60th ERA Congress, 15-18 June 2023

Congress Abstracts
GENERAL INFORMATION

Subscriptions
A subscription comprises 12 issues of Nephrology Dialysis Transplantation. Prices include postage, and for subscribers outside the UK delivery by Standard Air. NDT Advance Access contains papers that have been finalised, but have not yet been included within an issue. Advance Access is updated weekly.

Annual Subscription Rate (Volume 38, 12 issues, 2023)

Institutional
Print edition and site-wide online access: £1311/$2489/€1967 Print edition only: £1205/$2291/€1807 Site-wide online access only: £957/$1899/€1434

Personal
Print edition and individual online access: £505/$962/€759 Please note: US$ rate applies to US and Canada, Euros applies to Europe, UK£ applies to UK and Rest of World.

Oxford Journals Environmental and Ethical Policies
Oxford Journals is committed to working with the global community to bring the highest quality research to the widest possible audience. Oxford Journals will protect the environment by implementing environmentally friendly policies and practices wherever possible. Please see https://academic.oup.com/journals/pages/about_us/ethical_policies for further information on Oxford Journals’ environmental and ethical policies.

There may be other subscription rates available, for a complete listing please visit https://academic.oup.com/ndt/subscribe

Full prepayment, in the correct currency, is required for all orders. Orders are regarded as firm and payments are not refundable. Subscriptions are accepted and entered on a complete volume basis. Claims cannot be considered more than FOUR months after publication or date of order, whichever is later. All subscriptions in Canada are subject to GST. Subscriptions in the EU may be subject to European VAT. If registered, please supply details to avoid unnecessary charges. For subscriptions that include online versions, a proportion of the subscription price may be subject to UK VAT. Personal rate subscriptions are only available if payment is made by personal credit card and delivery is to a private address.

NDT is the official ERA journal. By becoming a member of ERA you receive a free subscription to the NDT journals! The 2023 membership fees are: full fee = £170.00 (includes individual online access). For more information please go directly to the official ERA website (https://www-era.org) and click ‘Membership’ or contact the ERA Membership Office directly (ERA Headquarters; Via XXIV Maggio 38; I-43123 Parma, Italy. Tel: +39 0521 988078; Fax: +39 0521 959242; Email: membership@era.org). IMPORTANT: Membership is open to individuals only, not institutions.

The current year and two previous years’ issues are available from Oxford University Press. Previous volumes can be obtained from the Periodicals Service Company, 11 Main Street, Germantown, NY 12526, USA. www.periodicals.com/oxford.html

Email: psc@periodicals.com. Tel: +1 (518) 537 4700. Fax: +1 (518) 537 5899.

For further information, please contact: Journals Customer Service Department, Oxford University Press, Great Clarendon Street, Oxford OX2 6DP, UK. Email: jnl.cust.serv@oup.com. Tel (and answerphone outside normal working hours): +44 (0)1865 353907. Fax: +44 (0)1865 353485. In the US, please contact: Journals Customer Service Department, Oxford University Press, 4000 CentreGreen Way, Suite 310, Cary, NC 27513, USA. Email: jnlorders@oup.com. Tel (and answerphone outside normal working hours): 800 852 7323 (toll-free in USA/Canada). Fax: 919 677 1714. In Japan, please contact: Journals Customer Services, Oxford University Press, 4-5-10-8F Shibuya, Minato-ku, Tokyo, 108-8386, Japan. Email: oupjnl@po.iijnet.or.jp. Tel: +81 3 5444 5885. Fax: +81 3 3454 2929.

Methods of payment. Payment should be made: by bank transfer to Barclays Bank Plc, Oxford Office, Oxford (bank sort code 20-65-18) (UK); overseas only Swift code BARC GB22 (UK£ Sterling Account no. 70299352, IBAN GB89BARC20651870299332, US$ Dollars Account no. 66014600, IBAN GB27BARC20651866014600; EUR EURO Account no. 78923655, Sort code 20-65-18, IBAN GB16BARC20651878923655, SWIFT BARCGB22); or by credit card (Mastercard, Visa, Switch or American Express).

The ten best-ranked Abstracts were invited to prepare a Graphical Abstract.
All Abstracts have been published in their original format.
Background and Aims: Autosomal recessive polycystic kidney disease is caused by mutations in PKHD1 encoding FPC, and is characterized by severe renal cystogenesis in neonates, yet mouse models do not fully recapitulate the human phenotype. Indeed, even the Pkh1d null allele does not cause renal cystogenesis in the mouse. Several cleavage products of FPC are reported yet their function remains unknown. The aim of this study was to determine the function of the FPC cleavage products and their effects on cyst development in ARPKD.

Method: Three Pkh1d mutant mouse lines and the cystic Pkd1V mouse were crossed to produce digenic mice with which to study renal cystogenesis. Biochemical analysis was used to investigate FPC cleavage patterns using a panel of new antibodies. Cell models and electron microscopy revealed underlying mitochondrial defects in Pkh1d Knokout mice.

Results: Pkh1d mutation modifies a Pkd1 uncleavable mutant (Pkd1V), enhancing the cystic phenotype in both the kidney and pancreas. The hypomorphic Pkh1d mutant and Pkh1d KO both enhance the Pkd1V kidney phenotype, making distal tubule cysts more severe and initiating cystgenesis in the proximal tubules. FPC displays differential cleavage to produce fragments of unknown function. New antibodies were generated to interrogate FPC cleavage products. Three small C terminal cleavage fragments were identified which contain a mitochondrial targeting sequence and are recruited to mitochondria. Mitochondrial ultrastructural changes were evident after deletion of Pkh1d including mitochondrial fragmentation and dilated cristae, suggesting disrupted mitochondrial function. Deletion of just the C-terminal fragment of FPC (ΔC'T), the portion that directly corresponds to the portion that cleaves and localises to the mitochondria, is sufficient to enhance the renal cystic phenotype of the PCl cleavage mutant. Unlike the other Pkh1d mutants however, FPC (ΔC'T) does not result in the pancreatic cystogenesis when combined with Pkd1V, suggesting that the FPC C terminus is not required to prevent pancreatic cyst development.

Conclusion: Our results suggest that the C-terminus of FPC plays an important role in preventing renal cystogenesis via a newly discovered mitochondrial specific function. Our work reveal some aspects of FPC's function, in particular a previously unrecognised mitochondria function that is mediated through FPC cleavage products and is essential in the kidney to prevent the enhancement of cystogenesis in the digenic model.

EXPRESSION OF THE COLLAGEN IV α345 MOLECULE ALONG THE RENAL TUBULE IN HEALTH AND DISEASE

Lisa Loderbauer¹, Karen Schneider¹, Karl Knap¹, Florian Wopperer¹, Mario Schiffer¹, Kerstin Amann², Katharina Broeker¹, Maike Buettner-Herold² and Michael Wiesener¹

¹University Hospital Erlangen, Department of Nephrology and Hypertension, Erlangen, Germany, ²University Hospital Erlangen, Department of Nephropathology, Germany and ³University of Regensburg, Institute of Physiology, Germany

Background and Aims: Patients suffering from Alport Syndrome (AS) have a high life time risk of kidney failure and hearing loss. The underlying molecular cause is a germline mutation in one of the COL4A3/4/5 genes, whose gene products collectively form an important component of the glomerular basement membrane and the inner ear. Recent genetic studies have shown that the AS is much more prevalent than clinically recognized, suggesting that atypical clinical cases are frequent. Thus, patients with AS may phenocopy other kidney diseases. To date, pathomechanistic studies of the AS have focused on the glomerular membrane, yet equally strong expression of other kidney diseases. Therefore, we postulate that the pathogenesis of AS may in part stem from the (distal) tubular apparatus, which is already known from other diseases such as ADPKD and nephrophthisis.

#3460 DEVELOPMENT OF A NEW CELLULAR MODEL TO EVALUATE THE CLINICAL IMPACT OF PKD1 VARIANTS EXPLOITING CRISPR/CAS9 SYSTEM

Martina Migliorero¹, Donatella Marsalla¹, Claudia Saglia¹,², Valeria Bracciali¹,², Francesca Arruga¹, Antonio Amoroso¹, Tiziana Vaisitti¹ and Silvia Deaglio¹,²

¹University of Turin, Department of Medical Sciences, Torino, Italy and ²Città della Salute e della Scienza University Hospital, Immunogenetics and Transplant Biology Service, Italy

Background and Aims: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common single-gene disorder and the most frequent progressive kidney disease, which ultimately leads to kidney failure and renal replacement therapy. Almost 80% of cases of ADPKD are attributed to germline mutations in PKD1, even though at least one second somatic event such as the inactivation of the remaining wild-type PKD1 allele is required for the disease's manifestation. A significant portion of all variants identified in PKD1 is classified as “variant of unknown significance” (VUS) and understanding their functional impact may be of diagnostic importance for patients and their families. So, a proper experimental model to study the functional impact of different genetic lesions is needed to readily confirm their pathogenicity.

Method: The HEK293T cell line was modified to express an inducible Cas9 and afterwards transfected with a sgRNA targeting exon 15 of PKD1 to generate clones carrying homozygous or heterozygous nonsense variants, validated by Sanger sequencing. Transcript level and protein expression were evaluated, and then functional read-outs were set-up to validate the model. Heterozygous clones were used to introduce a second PKD1 variant, c.11614G>A (p.Glu3872Lys) in exon 42, using a modified CRISPR system called base editors, able to operate single-base substitutions (Figure 1A).

Results: Heterozygous (+/−) and homozygous (−/−) exon 15 PKD1 clones were generated. These cells showed a slight decrement in PKD1 mRNA levels, and PC1 protein loss was confirmed in full knock-out clones. Functionally, immunofluorescence staining highlighted a different cytoskeletal rearrangement in cells lacking PC1, which did not present actin protrusions characterized by increased viability, resistance to cell death and a disrupted autophagic pathway, as demonstrated by LC3BI-I-I conversion, which in PKD1−/− cells is diminished. Validation of the model is also supported by RNA sequencing data indicating that double knock-out cell lines display an upregulation of genes involved in proliferative pathways and epithelial-mesenchymal transition, as well as a down-regulation of genes involved in cytoskeletal organization.

We then used the heterozygous exon 15 clones to introduce a specific variant in exon 42, classified as C4 according to ACGM criteria. To do so, PKD1+/− and PKD1−/− cell lines were transfected with a sgRNA guide that correctly positioned the Cas9 NHEJ. Using this approach we could generate a double knock-out cell line on exon 42 and a “double hit” cell line carrying a heterozygous variant on exon 15 and an homozygous one on exon 42, which represents a more likely real-life situation. Functional assessment of the variant's pathogenicity and comparison with exon 42 double knock-outs is currently ongoing.

Conclusion: In conclusion, we generated a new PKD cellular model that can be easily exploited to reproduce some of the VUS variants identified, by clinical exome sequencing, in our cohort of ADPKD patients. Results obtained provide a proof-of-principle of the feasibility of this approach and allowed to identify selective read-outs (Figure 1B) to be used for a rapid screening to assess the phenotypic impact of specific PKD1 variants.
Background and Aims: Primary Distal Renal Tubular Acidosis (dRTA) is a rare genetic condition characterized by impaired capacity of A-type intercalated cells to excrete excess of H⁺ ions. The disease is caused primarily by pathogenic variants in the SLC4A1 gene encoding for the basolateral anion exchanger 1 (AE1) or the ATP6V1B1 and ATP6V0A4 genes encoding for two subunits of the apical proton ATPase. The latter also cause variable degrees of sensorineural hearing loss (SNHL). Additional genes include WDR72 that is associated with amelogenesis imperfecta and FOXI1 that also causes SNHL. To understand better the impact of alkali treatment on the natural history of dRTA, a European prospective registry has been created in collaboration with the ERKNet European Reference Network.

Method: We present a first interim descriptive analysis of first 182 patients that have been collected from 2019 to 2022. Treatment data are under analysis and are not included.

Results: To date, mostly paediatric patients (79%) have been included in the registry. A genetic diagnosis was available in 111/182 (61%) of patients and showed the following distribution of underlying genes: ATP6V0A4: 45%, ATP6V1B1: 41%, SLC4A1: 14%. Variants in WDR72 and FOXI1 were reported in one patient each. Overall, we observed no major differences in blood pressure and in urinary/blood parameters, when comparing children vs adults or proton ATPase vs AE1 defects (partially shown in tables 1 and 2). Adult patients were on average diagnosed later, had more frequently nephrolithiasis and higher BMI. In part, differences may reflect selection biases that will be assessed with the collection of longitudinal data. As expected, patients with proton pump defects were diagnosed earlier and had more frequently SNHL. The degree of nephrocalcinosis and the estimated glomerular filtration rates were similar when comparing all groups. None of the patients had developed end stage kidney disease.

Conclusion: This first report demonstrates successful enrolment of a cohort of patients with dRTA. Enrolment is still ongoing. Longitudinal data will allow assessing the impact of alkali therapy on the long-term outcome.

