in this population.

MID-ARM CIRCUMFERENCE AS A CORRELATE TO DIFFERENT: ASPECT NEUROCognitive IMPAIRMENT IN HEMODIALYSIS PATIENTS

Emad Samaan1, Basma Ayman2, Amira Shams3, Nada Modam2, Mohamed Eltantawi1, Mohamed El Khaligy1, Mohamed El-Gamil1, Muhammad Shamsuddin4, Ibitihal Ibrahim5 and Eman Nagy5

1 Mansoura Nephrology and Dialysis Unit, Faculty of Medicine, Mansoura University, Mansoura, Egypt; 2 Mansoura University, Medical Intensive-Mansoura University Hospitals, Mansoura, Egypt; 3 Physician: Alahram Kidney Center, Gharbia, Egypt; 4 Mansoura Faculty of Medicine, Clinical Nutritionist and Toxicologist, Clinical Toxicology, Mansoura, Egypt and 5 Mansoura Faculty of Medicine, Psychiatry, Mansoura, Egypt

Background and Aims: Malnutrition is associated with poor cognitive function (CI) in Hemodialysis (HD) patients. Both have multiple ways of assessment scaled from simple bedside screening tests to more sophisticated time- and cost-consuming measures. This work aims to define the best nutritional assessment measure that correlates to the degree of CI.

Method: A cross-sectional study was carried out on 116 patients in 4 different HD units from Delta Nile, Egypt. The nutritional status was examined after the dialysis session in euvoletic patients using (1) anthropometric measurements, including body mass index (BMI), mid-arm circumference (MAC), skin fold thickness (SFT), and mid-arm muscle circumference (MAMC); (2) bioelectrical impedance analysis for assessment of skeletal muscle mass (SMM), skeletal muscle index (SMI), free fat mass (FFM), body fat mass (BFM), and total body water (TBW); (3) Hand grip strength was used to assess muscle power. The assessment of cognition was made using (1) a mini-mental state examination (MMSE) for orientation, registration, attention, recall, language, and copying; (2) Saint Louis University Mental Status Exam (SLUMS) for early CI and executive functioning; (3) Arabic version of Penn Web-Based Computerized Neurocognitive Battery (WebCNNP) for those who scored no CI in the previous two tests.

Results: The results of MMSE and SLUMS tests showed that 34.5% of our cohort (n = 40) had no CI, 34.5% (n = 40) had mild to moderate degrees of CI, and 31% (n = 36) had a severe form of CI. Comparing the nutritional assessment parameters between the categories of cognitive scores revealed that there were no significant differences except in significantly lower median values of MAC (P 0.01), SMI in bioelectrical impedance analysis (P0.01), and hand grip strength (P 0.002) in severe CI group than the normal to patients without CI. In correlation statistics, MAC and hand grip strength were negatively correlated to the degree of CI (r = -0.3, P 0.006 and r = -0.26, P 0.009, respectively). MAC was the only parameter correlated with attention, emotional recognition, and differentiation functioning in the forty patients with no CI who underwent computerized neurocognitive assessment. The highest reported positive correlations reported were between the MAC and response time of both emotion recognition (r = 0.57, P < 0.001) and different emotion recognition (r = 0.55, P < 0.001).

Conclusion: Of the different parameters of nutritional state assessment, MAC, the simple bedside measurement, was the best correlate with the degree of cognitive impairment in HD patients, even in its mild primitive forms.

DIFFERENT EFFECTS OF HYPOXIA-INDUCIBLE FACTOR PROLYL HYDROXYLASE INHIBITORS ON SERUM LIPOIDS LEVELS IN HEMODIALYSIS PATIENTS

Takayasu Taira

Yokohama Daichi Hospital, Nephrology, Yokohama, Japan

Background: The activity of hypoxia-inducible factor (HIF), an oxygen-sensing transcription factor involved in erythropoiesis, is regulated by HIF-prolyl hydroxylases. With reduced oxygen tension, the activity of these enzymes is suppressed, resulting in increased erythropoiesis. Chen et al. reported that the decrease in that total cholesterol (TC) was greater with roxadustat than with epoetin alfa, as was the decrease in low density lipoprotein-cholesterol (LDL-C) in patients undergoing dialysis [1]. Cuzy et al. reported roxadustat was superior to erythropoiesis-stimulating agent (ESA) in decreasing LDL-C in accordance to a previous study [2]. Roxadustat is an oral HIF-prolyl hydroxylase inhibitor (HIF-PHI) developed for dialysis-dependent chronic kidney disease (CKD) anemia. While the impact of HIF-PHI on mean hemoglobin (Hb) change in patients on hemodialysis (HD) has been investigated [1], its effects on serum lipid levels have yet to be explored. Clarifying such effects is particularly important because HD patients usually have lower plasma high-density lipoprotein-cholesterol (HDL-C) levels than healthy individuals. Low HDL-C levels are associated with an increased risk of death in HD patients. The effects of HIF-PHIs on dyslipidemia in patients on HD are unclear. This study aimed to investigate the effects of HIF-PHIs on serum lipid levels in HD patients.

Methods: We investigated the effect of HIF-PHIs in three groups by measuring the levels Hb, serum TC, LDL-C, HDL-C, triglycerides (TG), iron, total iron-binding capacity (TIBC), transferrin saturation (TSAT), ferritin. Study 1: We evaluated the efficacy of roxadustat in 13 patients (1 female and 12 males) with HD-dependent CKD anemia and dyslipidemia over 24 weeks. Study 2: We evaluated the efficacy of daprodustat in 9 patients (2 females and 7 males) with HD-dependent CKD anemia and dyslipidemia over 24 weeks. Study 3: We evaluated the efficacy of enarodustat in 15 patients (3 females and 12 males) with HD-dependent CKD anemia and dyslipidemia over 12 weeks.

Results: Study 1: The mean age and mean HD vintage were 77.7 and 6.6 years, respectively. After roxadustat treatment, the mean Hb values (from 10.4 to 10.7 g/dL) did not significantly change. There were no significant changes in mean serum iron, TG, ferritin. However, the following parameters showed a significant decrease: mean TC (from 138.4 to 106.6 mg/dL, p = 0.0002), LDL-C (77.7 to 53.8 mg/dL, p = 0.0002), HDL-C (from 43.3 to 35.9 mg/dL, p = 0.0005), and TSAT (from 32.6 to 31.2%, p = 0.0479). There was a significant increase in the mean TIBC (from 220.5 to 265.1 μg/dL, p = 0.0002). Study 2: The mean age and mean HD vintage were 74.6 and 3.2 years, respectively. After daprodustat treatment, the mean Hb values did not significantly change. There were no significant changes in the mean TC, LDL-C, TG, TSAT, ferritin. However, the following mean HDL-C levels showed a statistically significant decrease (from 50.4 to 45.3 mg/dL, p = 0.0117). Furthermore, there were significant increases in the serum iron level (from 72.5 to 89.1 μg/dL, p = 0.0078) and the mean TIBC level (from 229.7 to 272.8 μg/dL, p = 0.0039). Study 3: The mean age and mean HD vintage were 69.3 and 8.9 years, respectively. After enarodustat treatment, the mean Hb values did not significantly change. There were no significant changes in the mean TC, LDL-C, HDL-C, TG, TSAT, ferritin. There was a significant increase in the mean TIBC (from 230.0 to 259.4 μg/dL, p = 0.0151).

Conclusions: We found that HIF-PHIs had different effects on serum lipids levels in HD patients. Roxadustat treatment improved iron metabolism stabilized Hb levels, and significantly decreased LDL-C levels. Daprodustat and enarodustat treatment improved iron metabolism, maintained stable Hb levels.

Background and Aims: Despite the evolution of hemodialysis (HD) in recent years, cardiovascular diseases continue to be the main cause of death in this group of patients. Congestion is one of the factors associated with the highest morbidity and mortality. Unfortunately, there is no gold standard for the proper assessment of dry weight; in fact, physical examination, and even newer techniques such as bioimpedance have poor sensitivity, are difficult to interpret in some cases and fail to discriminate between tissue and vascular congestion. Recently, the use of Point-of-care Ultrasonography (PoCUS) has emerged as the fifth pillar of the conventional physical examination that allows dynamic assessment of congestion and enables congestion to be phenotyped. The aims of the present study were: 1. to phenotype congestion in HD patients and 2. to establish patterns of decongestion according to changes in phenotypes over the course of a HD session.

Method: Descriptive study carried out in HD units of two tertiary hospitals. Patients with more than three months on HD were included. Excluding patients with short life expectancy or who had an acute complication. In addition to the congestive composite score (CCS), a PoCUS evaluation was performed at the beginning and the end of the HD session on long dialysis interval. Tissular congestion was assessed by lung ultrasound and vascular congestion was assessed by evaluation of the inferior vena cava diameter and portal vein pulsation by pulsed Doppler. Four phenotypes of congestion were established: phenotype A: no congestion, phenotype B: predominance of tissue congestion, phenotype C: predominance of vascular congestion and phenotype D: mixed congestion. In addition, 4 patterns of decongestion were established: pattern 1: absence of congestion at the beginning and end of the HD session, pattern 2: change of phenotype from B, C or D to A, pattern 3: change in congestion phenotype and pattern 4: persistence in the same congestion phenotype as at the beginning.

Results: 20 patients were included, mean age: 70.5 ± 11.3 years, 14 (70%) were male, CCS: 3 (1.5 – 7.5), interdialysis weight gain: 2.93 ± 0.95 kg and mean UF: 2,570 ± 868 mL. 75% of patients reached the prescribed dry weight. At the beginning of the session the distribution of phenotypes was: phenotype A: 35%, phenotype B: 25%, phenotype C: 25% and phenotype D: 15%. At the end of the HD session: phenotype A: 55%, phenotype B: 30%, phenotype C: 10% and phenotype D: 5%. At the end of the HD session 45% of the patients persisted with some phenotype of congestion at the end of the session. An inverse correlation was found between age and phenotype at baseline (Rho: -0.506; p = 0.023). No correlation was found between dry weight and UF with decongestion patterns.

Conclusion: These results show the persistence of echographic congestion at the end of the HD session in a significant number of patients, suggesting that subclinical congestion is more frequent than clinically observed. Further studies are warranted to confirm these results.

5Rigshospitalet, Centre for Physical Activity Research, København, Denmark,
6Inland Norway University of Applied Sciences, Norway and
7Herlev Hospital, Department of Nephrology, Herlev, Denmark

Background and Aims: Fluid overload is a major challenge in haemodialysis (HD) patients and might cause hypervolaemia. We speculated that HD patients reaching dry weight could have undetected hypervolaemia and low haemoglobin concentration (Hb) due to haemodilution.

Method: The study included HD patients (n = 22) and matched healthy controls (n = 22). Blood volume, plasma volume, red blood cell volume, and total haemoglobin mass (Hb mass) were determined using a carbon monoxide (CO)-rebreathing method in HD patients reaching dry weight and controls. Blood volume measurements were also obtained by a dual-isotope labelling technique in a subgroup for validation purposes.

Results: Blood volume was higher in 16 out of the 22 HD patients compared to controls. In the HD group, the median blood volume was 89.3 mL/kg (interquartile range (IQR) 76.7–95.4 mL/kg) and was higher than in the control group (79.9 mL/kg (IQR 70.4–88.0 mL/kg); P = 0.037) (Table 1). The median plasma volume was 54.7 mL/kg (IQR 47.1–61.0 mL/kg) and 44.0 mL/kg (IQR 38.7–49.5 mL/kg) in the HD and control groups, respectively (P < 0.001). Hb was lower in HD patients (P < 0.001), whereas no difference in total Hb mass was observed between groups (P = 0.11). Changes in Hb levels during and after dialysis were observed in the HD group and is shown in Fig. 1. A correlation was found between blood volume measured by the CO-rebreathing test and the dual-isotope labelling technique in the control group (r = 0.83, P = 0.015), but not the HD group (r = 0.25, P = 0.60).

Conclusion: The HD group had increased blood volume at dry weight due to high plasma volume, indicating a hypervolaemic state. The total Hb mass was similar between HD patients and controls, unlike Hb, which emphasizes that Hb is an inaccurate marker of anaemia among HD patients.

SERUM 25(OH)-VITAMIN D AND 1,25(OH)2 VITAMIN D IN HEMODIALYSIS PATIENTS: FACTORS AFFECTING THEIR CONCENTRATIONS AND THEIR EFFECT ON SURVIVAL

Eiji Ishimura1,2,3, Shinya Nakatani2, Takao Fujimoto3, Kazunari Higashimoto1, Akihiro Kosoku1, Senji Okuno4 and Ryusuke Kakiya3

1Meijibashi Hospital, Matsubara, Osaka, Japan, 2Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan, 3Meijibashi Hospital, Osaka, Japan and 4Shirasagi Hospital, Osaka, Japan

Background and Aims: In haemodialysis patients, serum levels of vitamin D metabolites, 25-hydroxy-vitamin D (25D), a nutritional status of vitamin D, and 1,25-dihydroxy-vitamin D (1,25D), an active form of vitamin D, are previously reported to be low. In recent years of new CKD-MBD guidelines utilizing calcimimetics, vitamin D receptor agonists (VDRA) and new phosphate binders, relationship between serum 25D, 1,25D concentrations and clinical parameters in haemodialysis patients are not well known. We measured both serum 25D and 1,25D concentrations in chronic haemodialysis patients, and examined their association with several clinical factors and also with survival, in both cross-sectional and longitudinal analyses.