DIAGNOSTIC YIELD OF A TARGETED GENE PANEL FOR MONOGENIC KIDNEY DISEASES: A EUROPEAN STUDY

Silvia Giovanella¹, Antonio M Poyatos Andújar², Almudena Avila-Fernández³, Ana Bustamante-Aragones³, Antonio Percesepe⁴, Davide Martorana⁴, Alessandra Terracciano⁵, Laura Massella⁶, Giulia Ligabue⁷, Francesca Testa⁸, Camilla Ferri⁷, Marco Marino⁹, Enrico Tagliafico⁹, Olga Calabrese¹⁰, Gabriele Donati¹⁰ and Riccardo Magistrini¹⁰

Background and Aims: Despite advances in understanding the underlying causes of CKD, 20% of cases remain unexplained (1). A genomic approach has the potential to identify the cause of CKD in a significant portion of pediatric and adult patients, with estimated diagnostic rates of 5-30% (2). However, there is a lack of consensus in the scientific community on the best diagnostic algorithm. The DECIDE project (Diagnostic Efficacy Kidney Disease European) is a European collaboration that aims to address this issue by evaluating the diagnostic rate of a targeted gene panel in a large cohort of patients.

Method: DECIDE involved three Italian and two Spanish centers, encompassing both pediatric and adult patients. The study used the Nephropathies Solution Panel (NES, SOPHIA Genetics), which covers 44 kidney-related genes, to test patients with a high suspicion of genetic kidney disease. The clinical presentation was classified into cystic disease, glomerulopathy, CAKUT, tubulopathy, nephrocalcinosis, other, and negative phenotype. The diagnostic yield of the NES panel was calculated. To assess the genotype-phenotype relationship, Kaplan-Meier analyses were performed. Additionally, the diagnostic results obtained from alternative technologies, such as larger panels, WES and hybridization arrays, in cases of NES panel negative results, were also collected.

Results: As far as now the DECIDE project collected 632 genetic data. To evaluate the diagnostic accuracy of the panel, the number of (likely) pathogenic variants correlated to phenotype was analyzed. The diagnostic yield is shown in Figure 1, with 46% for cystic disease, 41% for glomerulopathy, 33% for tubulopathies, 28% for CAKUT, 14% for nephrocalcinosis, 2% for Nephronophthisis.

Conclusion: New approaches are necessary to uncover the hidden genetic components of rare renal conditions.

SINGLE TUBULE RNASEQ FROM GITLEMAN SYNDROME MICE REVEALING MAGNESIUM HANDLING IN DISTAL RENAL TUBULES
Chih-Chien Sung1, Yu-Juei Hsu1, Chien-Ming Lin1 and Shih-Hua Lin1

1Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan, R.O. C. and 2Department of Pediatrics, National Defense Medical Center, Taipei, Taiwan

Background and Aims: Gitelman syndrome (GS) is characterized by salt-losing hypotension, hypokalemic metabolic alkalosis, hypomagnesemia, and hypocalciuria caused by a specific mutation in the thiazide-sensitive sodium chloride co-transporter (NCC) gene SLC12A3. However, magnesium (Mg2+) associated gene in the distal renal tubules remains unclear.

Method: We performed small samples RNA-seq from manual microdissection of distal convoluted tubules (DCT1s) in nonsense Ncc Ser707X (S707X) homozygous knockin mice (NccS707X/S707X mice) (n = 4) and wild-type (WT, n = 4). Cortical thick ascending limbs of Henle (cTALs), connecting tubule (CNT), cortical collecting duct (CCD) were also microdissected.

Results: Among DCT makers, Slc12a3 (NCC) and Psalb- (Parabumin) were significantly downregulated (Log2TPMWT/WT: −4.45, P = 0.0003; −6.888258295, P = 0.0003, respectively). Mg2+ transporters of Trpm6 gene expression were significantly downregulated. In addition, Egf and Cnnm2 have
been reported to increase TRPM6 trafficking or activity, were also decreased in DCT segment. Rack1 was also decreased in DCT1. Claudins including Cldn10, Cldn16, and Cldn19, involving paracellularly reabsorption of Ca\(^{2+}\) and Mg\(^{2+}\), were not changed in cTALs. All findings indicate chronic hypokalemia may mediate DCT1 remodeling and affect development. 

Conclusion: Our small samples RNA-Seq from dissected DCT highlight the possible molecular pathway of hypomagnesemia in GS. Chronic hypokalemia caused by inactivation of Slc12A3 gene may affect the DCT development causing loss of Mg\(^{2+}\) associated transporters.

\(^4\)Eloxx Ltd, Massachusetts, United States of America

\(^5\)JAMCO Pharma Consulting AB, Stockholm, Sweden

\(^6\)Travere Therapeutics, San Diego, United States of America

\(^7\)Edinburgh Medical School, Edinburgh, United Kingdom

**Background and Aims:** Alport Syndrome (AS) is caused by pathogenic variants in COL4A3, COL4A4 & COL4A5 genes. The clinical course of AS can be highly variable, depending on gene affected, mutation type and Male (M) or Female (F) sex. Proteinuria is associated with worse prognosis. Previous genotype-phenotype correlation studies have shown protein length altering variants are associated with a more severe phenotype in males with COL4A5 variants, however studies in females have shown contradicting results. This study aims to describe demographics and investigate renal outcomes associated with pathogenic variant type in M vs F AS patients, using longitudinal data from the National Registry of Rare Kidney Diseases (RaDaR) which recruits patients at 108 UK renal clinics.

**Method:** RaDaR is linked to Regional Genetics hubs for clinical genetic reports, renal IT systems for routine test results and the UK Renal Registry for Renal Replacement Therapy (RRT) initiation data. eGFR was calculated using CKD-EPI Cr equation (2021) or Schwartz equation for those \(\leq 16\) yrs. eGFR slope was calculated over the last 3 years (or 3 years prior to End Stage Kidney Disease (ESKD)/death for patients who reached those outcomes), with patients required to have a minimum of 4 values over 2 years. For genotype data, variants classified in clinically issued reports as “Pathogenic” or “Likely Pathogenic” were included and classed as: 1. Protein Length Altering and 2. Missense variants. Where both protein length altering and missense variants in the same gene were identified in an individual, the missense variant was used. Data are presented as percentages for categorical variables and mean ± SD for continuous variables. Kaplan Meier analysis and the log rank statistic were used to compare age at RRT start, stratified by gender and variant types. Lower quartile (LQ) (25%) estimates are presented where too few events have occurred to calculate a median (50%) estimate.

**Results:** Between Jan 2013–Jul 2022, 920 AS patients were recruited; 53% M vs. 47% F. Genetic test reports were available for 343/920 (37%) patients. 294/343 (86%) reported a pathogenic or likely pathogenic variant, 140 protein length altering and 154 missense. Individuals with 2x COL4A3/COL4A4 variants were youngest at RRT start, whilst females with COL4A5 variants were oldest (LQ 20.1 vs 60.9 yrs, log-rank p < 0.0001) (Figure 1a). COL4A5 variants were younger at RRT start vs. those with missense variants (median age 30.2 vs 52.1 yrs, \(p = 0.01\)). Conversely 0/36 females with protein length altering COL4A5 variants had started RRT, compared with 6/37 with missense variants (\(p = 0.01\)) (Figure 1b-i). COLA3 or COLA4A4 variants Whilst females with homozygous protein length altering COL4A3/4 variants were younger at RRT start vs. those with missense variants (LQ 47.1 vs 64.9 yrs, \(p = 0.05\)), age at RRT start did not differ by mutation type for males with COLA3/4 heterozygous variants (Figure 1b ii-iv). However, males with homozygous or 2x protein length altering COLA3/4 variants were younger at RRT start than those with missense variants (median age 20.1 vs 24.3 yrs, \(p = 0.05\)), whilst no difference was observed by variant type for females with 2x COLA3/4 variants (Figure 1b v-vi). Proteinuria and eGFR slope were generally correlated with age at ESKD.

**Conclusion:** The observed effect of pathogenic variant type on renal outcomes varied by gene affected, number of mutations and sex. The relatively reduced severity among females harbouring a protein length altering COLA3/4 variant may represent an effect of skewed X-inactivation or a missense gain-of-function mechanism. RaDaR recruits patients with a clinical diagnosis of Alport syndrome or Thin Basement Membrane Nephropathy; ascertainment of individuals with a single COLA3 or COLA4A4 variant is therefore likely to favour those with more severe kidney disease. Linkage of the RaDaR AS cohort with genetic report data is ongoing; further correlations may be observed with larger numbers.
Figure 1: Kaplan Meier Survival Analyses of Age at ESKD stratified by (a) gene (b) variant type.
RAPIDLY PROGRESSIVE AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE: RISK FACTORS FOR DISEASE SEVERITY DURING CHILDHOOD AND EARLY ADULTHOOD

Stijn Wigerinck1,2, Pieter Schellekens2-4, Angélique Dachy2,4, Maroun Chedid1, Christian Hanna5, François Jouret6, Peter Harris1, Bert Bammens3, Fouad Chebib7 and Djalila Mekahli2,8

1Mayo Clinic, Rochester, MN, Nephrology and Hypertension, Rochester, United States of America, 2Catholic University of Leuven, PKD Research Group, Department of Development and Regeneration, Leuven, Belgium, 3Catholic University of Leuven, Department of Nephrology, Dialysis and Renal Transplantation, Leuven, Belgium, 4ULiège Academic Hospital, Department of Pediatrics, Laboratory of Translational Research in Nephrology (LTRN), Luik, Belgium, 5Mayo Clinic, Rochester, MN, Division of Pediatric Nephrology and Hypertension, Rochester, United States of America, 6ULiège Academic Hospital, Department of Internal Medicine, Nephrology, Luik, Belgium, 7Mayo Clinic, Jacksonville, FL, Nephrology and Hypertension, United States of America and 8Catholic University of Leuven, Department of Pediatric Nephrology, Belgium

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic kidney disease and is characterized by genetic complexity and phenotypic variability. The age of reaching kidney failure (KF) is variable and covers the complete age-spectrum. There is an unmet need for early biomarkers to differentiate between rapid and slow progressors. The PROPKD score identified hypertension before the age of 35 years as a risk factor for rapid kidney function decline. We aim to identify earlier risk factors for rapid disease progression by studying a population of ADPKD patients who reached kidney failure (KF) before the age of 40y.

Method: This multicentric retrospective study focuses on a unique population (n = 200) of ADPKD patients who reached KF before 40y. Kidney failure (KF) was defined as CKD5 or start of Kidney Replacement Therapy (KRT), whichever came first. Longitudinal data on childhood history, comorbidities and kidney function were collected. Life table and Proportional Hazards analysis were used to assess associations between clinical parameters and time to KF.

Results: Median age of ADPKD diagnosis was 22.3 (16.5 – 28.6) and median age of KF onset was 36.2 years (32.9-38.7 years). Forty-seven patients were genotyped (23.5%) of which 38 patients (81.0%) were PKD1T and 8 (17.0%) were PKD1NT and only 1 patient (2.1%) was PKD2. Median age at first urological event was 27.0 (20.7 – 32.0) years. 71 patients (35.5%) had history of UTI’s, 67 patients (33.0%) had hemorrhagic cysts on abdominal imaging, 66 patients (33.0%) presented with gross hematuria and 40 patients (25.0%) presented with kidney stones. There was a high prevalence of hypertension (N = 128, 64.0%). Four patients (N = 4/128, 3.1%) had a very early diagnosis of hypertension before the age of 10 years. Hypertension-onset before the age of 18 years correlated with a significantly faster progression (UV HR: 2.07 (1.32 – 3.25)).

Conclusion: This study describes a unique cohort of ADPKD patients with rapid disease progression. Hypertension at young age (<18) correlated with rapid disease progression, suggesting that ambulatory blood pressure in children might be useful to identify patients at risk for rapidly progressive ADPKD.

Figure 1: Survival analysis with endpoint defined as age of KF between patients with ADPKD and hypertension onset before or after 18 years old.
LONG-READ SEQUENCING IDENTIFIES NOVEL PATHOGENIC INTRONIC VARIANTS IN GITELMAN SYNDROME

Daan Vering1, Marguerite Hureaux2, Kornelia Neveling1, Anne Blanchard2, Martin Konrad1, René Bindels1, Karl Peter Schlingmann1, Rosa Vargas-Poussou2 and Jeroen de Baaij1

1Radboudumc, Physiology, Nijmegen, Netherlands. 2APHP, Paris, France and 3University of Münster, Pediatric Nephrology, Münster, Germany

Background and Aims: Gitelman syndrome is a salt-losing tubulopathy characterized by hypokalemic alkalosis and hypomagnesemia. It is caused by homozygous recessive or compound heterozygous pathogenic variants in SLC12A3, which encodes the Na+−Cl− cotransporter (NCC). In up to 10% of patients with Gitelman syndrome, current genetic techniques detect only one specific pathogenic variant. This study aimed to identify a second pathogenic variant in introns, splice sites, or promoters to increase the diagnostic yield.