Method: A total of 108 stable haemodialysis patients (72 ± 10 year-old, 64 males, haemodialysis duration 6.9 ± 7.5 years, 45 with type 2 diabetes) were examined. Serum 25D was measured by a ECRIA method, and 1,25D by a RIA2 antibody method, and serum PTH by a IRMA assay. In a cross-sectional analysis, association of these vitamin D metabolites with clinical parameters was examined. In a longitudinal study, patients were followed for 3 years and survival of the patients was examined in relation with these vitamin D metabolites.

Results: Serum 25D concentrations were 12.0 ± 4.0 ng/ml, being hypovitaminosis D (<30 ng/ml) in all patients. Serum 1,25D concentrations were 14.7 ± 8.7 pg/ml, being lower than normal ranges (60-120 pg/ml) in 93% of the patients. There was no significant differences in 25D or 1,25D between those with diabetes and without. Although there was no significant correlation between 25D and haemodialysis duration, there was a significant negative correlation between 1,25D and haemodialysis duration (r = -0.187, p = 0.042). Neither of 1,25D or 25D was significantly correlated with serum calcium or phosphate concentrations. There was a significant, positive correlation between 25D and serum albumin (r = 0.172, p = 0.0454), although there was no significant correlation between 25D and serum PTH, there was a significant, negative correlation between 1,25D and serum PTH (r = -0.310, p = 0.003). Similarly, although there was no significant correlation between 25D and serum intact PTH, there was a significant, negative correlation between 1,25D and serum alkaline phosphatase (r = -0.309, p = 0.001). There were no significant differences in serum two vitamin D metabolites between patients with (n = 65) and without VDRA treatment, nor between those with (n = 12) and without calcimimetics. In a multiple regression analysis after adjustment of age, gender, haemodialysis duration, and VDRA treatment, serum 25D concentrations were significantly, independently associated with serum albumin (β = -0.244, p = 0.0149) (R² = 0.123, p = 0.007). In a multiple regression analysis after the same adjustment, serum 1,25D concentrations were significantly, independently associated with serum intact PTH (β = -0.310, p = 0.003) (R² = 0.200, p = 0.002). In the follow-up of three year, 16
patients died. Kaplan Meier analysis revealed that there tended to be better survival in patients with higher 25D concentration (n = 52) than those with lower concentration (p = 0.1936), although no significant association was seen between 1,25D and survival.

Conclusion: These results indicate that hypovitaminosis D (low 25D<30 ng/ml) is seen in all haemodialysis patients, and in most of these patients, serum 1,25D concentrations are low. Lower serum 25D concentrations are significantly associated with lower serum albumin, i.e., poorer nutritional status. Higher serum 1,25D, even in low ranges, is significantly associated with lower intact PTH and alkaline phosphatase, i.e., lower bone metabolism status. The results suggest that, in the era of new CKD-MBD treatments with calcimimetics and new VDRA, serum 25D may represent a nutritional status, and that serum 1,25D concentrations with regard to bone metabolism may be re-considered for the assessment of CKD-MBD, particularly in regards to prevention of secondary hyperparathyroidism.

#5745
CORRELATION BETWEEN MATRIX GLA PROTEIN LEVEL AND EFFECT OF VITAMIN K2 THERAPY ON VASCULAR CALCIFICATION IN HEMODIALYSIS PATIENTS
Mohamed Taher, Ebah Wafa, Nagy Sayed-Ahmed and Khaled el Dahshan
Mansoura, Egypt

Background and Aims: In hemodialysis patients, vascular calcifications are precocious, frequent, and excessive. The association between the level of vascular calcifications and mortality has been described in dialysis patients. The dephosphorylated and uncarboxylated matrix GlA protein (dp-ucMGP) is an indicator of vitamin K2 status and correlates with markers of vascular calcification. It is activated by γ-glutamyl carboxylase that converts inactive matrix GlA protein into an active form, and vitamin K2 is a cofactor of this reaction. The active form of matrix GlA protein is a known inhibitor of arterial wall calcification and plays an essential role in bone turnover. The biological activity of the calcification-inhibitory matrix GlA protein can be achieved by simple administration of oral vitamin K2.

Aim: To assess the effect of vitamin K2 supplementation on vascular calcification and matrix GlA protein in hemodialysis patients. In addition, we wanted to clarify the role of vitamin K2 as prophylaxis against vascular calcification in hemodialysis patients not suffering from vascular calcifications.

Methods: The study included 112 hemodialysis adult patients not receiving vitamin K antagonists. The study was conducted at the Urology and Nephrology Center, Mansoura University. Patients who suffered from vascular calcification (68 patients) received oral 180 μg of vitamin K2 every day for one year. Uncarboxylated matrix GlA protein concentrations were quantified using ELISA before administering vitamin K2 and after 12 months of treatment.

In addition, we used an abdominal CT scan to assess aortic calcification with Agatston score. The scan was performed at the beginning of the study and after 12 months of follow-up. Patients who did not suffer from vascular calcification (44 patients) were randomly assigned to either receive oral vitamin K2 or no treatment. Uncarboxylated matrix GlA protein concentrations were quantified using ELISA at randomization and 12 months after treatment.

Aortic calcification was evaluated using Agatston score after an abdominal CT scan that was performed at the beginning and at 12 months of follow-up.

Results: There was a positive and statistically significant correlation between un-carboxylated matrix GlA protein level and vascular calcification (r = 0.64, P-value < 0.001). Among patients with vascular calcification, the baseline plasma (dp-ucMGP) significantly decreased by 21.3% after treatment of vitamin K2 for one year. Besides, the median baseline calcium score significantly decreased by 15.1% after 1 year of vitamin K2 treatment. On the other hand, patients without vascular calcification had their 1-year matrix GlA protein comparable between the two groups. Despite the reduction of matrix GlA protein in the vitamin K2 naïve group, there was no statistically significant difference. In addition, the calcium score after one year was comparable between both groups.

Conclusion: Hemodialysis patients are at risk of vascular calcification. There is a positive correlation between (dp-ucMGP) protein and vascular calcification. Supplementation of vitamin K2 is safe and improves the serum markers of its deficiency. Also, vitamin K2 supplementation slow the progression of calcification. On the other hand, there is a lack of strong evidence that vitamin K2 supplementation slows down the calcification progression in dialysis patients. Therefore, we recommend further studies to delineate the efficacy and cost-effectiveness of the drug.

#3720
ON THE DEVELOPMENT OF SOME PAIN SYNDROMES IN PATIENTS ON DIALYSIS
Javokhir Khalmukhamedov
Tashkent Pediatric Medical Institute, Internal Medicine, Nephrology and Hemodialysis, Tashkent, Uzbekistan

Background and Aims: To study the incidence and intensity of cramps in patients with end-stage CKD during dialysis.

Method: In a cross-sectional study in 2021, 160 male and female patients on program dialysis (PD), aged 22 to 77 (53.±7.11) receiving for 7.7 ± 1.83 (1 to 25) lasting 12 ± 0.24 hours per week (average KT / V 1.4 ± 0.03) on Fresenius and B. Braun devices. The incidence of cramps was assessed according to a numeric rating scale (NRS) from 0 to 10, as well as its impact on quality of life. To identify patients with intradialytic hypotension (IDH), we used the KDOQI guidelines, which define IDH as a 20 mm Hg decrease in systolic blood pressure (BP) from the origin, assessed over 3 consecutive sessions. All patients’ blood serum was checked for phosphorus (P), calcium (Ca), parathyroid hormone (PTH).

Results: Patients were divided into 2 groups, presence 81 (51.0%) or absence 79 (49.0%) of cramps (Table 1). Among patients with diabetes, the frequency of absence of cramps is 2 times higher than among patients with diabetes (6% vs. 94%, respectively) (Table 2). Among patients with hypotension, only in 15% there were no cramps, while without hypotension 85% (Table 3). No statistically significant difference was found between the groups for any of the 3 parameters (PTH, P, Ca).

Conclusion: Painful muscle spasms have been insufficiently studied, although their impact on the quality life of dialysis patients is clinically significant.
Background and Aims: In a normal physiological state, there are many Tashkent Pediatric Medical Institute, Internal Disease, Nephrology and Barno Mirzaeva and Botir Daminov HEMODIALYSIS CHRONIC KIDNEY DISEASE RECEIVING PROGRAMMED THE COURSE OF OSTEODYSTROPHY IN PATIENTS WITH STAGE 5 #2886

THE COURSE OF OSTEODYSTROPHY IN PATIENTS WITH STAGE 5 CHRONIC KIDNEY DISEASE RECEIVING PROGRAMMED HEMODIALYSIS

Barno Mirzaeva and Botir Daminov

Tashkent Pediatric Medical Institute, Internal Disease, Nephrology and Hemodialysis, Tashkent, Uzbekistan

Background and Aims: In a normal physiological state, there are many regulatory molecules that act as inhibitors of mineral formation to prevent the spread of tissue hardening. In patients with CKD, the levels or functions of these inhibitors may be abnormal, which in turn may predispose to or enhance ectopic calcification. To increase the effectiveness of early diagnosis of demineralization of the bone skeleton in patients with stage V chronic kidney disease receiving hemodialysis.

Method: The study included 94 CKD patients receiving hemodialysis for 15 months. The average age of the patients was 42.13 ± 12.16 years. Etiologically, the etiology of patients included in the study was diverse, with a significant predominance of chronic glomerulonephritis as the cause of CKD in 72 patients, chronic pyelonephritis in 22 patients occupied the second place among the causes of CKD, the remaining causes occurred with a single frequency. Anemia was diagnosed in 71 patients. The observation lasted 12 months. Pathological changes in phosphorus-calcium metabolism and secondary hyperparathyroidism in patients were associated with a significant decrease in bone mineral density; it was shown both for the bodies of the lumbar vertebrae and for the femoral neck, the significance of the difference from the control group for absolute values of mineral density and relative deviation.

Results: In dynamics for 6 months in the general cohort of patients, there was a significant increase in the absolute mineral density of the femoral neck by 11.38%, p < 0.01 the reliability of the difference with the baseline data, and a decrease in the degree of deviation of the mineral density index from the age norm -3.13%, p < 0.05 for the bodies of the lumbar vertebrae and -4.01%, p < 0.01 for the femoral neck, which confirms the effectiveness of osteoporosis therapy. In the present study, in 45 patients 37.5% at the time of inclusion in the study in the bodies of the lumbar vertebrae, the T-index was higher than -2.5 SD; in respect of the femoral neck – in all patients, the T was lower than 2.5 ST. The study of bone mineral density in patients with HCBP, the decrease of which reflects the syndrome of renal osteodystrophy, developing in response to secondary hyperparathyroidism, against the background of osteoporosis therapy.

Conclusion: In patients with CKD, against the background of programmed hemodialysis, there is a decrease in bone mineral density (1.93 times the bodies of the lumbar vertebrae and 2.83 times the femoral neck). The use of calcium carbonate, biphosphonate and vitamin D3 contributes to an increase in the mineral density of the femoral neck by 8.64% (p < 0.05). The introduction of sevelamer hydrochloride into the therapy regimen increases the effectiveness of therapy and increases the mineral density of the bodies of the lumbar vertebrae by 5.96% (p < 0.05) and the femoral neck by 14.04% (p < 0.05).

THE RELATIONSHIPS OF BONE TURNOVER MARKERS AND CEREBRAL WHITE MATTER ALTERATIONS IN PATIENTS UNDERGOING HEMODIALYSIS

Mei-Chuan Kuo1,2, Yi-Ting Lin1,3, Hsiu-Fen Lin2,4, Kung-Chao Chen1 and Ping-Hsun Wu1,2

1Kaohsiung Medical University Hospital, Internal Medicine, Kaohsiung, Taiwan, Rep. of China, 2Kaohsiung Medical University Hospital, College of Medicine, Kaohsiung, Taiwan, Rep. of China, 3Kaohsiung Medical University Hospital, Family Medicine, Kaohsiung, Taiwan, Rep. of China and 4Kaohsiung Medical University Hospital, Neurology, Kaohsiung, Taiwan, Rep. of China

Background and Aims: Patients with end-stage kidney disease (ESKD) have a higher prevalence rate of cognitive impairment than the general population. ESKD patients also present a worsening brain white matter damage than healthy subjects. Some studies showed a lower bone marrow density was associated with cognitive impairment, but limited studies investigated the relationship between bone turnover biomarkers and brain white matter damage in ESKD patients.

Method: Hemodialysis participants were enrolled in two hemodialysis units from August 2016 to January 2017. Participants’ baseline characteristics, bone-turnover proteins, and Fazekas scale of brain magnetic resonance imaging (MRI) white matter lesions were recorded. Fazekas scale of periventricular lesions was defined as cerebral white matter hyperintensities in MRI from grade 0 to grade 3. Multivariable ordinal regression and logistic regression models were analyzed to identify the independent association between bone turnover proteins and the Fazekas scale of periventricular lesions.