Method: Long-read sequencing of SLC12A3 was performed in 67 DNA samples from individuals with suspected Gitelman syndrome in whom a single likely pathogenic or pathogenic variant was previously detected. In addition, we sequenced DNA samples from 28 individuals with one variant of uncertain significance or no candidate variant. Midigene splice assays assessed the pathogenicity of novel intronic variants.

Results: A second likely pathogenic/pathogenic variant was identified in 45 (67%) patients. Those with two likely pathogenic/pathogenic variants had a more severe electrolyte phenotype than other patients. Of the 45 patients, 16 had intronic variants outside of canonical splice sites (nine variants, mostly deep intronic, six novel), whereas 29 patients had an exonic variant or canonical splice site variant. Midigene splice assays of the previously known variant in introns, splice sites, or promoter explained aberrant splicing patterns.

Conclusion: Intronic pathogenic variants explain an important part of the missing heritability in Gitelman syndrome. Long-read sequencing should be considered in diagnostic workflows for Gitelman syndrome, especially in patients with one pathogenic variant.

SYSTEMIC OXALOSIS: AN OVERVIEW OF THE FINDINGS AND PREVALENCE IN PRIMARY HYPEROXALURIA

Lisa Deesker, Sander Garrels and Jaap Groothoff

Emma children’s hospital, Amsterdam UMC, Department of pediatric nephrology, Amsterdam, Netherlands

Background and Aims: Systemic oxalosis is a severe co-morbidity that may arise in patients with primary hyperoxaluria type 1 (PH1). It is caused by precipitation of calcium oxalate crystals in organs besides the kidneys, as a result of high endogenous oxalate production. In this study, we aimed to provide an overview of the prevalence, features, screening modalities and factors that play a role in developing systemic oxalosis as cohort studies are currently lacking.

Method: A retrospective registry study was conducted using data from the OxalEurope registry, one of the largest registries of patients with PH1. All patients with primary hyperoxaluria and data on systemic oxalosis were identified. Data was analyzed using descriptive statistics, Chi-square tests, Mann-Whitney U tests and Kaplan Meier analyses.

Results: A total of 159 out of 291 (55%) screened PH1 patients were diagnosed with systemic oxalosis. In addition, 110 patients were recorded having no signs of systemic oxalosis at follow-up, however screening was not performed. Sixty-two patients had already developed systemic oxalosis at diagnosis and systemic oxalosis was most often found in patients with ESKD (95%). The eyes, bones and heart are most frequently affected, nevertheless deposits occurred in many organs, as shown by obduction. Fundus photography (n = 16), X-ray (n = 43), and echocardiography (n = 59) are the modalities used most often to screen respectively the eyes, bones and heart. Patients who developed systemic oxalosis had significantly higher upper plasma oxalate levels (median 22 versus 175 umol/L, p<0.001). Furthermore, patients with systemic oxalosis had a significant higher mortality rate compared to patients without systemic oxalosis (48 out of 142 versus 10 out of 212, p<0.001), which difference persisted after correcting for ESKD (p<0.001). Kaplan Meier analysis (Figure 1) showed that pediatric patients with ESKD tended to developed systemic oxalosis more frequently than adults (p<0.001).

Conclusion: This is the first research to systematically study and report systemic oxalosis in patients with primary hyperoxaluria type 1. Systemic oxalosis is prevalent among PH1 patients, especially when ESKD is present, and may lead to significant morbidity and mortality. Patients with systemic oxalosis have a higher mortality rate and pediatric patients may develop systemic oxalosis more frequently than adults. Given the high incidence and possible implications, we would like to make an appeal on screening all patients with systemic oxalosis. Future research should focus on reliable screening modalities for early signs of systemic oxalosis.

Figure 1: Kaplan Meier analysis of systemic-oxalosis free survival in patients with primary hyperoxaluria, stratified by age at onset of end-stage kidney disease (ESKD). Log-rank analysis showed patients with ESKD before the age of one year had a significant lower systemic-oxalosis free survival (p<0.001), meaning these patients developed systemic oxalosis more frequently and earlier in the disease course.
Background and Aims: Cystinosis is a rare multisystem lysosomal storage disease due to variants in the CTNS gene, coding for the carrier protein cystinosin, a lysosomal membrane transporter causing cystine accumulation with a reported incidence of 1/180,000 live births. Specific treatment by cysteamine decreases renal and extrarenal complications frequency and increases life expectancy. Recently, new treatments for cystinosis entered into the European market with an extended-release formulation of cysteamine and a new formulation of eye drops. The aim of this project is to describe the natural history of the disease and long-term clinical manifestations.

Method: We set up a European, multi-centre, longitudinal, non-interventional cohort, ECYSCO, that uses observational study methods to collect uniform data. 243 patients with a confirmed diagnosis of cystinosis and followed in 25 French and 5 European centers (Belgium, Italy, Spain and Germany) were included. Data are collected on the secure RaDiCo platform, via an e-CRF (REDCap).

Results: Data from 180 patients (50.0% male) were analyzed. Median age at diagnosis was 1.3 years [IQ 0.8; 1.9], with earlier diagnosis since the 1980s, but no further improvement in the 2000s. Genetic analysis was available for 174 patients: 57 (32.8%) presented with homozygous 57kb deletion in the CTNS gene, 71 (40.8%) with heterozygous 57kb deletion associated with another variant and 46 (26.4%) with other variants. The type of variant had no impact on the age at diagnosis. Median age at cysteamine start was 1.6 years [IQ 1.0–3.0]. An improvement on age at treatment start was observed after the 1990s. All but 6 patients were treated with cysteamine. 71 patients received immediate release formulation (Cystagon®) and 103 received extended release formulation (Procybi®). Median white blood cell cystine level was correct at 1.2 nmol ½ cystine/mg protein [IQ 0.59; 2.20]. The median duration of treatment was 21.5 years [IQ 11.7; 31.1]. 167 (95.9%) patients also received cysteamine ocular gel, Cystadrops®. Median age at inclusion was 19.08 years [IQ 10.43; 31.41]. At that time, 104 patients (57.8%) had reached end-stage renal disease (ESRD). At the time of ESRD, 71 patients received immediate release formulation (Cystagon®) and 103 received extended release formulation (Procybi®). Median white blood cell cystine level was correct at 1.2 nmol ½ cystine/mg protein [IQ 0.59; 2.20].

Conclusion: Cystinosis is a good example of a pediatric disease with multiorgan involvement extending into adult care. More than half of patients are adults and have reached ESRD even if age at renal replacement therapy start has increased. The high frequency of extra-renal manifestations demonstrates the importance of a multidisciplinary follow up of these patients.
and serve as autoantigens against ANCA in a vicious cycle. Although the role of NETs in AAV has been revealed, its treatment for targeting NETs remains established. Since nuclear factor-erythroid 2-related factor 2 (Nrf2) regulates antioxidant proteins against oxidative stress and functions as a defense system, we investigated the role of Nrf2 in the development of AAV.

**Method:** In vitro, human neutrophils treated with the Nrf2 activator bardoxolone methyl (Bard) were stimulated with ANCA, and the effects on NETs formation and signaling pathways including intracellular ROS were evaluated by cell imaging and biochemical approaches. The effects of Nrf2 activators on NETs-induced cytotoxicity were examined using human renal glomerular endothelial cells (HRGECs). Nrf2 knockout or WT mouse-derived neutrophils were stimulated with anti-MPO antibody to induce NETs. In vivo studies, Bard was administered to ANCA-transfer AAV model or spontaneous AAV developing mice models (SCG/Kj). Renal function was assessed by biochemical analysis, and the expression of ROS and antioxidant protein NAD(P)H Quinone Dehydrogenase 1 (NQO1) in tissues was evaluated by fluorescent immunostaining and immunoblotting. The formation of NETs in the glomeruli was evaluated by immunostaining and glomerular vascular endothelial damage was assessed by the expression of CD31 and TUNEL positivity. To assess the role of Nrf2 in immunological abnormalities during AAV, murine splenocytes were collected and flow cytometry were conducted using CD4, CD8, B220, MCHCII, CD11c, F4/80, Ly6G, Ly6b, and CD11b antibodies. Moreover, to assess the genetic role of Nrf2 in AAV, we established SCG/Kj mice carrying a germ-line deletion of the Nrf2 genes. A spontaneous mouse model of vasculitis genetically deficient in Nrf2 was analyzed by the same parameters to evaluate the effect of Nrf2. N1 offspring mice were generated by crossing Nrf2/-/- mice with SCG/Kj mice. These backcrossed mice were obtained by crossing Nrf2/-/- mice to background SCG/Kj mice for three generations. The experimental group was mated to N4 heterozygous mice, and female mice in the experimental group were analyzed at 18 weeks.

**Results:** In vitro, pharmacological activation of Nrf2 suppressed ANCA-induced NETs via the upregulation of NQO1 and inhibition of ROS. While Nrf2-deficient neutrophils showed the massive NETs in response to ANCA, compared to WT neutrophils. Furthermore, Nrf2 activation directly protected endothelium from cellular injury caused by the exposure of ANCA-mediated NETs. In vivo, the pharmacological activation of Nrf2 ameliorated glomerulonephritis in two kinds of AAV models through the upregulation of antioxidant and inhibition of ROS-mediated NETs. In contrast, Nrf2 genetic deficiency exacerbated vasculitis in spontaneous AAV model. The activation of Nrf2 regulated the expansion of splenocytes in AAV mice. In particular, pan-T cells in spleen and the infiltration of Th17 cells in kidney were suppressed by Nrf2 activation. **Conclusion:** During ANCA-stimulation in neutrophils, the activation of Nrf2 initiates antioxidant system and inhibits intracellular ROS, leading to the suppression of NETs formation. Nrf2 may be a novel therapeutic target for AAV.

**B2 - GLOMERULONEPHRITIS & SYSTEMIC DISEASES (AAV, SLE, ETC.)

#3280

**B-CELL RECOVERY IN A RANDOMIZED CONTROLLED TRIAL OF B-CELL DEPLETION WITH OBITUNZUMAB FOR THE TREATMENT OF PROLIFERATIVE LUPUS NEPHRITIS (NOBILITY)**

15 Giovanni Hospital, University of Turin, Italy; 2, University of Leeds, United Kingdom; 3, Hoffmann-La Roche Ltd, Canada; 4, Hoffmann-La Roche Ltd, United Kingdom; 5, Hoffmann-La Roche Ltd, Switzerland; 6, Genentech, Inc, United States of America and 7, Northwell Health, United States of America

**Background and Aims:** B cells are central to the pathogenesis of systemic lupus erythematosus and lupus nephritis (LN). Obinutuzumab, a humanized type II anti-CD20 monoclonal antibody, induces more potent B-cell depletion than rituximab. Patients with LN who received obinutuzumab with standard-of-care (mycophenolate mofetil [MMF]) immunosuppression (Phase II NOBILITY trial; NCT02550652) showed improved clinical responses through Week 104 compared with those who received MMF alone. Further analysis could provide insights into the possible association between B-cell depletion duration and duration of renal response.

**Method:** A total of 125 patients with active Class III/IV LN receiving MMF and corticosteroids were randomized and received either obinutuzumab 1000 mg (n = 63) or placebo (n = 62) on Day 1 and Weeks 2, 24, and 26, and followed through Week 104 or to B-cell recovery, whichever was longer. B cells were measured using both a T and B natural killer cell (TBNK) assay with a lower limit of quantification (LLoQ) of 0 CD19+ cells/μL and a high-sensitivity minimal residual cell-1.1 (MRB1.1) assay with an LLoQ of 0.4 cells/μL. Peripheral B-cell depletion was defined as ≥ 0.4 cells/μL. Peripheral B-cell recovery was defined as ≥ 20 cells/μL or the patient's predose baseline, whichever was lower. Time to peripheral B-cell recovery after the last dose of obinutuzumab (Week 26 in 57 of 63 patients), the relationship of time to recovery to efficacy at Week 104 and safety throughout the main study and follow-up period were evaluated (severe adverse event [SAE] and infectious SAE rates, adjusted for patient-years [PY] at risk).

**Results:** Of 63 patients who received obinutuzumab, 4 did not achieve full B-cell depletion during the study. By Week 24, 59 patients (93.7%) achieved B-cell depletion (before obinutuzumab redosing) of those, 4 discontinued prior to B-cell recovery, and 4 completed the study at or after Week 104 but before achieving B-cell recovery. The remaining 51 patients constitute the population for this analysis. Based on the distribution of time to B-cell recovery, 93 weeks passed after their last dose of obinutuzumab infusion was used to group patients (Figure 1). Of the 51 patients, 3 (5.9%) recovered B cells before redosing at Week 26; 1 of the 3 achieved CRR at Week 104. A total of 37 patients (72.5%) attained B-cell recovery within 93 weeks of their last dose of obinutuzumab (median time to B-cell recovery, 78.1 weeks), 18 of 37 (48.6%) and 23 of 37 (62.2%) achieved CRR and overall renal response (ORR) at Week 104, respectively. In these 37 patients, SAE and infectious SAE rates per 100 PY were 13 and 8, respectively. In 11 patients (21.6%), > 93 weeks passed after their last dose to achieve B-cell recovery. Nine of 11 patients achieved B-cell recovery with a median time of 102 weeks, and 2 of 11 had not yet achieved B-cell recovery at the time of writing. Five of 11 patients (45.5%) achieved CRR, and 8/11 (72.7%) achieved ORR at Week 104. In these 11 patients, SAE and infectious SAE rates per 100 PY were 10 and 0, respectively.