Results: In 59 hemodialysis patients, a higher Fazekas scale of periventricular lesions was found in elderly patients and correlated to a lower Mini-Mental State Examination (MMSE). Among 8 bone turnover proteins, the serum level of sclerostin (SOST) showed a dose-response effect (P value for trend = 0.004), corresponding to a higher level of SOST correlated with a lower grade on the Fazekas scale. After full adjustment with potential confounders, a negative association between SOST and Fazekas scale of periventricular lesions remained in the ordinal regression model (Odds ratio [OR] 0.886; 95% confidence interval [CI] 0.828-0.947, P value <0.001) and in the logistic regression model (OR 0.828; 95% 0.712-0.963, P value = 0.014).

Conclusion: The circulating SOST level was negatively associated with brain white matter damage. Our study result provided a potential link between bone turnover markers and brain damage.
RELATIONSHIP BETWEEN EXTRACELLULAR WATER PERCENTAGE AND MORTALITY IN PATIENTS UNDERGOING CHRONIC HEMODIALYSIS

Silverio Rotondi, Lida Tartaglione, Adolfo Perrotta, Miriana Moscatelli, Emanuela Paoloni, Marzia Pasquali, Silvia Lai and Sandro Mazzaferrro

Sapienza University of Rome, Roma, Italy

Background and Aims: Chronic hemodialysis (HD) patients have a high cardiovascular and mortality risk. This is secondary to numerous risk factors specific to the HD population. Relevant on cardiovascular disease and mortality in HD, is the sodium intake and the extent of the sodium pool of patients. An increase in the total sodium pool may have a negative action on cardio vascular system directly and mediated by the increase in total body water associated with an increase in the sodium pool. However, the assessment of the sodium pool in patients is clinically complex. Some evidence has suggested that the assessment of the extracellular water percentage (ECW%) in the HD patient may be a marker of the sodium pool. In fact, the increase in extracellular sodium is followed by a shift of water from the intracellular compartment to the extracellular compartment. The assessment of ECW% could therefore identify patients with greater ECW increase secondary to the greater sodium pool and therefore with high clinical risk. Primary aim: to evaluate the relationship between extracellular water percentage and mortality in patients on chronic hemodialysis.

Method: This is an observational prospective cohort study. The inclusion criteria were chronic HD for at least three months, minimum follow-up of six months, age greater than 18 years. In all of the included patients we performed the bioimpedance examination with a dedicated instrument after hemodialysis session, after the long interdialytic interval, for the evaluation of ECW (L), ECW (%), TBW (L/m), ICW (L). The protocol involved dividing the population into two groups based on normal or pathological ECW%, according to values calculated by gender and age and then evaluating the incidence of death in a 36-month follow-up.

Results: We enrolled 101 patients with an average age of 71 ± 14 years in HD for 51 ± 15 months. During the average follow-up of 19 months we observed 31 deaths (30% of the population) with an annual mortality of 15%. ECW % correlated positively with age (R: 0.498 P<0.01) and differential post-dialysis pressure (R: 0.260; P<0.01). 41 patients (aged 64 ± 13 years) had a normal ECW% (ECW-N) and 60 patients (75±13 years) had pathological ECW% (ECW-P). ECW-P patients had an increased mortality respect to ECW-N patients (60% vs 20%; P<0.01). The survival curve confirmed higher mortality in the ECW-P group (log-rank test P=0.02). These results were confirmed in a sub-analysis of two age-matched ECW-N (n. 20 age 64±10 years) vs ECW-P (n. 20 age 65±12 years) subgroups (log-rank test P<0.05).

Conclusion: Our data showed that ECW% identifies HD patients at increased mortality risk in 36-month follow-up. These data are also confirmed in age-related subgroups, suggesting the ECW% assessment can be a simple and useful parameter to evaluate for targeted treatment choices in patients with chronic HD.

AMBULATORY BLOOD PRESSURE LEVELS AFFECT THE ASSOCIATION OF INTRADIALYTIC HYPERTENSION WITH ADVERSE CARDIOVASCULAR EVENTS IN HEMODIALYSIS PATIENTS

Foteini Iatridi1, Marieta Theodorakopoulou1, Areti Georgiou1, Antonios Karpetas2, Eva Pella3, Ioannis Tsouchnikas4, Panagiotis Giamalis1, Alkaterini Papagiani2 and Pantelis Sarafidis1

1Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece and 2Therapeutiki Hemodialysis Unit, Thessaloniki, Greece

Background and Aims: Patients with intradialytic hypertension (IDH) display also higher ambulatory blood pressure (BP) levels during the whole 44-h interdialytic interval compared to patients without the phenomenon. Sustained high 44-h ambulatory BP levels is a potential risk factor for cardiovascular events and mortality in these individuals. The aim of this study is to evaluate the influence of elevated 44-h BP levels on the high cardiovascular risk of individuals with IDH.

Method: A total of 242 hemodialysis patients with valid 48-h ABPM with Mobil-O-Graph-NG had an extended follow-up for a median of 57.8 months. HD was defined as: rise in SBP greater or equal to 10 mmHg from pre-to-post dialysis and post-dialysis SBP greater or equal to 150 mmHg. The primary end-point was a composite of cardiovascular death, non-fatal myocardial infarction, non-fatal stroke, resuscitation after cardiac arrest, hospitalization for heart failure, coronary or peripheral revascularization procedure. The secondary endpoint was cardiovascular mortality.

Results: 5 patients with and 197 without were included in this prospective analysis. Cumulative freedom from the primary and secondary endpoint was significantly lower for patients with IDH (log-rank p = 0.019), while freedom from the secondary endpoint did not differ significantly between the two groups (log-rank p = 0.321). Patients with IDH presented a significantly higher risk for the composite endpoint (HR = 1.651, 95%CI[1.083, 2.516]), while, however, showing a significant difference in the risk for cardiovascular mortality (HR = 1.320, 95%CI[0.762, 2.288]). After adjustment for 44-h SBP, the association of IDH with the primary endpoint slightly attenuated, while the association with the secondary outcome had no significant changes (HR = 1.421, 95%CI[0.906, 2.228] and HR = 1.270, 95%CI[0.708, 2.276], for primary and secondary outcome respectively).

Conclusion: IDH is associated with higher risk for adverse cardiovascular outcomes. High ambulatory BP during the interdialytic interval contributes to the excess cardiovascular risk observed in this population.

EFFECT OF IMMUNO-NUTRITION ON SYSTEMIC INFLAMMATION AND MUSCLE MASS IN A HAEMODIALYSIS POPULATION: A FEASIBILITY STUDY

Daniela Viramontes Hörner1, Bethan Phillips2, Philip Atherton3, Kenneth Smith4, Daniel Wilkinson2, Nick Selby1,3 and Maarten Taal1,3

1Centre for Kidney Research and Innovation, Academic Unit for Translational Medical Sciences, School of Medicine, University of Nottingham, Derby, United Kingdom, 2Academic Unit of Injury, Recovery and Inflammation Sciences, School of Medicine, University of Nottingham, Derby, United Kingdom and 3Department of Renal Medicine, University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom

Background and Aims: Decreased skeletal muscle mass (SMM) and systemic inflammation are frequent complications associated with poor outcomes in people receiving haemodialysis. Although these problems are widely acknowledged, it has become clear that simply providing conventional oral nutritional supplements (ONS) is often not effective in increasing SMM. This is partly because systemic inflammation causes "anabolic resistance", a condition that inhibits optimal rates of muscle protein synthesis being achieved despite adequate protein intake/availability. Immuno-nutrition supplements are high in energy and protein (similar to conventional ONS), but also contain a unique combination of nutrients that have shown to reduce inflammation in people with cancer. Therefore, the purpose of this feasibility study is to explore the potential effect of immuno-nutrition on systemic inflammation and SMM in a haemodialysis population.

Method: This was a single-centre, non-randomised, interventional feasibility study where 14 haemodialysis patients received 1 sachet per day (74 g dissolved in 125 ml of water) of a commercially available immuno-nutrition supplement (Oral Impact®, Nestlé) for 6 weeks. C reactive protein (CRP), skin autofluorescence (SAF, a marker of systemic inflammation), body composition assessment using bioelectrical impedance analysis (InBody 770), weight, body mass index (BMI), handgrip strength (HGS), routine biochemical variables (pre-dialysis), and energy, protein and fat intake were measured at baseline and after the 6-week intervention.

Results: Mean participant age was 69 ± 13 years and median dialysis vintage was 26 (interquartile range 9 to 94) months. Twelve participants (86%) were male and of white ethnicity. Diabetes and heart disease were present in 9 (64%) and 7 (50%) participants, respectively. Adherence to the intervention was high (98%). Participants reported that the taste of the supplement was nice and acceptable. No safety issues were observed in terms of development of hyperkalaemia or fluid overload. We observed a significant increase in HGS and urea. Fat-free body mass and SMM remained stable, while body weight, BMI and body fat mass tended to increase, though changes did not reach statistical significance. Markers of systemic inflammation and dietary intake did not show any significant change (Table 1).

Conclusion: In this interventional feasibility study, we observed that provision of an immuno-nutrition supplement was associated with an improvement in muscle strength, as well as maintenance of SMM. This suggests that immuno-nutrition may be effective in preventing SMM loss over time in people on haemodialysis. The findings of this feasibility study will help design a randomised controlled clinical trial investigating whether immuno-nutrition supplementation can improve SMM and other nutritional markers, and to evaluate the impact on long-term outcomes, including quality of life.
Table 1: Changes in markers of systemic inflammation and nutritional status from baseline to 6 weeks of treatment with an immuno-nutrition supplement.

DIALYSIS ADEQUACY AND INCIDENT ATRIAL FIBRILLATION IN HEMODIALYSIS PATIENTS
Ga Young Heo 1, Jung Tak Park 1, Hye Jong Kim 1, Kyung Won Kim 1, Young Uk Kwon 2, Soo Hyun Kim 3, Gui Ok Kim 3, Seung Hyeok Han 1, Tae-Hyun Yoo 1, Shin-Wook Kang 1 and Hyung Woo Kim 1
1 Yonsei University College of Medicine, Department of Internal Medicine, Rep. of South Korea, 2 Health Insurance Review and Assessment Service, Healthcare Review and Assessment Committee, Rep. of South Korea and 3 Health Insurance Review and Assessment Service, Quality Assessment Department, Rep. of South Korea

Background and Aims: Atrial fibrillation (AF) can lead to stroke, heart failure, and mortality, and has a greater prevalence in dialysis patients than in the general population. Several studies have proposed that uremic toxins might promote AF development. However, the association between dialysis adequacy and incident AF has not been well established.

Method: In this retrospective study, we analyzed 27,475 patients receiving maintenance hemodialysis, included in the Periodic Hemodialysis Quality Assessment by Health Insurance Review & Assessment Service (HIRA). The main exposure was single pooled Kt/V and the primary outcome was the development of AF.

Results: During a median follow-up of 4.8 years, incident AF occurred in a total of 4,229 (15.4%) patients. Participants with higher single pooled Kt/V tended to have lower AF incidence. In survival analysis, there was a graded association between the risk of incident AF and single-pool Kt/V quartiles: subdistribution hazard ratios and 95% confidence intervals (CI) for the second, third, and the highest quartile compared with the lowest quartile were 0.90 (95% CI, 0.83-0.98), 0.85 (95% CI, 0.78-0.93), and 0.80 (95% CI, 0.73-0.89), respectively. When treating single-pool Kt/V as a continuous variable, a similar association was found. In addition, the risk of incident AF in the highest quartile of urea reduction ratio was 0.83-fold (95% CI, 0.76-0.91) lower than in the lowest quartile. Sensitivity analyses showed consistent results. This association was more pronounced in men.

Conclusion: As the part of the Joint Project on Quality Assessment Research by HIRA, this nationwide cohort study showed that lowering uremic toxin burden through increased dialysis clearance could be associated with a lower AF development risk in patients receiving maintenance hemodialysis.

Note: Model 1: minimally adjusted for age and sex. Model 2: Model 1 + medical aid, dialysis vintage, body mass index, predialysis systolic blood pressure, ultrafiltration, and a history of diabetes mellitus, congestive heart failure, myocardial infarction, cerebrovascular disease, and chronic obstructive pulmonary disease. Model 3: Model 2 + the use of medications (antihypertensive drugs and statins), and laboratory measurements (hemoglobin, serum albumin, and serum calcium).

Abbreviations: sHR, subdistribution hazard ratio; CI, confidence interval; spKt/V, single pooled Kt/V; URR, urea reduction ratio.
duration of the dialysis session emerged as risk factors for IDH. Indeed, when the number of antihypertensives increased by 1 unit, the IDH score was multiplied on average by 2.74 ($p < 0.001$), and when the session duration (h) increased by 0.1 units, the IDH score was multiplied by an average of 1.39 ($p = 0.019$). Residual natriuresis appeared as a protective factor against interdialytic weight gain, because when urinary sodium (mEq/l) increased by 10 units, mean interdialytic weight gain (kg) decreased by an average of -0.116 ($p = 0.043$).