**Conclusion:** Most patients in NOBILITY recovered peripheral B cells within 80 weeks after the last obinutuzumab dose. In 5.9% of patients, recovery occurred very rapidly, even before redosing at 26 weeks, whereas in ~20%, recovery occurred ≥ 2 years (102 weeks) after the last dose. B-cell depletion was similar among patients who recovered B cells within 2 years of their final obinutuzumab infusion, those who recovered later and those who are still depleted, suggesting a greater mechanistic effect of early sustained depletion vs duration of depletion. Within the limitation of small sample size, the SAE and infectious SAE rates appear to be similar regardless of duration of B-cell depletion.

COMBINED ACTIVITY AND CHRONICITY SCORE FOR PROGNOSTIC ASSESSMENT IN ANCA-ASSOCIATED VASCULITIS WITH GLOMERULONEPHRITIS

Marta Casal Moura¹, Fernando Custodio Fervenza², Kenneth Warrington³, Ulrich Specks¹ and Sanjeev Sethi¹
Background and Aims: Previous studies have shown that chronic changes on kidney biopsy are useful for stratifying the risk of kidney failure in patients with AAV-GN. We aimed to evaluate the impact of inflammatory activity for the prediction of renal outcomes.

Method: A retrospective cohort study of MPO- or PR3-ANCA positive patients with AAV and active renal disease. Inflammatory activity was assessed by the Activity Index (AI): a ratio between the number of crescents and/or necrosis and the total number of glomeruli (in percent). We calculated the AI score: 0-5 = 0; 6-10 = 1; 11-15 = 2; 16-20 = 3; 21-25 = 4; 26-37.5 = 5; 37.6-50 = 6; 51-65 = 7; 66-80 = 8; 80-90 = 9; 90-100 = 10. Chronicity was evaluated with the Mayo Clinic Chronicity Score (MCCS). The combined score, we summed the MCCS and the AI.

Results: We analyzed 326 patients with kidney biopsies available to score. The biopsies had in median (IQR), 13 glomeruli (9-20), 4 crescents (2-6) and an AI of 28.6% (15.3-47.6). The population was classified according with the risk of progression to kidney failure (KF) in 3 classes as (i) low (0-6) – 114 (35.0%), (ii) intermediate (7-11) – 152 (46.6%), and (iii) high (≥12) – 60 (18.4%). Median eGFR at baseline correlated with the overall risk categories: 42.2 vs. 22.1 vs. 13.4 mL/min/1.73 m², p <0.0001. The proportion of patients with eGFR < 30 mL/min/1.73 m² was increased in patients classified as high: 88.3% vs. 66.4% vs. 36.0%, p <0.0001. Renal recovery was more frequent in patients at low risk of progression: 87.7% vs. 64.6% vs. 36.6%, p <0.0001, whereas kidney failure at 12 months and dialysis were more frequent in patients at higher risk (36.7% vs. 12.4% vs. 3.8%, p <0.0001; 35.6% vs. 13.0% vs. 2.9%, p <0.0001, respectively). The combination of AI with MCCS independently predicted the risk of KF at 12 months (HR 1.916, 95%CI 1.210 - 3.033, p = 0.006), particularly increased in patients classified as high risk (HR 3.124, 95%CI 1.224 – 7.970, p = 0.017) and in patients with PR3-ANCA (HR 1.896, 95%CI 1.012-3.551, p = 0.046) independently of eGFR at AAV-GN diagnosis and adjusted for severity of renal involvement and age.

Conclusion: The combined assessment of acute inflammatory activity and chronic changes on kidney histology independently predicted renal outcomes in patients with AAV-GN. The impact of the inflammatory activity is cumulative to the chronic changes.

Figure 1: Kaplan Meier plots of kidney failure (KF) over 12 months according with the risk group defined by the AAV kidney score.
LONG-TERM PROGNOSIS OF LATE-ONSET LUPUS NEPHRITIS

Amir Shabaka, Ana Mendoza, Antolina Rodriguez-Moreno, Irene Agraz Pamplona, Cristina Rabasco, Fabio Procaccini, Hernando Trujillo Cuellar, Tamara Malek, Fernando Hadad-Arrascue, Carmen Cobelo, Antonia Guerguievia, Milagros Sierra, Mariana Garbíras Serrano and Gema María Fernandez Juárez

Background and Aims: Systemic lupus erythematosus (SLE) occurs mainly in young women of child-bearing age and is not commonly found in the elderly population. Several studies have described that an early onset of lupus nephritis (LN) has a worse prognosis than a late-onset, presenting with greater complications and higher mortality, whereas other studies have shown that late-onset SLE present higher rate of organ damage and mortality. There are no series of late-onset LN that have been described in a European population to date. The KDIGO guidelines do not distinguish early from late-onset LN regarding their immunosuppression strategy recommendations. The objective of this study was to compare the presentation, course and outcomes of late-onset LN compared to early-onset LN in a Spanish population, and detect differences in outcomes according to treatment received.

Method: We performed an observational retrospective multicenter study that included adult patients who developed LN confirmed by a kidney biopsy after the age of 50 years, defined as late-onset LN. We compared them to a group of selected patients aged younger than 50 years at the diagnosis (early-onset LN), matched for disease duration. Baseline demographic, clinical, serological and histological characteristics were compared between both groups. We compared the course of the disease in both groups including renal flares, serious adverse effects, and a composite outcome defined as doubling serum creatinine, developing end-stage kidney disease and/or death. Cox regression analysis was used to examine the association between late-onset LN and its outcomes.

Results: The study included 229 patients; 67 with late-onset LN and 162 early-onset LN patients. Late-onset LN patients presented more frequently hypertension (p < 0.001) and diabetes (p = 0.008). There was a lower frequency of cutaneous manifestations (p < 0.001) and oral ulcers (p = 0.008), higher frequency of hematological manifestations (p = 0.015) and Sjogren syndrome (p = 0.05). Patents with late-onset LN showed a worse baseline kidney function (p < 0.001) and higher serum complement levels (p < 0.001). Late-onset LN patients showed higher chronicity indices in kidney biopsies, with more glomerulosclerosis (p = 0.003), interstitial fibrosis (p = 0.021) and tubular atrophy (p = 0.011). There were no differences in the distribution of LN histological classification between both groups. We did not find significant differences between early and late-onset LN as regards induction and maintenance immunosuppression therapies, showing only a lower rate of antimarial drug use in late-onset LN as maintenance therapy (p = 0.001). After a median follow-up of 7.4 (2.8-13) years, patients with late-onset LN showed a lower number of flares (p = 0.015), and a higher rate of serious adverse events related to immunosuppression, particularly infectious complications (34.3% vs 18.5%, p = 0.01). There were no differences in complete or partial remission or kidney function between both groups at the end of follow-up, however mortality was higher in late-onset LN patients, developing more frequently the composite outcome (19.4% vs 8%, p = 0.014). No significant difference was found in kidney survival (log-rank chi-square = 2.09, p = 0.148). Cox regression analysis showed that late-onset LN (hazard ratio = 3.26, 95% CI 1.18-8.98, p = 0.02), % sclerosed glomeruli (HR = 1.03, 95% CI 1.01-1.06, P = 0.019) and presence of severe side effects related to immunosuppression (HR = 10.09, 95% CI 3.2-31.7, p < 0.001) were independent risk factors for reaching the composite outcome.

Conclusion: Although patients with late-onset LN present with worse kidney function and more severe chronic lesions in kidney biopsy, they show comparable kidney outcomes to patients with early-onset LN, and despite receiving similar immunosuppressive regimens they develop less renal flares but more serious adverse events, leading to a worse overall outcome. Minimization of immunosuppression regimens in late-onset LN may be an adequate option to improve patient outcomes.

Table 1: Kidney function, histopathology, and outcomes of patients with Anti-Neutrophil Cytoplasmic Antibodies (ANCA) associated vasculitis (AAV) glomerulonephritis (AAV-GN) based on the AAV combined score (combination of the chronicity score and activity index) (n = 326).

APOL1 GENOTYPE IS A MAJOR DETERMINANT OF LUPUS NEPHRITIS SEVERITY IN PATIENTS OF AFRICAN ANCESTRY

Carole Burger1, Nicolas Benichou1, Céline Narjou2, Nathalie Costedoat-Chalumeau3, Veronique Le Guern3, Aurélie Hummel4, Noemie Jourde-Chiche5, Julie Chezel3, Eric Thervet1, Nicolas Pallet2 and Alexandre Karras1

1Hopital Européen Georges Pompidou, Nephrology, Paris, France, 2Hopital Européen Georges Pompidou, Paris, France, 3Cochin Hospital, Internal Medecine, Paris, France, 4Necker Hospital, Paris, France and 5Hospitals Academics De Marseille, Marseille, France

Background and Aims: Two polymorphisms of APOL1 gene, G1 and G2, exclusively found among patients of African ancestry, have been associated with chronic kidney disease (CKD) and end-stage kidney disease (ESKD)1. These high-risk polymorphisms have also been associated with collapsing glomerulopathy in various diseases. We aimed to evaluate the impact of APOL1 G1 and G2 polymorphisms on the clinical and pathological course LN which is already known to be more severe among patients of African ancestry2.

Method: We included patients from 6 hospitals in Paris and Marseille in France, between January 2017 and March 2020, with biopsy-proven LN, African ancestry and age >18 years at the time of inclusion. We excluded those with HIV infection. The data were retrospectively collected at LN diagnosis, 1 year after diagnosis and at last follow-up. APOL1 genotyping was performed and we divided patients in 2 groups: the high-risk genotype (HRG) group with 2 risk alleles and the low risk genotype (LRG) group with 1 or 0 risk allele. All patients signed a consent form for the genetic analysis and protocol approval was obtained from the ethic committee CERAPHP (Comité d’Ethique de la Recherche AP-HCP Centre), registration number 00011928.

Results: Ninety-nine patients were included in the study, 13 in the HRG group and 86 in the LRG group. The median duration between LN diagnosis and inclusion in the study was 9.6 years [4.9-16.9]. At LN diagnosis, clinical and biological characteristics were similar except for kidney function that was lower in the HRG group compared to the LRG group with a median serum creatinine of 151 μmol/L [69-687] versus 66 μmol/L [52-133] (p = 0.0085). Patients in the HRG group were more likely to have a serum creatinine above 200 μmol/L compared to the LRG group (45.5% versus 10.5%, p = 0.0096, OR 7.1[1.8-28.6]), and required acute haemodialysis more frequently (30.8% versus 1.3% respectively, p = 0.0012, OR 34.7[3.5-345.1]). Collapsing glomerulopathy was more frequent in the HRG group (45.5% of patients, versus 4.5%, OR 17.5[3.3-91.9], p = 0.001). No significant difference was observed in the proportion of kidney response at 12 months, however, patients in the HRG group were more likely to develop CKD (33.3% versus 4.9%, OR 9.6[2.0-46.1]). Median follow-up from LN diagnosis to the end of study, ESKD or last follow-up was 7.9 years [3.4-13.3] and was similar between the 2 groups. At last follow-up, median eGFR was 22mL/min/1.73m² [10-98] vs 99mL/min/1.73m² [55-118] respectively, p = 0.0189. Survival without ESKD was poorer in the HRG group than in the LRG group with a hazard ratio (HR) of 5.0[1.6-15.8], p = 0.006, even after adjusting with the kidney response at 12 months (adjusted HR 6.24[1.8-21.6], p = 0.004) (Figure 1).

Conclusion: APOL1 genotype affects LN prognosis, resulting in a worse kidney function at diagnosis, development of collapsing glomerulopathy and higher risk of subsequent ESKD. Kidney survival remained significantly lower in the HRG group, after adjustment for kidney response at 12 months, suggesting that the progression of LN is heavily driven by APOL1 genotype regardless of the kidney response. APOL1 inhibitors are currently being developed, and could be used in the next future, for HRG patients with primary or secondary forms of collapsing glomerulopathy.