**Conclusion:** Intradialytic hypertension is common and multifactorial. Antihypertensive combination therapy, usually reflecting resistant high blood pressure, is a major risk factor. The present study, at the expense of the definition criteria used, did not find significant associations with peridialytic natremia and residual natriuresis. However, the latter remains protective against interdialytic hypervolemia. Hence, the need for its preservation.

**Background and Aims:** Chronic kidney disease (CKD) is a major health problem worldwide. The last stage of CKD is end-stage renal disease (ESRD), which is characterized by a progressive decrease in glomerular filtration rate (GFR). End-stage renal failure is often complicated by anemia, uremic cardiomyopathy, and renal osteodystrophy, which can be fatal. Therefore, it is necessary to identify the risk factors that can lead to ESRD or death. In addition to well-defined early markers such as diabetes, hypertension, and obesity, it is necessary to identify other markers that would help in the prediction of the disease. It has been shown that genetic factors also have an influence on renal function, pathogenesis, and disease progression, which is confirmed by the results of genome-wide association studies (GWASs). The results of GWASs show that glomerular filtration rate and renal function are affected by several gene loci. Galectin 3 (Gal-3) is the only representative chimera type of the galectin family, which forms a pentameric structure on
the cell surface after binding to glycoproteins or glycolipids. The results of numerous studies have shown that Gal-3 plays a significant role in fibrosis, inflammation, and proliferation. Increased circulating levels of Gal-3 have been associated with various diseases, including cancer, immunological disorders, and cardiovascular disease.

Method: A total of 108 ESRD patients and 38 healthy controls were enrolled in the study. Genotyping of LGALS3 geners 4644, rs4652, and rs11125 polymorphisms was performed by polymerase chain reaction–restriction fragment length polymorphism (PCR-RFLP).

Results: By multivariate logistic regression analysis, we found that LGALS3 rs4644 CC and rs4652 AA genotypes were significantly associated with a higher risk for lower hemoglobin, higher level of parathyroid hormone, and also occurrence of diabetes mellitus and arterial hypertension. The CAA haplotype was significantly more common in patients with diabetes, low hemoglobin level, and normal PTH level. It has been observed as well that the ACT haplotype was more common in patients with low glomerular filtration, lowPTH, and normal hemoglobin level.

Conclusion: We found that the LGALS3 rs4644 and rs4652 gene polymorphism may be involved in the pathogenesis and appearance of complications in ESRD patients and thus could be considered a new genetic risk factor in this population.

THE USE OF REGDANVIMAB FOR THE PREVENTION OF SEVERE COVID-19 IN PATIENTS ON HEMODIALYSIS

Evgeny Shutov1,2, Stepan Bolshakov1, Galina Kotlyarova1, David Dolidze1 and Sergey Sorokoletov1

1City Clinical Hospital named after S.P.Botkin, Moscow, Russia and 2Federal State Budgetary Educational Institution of Further Professional Education

"Russian Medical Academy of Continuous Professional Education" of the Ministry of Healthcare of the Russian Federation., Moscow, Russia

Background and Aims: A new coronavirus infection has become a serious threat leading to increased mortality worldwide. COVID-19 is an acute airborne disease caused by severe acute respiratory syndrome virus (SARS-CoV-2). Evolution of the virus, emergence of new mutant strains, changes in virulence dictate the need to search for new tools both in treatment and prevention of severe disease. The aim of our study was evaluation of the efficacy of Regdanvimab (Regkirona, Samsung BioLogics) to prevent severe COVID-19 in patients receiving ambulatory hemodialysis in the period of increasing morbidity.

Method: The study included 20 patients on program hemodialysis, mean age 54.9±17.6 years, vaccinated or who underwent COVID-19 more than six months ago. All subjects of the study received Regkirona at a standard dose of 40 mg/kg of body weight intravenously once at the end of the hemodialysis procedure after the physician assessed the feasibility of prophylaxis. All subjects were assessed for humoral immunity before Regkirona administration and after Regkirona administration according to the level of total SARS-CoV-2 IgG and IgG antibodies to the subunit of the S1 receptor-binding domain of the SARS-CoV-2 protein.

Results: Total SARS-CoV-2 IgG level and IgG level of antibodies to SARS-CoV-2 receptor-binding subunit S1 was 83.9±69.5 U/ml and 260.7±199.5 BAU/ml respectively before drug administration. During the 6-month follow-up period from July to November 2022, which paralleled the next round of increased morbidity, four patients with SARS-CoV-2 PCR test positive reported mild to moderate symptoms of SARS (marked weakness, fever, loss of smell, catarrhal symptoms, cough, shortness of breath, and chest pain unassociated with other causes). None of the subjects required hospitalization. We evaluated IgG antibody titers to the receptor-binding domain of the SARS-CoV-2 protein subunit S1 after 1, 3 and 6 months and demonstrated a nonlinear decline titers from 5104±2257.1 BAU/ml, 1988.7±1440.4 BAU/ml
to 407.8±350.2 BAU/ml respectively, which may indirectly reflect short half-life of Regdanvimab.

Conclusion: The results of our study showed the efficacy of Regdanvimab to prevent the severe disease of COVID-19 in high-risk patients during the period of rising morbidity.

SUCCESSFUL LIMB SALVAGE IN A CHALLENGING PATIENT ON DIALYSIS BY IMPLANTATION OF AUTOLOGOUS PERIPHERAL BLOOD MONONUCLEAR CELLS: A CASE REPORT
Martina Capone, Lorenzo Di Liberato, Olsi Ndreka, Maria Pia Monaco, Vittorio Sirolli, Valeria Vezzani, Chiara Alessia Orfeo, Bianca Lo Giudice and Mario Bonomini
SS Annunziata Hospital, Nephrology Division, Chieti, Italy

Background and Aims: Peripheral arterial disease (PAD) is an extremely common condition in patients with End-Stage Renal Disease (ESRD) on dialysis. Concomitant comorbidity such as diabetes may be associated with complex vascular dysfunction, and ESRD itself is a recognized risk factor for PAD leading to non healing ulcers and lower limb amputation, which occurs in a high rate of patients [1]. Despite improvement in endovascular techniques for lower extremity revascularization, the incidence of limb salvage among dialysis patients remains poor. Furthermore, lower extremity amputation in these patients is associated with higher mortality rates [2], in addition to important social and economic implications. In this Case Report, an emergent therapy approach was applied aiming to limb salvage in a 74 years old female patient on hemodialysis suffering from lower extremity critical ischemia in diabetic foot infection, otherwise candidate for major amputation, after ineffective angioplasty and Negative Pressure Wound Therapy (NPWT).

Method: After surgical debridement of the ischemic lesion, an innovative therapeutic approach [3] was performed. It consisted in implantation, in the perifemoral area of the affected lower limb, of a concentrate of autologous peripheral blood mononuclear cells (PBMCN) taken from 120 ml of peripheral blood of the patient, by using a selective filtration separation system. This procedure was managed in the operating room and was repeated three times at intervals of 15 days from each other. Since concomitant osteomyelitis occurs in the ischemic diabetic foot under treatment, it was managed with a 2-dose regimen of weekly Dalbavancin, reaching infection control. The patient was followed twice a week for 7 months for regular medications.

Results: After the treatment approach, the granulation tissue improved gradually, obtaining complete surgical wound healing. Since toess gangrene occurs, amputation of the toes was necessary, but limb rescue was successfully reached.

Conclusion: The autologous implantation of PBMCN resulted in limb salvage in this patient on dialysis affected by critical peripheral arterial disease in diabetic foot. This approach has not been described in literature among patients on dialysis, despite the higher mortality rate associated with lower limb amputation in these patients. It seems to be a very promising therapy, with the potential to modify the natural history of no-options critical limb with diabetes complications, in terms of major amputation and overall survival rates. After thorough validation, the reported management could be considered for similar cases.

FIRST EXPERIENCES IN REAL LIFE WITH DIFELIKEFALIN IN GABAPENTIN RESISTANT UREMIC PRURITUS (CKD-aP)
Lucio Manenti1, Vincenzo Oliva1, Laura Pavone1, Tommaso Di Motta2 and Enrico Fiaccadori2
1 Azienda Sociosanitaria Liguria 5- La Spezia, Nephrology, La Spezia (SP), Italy and 2 Azienda Ospedaliero Universitaria di Parma, Nephrology, Parma, Italy

Background and Aims: Chronic kidney disease associated pruritus (CKD-aP) has been recognized for over a century. The actual proposed off-label therapeutic option is gabapentin, that showed relevant efficacy in some small trial. Recently difelikefalin (DFK), a k-opioid receptor agonist, has been the first FDA and EMA approved drug for CKD-aP treatment. We report the first three treated patients suffering gabapentin-resistant CKD-aP in our dialysis center.

Method: Since March 2022, 2 patients have been treated with DFK. Before starting the treatment and every week thereafter until now, the patients completed the following scales: Worst-Itch Numerical rating scale (WI-NRS, 0 = no Itch, 10 = worst itch), and the sleep quality scale (SQS) (from 0 = worse to 10 = best quality).

Results: Case 1 (Male, 58-years old). The patient started hemodialysis (HD) 5 years ago. He was suffering gabapentin resistant CKD-aP (WI-NRS 10, SADS = C, SQS = 3). As soon as DFK was available the patient started DFK 0.5 mcg/kg/Every HD Session. There was immediate and persistent treatment efficacy. After 1 month gabapentin was stopped and after 4 months of DFK therapy, WI-NRS = 0 and SQS = 10, in the absence of side effects. After 6 months DFK was stopped but 4 weeks later CKD-aP returned (WI-NRS 7, SQS = 7). DFK was administered again with immediate response (Fig.1a). Case 2 (Female, 81-years-old). The patient started HD 5 years ago. Two years after she started suffering moderate to severe gabapentin-resistant CKD-aP. Before starting DFK 0.5 mcg/kg/Every HD WI-NRS = 6 and SQS = 3. In the next weeks we obtained a progressive reduction of CKD-aP. After 3 months WI-NRS = 3, SQS = 6. At 6 month follow up CKD-aP ameliorated significantly (WI-NRS 0 and SQS = 9) (Fig. 1b). Case 3. (Male, 75-years-old). The patient suffers initial dementia. He started hemodialysis 1 year ago. He presented with scratching lesions on his arms and legs and complained of itching. After an initial period treated with Gabapentin without success Difelikefalin was tried. At the first assessment WI-NRS 7 and SQS 5; after an initial apparent benefit the rating scales were particularly fluctuating. There was also a dissociation between the improvement of the scratching lesions and the persistence of high values on the WI-NRS (after 3 months WI-NRS = 8). At 6 months’ follow-up the patient presented WI-NRS 9 and SQS 6 (Fig. 1c). The scratching lesions had almost disappeared.

Conclusion: Our initial experience with DFK in the treatment of CKD-aP in 3 gabapentin-resistant patients seems to recognize a remarkable efficacy of the drug. In particular, Case 1 showed a complete, immediate and lasting response, whereas no other drug had been able to improve very severe CKD-aP. Case 2 showed a slowly reduction but achieved complete response at 6 months. In Case 3 the improvement of the scratching lesions suggests a partial benefit of DFK, but to date no relevant results with the adopted scales has been achieved. In conclusion DFK seems to show promising efficacy particularly in CKD-aP resistant to gabapentin. In older patients with cognitive problems the actual tools identified to measure CKD-aP seems inadequate.
Exercise Physiology & Biochemistry Laboratory, Department of Sport Sciences at Thessaloniki, Greece and "Papageorgiou General Hospital, Department of Nephrology, Greece".

Background and Aims: Cardiac arrhythmias and sudden death are the leading causes of cardiovascular mortality in end-stage-kidney-disease (ESKD). Autonomic dysfunction contributes to the arrhythmogenic background of ESKD patients. This is the first study to compare linear and non-linear heart-rate-variability (HRV) indices between hemodialysis (HD) and peritoneal (PD) patients, both at rest and in response to mental- and physical-stimulation maneuvers.

Method: Thirty-four HD and 34 PD patients matched for age, sex, and dialysis-vintage, as well as 17 age- and sex-matched controls were studied. Autonomic function was examined by linear and non-linear-HRV indices. Heart-rate was recorded continuously with Finometer-PRO at rest and during orthostatic, mental-arithmetic, sit-to-stand, and handgrip-exercise tests.

Results: No significant between-group differences were observed in resting HRV indices (RMSSD: HD:57.1±81.1 vs PD:69.6±113.4ms; p = 0.792) except for DFA-a1 index (HD:0.87±0.40 vs PD:0.70±0.20, p = 0.047). All HRV indices during the mental arithmetic test (RMSSD HD:128.2±346.0 vs PD:87.5±150.0ms; p = 0.893) and the physical stress tests were similar between HD and PD patients. Both dialysis groups presented similar patterns of HRV responses to orthostatic and handgrip exercise tests; however, after the sit-to-stand test RMSSD, SD1,SD2 and DFA-a2 indices were higher compared to rest only in HD patients (RMSSD: HD:57.1±81.1 vs PD:126.7±185.7ms, p = 0.028), suggesting a greater difficulty of HD patients in recovering normal ANS function following a physical stress-test.