REFERENCES

Figure 1: Patient survival without End-Stage Kidney Disease. Data were censored at 15 years after LN diagnosis. Kaplan Meyer curve was analyzed with the log rank test. ESKD: End stage kidney disease; HRG: High risk genotype; LRG: Low risk genotype; HR: Hazard Ratio. Hazard ratio was calculated based on the Cox regression, and was adjusted with the kidney response at 12 months (overall response versus none).
COVID VACCINE RESPONSES DURING SIBEPRENLIMAB TREATMENT OF IGA NEPHROPATHY (IGAN): AN INTERIM ANALYSIS

Kieran McCafferty1, Kristin Follman2, Marcela Pasetti3, Asher Schachter4, Mohit Mathur4, Jill Yarbrough4, Mallory Shriver3, Frank Engler3, David Oldach4 and Yusuke Suzuki5

1BARTS Health, NHS, Nephrology, London, United Kingdom, 2Certara, Pharmacokinetic Modeling, Princeton, United States of America, 3University of Maryland School of Medicine, Center for Vaccine Development, Baltimore, United States of America, 4Visterra, Inc., Clinical Development, Waltham, United States of America and 5Juntendo University, Nephrology, Tokyo, Japan

Background and Aims: ENVISION, an ongoing global P2 trial of sibeprenlimab, a mAb that neutralizes A Proliferation Inducing Ligand (APRIL) for the treatment of IgAN, previously reported an interim 43% placebo (pbo)-adjusted reduction from baseline in 24-hour uPCR at 9 months. The trial has been conducted through the ongoing COVID pandemic. To assess the effect of sibeprenlimab on COVID-risk, infection and vaccination (vac) data were recorded for all subjects. For consenting substudy subjects (SS) (n = 72), serologic responses to SARS-CoV2 proteins were measured monthly.

Method: Serum IgG antibodies specific for SARS-CoV-2 antigens were quantified using Meso Scale Discovery (MSD) V-PLEX SARS-CoV-2 Panel 24, a validated multiplexed assay. IgG levels were reported in WHO binding antibody units (BAU)/mL. Peak Receptor Binding Domain (RBD) IgG antibody titers were evaluated for SS following primary (2-dose) mRNA vaccination. Slopes of IgG RBD decline were utilized to generate preliminary estimates of time above protective threshold. A Welch two-sample t-test was applied to the log-transformed peak RBD titer values for significance testing.

Results: Among 155 IgAN patients enrolled and followed for 16 months (with 12 monthly sibeprenlimab or pbo infusions) between August 2020 and the present, COVID infection was reported in 55 overall. Two patients were hospitalized in accordance with standard local COVID protocols; none were admitted to ICU or mechanically ventilated and there were no fatalities. All other episodes of COVID infection were considered to be of mild or moderate severity (treatment status remains blinded for AE evaluation). COVID vaccination was administered to 46 SS; including 34 recipients of mRNA vaccines only (1, 2, 3 or 4 doses). There were no identified IgAN disease flares following vaccinations. Parameters characterizing IgG RBD titer were obtained from subjects receiving a 2-dose mRNA primary vaccination with sufficient data, excluding subjects with confounding COVID infection at the time of vaccination (n = 22). All subjects achieved a peak titer of >935 BAU/mL, with similar kinetics between arms. Geometric mean peak RBD IgG antibody level (Fig. 1) following vaccination was higher in pbo recipients (5600 BAU/mL) vs Sibeprenlimab (2410 BAU/mL) (p = 0.033). RBD IgG decline post mRNA vaccination (in any patient with at least one mRNA dose without confounding subsequent vac or infection) was evaluable in 28 SS. Rates of decline were similar between groups (Fig. 2), with comparable modeled time above an arbitrary protective threshold of 300 BAU/mL (~ 5-6 months, data not shown). In addition, there was no evidence that sibeprenlimab impeded robust humoral immune responses to actual infection.

Conclusion: Sibeprenlimab is a promising immunomodulatory therapy for treatment of IgAN. COVID-specific vaccine and infection-induced humoral immune responses were preserved during Sibeprenlimab therapy.

Figure 1: Peak IgG levels achieved following primary (2-dose) mRNA vaccination to SARS-CoV2 Receptor Binding Domain of envelope protein (IGG-RBD). Geometric Mean Cmax 5600 and 2410 BAU/mL for pbo and sibeprenlimab, respectively. Dotted line: 300 BAU/mL, a previously estimated Day-29 post-vac RBD BAU/mL level with ~90% vaccine efficacy (Gilbert et al, Science, 2022)

Figure 2: Observed data, decline of IGG-RBD antibody titers in pbo and sibeprenlimab recipients, with time of mRNA vaccination established as day 0.
INVESTIGATING THE ROLE OF CFH VARIANTS AND HAPLOTYPES AS A RISK FACTOR OF IGA NEPHROPATHY IN A FRENCH COHORT

Background and Aims: Excessive complement activation is particularly important in the pathogenesis of IgAN nephropathy (IgAN). The relationship of complement CFH gene genetics and IgAN phenotype has not been clearly established in IgAN.

Method: We performed a genetic analysis of 234 French IgAN patients by next generation sequencing and Sanger. CFH polymorphisms were combined into haplotypes using the Michigan imputation Server1. CFH rare variants and haplotypes frequencies were compared to the 1k genome population of European ancestry. Recombinant full-length FH rare variants were produced and studied functionally in vitro.

Results: Genetic analysis revealed an enrichment in CFH non-synonymous rare variants in IgAN patients (n = 234) compared to the reference population (n = 503) (5.1 versus 1.8%, p = 0.010). Interestingly, the identified variants preferentially located in FH functional domains. In vitro functional studies based on new functional Luminex® assays showed a decrease in C3b-binding, C3bBB decay-accelerating activity and/or C1r/C1s cofactor activity for 4 variants, classifying a newly identified variant as a pathogenic variant. CFH haplotypes distribution differed between the IgAN group and controls (p = 0.001), with a higher prevalence of the H3 haplotype (rs80029 c.184G>A, rs1061170 c.1204T>C, rs542235 chr1:196854483 A>G, GTA) in IgAN patients (28.2 versus 21.1%, p = 0.0029), but this haplotype was not associated with renal survival.

Conclusion: In our series of French IgAN patients, CFH rare variants and haplotypes are associated with disease’s susceptibility. Our results support the hypothesis of a complement dysregulation underlying the IgAN pathogenesis.

Background and Aims: The most important determinant of renal and patient survival in anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is early initiation immunosuppressive (IS) therapy. Other factors associated with survival are age, sex, renal functional and renal involvement at diagnosis. The prognosis is poor in patients with AAV who do not receive IS treatment. The effect of plasma exchange (PE). in patients who underwent plasmapheresis with IS treatment has been questioned in recent studies. Renal histology is a predictor of long-term risk of renal failure in patients with crescentic glomerulonephritis, and prognostic histological scorings have been developed. In this study, we investigated clinical and pathological risk factors that may affect patient and renal survival in patients with AAV.

Method: Data of 225 AAV patients diagnosed by renal biopsy in the age range of 16-85 years in 30 centers were used which were obtained from the Turkish Society of Nephrology Glomerular Diseases (TSN-GOLD) Working Group database. Patients who did not have regular follow-up for at least

3 months, patients with immunocomplex glomerulonephritis, and patients with rapidly progressive glomerulonephritis who were positive for anti-GBM antibodies were excluded from the study. Patients with negative ANCA (n: 17) and unknown ANCA results (n: 28) were included in the study according to their renal biopsy findings.

Results: The mean age of the study population was 52.1±15.2 years and 126 (50%) were male. After renal biopsy, 154 patients (85.1%) received only cyclophosphamide and steroid treatment as initial IS treatment, 23 patients (12.6%) also received PE. When the clinical results of the patients were evaluated, end-stage renal disease (ESRD) was detected in 50 (22.2%) patients, while 36 (16%) patients died. When the factors affecting the development of ESRD were evaluated with the logistic regression analysis model, it was shown that the low albumin level of the patients at the time of diagnosis and the percentage of interstitial fibrosis (IF) >25% in renal pathology were more effective for the development of ESRD (p = 0.02, p = 0.01). When the factors affecting the survival of the patients were evaluated with the logistic regression analysis model, we demonstrated that there was no significant effect of PE and IF > 25% in renal pathology; age [HR = 1.035 (1.001-1.069)] and patients with lower albumin value [HR = 0.488 (0.241-0.987)] were found to be more risky in terms of death (p = 0.041, p = 0.004) (Table 1).

Conclusion: In this study, the serum albumin level of the patient at the time of biopsy was determinant in renal and patient survival in AAV. IF > 25% in renal pathology was effective in renal survival, but it was not found to be effective in patient survival. Plasma exchange did not provide additional benefit to standard treatment. Prospective and multicenter studies with a larger number of patients are needed to confirm our findings.

Background and Aims: Primary glomerulonephritis (PGN) is among the leading causes of end-stage kidney disease (ESKD) in patients initiating kidney replacement therapy (KRT). To date, most studies have examined KRT outcomes from all PGN subgroups combined. Using data from the European Renal Association (ERA) Registry we examined trends and outcomes in individuals with PGN and its subgroups commencing KRT. Firstly, we described the incidence of KRT for ESKD due to PGN for all countries combined and by country; and secondly, we compared patient characteristics, survival outcomes, and causes of death.

Method: We used data from 31 national and regional renal registries providing individual patient data to the ERA Registry for at least three years between 2000-2019. PGN was categorized into six subgroups based on the ERA primary renal disease codes: Immunoglobulin A nephropathy [IgAN], membroproliferative glomerulonephritis [MPGN] (type I and type II), membranous nephropathy [MN], focal segmental glomerulosclerosis [FSGS], crescentic glomerulonephritis [crescentic GN], and other PGN (historically examined and histologically not examined). The age-and-sex-standardized incidences were estimated using the 2015 EU28 population as a reference. Jointpoint regression analysis was used to determine the annual percentage change (APC) in the incidence. Kaplan Meier and Cox regression analyses were used for the survival analyses. We adjusted for age, sex, KRT initiation era, and country.

Results: In total, 69,854 individuals started KRT due to PGN between 2000-2019, of whom 27.8% had IgAN, 15.8% FSGS, 8.5% MPGN, 5.8% crescentic GN, and 4.5% MN. The remaining 37.7% were categorized as other PGN (14.1% not biopsied). The standardized incidence of KRT due to PGN was 16.6 per million population (pmp), ranging from 8.8 pmp in Serbia to 20.0 pmp in France. The incidence was the highest for IgAN (4.6 pmp) and FSGS (2.0 pmp) particularly in age group 65-74 year. The incidence of KRT due to PGN [APC: -1.8% (-2.2; -1.4)] declined between 2000-2013, then it stabilized. Conversely, the incidence of KRT due to IgAN [APC: 5.1% (2.7;7.6)] between 2012-2019 and due to FSGS [APC: 3.1% (2.3-3.8)] between 2000-2019 increased. During a five-year follow-up 8,928 patients died. The five-year survival probabilities varied from 57.0% for crescentic GN to 83.6% for IgAN. The risk of death was highest in crescentic GN [The adjusted hazard ratio: 1.8 (95% confidence interval: 1.6-1.9)] compared to IgAN. Cardiovascular disease was the most common cause of death (33.9%) followed by infection (18.5%).

Conclusion: The incidence of KRT due to PGN was highest in IgAN and FSGS and varied largely across the European countries. The number of non-histologically examined PGN cases may reflect a lack of renal biopsy facilities which in turn hamper reporting of the true histological diagnosis. There was an initial decline in the incidence of KRT due to PGN, followed by stabilization. This could imply advances in the management protocols with better prognosis. Further studies are needed to explain the observed difference in the incidence over time and to identify factors leading to less initiation of KRT among patients with PGN.

#3649 EPIDEMIOLOGY OF IGA NEPHROPATHY AT A UK CENTRE OVER 2 DECADES – EFFECTS OF IMMUNOSUPPRESSION

Josh Storrar, Rajkumar Chinnadurai, Smeeta Sinha and Philip A. Kalra
Salford Royal, United Kingdom

Background and Aims: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide. The clinical course is heterogeneous. As such, determining which patients to treat with immunosuppression (IS) is often the key decision in management. Here, we present a 20-year retrospective study from a single centre with the following aims: to describe the epidemiology of our cohort, to assess outcomes (such as progression to end-stage kidney disease [ESKD] requiring renal replacement therapy [RRT] and mortality), and to determine the effect of IS.

Method: We collected all cases of IgAN from our biopsy database between January 2000 and December 2019. After exclusion, the total number for analysis was 401 patients. We collected demographic data for each patient, along with creatinine and proteinuria values over time, MEST-C histological scores, progression to ESKD, mortality, use of renin-angiotensin system blockade (RAS) blockade and IS treatment. CKD progression in the overall cohort was computed using the rate of change of estimated glomerular filtration rate [eGFR] (delta eGFR) from baseline to study endpoint, with the linear regression slope generated using all available eGFR measurements. Similarly, the rate of change of urine protein creatinine ratio [uPCR] (delta uPCR) from baseline to study endpoint was calculated using linear regression from serial uPCR measurements.

Results: Median age of the cohort was 45.0 years, with 69.6% male and 87.5% were Caucasian. Baseline laboratory values (median) included: mean estimated Etonnium 142μmol/L, eGFR 46.7ml/min/1.73 m², uPCR 183mg/mmol/L. The median rate of decline of eGFR was -1.31ml/min/1.73 m²/yr and median change in uPCR was -4.46mg/mmol/yr. RAS blockade was used in 79.6% and IS in 20.4%. Progression to ESKD requiring RRT was seen in 29.7% and mortality in 19.7%. Median follow up duration was 51 months. Cox regression analysis revealed several factors associated with mortality, including increasing age, non-Caucasian ethnicity, diabetes, hypertension, cardiovascular disease, systolic blood pressure, creatinine, uPCR, ACEI/ARB use, and E and T score on biopsy. Several factors were associated with need for RRT including hypertension, various histological markers, creatinine, uPCR and ACEI/ARB use. IS was not found to be a factor associated with all-cause mortality or RRT. Those treated with IS (table 1) had a higher uPCR (301.5mg/mol vs 141mg/mol, p<0.001), were more likely to have a C score (37.7% vs
Table 1: Baseline characteristics, laboratory values and outcomes for those who received IS and those who did not.

Conclusion:
This is one of the largest retrospective observational studies assessing clinical and histological characteristics, along with outcomes, for IgA nephropathy (IgAN). This provides important real-world data which will be useful for clinicians, particularly as the IgAN landscape changes with the introduction of novel therapies. Whilst IS was associated with a greater proteinuria reduction over time, this did not translate into an amelioration of eGFR decline.

The study received grant support from CSL Vifor.

B4 - PREVENTION, TREATMENT & CLINICAL TRIALS

#4503

ESTIMATING DELAY IN TIME TO KIDNEY FAILURE OR DEATH FOR TREATMENT EFFECTS ON PROTEINURIA IN IGA NEPHROPATHY
Alex Mercer1, Kevin Carroll2, Leah Conley3, Bruce Hendry3, David Pitcher4, Daniel Gale5 and Jonathan Barratt6

1JAMCO Pharma Consulting, Enskede, Sweden, 2KJC Statistics Ltd, Cheshire, United Kingdom, 3Traveere Therapeutics, Inc., San Diego, United States of America, 4The UK Kidney Association, Filton, United Kingdom, 5University College London, United Kingdom and 6University of Leicester & Leicester General Hospital, Leicester, United Kingdom

GRAPHICAL ABSTRACT

Background and Aims: Reduction in proteinuria is associated with lower risk of kidney failure (KF) in IgA nephropathy (IgAN) (Thompson et al, 2019). In phase 3 randomized controlled trials in IgAN patients, a treatment effect on proteinuria reduction is typically evaluated as a mean percent change in proteinuria from baseline at 6-9 months. In this study, we aim to estimate the delay in time to KF or death associated with treatment effects of 40% and 50% reduction of proteinuria at this timepoint.

Method: In this study, we used individual patient level data from the UK National Registry of Rare Kidney Disease (RaDaR) IgAN cohort. Adult IgAN patients (n = 535) with a urine protein-creatinine ratio ≥ 100 mg/mmol (0.88 g/g) ≥ 6 months from diagnosis (time point defined as baseline) and eGFR ≥ 30 ml/min at baseline (study population mean = 61 ml/min/1.73 m² [SD 26]) were included. Predicted risk of KF (eGFR < 15 ml/min, initiation of dialysis, transplantation/doubling serum creatinine/death) associated with treatment effects reducing proteinuria by 40% and 50% at 9 months were calculated from IgAN trial level analysis data (Thompson et al, 2019). Accelerated failure time modelling was used to analyse time to KF/death during follow up in the RaDaR IgAN study population, and to estimate the effect that changes in hazard ratio had on median survival time and 5-year survival rates. Weibull, Log-Logistic and Log-Normal distributions were applied with the fitted survivor function reported from the model with the lowest AIC.

Results: Treatment effects reducing proteinuria by 40% and 50% in IgAN patients predict a 59% and 67% lower risk of KF/death, respectively. A 59% reduction in risk, is estimated to extend the median time to KF/death by 6.3 years, from 8.6 years (95% CI 7.8, 9.5) to 14.9 years (95% CI 13.6, 16.4), while the corresponding extension in median time to KF/death estimate for a 67% reduction in risk is 8.5 years (from 8.6 years [95% CI 7.8, 9.5] to 17.1 years [95% CI 15.6, 18.8]) (Figure 1). Five-year KF/death free survival rate increased from 75% to 89% and 91%, for 59% and 67% reduced risk in KF/death, respectively.

Conclusion: Therapeutic interventions that reduce proteinuria and the risk of KF can confer important and clinically meaningful extensions in the time patients are alive and free from KF.

ESTIMATING DELAY IN TIME TO KIDNEY FAILURE OR DEATH FOR TREATMENT EFFECTS ON PROTEINURIA IN IGA NEPHROPATHY
PHASE I STUDY OF THE SAFETY, TOLERABILITY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF POVETACICEPT FOR AUTOIMMUNE GLOMERULONEPHRITIDES

Stacey Dillon1, Rupert Davies1, Jason Lickliter2, Kristi Mcendon1, Kristi Manjarrez1, Alina Smith1, Lori Blanchfield1, Russell Sanderson1, Allison Chunjxk1, Amanda Enstrom1, Tiffany Blair1, Hany Zayed1, Jiahua Li1 and Stanford Peng1

1Alpine Immune Sciences Inc, Seattle, United States of America, 2Nucleus Network, Melbourne, Australia and 3Nucleus Network, Brisbane, Australia

Background and Aims: B cell activating factor (BAFF) of the tumor necrosis factor (TNF) family and a proliferation-inducing ligand (APRIL), cytokines which bind and signal through BAFF-R, transmembrane activator and CAML interactor (TACI), and/or B cell maturation antigen (BCMA) on B cells, play overlapping and non-redundant roles in B cell development, proliferation, function, and survival. Therapeutic agents targeting BAFF and/or APRIL have demonstrated promising clinical potential in autoantibody-related glomerulonephritides (GN) such as lupus nephritis (LN), immunoglobulin (Ig) A nephropathy (IgAN), membranous nephropathy, and other B cell-related diseases such as systemic lupus erythematosus (SLE); however, there is still need for more safe and efficacious therapies. Povetacicept (ALPN-303) is an Fc fusion protein of an engineered TACI variant TNFRSF domain (vTD) with enhanced affinity for APRIL and BAFF which mediates more potent inhibitory activity than wild type (WT) TACI-Fc or BAFF- or APRIL-specific antibodies. In preclinical studies, povetacicept demonstrated enhanced pharmacokinetic (PK) and immunomodulatory properties vs. WT TACI-Fc, which may translate to lower and/or less frequent doses in humans. Povetacicept also suppressed autoantibodies, renal IgG deposition, and nephritis in mouse models. Povetacicept may therefore significantly improve clinical outcomes in autoantibody-mediated GNs and other B cell-related diseases.

Method: In this first-in-human study (NCT05034484), 66 healthy adult volunteers were randomized 4:2 into single ascending dose cohorts of intravenous (IV) or subcutaneous (SC) povetacicept or placebo. Participants were followed to assess safety and PK, circulating Ig, galactose-deficient IgA1 (Gd-IgA1), and circulating leukocyte populations.

Results: Povetacicept has been well tolerated in all cohorts evaluated as single IV or SC doses of up to 960 mg. Overall, it exhibits dose-related PK and expected pharmacodynamic (PD) effects, including dose-related reductions in serum IgA, IgM, IgG, and Gd-IgA1 (Figure 1), and in circulating antibody-secreting cells (ASC: plasmablasts and plasma cells) (Figure 2). In the same setting, these PD effects appear greater than those reported for WT TACI-Fc molecules and appear to be saturated at doses ≥80 mg. Coverage of free APRIL was maintained for 2-3 weeks with 80 mg and ≥4 weeks with 240 mg, respectively. The most frequent adverse event has been mild headache. To date, there have been no imbalances of infections between placebo and povetacicept groups, no treatment-related reactions other than mild injection site pain, and no adverse trends in safety laboratories.

Conclusion: To date, povetacicept has demonstrated acceptable safety and tolerability as single IV or SC doses, exhibiting dose-dependent PK and PD that appear to differentiate favorably vs WT TACI-Fc. Based on the magnitude and duration of the observed PD effects, dose regimens of 80-240 mg SC every 4 weeks are anticipated for use in future studies. Overall, the study findings support future clinical development of povetacicept in multiple autoantibody-related GN, as well as other B cell- and/or autoantibody-related diseases such as SLE and autoantibody-associated cytopenias.
Figure 1: Povetacicept Dose-Dependently Reduces Circulating Immunoglobulins and Gd-IgA1 Levels. Top six panels: Effects generally appear saturated ≥ 80 mg for ≥ 4 weeks. Bottom two panels: Serum galactose-deficient IgA1 (Gd-IgA1) levels were measured using an ELISA kit using the KM55 rat anti-human Gd-IgA1 antibody (Immuno-Biological Laboratories/IBL). The % change from baseline (predose) values are plotted.
Figure 2: Povetacicept Dose-Dependently Reduces Circulating Antibody-Secreting Cells. Human peripheral blood mononuclear cells (2 × 10⁷) collected from healthy volunteers treated with a single IV or SC dose of placebo (PBO) or povetacicept at the various dose levels indicated were evaluated by flow cytometry. After an initial gating step to remove CD45⁻⁺⁺⁺⁺, CD3⁺, CD14⁺, doublets, and debris, %antibody secreting cells (plasmablasts and plasma cells) were gated as CD19⁺ CD27⁺ IgD⁻ CD38⁺⁺ cells.

Background and Aims: IgA nephropathy (IgAN) is the most common primary glomerulonephritis in the world. Galactose-deficient IgA1 (Gd-IgA1), anti-Gd-IgA1 autoantibodies (anti-Gd-IgA1), and IgA-IgG-containing immune complexes (ICs) are central in the pathogenesis of IgAN, contributing to kidney damage. The potential of targeting these disease-causing species was demonstrated in the Phase 2a JANUS trial (NCT02808429), evaluating the safety and efficacy of atacicept in patients with IgAN. Atacicept is a fusion protein that binds B-lymphocyte stimulator (BlyS) and a proliferation-inducing ligand (APRIL) inhibiting maturation and class-switching of B-cells and plasma cells. In JANUS, patients treated with atacicept 25 mg or 75 mg experienced stabilization of estimated glomerular filtration rate (eGFR) compared with placebo over 72 weeks. Patients in the atacicept arms also experienced dose-dependent reductions in Gd-IgA1, anti-Gd-IgA1 and ICs during the treatment period compared with placebo. The Phase 2b ORIGIN trial (NCT04716231) is a dose-ranging study evaluating atacicept versus placebo in an IgAN population with significant proteinuria.

Method: ORIGIN is a double-blind, placebo-controlled Phase 2b clinical trial including 116 patients with biopsy-proven IgAN, 24-hour urine protein > 0.75 g per day or urine protein-to-creatinine ratio (UPCR) > 0.75 g/g, and eGFR > 30 mL/min/1.73 m² despite optimized renin–angiotensin system blockade. Patients were randomized to atacicept 150 mg, 75 mg, or 25 mg, administered by subcutaneous injection once per week versus placebo (2:2:1:2) for up to 36 weeks followed by an open-label extension during which all patients may receive active atacicept 150 mg for an additional 60 weeks. The primary endpoint was the change in 24-hour UPCR at 24 weeks in the pooled atacicept 150 mg and 75 mg arms compared with placebo. Secondary objectives include UPCR at additional time points, the effect of atacicept on change in eGFR, safety and tolerability.

Results: Between May 2021 and June 2022, 232 patients were screened. Of these, 116 patients were randomized and included in the primary analysis (33, 33, and 16 receiving atacicept 150, 75, and 25 mg, respectively; and 34 receiving placebo) of the intent-to-treat (ITT) population. At 24 weeks, mean UPCR was reduced from baseline by 31% in the pooled atacicept 150 mg and 75 mg arms compared with a 7% reduction from baseline in the placebo (Δ = 25%, p = 0.037). The atacicept 150 mg arm achieved a 33% reduction from baseline at Week 24 and was the only individual treatment arm that showed a statistically significantly greater reduction than placebo (Δ = 28%, p = 0.047). Results of the ITT analysis are supported by a pre-specified per-protocol (PP) analysis (n = 27, 32, and 14 for atacicept 150, 75, and 25 mg, respectively; n = 29 placebo): the atacicept 150 mg arm showed a 41% reduction from baseline in UPCR at 24 weeks compared with a 10% reduction in the placebo arm (Δ = 34%, p = 0.025). The secondary endpoint, eGFR, showed stability at 24 weeks. Gd-IgA1 reduction of 60% was achieved at Week 24 with atacicept 150 mg. The safety results indicated that atacicept was generally well-tolerated with no increased rate of infections compared to placebo, a low rate (2%) of serious AEs overall with none in the atacicept 150 mg group, and no study drug discontinuation or interruptions due to hypogammaglobulinemia.