Conclusion: HRV indices at rest and after mental and physical stimulation did not differ between HD and PD patients, however the ANS response following the sit-to-stand test was more impaired in HD. These findings suggest that ANS dysfunction is not largely affected by dialysis modality but small differences in normal ANS recovery may exist.

Heart rate variability at rest and in response to physical and mental stress: a comparative study between hemodialysis and peritoneal dialysis patients

ERYTHROPOIETIN RESISTANCE IN HAEMODIALYSIS PATIENTS POST SARS-COV-2 INFECTION

Guido Gembilo, Vincenzo Labbrozetta, Luigi Peritore, Alfonso Edoardo Giuffrida, Adolfo Romeo, Antonella Lipari, Claudia Spinella, Alessia Tigan, Eugenia Spallino, Vincenzo Calabrese and Domenico San FOLLOW

University of Messina, Unit of Nephrology and Dialysis, Department of Clinical and Experimental Medicine, Messina, Italy.

Background and Aims: During the SARS-CoV-2 pandemic, patients undergoing chronic haemodialysis treatment were at particularly high risk of infection. This was due to their vulnerability given their state of immunosuppression and multiple comorbidities, on the one hand, and the circumstances that limited physical distancing during treatment, on the other. Even after negativation, patients with a previous infection experience symptoms such as persistent asthenia, muscle weakness, widespread pain and deterioration in perceived health status. In our study, we aimed to investigate the parameters of anaemia and the change in the erythropoietin resistance index (ERI) in haemodialysis patients with previous infection.

Method: We included 25 patients with a dialysis age >6 months, giving a total of 72 measurements. The distribution was assessed with the Kolmogorov-Smirnov test and with a graphical evaluation of the same. We calculated the ERI 3 months before the date of infection and in the 3 and 6 months after. These data were also compared with a control group. Patients were divided into 2 groups: Group A (patients with previous infection) and Group B (control group). Linear mixed models were performed to calculate the slope between the group and the ERI index.

Results: No statistically significant differences were found. The LMMs showed a significant interaction between the scores obtained at the visits performed and the study group, with a decrease in ERI over time of 0.21 at each visit.

Conclusion: Our results show that patients with previous Covid 19 infection have higher resistance to erythropoietin and require higher doses even months after infection. The response to erythropoietin in this population should be investigated in studies with larger cohorts, as anaemia is an important factor affecting the quality of life of our patients.

Erythropoietin resistance in haemodialysis patients post SARS-COV-2 infection

DIFFERENTIAL LIPIDIC PROFILE WITH THE USE OF CITRATE OR ACETATE DIALYSATES

Jose Jesus Broseta Monzo, Diana Rodriguez, Elena Cuadrado, Luis Carlos Lopez Romero, Sergio Bea Granell and Julio Hernandez Jaras

Hospital Clinic de Barcelona, Barcelona, Spain; Consortium General University Hospital of Valencia, Valencia, Spain and La Fe University and Politechnic Hospital, Valencia, Spain.

Background and Aims: Unlike other high-cardiovascular-risk populations, the efficacy obtained from lipid-lowering therapy remains uncertain in dialysis-dependent chronic kidney disease (DD-CKD) patients. This is probably due to the exclusion in clinical trials of patients with very high LDL levels, their population heterogeneity, accompanying cardiovascular morbidities, and the higher mortality risk explained partly by chronic inflammation. The latter has been associated with the accumulation of uremic toxins, membrane biocompatibility, and acetate-based dialysates, which promote inflammation. Different dialysate weak acidifying agents such as lactic, pyruvic, hydrochloric, or citric acids have surged as less-inflammatory alternatives to acetate. This study aims to evaluate the effects of the metabolism of acetate and citrate in the lipidic profile of DD-CKD patients.

Method: In a unicentric, cross-over prospective study, we compared the lipidic profile by assessing the plasma levels of total cholesterol (TC), low-density lipoprotein (LDL), triglycerides (TG), high-density (HDL) and very low-density (VLDL) lipoprotein cholesterol, and lipoprotein (a) (Lp[a]) comparing the use of citrate (CD) vs. acetate (AD) as dialysate buffers, after twelve sessions with each one. Prealbumin was also measured to rule out malnutrition as a potential confounding factor. Prevalent (i.e., dialysis vintage >3 months) adult patients on maintenance haemodialysis were included. The dialysis prescription parameters and additional medical treatments remained unchanged during their sessions with both dialysates. Quantitative values are reported with mean and standard deviation. Normal distribution was assessed with the Shapiro-Wilk test, and the comparisons were made with the Student's paired T-test or Wilcoxon's signed-rank test, accordingly. A two-sided p-value ≤0.05 was considered statistically significant.

Results: After twelve dialysis sessions with CD, compared to AD, there was a statistically significant decline in TG and HDL and an increase in LDL. There was also a notable but non-significant reduction in VLDL (Table 1).

Conclusion: There were noteworthy differences in the lipid profile that can only be attributed to the change of dialysis fluid, as we avoided inter-individual (with a cross-over design) and intra-individual (different inflammatory or nutritional profiles would not be expected with this short-term setting)
Table 1: Measured lipidic plasma levels after twelve dialysis sessions with each dialysate.

THE BARRIERS TO TRANSPLANTATION IN OUR DIABETIC HAEMODIALYSIS POPULATION AT THE LEEDS TEACHING HOSPITALS NHS TRUST

Maria Angela Gauci, Marwa Ahmed, V R Latha Gullapudi and Mark Wright

Leeds Teaching Hospitals NHS Trust, Renal Medicine and Transplantation, Leeds, United Kingdom

Background and Aims: According to the 24th Annual Renal Registry Report, diabetes is the most common identified primary renal disease in patients starting renal replacement therapy (RRT). The prevalence of this underlying disease amounted to 30.5% by the end of 2020, a statistic which increased from 27% in 2015. This highlights the challenges faced by healthcare services in meeting the accrescent demands of this cohort of patients. The Renal Association and British Transplantation Society suggest that patients with a BMI >30 kg/m² are at a heightened risk of complications and is therefore discouraged. Our local transplant centre at St James’s University Hospital accepts recipients with a BMI of up to 35 kg/m² for kidney alone transplantation should no other medical/surgical contraindications to transplantation prevail. Despite this threshold, there remains a significant proportion of patients suspended from the deceased donor transplant waiting list due to an unacceptably raised BMI.

Method: Data was collected through the use of clinic letters or GP records uploaded to Patient Pathway Manager and BHLY (Bradford, Hull, Leeds and York) Renal Patient System. Our patient population consisted of those diabetic patients on home and in-centre haemodialysis (Leeds St James’s University Hospital, Pontefract, Seacroft, Beeston, Dewsbury, Calderdale and Huddersfield). The aims of our study are to assess the demographics of the diabetic haemodialysis (HD) population at the Leeds Teaching Hospitals NHS Trust, to determine the reasons for suspension from the renal transplant waiting list, with a particular interest in obesity. We also assessed the commonest treatment modality (insulin vs other) and the use of continuous glucose monitoring.

Results: The Leeds renal services provide haemodialysis for 631 patients, 248 of these being diabetic patients - 66% of whom are male, with a mean age of 60. Just over 50% of this cohort of patients are Caucasian in ethnicity, while 30% are South Asian. By the end of December 2022, just below 20% (n = 119) of all haemodialysis patients were active on the national deceased transplant waiting list. On the other hand, only 14% (n = 35) of the diabetic haemodialysis subpopulation were active by the end of 2022, while 13% (n = 31) were under assessment, 14% (n = 35) declined and/or disengaged from assessment for transplantation, while the rest were either temporarly or permanently suspended. Almost 10% (n = 24) of all diabetic haemodialysis patients are suspended due to a BMI >35 kg/m².

Conclusion: Our audit reveals that only 14% of the haemodialysis diabetic population is presently active on the deceased transplant waiting list. This remains suboptimal, as renal or simultaneous pancreas kidney transplantation is the gold standard for diabetes-induced ESKD. Obesity (BMI >35) was a reason for temporary suspension in 10% of our haemodialysis diabetic population. Therefore we need to target this comorbidity in a timely manner in order to optimise patients for transplantation. NICE recommend pharmacological weight-lowering therapy for people who have failed to achieve a healthy BMI following conservative methods. Such medical therapy (eg. liraglutide) is still yet to be evaluated in depth in the ESKD-haemodialysis obese population. Only one patient in our cohort was being treated with liraglutide, while the rest was either on insulin, linagliptin, glitazide or non-pharmacological dietary modification. The authors of this study encourage the inclusion of CKD5 patients on liraglutide, before they are started on haemodialysis, in order to pave their way to transplantation before it is too late.

#2779

THROMBOMODULIN IS A SPECIFIC MARKER OF ENDOTHELIAL DISFUNCTION IN HEMODIALYSIS PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Hayam Hehab¹, Manal Sabry², Mohamed Elmagar³ and Shaimaa Abdelmegied⁴

¹Internal Medicine and Nephrology Department, Faculty of Medicine, Ain Shams University, Cairo Egypt, ²Internal Medicine and Gastroenterology Department, Faculty of Medicine, Ain Shams University, Cairo Egypt and ³Internal Medicine and Nephrology Department, Banha Teaching Hospital, Banha Egypt

Background and Aims: Non-alcoholic fatty liver disease (NAFLD) is associated with endothelial dysfunction which is a common problem in hemodialysis patients and a risk for high cardiovascular mortality in hemodialysis. Thrombomodulin is a promising marker of endothelial cell injury in different pathological conditions. This study evaluates the additive

Table 1: Risk estimation of endothelial dysfunction using Thrombomodulin in patients with NAFLD.

*: significant p value <0.05.
effect of non-alcoholic fatty liver disease (NAFLD) in prevalent HD patients on endothelial dysfunction.  

**Methods:** A case-control study was conducted on 60 end-stage renal disease (ESRD) patients on conventional hemodialysis: group A: 30 patients with NAFLD, group B: 30 patients without NAFLD, and control group of 30 apparently healthy subjects. Excluding elderly, diabetic patients, chronic liver disease, advanced heart Failure, active infection, COVID-19 infection, autoimmune diseases and patients with hemodialysis catheters. Thrombomodulin was measured for all participants by ELISA technique.

**Results:** Thrombomodulin could detect endothelial dysfunction in patients with NAFLD at Cut off value <0.8 ng/ml with sensitivity 53.33%, specificity 80%, PPV 72.72%, and NPV 63.2%. On comparing Thrombomodulin in patients with NAFLD (4.378±3.762 ng/ml), Non-NAFLD (1.126±0.591 ng/ml), and control (0.755±0.314 ng/ml) there was a significant difference (P-value<0.001). Post hoc analysis showed significantly high Thrombomodulin levels in patients with [NAFLD versus Non-NAFLD] and [NAFLD versus control] with p-value<0.001, 0.001 respectively while there was no significant difference between patients with Non-NAFLD and control p-value 0.792. NAFLD patients with positive thrombomodulin have a risk of 2.5 times having endothelial dysfunction. There was no significant correlation between Thrombomodulin and all variables in the study.

Conclusions: Thrombomodulin can be used as specific marker for endothelial dysfunction in hemodialysis patients with Non Alcoholic fatty liver disease.

#3270
TRANSPORT AND HYDROLYSIS OF ICODEXTRIN DURING PERITONEAL DIALYSIS
Joanna Stachowska-Pietka1, Jacek Wanięwski1, Anna Olszowska2, Elvia Garcia-Lopez3, Zofia Wankowicz2 and Bengt Lindholm3

1Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw, Poland, 2Military Institute of Medicine, Central Hospital of the Ministry of Public Defence, Warsaw, Poland and 3Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Division of Renal Medicine and Baxter Novum, Stockholm, Sweden

Background and Aims: α-amylase, an enzyme present in plasma and peritoneal tissue, takes part in the process of starch digestion. During peritoneal exchange with icodextrin-based solution, polysaccharide chains are hydrolysed to shorter oligosaccharide chains, influencing osmotic properties of peritoneal dialysate. We estimated peritoneal transport parameters and

Figure 1:

Figure 2:
compared them with hydrolytic clearances using a new model that takes into consideration absorption of icodextrin from the peritoneal cavity and its degradation by α-amylase.

**Method:** Frequent dialysate and blood samples were taken in 11 patients (8 icodextrin-naïve, 3 icodextrin-exposed) undergoing 16-hour dwell studies with icodextrin-based dialysis solution and labeled serum albumin (RISA) added as a volume marker. Using data on the intraperitoneal volume and dialysate and blood concentrations of glucose, urea, creatinine, and 7 icodextrin molecular weight (MW) fractions (glucose polymer size classes) and dialysate concentrations of α-amylase the extended three-pore model was applied to estimate individual parameters related to the peritoneal transport induced by dialysis and to hydrolysis of icodextrin by α-amylase. The following MW cut-off values were assumed for icodextrin fractions: up to 1.08, 4.44, 9.89, 21.4, 43.5, 66.7 and over 66.7 kDa, called Fractions 1–7, respectively. The hydrolytic clearances were defined as rate at which dialysate volume is cleared of the fraction by hydrolysis. The time-dependent hydrolytic clearances of icodextrin fractions were calculated and compared with diffusive ones. For the first time the extended three-pore model was validated not only with respect to the peritoneal transport of water and small solutes but also regarding concentration of icodextrin fractions.