Conclusion: The ORIGIN Ph2b study met its primary endpoint demonstrating a favorable impact on disease biomarkers and a clinically meaningful reduction in proteinuria and demonstrated a favorable safety profile. These promising results at Week 24 support atacicept 150 mg for further evaluation as a potential disease modifying treatment of patients with IgA nephropathy.

#4057
SUPERIOR PROTEINURIA REDUCTION WITH SPARSENTAN IN IMMUNOGLOBULIN ANEPHROPATHY (IGAN): A PROTECT STUDY INTERIM ANALYSIS
Jonathan Barratt1, Hiddo Lambers Heerspink2,3,1, Muh Wong2,4, Radko Komers3, Alex Mercer5 and Jai Radhakrishnan1
1University of Leicester General Hospital, Leicester, United Kingdom, 2Concord Repatriation General Hospital, Australia, 3University Medical Center Groningen, Netherlands, 4Concord Clinical School, University of Sydney, Australia, 5Travere Therapeutics, Inc., San Diego, United States of America, 6JAMCO Pharma Consulting, Sweden and 7Columbia University, United States of America

Background and Aims: IgAN is the most common glomerular disease worldwide. Despite optimized standard of care, most patients with IgAN progress to kidney failure within 10-15 years, consequently seriously affecting their quality of life and mortality. Treatments that reduce proteinuria and risk of kidney disease progression are urgently needed for IgAN. Sparsentan is a novel, oral, non-immunosuppressive, single molecule that is a dual endothelin and angiotensin receptor antagonist being investigated for IgAN and focal segmental glomerulosclerosis. The Phase 3 PROTECT study is examining the long-term antiproteinuric and nephroprotective potential and safety of sparsetan compared with an active control, angiotensin receptor blocker (ARB) irbesartan, in adults with IgAN. Reported here are the PROTECT pre-specified interim primary efficacy endpoint and safety outcomes.

Method: PROTECT is an ongoing, global, Phase 3, multicenter, randomized, double-blind, active controlled study designed to evaluate the efficacy and safety of sparsetan versus the active control irbesartan in adults with IgAN with overt proteinuria despite receiving maximized treatment with an angiotensin converting enzyme inhibitor (ACEI) and/or ARB. The study duration is 270 weeks; the double-blind period is 114 weeks (110 treatment and 4 follow-up) with an open-label extension period up to 156 weeks. Adult patients with biopsy-proven IgAN (excluding IgAN secondary to another condition or IgA vasculitis), urine protein excretion value ≥1.0 g/day, eGFR ≥30 mL/min/1.73m², systolic/diastolic blood pressure ≤150/100 mmHg,

Abstracts
and on a stable dose of ACEi and/or ARB therapy for at least 12 weeks prior to screening that is both the patient's maximum tolerated dose and at least one-half of the maximum labeled dose were eligible for inclusion. Patients took their last ACEi and/or ARB dose the day before randomization. Patients were randomized 1:1 to sparsentan or irbesartan (target dose 400 and 300 mg/day, respectively), stratified by screening eGFR and urine protein excretion values. The pre-specified interim primary efficacy endpoint of change from baseline in urine protein/creatinine ratio (UP/C, based on a 24-hour urine sample) at week 36 was analyzed using a mixed model repeated measures analysis. The safety evaluation included assessment of treatment emergent adverse events.

Results: A total of 671 patients were screened; 406 patients from clinical sites in 18 countries, including sites in North America, Europe, and Asia Pacific, met eligibility criteria and were enrolled and randomized into PROTECT. Two randomized patients withdrew from the study prior to initiating study treatment. The 404 randomized patients who received study drug were included in the primary analysis population. The mean reduction in UP/C from baseline at 36 weeks was significantly greater in the patients who received sparsentan (-49.8%) versus irbesartan (-15.1%, P < 0.0001). Proteinuria reduction changed across baseline demographic and clinical characteristics and rates of complete and partial remission are reported, as well as sustained proteinuria reduction over time. Safety outcomes related to edema and liver function tests are reported. Overall, sparsentan was generally well-tolerated and comparable to irbesartan.

Conclusion: The interim results of the PROTECT study show that in adult patients with IgAN and persistent proteinuria above 1 g/day despite being treated with ACEis and/or ARBs, once-daily treatment with sparsentan produced a robust and clinically meaningful reduction in proteinuria. The safety of sparsentan was consistent with previous studies in FSGS and comparable to irbesartan.

EFFICACY AND SAFETY OF VOCLOSPORIN IN PATIENTS WITH PROTEINURIA ≥2 MG/MG: AN INTEGRATED ANALYSIS OF THE AURA-LV AND AURORA 1 STUDIES
Salem Almaani1, Emily Littlejohn2, Lucy Hodges3, Christopher Mela2 and Christopher Collins3
1The Ohio State University Wexner Medical Center, Columbus, United States of America, 2Cleveland Clinic Main Campus, Cleveland, United States of America and 3Aurinia Pharmaceuticals, Victoria, Canada

Background and Aims: Proteinuria has been established as a mediator of progressive renal damage in many nephropathies. However, recent studies of several monoclonal antibodies demonstrated a lack of efficacy in patients with lupus nephritis and moderate to high levels of proteinuria (UPCR ≥2 to ≥3 mg/mg), potentially due to an increase in renal antibody clearance.1-4 Given that, we examined the efficacy and safety of voclosporin in patients with lupus nephritis and a UPCR of ≥2 mg/mg using the pooled dataset from the Phase 2 AURA-LV and Phase 3 AURORA 1 trials.

Method: Both studies enrolled patients with biopsy-proven LN (Class III, IV, or V ± III/IV), biopsied within 6 months in AURA-LV or up to 2 years in AURORA 1) and proteinuria ≥1.5 mg/mg (≥2 mg/mg for Class V). Patients were randomized to receive either voclosporin (23.7 mg BID) or placebo and treated for up to one year (48 weeks [AURA-LV], 52 weeks [AURORA 1]); all patients received MMF and low-dose steroids. For this post-hoc analysis, changes in UPCR and renal response rates were evaluated in patients with baseline UPCR ≥2 mg/mg. Complete renal response (CRR) was defined as UPCR ≤0.5 mg/mg with stable renal function, low-dose steroids, and no rescue medication; partial renal response (PRR) was defined as ≥50% reduction in UPCR from baseline. Safety outcomes were also assessed.

Results: The pooled analysis included 268 and 266 patients in the voclosporin and control arms, respectively. Of those, 217 and 215 patients had UPCR ≥2 mg/mg (baseline mean [SD], 5.2 [3.4] vs. 4.6 [2.9] mg/mg, respectively). A significantly greater percentage of voclosporin-treated patients achieved a CRR at one year compared to the control arm (41.0% vs. 21.9%; odds ratio [OR] 2.48, p < 0.0001). Similarly, significantly more patients in the voclosporin arm (69.6%) than control arm (50.0%) achieved a PRR at the same time point (OR 2.3, p < 0.0001); this endpoint was met significantly earlier in voclosporin-treated patients as well (29 vs. 57 days, hazard ratio [HR] 2.0, p < 0.0001). The median time to UPCR <0.5 mg/mg was also significantly earlier in the voclosporin arm (211 days); less than 50% of the control arm achieved this endpoint within the study period (OR 1.9, p < 0.0001, Figure 1B). Adverse event rates were comparable in both arms (Table 1), and mean eGFR levels were similar and stable over the study period, a trend that was maintained for AURORA 1 patients who continued randomized treatment for another two years in the AURORA 2 study.

Conclusion: Consistent with results from the overall pooled study population, patients with UPCR ≥2 mg/mg at baseline treated with voclosporin achieved significantly higher renal response rates and significantly earlier reductions in UPCR than patients treated with MMF and low-dose steroids alone. These findings are clinically important given the lack of effective therapies available for patients with high baseline proteinuria.

AEs were reported using Preferred Terms (PT) based on investigator clinical judgement and discretion. AEs were aggregated by System Organ Class (SOC) and coded using Medical Dictionary for Regulatory Activities (MedDRA) version 20.0.
MODELLING LONG-TERM OUTCOMES FOR PATIENTS WITH IMMUNOGLOBULIN ANEPHROPATHY (IgAN) FROM SHORT-TERM PROTEINURIA DATA

Mark Bensink1, Sean Sullivan2 and Jenny Zhou3
1Travere Therapeutics, Inc., San Diego, United States of America, 2The CHOICE Institute, School of Pharmacy, University of Washington, Seattle, United States of America and 3Analysis Group, Inc., London, United Kingdom

Background and Aims: Immunoglobulin A nephropathy (IgAN) is rare kidney disease that leads to glomerular injury, progressive loss of kidney function and progression to kidney failure. Pre-specified interim proteinuria data from ongoing clinical trials is being used as the basis of regulatory approval of new therapies but little is known about the translation of these results to long-term patient outcomes; a topic of particular interest to health technology assessment (HTA) groups looking to inform decisions on reimbursement before final renal outcome data are available. The objective of this study was to model long-term outcomes for patients with IgAN based on short-term proteinuria data.

Method: We developed a de novo model including a short-term (36-week) decision tree and a long-term Markov model to capture expected lifetime outcomes associated with treatment for IgAN. We used achievement of proteinuria <1 g/day as a clinically relevant treatment target. The short-term model included data on proteinuria level and distribution of chronic kidney disease (CKD) health states (CKD 1/2, 3, 4, and 5). At the end of 36 weeks of treatment, patients were categorized into groups based on their proteinuria level (<1g/day and ≥1g/day) and CKD stage before transitioning to the long-term Markov model. In the long-term model, proteinuria level-based, CKD health state transition matrices derived from analysis of UK National Registry of Rare Kidney Disease (RaDaR) data, and transition matrices to dialysis and transplant derived from the US Renal Data System (USRDS) were used. Other included clinical inputs of complications and mortality were derived from extension of US Optum data analyses and literature. Health-related quality of life (HRQoL) was assessed as health state utilities and disutility associated with complications. Hypothetic scenarios of improvement in short-term proteinuria and impact on long term outcomes were tested. Model outputs included life years (LYs) and quality-adjusted life years (QALYs). Effectiveness was discounted at 3% annually. Deterministic sensitivity analysis was conducted.
Results: Over a lifetime, patients receiving treatment that increased the probability of achieving proteinuria $<1$ g/day by 10% in the short-term, were modelled to have gained an additional 0.388 LYs from reduced CKD/transplant/dialysis-related mortality and 0.633 QALYs from delaying CKD progression to kidney failure. As expected, results improved when the probability of achieving proteinuria $<1$ g/day increased; with a 30% increase in the probability of achieving proteinuria $<1$ g/day, LYs gained were 0.562 (Figure 1) and QALYs 0.968 (Figure 2). Results were most sensitive to time horizon and long-term extrapolation of CKD health state transition matrices. Conclusion: Despite challenges inherent in the translation of surrogate endpoints to long-term outcomes, combining short-term proteinuria from clinical trials and long-term CKD data from real-world registry and claims-based data provides a solution. Based on modelling, treatments that increase the probability of achieving $<1$ g/day in the short-term, are expected to provide benefits to patients with IgAN in the long-term including less time with advanced kidney disease, less time on dialysis and avoiding the need for kidney transplant resulting in improved survival, and better quality of life. Refinement and customization of country-specific model inputs will help ensure outputs are relevant for different jurisdictions and as representative of anticipated real-world outcomes as possible.
Background and Aims: Several retrospective observational studies have supported kidney protective effects of arteriovenous fistula (AVF) formation. However, these studies were limited by immortal time and selection biases. We investigated whether AVF formation delays the initiation of kidney replacement therapy (KRT) in patients with stage 5 CKD by applying target trial emulation methods, which do not suffer from these biases.

Method: We included adult patients who had an eGFR \(\leq 15 \text{mL/min/1.73m}^2\), attended the 'low clearance' nephrology clinic in the West of Scotland between January 1st 2010 and May 1st 2022, and had no prior AVF or AV graft formation. Available data were obtained from the Strathclyde Electronic Renal Patient Record. The target trial would randomize patients to either receive an AVF immediately or to not receive an AVF. To emulate this trial, we matched each patient who underwent AVF formation to patients who had not undergone AVF formation but remained eligible to participate in the trial, and were matched in sex, age (within 5 years) and eGFR (within 0.5 mL/min/1.73m\(^2\)). Inverse probability of treatment weighting was used to adjust for baseline confounders, including age, sex, comorbidities, medication use, serum and urine biochemical measurements (eGFR CKD-EPI, eGFR CKD-EPI slope for 6 months preceding trial, haemoglobin, C-reactive protein, albumin, phosphate, adjusted calcium, ferritin, urine protein:creatinine ratio), and blood pressure. The primary outcome was kidney replacement therapy. The eGFR slope closest to the time of AVF creation was estimated as a co-primary endpoint. We estimated hazard ratios using Cox regression and estimated restricted mean survival time (RMST) from the Kaplan-Meier curves. The eGFR slope co-primary endpoint was analysed with a mixed-effects model.