**Results:** Mean measured and simulated dialysate to plasma concentration ratios for glucose, urea and creatinine are presented in Figure 1, left panel. The peritoneal kinetic of icodextrin (dialysate concentrations of each fraction over its initial concentration) is presented for mean measured data and numerical simulation results in Figure 1, right panel. The results showed that the model provides a good estimate of the initial domination of PS slowly decreased during the dwell time, being dominated by hydrolysis processes at the end of the exchange, at least partly due to the changes of intraperitoneal volume and α-amylase concentration. In case of polysaccharides from Fractions 6 and 7, their hydrolytic clearances remained higher than the diffusive ones during whole dwell time. Interestingly, the obtained values of H in icodextrin-exposed patients typically remained below 1.2 mL/min except for Fraction 6, for which H increased from initial value of 0.83 ± 0.30 to 1.43 ± 0.64 mL/min at the end of the peritoneal dwell. On the other hand, the estimated final values of H in icodextrin-naïve patients were on average higher than 1.2 mL/min in all fractions except Fractions 4 and 5.

**Conclusion:** The model provided accurate description of peritoneal transport and icodextrin hydrolysis during long icodextrin dwells. The model showed that hydrolytic processes dominate over diffusive ones during whole dwell time in case of Fractions 6 and 7, whereas diffusive processes dominate for Fractions 1–3.

**Figure 1:** Mean measured (symbols) and simulated (lines) **Left panel:** dialysate to plasma concentration ratio, D/P, for glucose (circles), urea (squares), and creatinine (diamonds) and **Right panel:** normalized (by initial value) dialysate concentration, D/D<sub>0</sub>, for icodextrin Fractions: 1 – circles, 2 – plus marker, 3 – filled circles, 4 – crosses, 5 – squares, 6 – diamonds, 7 – triangles, during 16-hour dwell.

---

**Background and Aims:** Despite being energy and resource-intensive, hemodialysis (HD) is the most common therapy for end stage kidney disease. Considering the extensive amount of energy, water, and consumables involved, this modality is expected to have a significant environmental impact. Through a comparative lifecycle assessment (LCA), this study aims to analyze the environmental impacts of hemodialysis in British Columbia, Canada.

**Method:** A process-based life cycle assessment was performed for three hemodialysis modalities: i) in-centre HD (ICHD), ii) home HD with NxStage machine (HHD-Nx), and iii) home HD with Baxter AK-98 machine (HHD-B). The scope of study included patient and staff commute, supply transportation, dialysis services, patient training for home hemodialysis, and waste management. The functional unit considered is HD energy and material consumption for one patient per year. Based on the patient's record, two prescriptions including standard (three dialysis sessions per week for 4 hours daily) and extended (six HD sessions per week for 8 hours daily) were considered. LCAs were performed using ISO 14040, 14041 standards in which ReCiPe (world) midpoint method and a cut-off criterion of 0.5% was used to assess the environmental impacts of selected impact categories.

**Results:** For both prescriptions, ICHD had highest impact on all environmental impact categories (climate change, human toxicity, freshwater eutrophication, particulate matter formation, marine ecotoxicity and water depletion), except ozone depletion in which HHD-B had highest impact. The fewest impacts were associated with HHD-Nx. CO<sub>2</sub> emissions observed for a standard HD prescription are 3590 kg carbon dioxide equivalents (CO<sub>2</sub>eq) per patient/year by ICHD, 1350 kg CO<sub>2</sub>eq/patient/year by HHD-Nx and 733 kg CO<sub>2</sub>eq/patient/year by HHD-Nx. For extended prescriptions, the highest impact observed is from HHD-B (2210 kg CO<sub>2</sub>eq/patient/year) followed by HHD-Nx (1110 kg CO<sub>2</sub>eq/patient/year). With respect to ICHD, HHD-Nx only accounts for 13% (standard) and 18% (extended) of total environmental impact. Patient and staff commute in ICHD (40% of total impact) and dialysis services in HHD (75% in HHD-B and 63% in HHD-Nx) are the highest contributors to the majority of environmental impacts.

**Conclusion:** Our study demonstrates the environmental impacts of various modes of HHD through LCA. HD modalities have substantial differences in their environmental impacts as compared to ICHD, both HHD systems have lower impact, with NxStage having less impact than Baxter. Our results also demonstrate that a shift from standard to extended prescriptions increases overall environmental impact by 5%. Combined with existing clinical and economic data, these results could assist policy and decision-makers to optimize the provision of kidney replacement therapies. Lower environmental impact of HHD may add to the patient and provider appeal of these therapies, and when clinical equipoise exists, NxStage may be preferred over Baxter in eligible patients.
LIQUID BIOPSY IN PATIENTS TREATED WITH BIOCOMPATIBLE PERITONEAL DIALYSIS FLUIDS – ITS RELATIONSHIP WITH CYTOLOGICAL AND HISTOLOGICAL FINDINGS

Gloria del Peso Gilsanz 1, Patricia Albar 2, Jose Jiménez-Heffernan 3, Marta Osorio 1, Lina María Leon Machado 2, Yanieli Hernandez Perdomo 4, Mario Botella 4, Manuel López-Cabrera 5 and María Auxiliadora Bajo Rubio 1

1Hospital Universitario la Paz, IdiPAZ, Spain, 2Instituto de Investigación Hospital Universitario La Paz, IdiPAZ, Madrid, Spain, 3Hospital de La Princesa, Madrid, Spain, 4La Paz University Hospital, Madrid, Spain and 5Centro de Biología Molecular Severo Ochoa, Madrid, Spain

Background and Aims: Peritoneal fibrosis can limit long term peritoneal membrane function in peritoneal dialysis (PD) patients. It has been related to bioincompatible PD fluids and peritoneal infections. There are no prospective studies regarding correlation between effluent biomarkers and peritoneal biopsy findings. Our aim was to study the possible relation of peritoneal effluent biomarkers and peritoneal morphology alterations.

Method: Multicenter prospective study in a cohort of stable PD patients treated with biocompatible PD fluids who received a kidney transplant. We collected in each patient peritoneal biopsy samples and peritoneal effluent fluid. We analyzed the relation between effluent biomarkers, phenotype of mesothelial cells (MC) cultured ex vivo, and peritoneal biopsy parameters (mesothelial integrity, fibrosis and hyalinizing vasculopathy). We compared them with patient characteristics, including peritoneal transport parameters. The biomarkers tested were Collagen-1 (COL-1), Fibronectin (FN), Collagen-13 (COL-13), Interleukin-6 (IL-6), Trombospondin-1, Cadherin 13 (CDH-13), CA-125, Gremlin-1 (GREM-1), Matrix metalloproteinase 2 (MMP-2), CC chemokine ligand 18 (CCL18), Plasminogen activator inhibitor 1 (PAI-1) and Vascular endothelial growth factor A (VEGF-A).

Results: Forty patients were included (mean age 54.5±15 years, 64% male, 24.1% diabetics). Mean time on PD was 25.5±27 months, 62.1% were on automated PD (APD) and 17.2% had prior peritonitis episodes. A normal MC culture phenotype was observed in 78% of patients. In peritoneal biopsies samples we found partial or total mesothelium preservation in 39%, submesothelial thickness in 42% and vasculopathy in 14% of cases. Effluent PAI-1 levels were significantly lower in patients with mesothelial cell loss than in those with mesothelial preservation (21.62 vs. 38.59 pg/ml respectively; p = 0.031). Patients with peritoneal fibrosis showed significantly higher ef fluent CDH-13 levels (3.51 vs. 2.32 pg/ml; p = 0.048) and supernatant PAI-1 levels (1183 vs. 72.73; p = 0.000) than those without fibrosis. No other statistical differences were found in other biomarkers analysed.

Conclusion: Most patients treated with biocompatible peritoneal dialysis fluids showed normal mesothelial cell phenotype in peritoneal ef fluent culture. Lower PAI-1 ef fluent levels were associated with mesothelial cell loss and higher effluent CDH-13 levels were related to peritoneal fibrosis.

CHARACTERIZING THE RESIDUAL VOLUME IN PERITONEAL DIALYSIS PATIENTS

Elin Lindholm, Carl Oberg and Karin Bergling

Lund University, Department of Clinical Sciences Lund, Lund, Sweden

Background and Aims: Peritoneal dialysis (PD) is the most common home dialysis treatment, and is associated with lower societal costs and increased patient autonomy. During routine PD, the exact amount of fluid inside the peritoneal cavity is in general unknown, and the peritoneal catheter may also change position, which may lead to a large residual volume, inefficient dialysis, and potentially harmful overfill. A practical, clinical method to estimate the residual volume is from the dilution of a marker molecule before and after fill of a known volume of fresh dialysis fluid. However, ultrafiltration and transport of the marker molecule during the fill phase may introduce large errors, especially when low molecular weight marker molecules are utilized.

Method: Here we performed a retrospective analysis of clinical data consisting of 56 residual volume estimations utilizing either 1.5% glucose (n = 28) or 4.25% glucose fluid (n = 28). Residual volumes were estimated using creatinine, urea and albumin. The contribution of ultrafiltration and mass transport of the marker molecules were quantified using the Three-pore model.

Results: During the fill phase, the median ultrafiltration volume was 16 mL (IQR 3 to 31) in 1.5% glucose dwells, compared to 52 mL (IQR 38 to 66) during 4.25% glucose dwells (Fig. 1). Assuming that 40% of the ultrafiltration occurs as free-water transport, the median difference between Three-pore model and albumin dilution equation residual volumes were only -1 mL (-8 to 5.5) in 1.5% glucose dwells and 1 mL (-3 to 6) in 4.25% glucose dwells (Fig. 2A). Dilution-based calculations using creatinine overestimated residual volumes by 121 mL.
DYNAMICS AND ORIGIN IN PERITONEAL DIALYSIS
CROSS-OMIC PROFILING OF PROTEOME, METABOLOME, AND TRANSCRIPTOME REVEALS MOLECULE AND CLEARANCE DYNAMICS AND ORIGIN IN PERITONEAL DIALYSIS
Rebecca Herzog, Fabian Eibensteiner, Christoph Aufricht and Klaus Kratichwill
Medical University of Vienna, Austria

Background and Aims: Peritoneal dialysis (PD) effluent is not only a rich source of markers for therapy monitoring and investigation of deranged processes during PD it is also surprisingly underexplored and therefore poorly defined. Modern high performance mass spectrometry (MS) and sequencing methods allow monitoring of hundreds of analytes in parallel. For understanding PD transport dynamic and pathomechanisms and on a systems biology level, a multi-level omics approach is particularly attractive.

Method: Samples were obtained from stable patients chronically treated with PD at different time-points of standard 4h peritoneal equilibration tests (PETs). Effluent was collected after the pre-PET (overnight) dwell and at 4h, 1h and 4h dwells. Plasma samples were taken at the 2h PET time point. Effluent was separated into a cellular and cell-free component. Soluble proteins and metabolites in the cell-free compartment were processed using material-specific protocols and standardized LC-MS workflows. The cellular material was subjected to RNA sequencing. The Plasma-Proteome database was used for referencing plasma proteins and estimating plasma concentration. A bioinformatic workflow conjoined information from the datasets to reveal novel insights into the “PD-effluentome”, especially unravelling the origin of proteins and metabolites in PD effluent.

Results: Metabolomics enabled detecting of 207 unique metabolites in cell-free PD effluent. A mixed-effect ANOVA of all metabolites demonstrated dwell time-dependent concentration changes in 173 metabolites. Post-hoc testing revealed most metabolites to be changed between 1h and overnight time points, followed by 1h and overnight and 1h and 4h, respectively. We quantified 9,797 transcripts in PD-effluent cells and 2,729 proteins in PD effluent. 342 proteins were filtered from plasma, while 800 proteins were attributable to local origin or production. A quantitative analysis of the interaction proteome and cellular transcripts of ~1700 protein-transcript pairs showed clusters of proteins explained by over-expression in peritoneal cells compared to plasma concentrations.

Conclusion: Cross-omic profiling of PD effluent can be a valuable approach for revealing small molecule related changes during PD. The exploitation of PD effluent on multiple levels could improve the understanding of pathophysiological molecular processes and transport dynamics in the peritoneal cavity and their role in development of PD complications.

FLUID OVERLOAD AT THE BEGINNING OF PERITONEAL DIALYSIS: A CROSS-SECTIONAL STUDY TO DETERMINE ITS ASSOCIATION WITH SERUM BIOMARKERS
Rita Afonso1,2, Gonçalo Pimenta1, Patricia Matias1, Ana Carlota Vida1, Sara Lobo1, Elisabete Santos3, Patricia Branco1 and Rita Calça1
1 Centro Hospitalar Universitário do Algarve - Hospital de Faro, Nephrology, Faro, Portugal, 2Faro, Portugal, 3Hospital de Santa Cruz, Carmaxide, Lisboa, Portugal and 4Hospital Dr. Nélio Mendonça, Funchal, Madeira, Portugal

Background and Aims: Volume management in peritoneal dialysis (PD) patients is of major importance as fluid overload has been associated with cardiovascular and non-cardiovascular morbidity and mortality. Clinical examination itself has a poor diagnostic accuracy for minor deviations from normohydration, highlighting the need of additional tools. The aim of this study was to evaluate the association between serum biomarkers (CA-125 and NT-proBNP) and volume status, evaluated by clinical and bioimpedance analysis, at the initiation of PD technique.

Method: Single-center cross-sectional study including PD patients that started technique between 2017 and 2022. Demographic and clinical data were collected from the electronic records. Parameters evaluated were clinical examination, serum biomarkers, bioimpedance and dialysis adequacy.

Results: A total of 79 patients (51 male) were included with a mean age of 57±15 years. All of them started with CAPD and 52% were under icodextrin. Hypertension, cardiovascular disease and diabetes were present in 94%, 51% and 34%, respectively. The great majority were under renin-angiotensin-aldosterone system inhibitors (91%), beta-blockers (48%) and diuretic therapy (94%). Baseline PET showed that 77% were high or high-average transporters. Mean weekly Kt/V was 2.4±1.4. The mean residual renal function (RRF) and residual diuresis were 6.7±15 ml/min/1.73 m² and 1.6±0.8 L (4% anuric), respectively, and 11% had ultrafiltration failure. Median nPCR was 0.9 g/Kg/day (IQR 0.3). Median NT-proBNP and CA-125 were 1337 pg/mL (IQR 3401) and 14.6 U/mL (IQR 17.6), respectively. NT-proBNP was still associated with overhydration in a multivariable analysis, adjusted to diabetes, icodextrin use, RRF and CA-125 (p = 0.024).

Conclusion: Serum NT-proBNP and CA-125 seem to be good markers of overhydration at PD baseline. They were also associated with worse dialytic overload at the beginning of PD.
efficacy and ultrafiltration, lower residual renal function and an early need for peritoneal equilibration test results. The impact of this factor on peritoneal membrane function and PD technique survival has not been adequately investigated. The aim of our study was to disclosure the effect of prior abdominal surgical procedures on PD technique survival (main outcome), efficacy rates and also evaluate the risk of infectious complications (secondary outcomes).

Method: We performed a retrospective, longitudinal study, that included 155 PD patients followed at our unit, since September 2018 to September 2022. Two groups were created: G1 (without previous abdominal surgery) and G2 (with previous abdominal surgery). Demographic and clinical characteristics, such as age, gender, chronic kidney disease (CKD) etiology, time on PD program, dialytic efficacy and ultrafiltration, lower residual renal function and an early need for peritoneal equilibration test results were registered from our unit database. Statistical analyses were performed using SPSS statistics version 23.0. The statistical hypothesis tests performed using SPSS statistics version 23.0. The statistical hypothesis tests were considered significant.

Results: One-hundred and fifty-five patients (female: 50.9%) with a mean age of 55.4 ± 7 years were selected. The main CKD cause was glomerular diseases (n = 43, 27.7%), followed by uncertain etiology (n = 32, 20.6%) and autosomal dominant polycystic kidney disease (n = 21, 13.5%). G1 (n = 87; 56.1%) and G2 (n = 68; 43.9%) had similar distributions of gender (female: 50.6% vs 47.1%, p = 0.061), age (50.4± 9 vs 55.4± 10 years, p = 0.076) and dialysis vintage (27.9 vs 28.2 months, p = 0.081). In G1, 62.1% of patients were on continuous ambulatory peritoneal dialysis (vs 55.9% in G2). The majority of patients were high-average transporters in both groups (58.6% vs 54.4%, p = 0.066). Previous comorbidities were G1 (vs G2): arterial hypertension (95.4% vs. 98.5%, p = 0.87), diabetes (27.6% vs. 26.5%, p = 0.83), heart failure (25.3% vs. 26.5%, p = 0.64), peripheral arterial disease (28.7% vs 35.3%, p = 0.082), body mass index >30 kg/m2 (30.7% vs 29.4%, p = 0.072) and dyslipidemia (64.4% vs 64.7%, p = 0.91). In G1, Kt/V was inferior to 1.7 in 36.8% of patients (vs 66.2% in G2, p<0.001). Seven patients (8.1%) have reported more than one peritonitis during time in PD in group 1 (vs 32.4% in G2, p<0.001). We found no differences in PD technique survival between both groups. Transition to hemodialysis happened in 26.4% of patients in G1 (vs 26.5% in G2, p = 0.092). Mortality rate was similar in both groups (6.9% vs 10.3%, p = 0.063).

Conclusion: According to our results, prior abdominal surgical procedures do not appear to compromise technique survival in patients on PD. Although, abdominal surgical events places PD patients in a higher risk of infectious complications and lower efficacy rates. Thus, this group of patients deserve a more detailed evaluation before starting PD, in order to understand if they are good candidates for the technique, as this may not be the most advantageous for them in the long term.
Figure 1: Graph below summarize study recruitment and mortality. Overall patients and families were satisfied with program.

Results: 946 patients screened for the program. 237 were eligible (exclusion mostly due to lack of national insurance coverage or not meeting mobility/transport criteria). 121 patients refused to participate (mostly for feeling safer in the clinic setting or improper home environment), 40 patients were undecided, and 76 patients accepted and started AHHD. Age was 73±11 years. We had 32 males and 44 females. Mean follow up period were 7 months. 12 patients died and 2 patients returned to dialysis centre during follow up period. Only 15 out of the total 126 hospitalizations were related to dialysis (mostly due to volume overload and non-compliance with dialysis schedule and time). We had 55 patients with permcath and 21 with AV fistulas. We had 8 incidents of dialysis catheter malfunction (6 required tissue plasminogen activator installation in the house setting and only two needed catheter exchange (one had catheter related infection)). No reported significant access bleeding or hypotension episodes. We had 20 technical incidents during the study related to electricity or water supply failures. All incidents were resolved without much interruption of treatment. The program overall was cost effective and reduced cost by over 25% (mostly related to saving of ambulance cost). Patients and their families were very satisfied with the program overall. Conclusion: We present a unique successful program related to providing AHHD. Targeting certain dialysis population showed great care, safety, cost saving, better QOL and satisfaction.
TREATMENT PREFERENCES TO SERIOUS ILLNESS IN PATIENTS RECEIVING PERITONEAL DIALYSIS
Ching-I Cheng¹, Pei-Ni Chuang¹, Jen-Kuei Peng¹, Shu-Neng Chueh¹, Chun-Fu Lai¹, Hung-Bin Tsai¹, Chih-Kang Chang² and Jaw-Shiun Tsai*¹
¹National Taiwan University Hospital, Department of Nursing, Taipei, Taiwan, Rep. of China, ²National Taiwan University Hospital Hsin-Chu Branch, Department of Family Medicine, Hsin-Chu, Taiwan, Rep. of China, ³National Taiwan University Hospital, Department of Family Medicine, Taipei, Rep. of China, ⁴National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Rep. of China, and ⁵National Taiwan University Hospital, Department of Integrated Diagnostics & Therapeutics, Taipei, Taiwan, Rep. of China and ⁶National Taiwan University Hospital, Department of Family Medicine, Taipei, Taiwan, Rep. of China.

Background and Aims: People with end-stage kidney disease receiving maintenance dialysis are more likely to receive intensive pattern of end-of-life care than those with other severe illness. It’s important to understand the preferences to cardiopulmonary resuscitation (CPR) and other end-of-life care. However, no prior studies have investigated patients receiving peritoneal dialysis. This study aimed to explore the preference to CPR and patterns of end-of-life care in patient receiving peritoneal dialysis (PD), which had not been specifically investigated in the literature.

Method: This cross-sectional study of patients receiving PD was conducted in the National Taiwan University Hospital between Dec. 2021, and Mar. 2022. Patients were enrolled if they were 20 years or older, sufficiently fluent to complete surveys and cognitively able to provide written informed consent and had received maintenance peritoneal dialysis for at least 3 months. Enrollee were asked to the Chinese version of Physician Orders for Life-Sustaining Treatment questionnaire.

Results: Among 400 eligible patients, 364 (91%) responded to the questionnaire. The average age was 55.5 years; 50.3% were men. Among the 364 responders, 73.6% selected do not attempt resuscitation (DNR) and 26.4% preferred CPR. Multivariate logistic analysis revealed that age (OR = 0.96, 95% CI 0.94-0.98), male (OR = 2.44, 95% CI 1.45-4.1) and residual kidney Kt/V (OR = 2.45 95% CI 1.24-4.82) were associated with CPR. If they are facing on serious illness, 47.5% of participants prefer to “Focus on comfort”, 28.6% choose “try treatments, but do not suffer” and 23.9% request “live as long as possible”. Furthermore, 51.4% of participants selected “No artificial nutrient support” in the end of life and 87.1% select “comfort care” as their first priority. Paradoxically, only 13.5% of the patients who preferred CPR took “staying alive” as their first priority, while 71.9% focused on “comfort care”.

Conclusion: Around 75% of PD patients selected DNR when cardiopulmonary arrest. Age, gender, residual Kt/V were important factors associated with CPR preference. Most patients preferred supportive pattern of end-of-life care. Integrating patients’ treatment preference to serious illness and values and goals of end-of-life care in shared decision making is important for patients receiving dialysis.

IMPLEMENTATION OF AN INNOVATIVE ARTIFICIAL INTELLIGENCE CHAT ROBOT APPLICATION OF NURSING CARE IN PERITONEAL DIALYSIS
Ching-I Cheng¹, Woan-Jean Lin¹, Hui-Ting Liu¹, Ching-Wen Lee¹, Yi-Ting Chen¹, Yu-Hsiang Chou¹ and Chih-Kang Chang²
¹National Taiwan University Hospital, Department of Nursing, Taipei, Taiwan, Rep. of China, ²National Taiwan University Hospital, Department of Integrated Diagnostics & Therapeutics, Taipei, Taiwan, Rep. of China and ³National Taiwan University Hospital, Department of Internal Medicine, Taipei, Taiwan, Rep. of China

Background and Aims: During the Covid-19 pandemic, this study used an innovative intelligent chatbot to investigate satisfaction. The higher score was associated with more agreement with innovative intelligent robot application. And chatbot satisfaction was scored with 1–5 points in which 5 points meant the highest satisfaction.

Method: During a period from May 1st to August 31st, 2021, we utilized questionnaire with the LIKER4 score before and 3 months after the implementation of chatbot to investigate satisfaction. The higher score was associated with more agreement with innovative intelligent robot application. And chatbot satisfaction was scored with 1–5 points in which 5 points meant the highest satisfaction.

Conclusion: We reported similar patient survival, but higher peritonitis rates and PD technique failure in the PDPotTx group, when compared to patients who started PD for other reasons. Considering these findings, taking precautions against peritonitis is more important for patients who started PD after KTx failure.
METHOD: In an observational study of 8113 prevalent PD patients treated with APD (n = 2692) or CAPD (n = 5421), PO4 levels together with demographic and clinical data, including dialysate to plasma ratio of creatinine at 240 min (D/PCr240min at peritoneal equilibration test) and body mass index (BMI), were recorded. During follow-up for a median of 1.99 years, 3619 patients died, and 988 patients underwent kidney transplantation (KT). We divided patients into 5 groups (P1 to P5) according to their baseline PO4 levels (first available measurement) with the following cut-off values for groups: up to 3.5, 3.5-4.5, 4.5-5.5, 5.5-6.5, and over 6.5 mg/dL, respectively. The association of baseline PO4 levels with all-cause and CV mortality risk was analyzed with a competing-risk regression model and KT as a competing risk.

RESULTS: Characteristics of patients classified into groups P1 (16%), P2 (33%), P3 (27%), P4 (13%), and P5 (9%) are presented in Table. P5-patients were in general younger, more often men, less often diabetic (DM), and had lower residual renal function, DM, and hypertension) was increased in P4- and P5-patients compared with P2-patients, sub-hazard ratio (sHR) of 1.14 (95% CI: 1.01-1.27) and sHR of 1.27 (95% CI: 1.10-1.46), respectively. Higher PO4 levels were not associated with significantly increased CV mortality risk for P4-

ASSOCIATION OF HIGH SERUM PHOSPHORUS WITH INCREASED MORTALITY RISK IN PATIENTS ON PERITONEAL DIALYSIS: RESULTS FROM COLOMBIA

Rafael Gomez1, Abdul Rashid Tony Qureshi2, Xiejia Li1, Joanna Stachowska-Pietka1, Malgorzata Debowska1, Jacek Waniewski1 and Bengt Lindholm2

1RTS San Fernando, Renal Unit, Cali, Colombia, 2Karolinska Institutet, Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden and 3Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Poland

Background and Aims: Elevated levels of serum phosphorus (PO4) in patients with kidney failure are associated with complications such as cardiovascular (CV) disease, bone disease and impaired wound healing, and increased mortality in hemodialysis patients. A recent PDOPPS study (Lopes et al NDT 2023) showed that high PO4 is associated with increased mortality also in patients undergoing peritoneal dialysis (PD). We explored PO4 levels in a large cohort of patients undergoing chronic PD in Colombia to determine the association of PO4 levels with mortality.

Table 1: Demographic and clinical data of peritoneal dialysis patients, according to transplantation status.

APD, automated peritoneal dialysis; CAPD, continuous ambulatory peritoneal dialysis; ESRD, End Stage Renal Disease; HD, hemodialysis; ON, obstructive nephropaty; PD, peritoneal dialysis; PN, pyelonephritis; SD, standard deviation; Tx, transplantation; UF, ultrafiltration; VUR, vesicoureteral reflux.

Abstracts
patients, sHR of 1.10 (95% CI: 0.93-1.31), or for P5-patients, sHR = 1.14 (95% CI: 0.93-1.39) compared to P2-patients.

**Conclusion:** Among 8113 PD patients in Colombia, 49% had baseline PO4 > 4.5 mg/dL and 22% PO4 > 5.5 mg/dL. Baseline PO4 levels > 5.5 mg/dL (P4 and P5 groups) were associated with increased all-cause mortality. These results are in agreement with the results of the PDOPPS study and suggest that effective management of hyperphosphatemia is important to improve clinical outcomes in PD patients.

**TELEDIALYSIS: THE FIRST NORTHEAST ITALY EXPERIENCE OF TELEHEALTH IN PERITONEAL DIALYSIS PATIENTS**

Paolo Lentini¹, Giorgio Laudadio¹, Valeria Fuso¹, Claudia Benedetti¹, Antonio Previti¹, Sofia Andrighetto¹, Federica Vienna¹, Daniela Cremasco¹ and Giovanni Gambaro²

¹Azienda Ospedaliera AULSS7 Pedemontana, Nephrology and Dialysis Unit, Bassano del Grappa (VI), Italy and ²AOUVR, Nephrology, Verona, Italy

**Background and Aims:** During Covid19 epidemic, International Society of Peritoneal Dialysis recommend "People on PD should stay at home. Hospital visits should be minimized for only urgent indications. Consultations should otherwise be conducted by telehealth". In 2021 in Italy Government enforce plan to develop Telehealth and to create a new Nephrology home model to provide better oversight of care with remote monitoring. Telehealth has been used to manage patients with chronic kidney disease (CKD) and demonstrated equal outcomes in CKD care by either in-person or virtual visits. Telehealth also help facilitate patient education about home dialysis modalities and self-care, especially in peritoneal dialysis setting (PD). We report the first experience in the Northeast of Italy with Teledialysis, a combination of PD technique and new technology devices that we used together to overcome clinical, social and psychological barriers to PD.

**Method:** In our pilot study, we enrolled 12 consecutive Automated Peritoneal Dialysis (APD) patients from our Nephrology program in “San Bassiano Hospital”, Bassano del Grappa, VI, Italy. Teledialysis was perform with the combination of two systems:

1- A Web platform Sharesource (Baxter Renal care ®) that with a mod-M added to APD device supports remote patient management through secure communication with and allows details of the home dialysis treatment and provide to the clinician the ability to act on that assessment by updating the patient device setting to the cycler.

2- Totem eVISUS System (TesiSquare ®) that is a plug and play system consisting of two units: a) a transportable remote station at the patient’s home (Totem) equipped with high performance camera, touchscreen monitor, speaker microphone hand free and computers, internet routers for fixed and mobile phone, wireless access point and remote control to answer calls remotely and b) a Control Station (in our Hospital) that by a simple use of a mouse form our healthcare personnel can connect to one or more patients at the same time and check the Totem Camera. (Figure 1) We control day by day PD sessions by sharesource and we provide virtual support to our patients for medications of catheter exit-site and catheter exit-site monitoring and instructions for PD training; we also perform clinical evaluation status, we check PD effluent color and we aid patients and care givers for PD session management.

**Results:** During an observation period of 11 months we enrolled 12 consecutive patients (4m/8F) with an average age of 73 yrs; cognitive impairment, diabetes, hypertension, chronic heart failure and peripheral vascular disease (PVD) were common comorbidities (see Figure 2). We

![Figure 1: The Teledialysis System: 1) Sharesource for remote control; 2) Totem at home access point with remote control. 3) Central station in the hospital for virtual evaluation.](image-url)
perform 60 tele-dialysis sessions with an average duration of 26’ minutes. We don’t detect any exit Site Infection (ESI), Tunnel infection or Peritonitis in our population; none of our patients require urgently hospital or emergency room admission. Only once we suggest access to our department for fever and dyspnea and the patient require a one week hospitalization for acute bacterial pneumonia. (Table 1)

Conclusion: Our preliminary results shown that Tele-dialysis is a safe, reliable, flexible and effective system and is easy to use for our patients; we assert that technology really can help nephrologist to improve PD program and aid patients to overcome barriers to select PD and avoid fear of the failure. Tele-dialysis promote a real integration between Hospital and our territory by a new care pathway.

**PERITONEAL DIALYSIS AND POSTOPERATIVE OUTCOMES IN CHILDREN AFTER CARDIAC SURGERY: A SINGLE-CENTER COHORT STUDY**

Gonçalo Pimenta¹, Rita Afonso², Ana Carlota Vida³, Rita Calca³, Isabel Graça³, Maria Estevens⁴, Patrícia Matias¹, Rui Anjos⁴ and Patricia Branco⁵

¹Hospital de Santa Cruz, Pediatric Cardiology, Carnaxide, Lisboa, Portugal, ²Centro Hospitalar Universitário do Algarve - Hospital de Faro, Nephrology, Faro, Portugal, ³Hospital Dr. Nélia Mendonça, Nephrology, Funchal, Madeira, Portugal and ⁴Hospital de Santa Cruz, Pediatric Cardiology, Carnaxide, Lisboa, Portugal

*Background and Aims:* Acute kidney injury (AKI) is a frequent complication in neonates and infants after congenital heart disease surgery, with great impact on morbidity and mortality. Peritoneal dialysis (PD) is the renal replacement therapy of choice, as it allows continuous gentle ultrafiltration with minimal impact on hemodynamic status. However, there is no standardized prescription. The present study aimed to describe our experience of using PD in the management of AKI after cardiac surgery in pediatric patients and the postoperative outcomes.

**Method:** Single-center cross-sectional study including 21 children undergoing cardiac surgery between 2017 and 2022, in a congenital heart disease reference center. Demographic and clinical data were collected from the electronic records.

**Results:** Of the 21 patients treated with PD, 11 were female. Mean age was 32 ± 45 days and median weight was 3.4 kg (IQR 0.5). All pregnancies had been full-term with a mean birth weight of 3.2 ± 0.3 kg. No congenital urinary tract anomalies had been previously documented. Previous history of AKI was present in 2 patients. Transposition of the great arteries was the most common surgical indication (52%). RACHS-1 score was >4 in 12 patients and median PRISM-IV score was 6.5% (IQR 6). Cardiopulmonary bypass was performed in 19 patients with a mean time of 181 ± 72 minutes and a mean aortic clamping time of 94 ± 29 minutes. All patients required inotropic support after cardiac surgery with ≥2 drugs, for 197 ± 136 hours. Median time with mechanical ventilation support was 126 hours (IQR 288) and median length of stay at the intensive care unit (ICU) was 9 days (IQR 15.3). The indications for PD initiation were anuria (66.7%), oliguria (23.8%) and fluid overload (9.5%). Median time between cardiac surgery and AKI diagnosis was 2.5 hours (IQR 8.8) and between AKI diagnosis and PD initiation was 1.8 hours (IQR 4.3). Median duration under dialysis was 2 days (IQR 3.5). Exchange volume of dialysate varied between 6 and 15 mL/kg at the beginning of PD. In 11 patients, this volume was progressively increased to a maximum of 60 mL/kg (minimum: 30 mL; maximum: 120 mL). Continuous veno-venous hemodialfiltration was required in 3 patients, mainly due to mechanical catheter dysfunction. Complications related to PD occurred in 5 patients: 1 patient developed peritonitis, 1 patient had mechanical catheter dysfunction and 3 patients had peri-catheter leak. Complete recovery of renal function was achieved in 14 patients. Longer time on PD was associated with lower weight before surgery (p = 0.04), longer time on mechanical ventilation and inotropic support (p < 0.001), and longer stay at the ICU (p < 0.001). Time on inotropic support could predict time on PD using a multiple regression model (adjusted R² = 59%, p = 0.003), adjusted to cardiopulmonary bypass time, time on mechanical ventilation support and weight before surgery (adjusted R² = 0.7, p = 0.005). Eight patients died during hospitalization, due to multiorgan failure (38%), cardiogenic shock (38%), disseminated intravascular coagulation (13%) and septic shock (13%). Longer cardiopulmonary bypass time was associated with in-hospital mortality (149 ± 53 vs 235 ± 46, p = 0.004). Both the time between AKI diagnosis and PD initiation and the time on PD were not associated with in-hospital mortality.

**Conclusion:** Our study suggests that PD is a safe and effective dialysis modality in the management of post-cardiac surgery AKI in pediatric population. Early identification of high-risk infants is important to implement preventive measures.

DEVELOPMENT OF A HOME DIALYSIS PATIENT SUPPORT SYSTEM WITH EXERCISE FUNCTION PART II: RESULTS OF A TRIAL OF ADDED EXERCISE FUNCTION
Akiko Okawa1,2, Natsumi Yamamoto1, Yuki Sekine3 and Tokuo Umeda
1Japan, 2Mie Prefectural College Of Nursing, Faculty of Nursing, Tsu, Japan and 3Japan

Background and Aims: In Japan, peritoneal dialysis patients are required to record daily dialysis information in continuous ambulatory peritoneal dialysis (CAPD) notes. However, as the CAPD notes are a list of numbers, it is difficult for medical staff to quickly understand the patient's physical condition. Although many people now use communications infrastructure, access to medical information on the Internet is restricted from the viewpoint of patient information security in medical institutions in Japan. Therefore, patient information outside the medical institution cannot be viewed on the system inside the medical institution. Therefore, we are developing a safe and securedialysissupportsystemtoconnectdialysispatients’ homes and medical institutions. We have developed a dialysis support system that can share the patient’s vital data, dialysis records, meal records, etc., between patients and medical institutions. Here, we added a function to support the exercise of dialysis patients, and present the results of a trial.

Method: The display and recording items of the previously developed system include vital data, and exchange start time as records necessary for peritoneal dialysis, dialysate concentration, drainage volume, fluid injection volume, drainage volume, drainage time, drainage confirmation, blood pressure, and blood sugar level. In addition to these items, we have added a new function to the system that can automatically input the patient’s exercise records from ergo-storage device. This added functionality links movement information from the ergo-storage device with relevant patient information in the previously developed system. It also enables medical staff to view and share the graphical data as visible information from within the facility. The patients exercise using the developed ergo-storage device, and the amount of exercise is stored in the charger. Patients can exercise with this ergo-storage device on both dialysis and non-dialysis days.

Results: To prevent erroneous input, the dialysis records could be entered automatically or selected using radio buttons. In addition, when confirming drainage, it was possible to transmit images to medical institutions. In the added exercise function, the strength of pedaling on the ergo-storage device, the number of rotations, etc., could be output in CSV format. The amount of exercise was sent to the previously developed system. In addition, the

Figure 1: Display of the developed dialysis support system with exercise function (patient side).

Figure 2:
system allowed storage of the electricity generated by rotating the pedals in the storage device. Therefore, the patients were motivated not only to exercise but also to continue to exercise. The accumulation of exercise data enabled the patients to understand changes over time, leading to self-management. Furthermore, exercise could be continued even on non-dialysis days. Medical institutions could also share not only the patient’s dialysis records, but also information on their amount of exercise, leading to improved patient care.

Conclusion: This developed system with new exercise function supported patients’ exercise and its continuation on both dialysis and non-dialysis days. The amount of exercise by the patient was stored as electricity, which could be used to charge the patient’s cell phone, etc. This increased the patients’ motivation to exercise. Furthermore, this information can be shared with medical institutions. This research was supported in part by Gakushin Kaken (JP20H03982).

#4062 PERITONEAL DIALYSIS CATHETER SURVIVAL: A TEN-YEAR SINGLE CENTER STUDY
Bárbara Beirão Rodrigues, Mariana Freitas, José Francisco, João Borges, Ana Beatriz Pereira, Ciria Sousa, Pedro Reis Pereira, Catarina Prata, Rui Castro and Teresa Pinto Ribeiro Morgado

Centro Hospitalar de Trás-os-Montes e Alto Douro, Nephrology, Vila Real, Portugal

Background and aims: Timely insertion and adequate management of peritoneal dialysis catheter (PDC) related complications are crucial for the success of Peritoneal Dialysis (PD). The aim of the present study was to review the peritoneal dialysis catheter outcomes at our center and evaluate variables influencing catheter survival.