Results: Among 2,988 included patients (55% men; mean [SD] age 64 [15] years), AVF formation was associated with a higher risk of KRT (HR 1.45; CI 1.20–1.49, \(p < 0.001\), Figure 1) and a lower risk of death (HR 0.68; (0.64–0.80, \(p = 0.001\)). The AVF group had a lower KRT-free survival with an estimated RMST difference of 265 days (95% CI \(-331 \text{ to } -199, p < 0.001\) and higher overall survival (RMST difference of 191 days; 95% CI 57 to 326, \(p = 0.005\)). Finally, we used a mixed-effects model to analyse the association between eGFR CKD-EPI, time, and AVF formation. AVF formation and time were both associated with a negative slope in the model (estimates \(-1.28; 95\% \text{CI } -1.36 \text{ to } -1.19, p < 0.001\) and \(-0.01; 95\% \text{CI } -0.01 \text{ to } -0.01, p < 0.001\), respectively, Figure 2). Their interaction was also associated with a negative slope (estimate \(-0.001; 95\% \text{CI } -0.0022 \text{ to } -0.0004, p < 0.001\), suggesting those undergoing AVF formation had a more rapid eGFR decline compared to the control group.

Conclusion: Unlike what was observed in previously published work, we did not identify a kidney protective effect of AVF formation. The estimated time of dialysis initiation remains the main determinant for timing of access surgery. These findings illustrate the usefulness of target trial emulation in approaching research questions where randomised controlled trials would be impractical.
Background and Aims: The transition to kidney failure is the period of the highest risk for adverse outcomes in chronic kidney disease (CKD). A smooth and timely transition of care, assuring informed and patient-centric decision-making, is paramount to fostering better kidney care. We described the two-year incidence of clinical outcomes and nephrology practices among advanced CKD patients in CKDopps.

Method: CKDopps is a prospective cohort study designed to describe and evaluate variations in CKD practices and outcomes in nephrologist-led CKD clinics. For this analysis, we included CKDopps participants who reached a three-month average estimated glomerular filtration rate (eGFR) of less than 20 mL/min/1.73 m² in the US, France, and Brazil. Time at risk for outcomes started at the end of the first three-month window in which the average eGFR was lower than 20 mL/min/1.73 m² during study follow-up. Education was defined as participation in at least one educational session about KRT modalities. They were considered to have been referred to vascular access (VA) creation if reported in medical records. Education or VA referral happening before the start of follow-up were classified as occurring at baseline. Patients were considered waitlisted if they had been registered on a pre-emptive kidney transplant waiting list. Cumulative incidence functions adjusting for the competing risk of mortality or KRT were used to estimate the 2-year probability of clinical outcomes and planning events.

Results: 2,645 patients were included – 51% from France, 36% from the US, and 14% from Brazil. Overall, 56% of patients were male, the mean age was 66 ± 14 years, approximately 50% had diabetes, 27% had coronary artery disease, and 16% had heart failure. Patients in Brazil tended to be younger (63 years) than those in France (67) and the US (67); patients in the US had the greatest burden of cardiovascular comorbidities. The mean eGFR at the study baseline was 16.6 mL/min/1.73m² (15.4 in Brazil, 15.9 in the US, and 17.3 in France). Over a median follow-up of 15.7 [7.2–24] months, 1140 patients (43.1%) started KRT, whereas 377 (14.3%) died before KRT. The 2-year cumulative incidence of KRT was 32% in Brazil, 33% in France, and 44% in the US (Figure 1). The median eGFR at KRT initiation was 11.7 in Brazil, 9.0 in France, and 10.3 in the US. Pre-KRT death risk in two years was 7.3% in Brazil, 10.9% in France, and 16.4% in the US. In two years, approximately one-third of patients had a VA created across countries (Table 1). The probability of transplant waitlisting was higher in France and the US, while patient-reported KRT education was more common in Brazil (Table 1).

Conclusion: In this international analysis of advanced CKD patients, we found important variations in nephrology practice and outcomes across countries. Patients in the US have a higher risk of both pre-KRT death and KRT. Patient-reported education was far more common in Brazil than in the US and France. Although patients in Brazil are referred for VA creation earlier in the course of advanced CKD, 2-year cumulative incidences for such are similar across countries. The 2-year probability of pre-emptive kidney transplant listing was higher in France and the US. Further international studies evaluating risk factors for adverse outcomes and barriers to KRT planning among advanced CKD patients are warranted.

PREDICTION OF ALL-CAUSE MORTALITY FOR CHRONIC KIDNEY DISEASE PATIENTS USING FOUR MODELS OF MACHINE LEARNING

Nu Thuy Dung Tran1, Margaux Balezeaux2, Granal Maelys3, Denis Fouque4, Ducher Michel5 and Jean Pierre Fauvel5

1Lyon, Auvergne-Rhône-Alpes, Lyon, France and 2Lyon, Auvergne-Rhône-Alpes, Lyon, France

Background and Aims: Prediction tools developed from general population data to predict all-cause mortality are not adapted to patients with chronic kidney disease (CKD), as this population has a higher risk of mortality. This study aimed to create a clinical prediction tool with good predictive performance to predict 2-year all-cause mortality in patients with stage 4 or 5 CKD using an innovative approach with machine learning models and a synthetic population.

Method: The national, observational, descriptive and prospective PhotoGraphe 3 study was used to create the learning database. Four models (i) logistic regression; (ii) deep learning; (iii) random forest and (iv) Bayesian network were used to create four prediction tools. The performance of each model, including the area under the receiver operating characteristic curve (AUC-ROC) value, accuracy, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), was evaluated and compared using 10-fold cross-validation. The prediction tool with the best performance was selected and optimized using a synthetic population and the explanatory variables most related to mortality. The synthetic population was created by the Bayesian imputation method. The variables most associated with 2-year all-cause mortality were determined by compromising the number of variables selected and the AUC-ROC value when successively adding the variable according to its percentage variance value. The performance of the optimized prediction tool in predicting 2-year mortality was then evaluated by 10-fold cross validation.

Results: All prediction tools except the one developed with the random forest model showed satisfactory discrimination (AUC-ROC ≥ 0.70). Overall, the prediction tools developed using the Bayesian network and logistic regression tended to have better performance. Although not significantly different from logistic regression, the prediction tool developed using the Bayesian network was chosen for further development because of its advantages.

From the 534 patients in the study population, a synthetic population of 2000 patients (survivor:death ratio = 1:1) was created. The seven most informative variables ranked in descending order were: age, ESA, CV history, smoking status, 25-OH vitamin D level, PTH level, and ferritin level (Figure 1). The optimized clinical prediction tool had satisfactory internal performance. The mean accuracy was 73.8% (SD = 3.6), the mean AUC-ROC was 0.81 (SD = 0.03), the mean sensitivity was 71.0% (SD = 5.4), the mean specificity was 76.5% (SD = 3.0), the mean PPV was 75.1% (SD = 3.2), and the mean NPV was 72.6% (SD = 4.1).

Conclusion: Bayesian network model was used to create a seven-variable prediction tool to predict the 2-year all-cause mortality in patients with stage 4–5 CKD. This prediction tool has a satisfactory performance. Prior to external validation, the proposed prediction tool can be used at: https://bit.ly/3JPhrkh for research purpose. This is the first time that a synthetic population has been applied to create predictive models. In this study, the synthetic population showed its advantage in dealing with sample size issues in developing predictive models and in improving the performance of the prediction tool in terms of sensitivity and PPV.

MENOPAUSAL HORMONE THERAPY AND RISK OF DEMENTIA IN WOMEN WITH PRE-DIALYSIS CKD: A NATIONWIDE OBSERVATIONAL COHORT STUDY
Hyuk Huh¹, Dong Ki Kim², Semin Cho³, Jung-Hyun Kim⁴ and Kwon Wook Joo²
¹Inje University Busan Paik Hospital, Busan, Korea, Department of Internal Medicine, Korea, Rep. of South, ²Seoul National University College of Medicine, Seoul, Korea, Korea, Rep. of South, ³Chungang University Gwangmyeong hospital, Gyeonggi-do, Korea, Korea, Rep. of South and ⁴PaiChai University, Home Economics Education, Korea, Rep. of South

Background and Aims: The risk of dementia is increased in postmenopausal women. The incidences of premature menopause and dementia are increased in patients with chronic kidney disease (CKD). Therefore, the potential benefit of hormone replacement therapy (HRT) for cognitive function may be a more critical issue in CKD patients.

Method: Menopausal women over 40 years with or without HRT were identified through the National Health Screening questionnaire in 2009. Among the subjects, those newly diagnosed with CKD between 2009 and 2013 were enrolled. HRT was used as an exposure variable and was followed from the day when CKD was diagnosed to December 2019. The hazard ratio (HR) of dementia was evaluated using a Cox proportional hazards regression analysis.

Results: We included 755,426 postmenopausal women with CKD. The median follow-up period was 7.3 (IQR, 5.8-8.7) years. All-cause dementia occurred in 107,848 (14.3%), Alzheimer’s disease in 87,833 (11.6%), and vascular dementia in 10,245 (1.4%). HRT was significantly associated with a lower risk of dementia in the adjusted Cox regression model (all-cause dementia: hazard ratio [HR] 0.796, 95% confidence interval [95% CI] 0.776-0.816, P < 0.001; Alzheimer’s disease: HR 0.795, 95% CI 0.773-0.818, P < 0.001; vascular dementia: HR 0.803, 95% CI 0.743-0.868, P < 0.001).

Conclusion: HRT was significantly associated with a lower risk of CKD-related cognitive dysfunction in postmenopausal women. Prospective studies on whether HRT lowers the risk of dementia in menopausal women with CKD are needed.
Figure 1: Cumulative incidence of outcome according to hormone replacement therapy. The x-axis indicates the time (years), and the y-axis indicates the cumulative incidence (percentage) of dementia during the observation period. The survival curves are stratified by hormone replacement duration (black: No replacement; red: duration <2 years; green: 2-5 years; and blue: ≥ 5 years).

FIRST IDENTIFICATION AND CHARACTERIZATION OF MICROPLASTICS IN HUMAN KIDNEY AND URINE
Ottavia Exacoustos1, Cristina Artini2, Sara Massardo2, Claudia Caboni2, Andrea Pastorino1, Silvio Chiarenza1, Gianluigi Zaza1, Giovanni Stallone1, Gian Marco Ghiglieri1, Andrea Angeletti1, Francesca Lugani1, Enrico Eugenio Verrina1, Edoardo La Porta1, Pasquale Esposito5, Francesca Viazzi5, Daniela Verzola6, Chiara Paccagnella7 and Stefano Alberti2

1Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Istituto Giannina Gaslini, Genoa, Italy., Department of Pediatrics, Italy. 2University of Genoa, Department of Chemistry and Industrial Chemistry, Italy. 3University of Foggia, 71122 Foggia, Italy, Division of Nephrology, Dialysis and Transplantation, Italy. 4Istituto di Ricovero e Cura a Carattere Scientifico (IRCCS) Istituto Giannina Gaslini, Genoa, Italy, Division of Nephrology, Dialysis and Transplantation, Italy. 5IRCCS Ospedale Policlinico San Martino, Department of Nephrology, Italy. 6University of Genoa, Department of Internal Medicine, Italy and 7Azienda Ospedaliera Universitaria Integrata Verona, Department of Nephrology, Italy.

Background and Aims: Microplastics (MPs), plastic fragments less than 5mm in diameter, have been recognized as a global environmental issue. Various studies have shown their ubiquitous presence and their toxicity on marine and terrestrial fauna. Currently in humans, the presence of MP has been evidenced in lungs, placenta, blood, and liver. However, there is still very little knowledge about their presence in different organs and tissues and their prospectivetoxicity. The objective of this study was to investigate the presence of microplastics in human kidneys and urine.

Method: We obtained 10 urine samples from healthy individuals and 10 kidney healthy tissue samples from nephrectomies in renal cancer. The detection and characterization of microplastics was performed by a light microscope (Leica, total magnification of 800x) coupled to a Raman spectrometer (Renishaw System 2000). To this purpose, specimens were digested by a 10% KOH solution at 60°C and subsequently filtered on membrane filters with micropores of 0.2 μm to retain possible particles. This procedure was performed adopting a “plastic-free” protocol. Procedural blanks were performed as controls using the same protocol. To determine the nature of the detected particles, Raman spectra were compared to the ones present in the Renishaw spectrometer database (inorganic materials, polymers and forensic materials) [i], in the SLOPP Library of Microplastics [ii], and in the IRUG Spectral Database (pigments section) [iii]. A home-developed software was employed to compare spectra. Data analysis was performed by using the statistical software package Prism6 (Graphpad Software) Chi-square test, Student’s t-test were performed to compare data accordingly. The significance threshold was set at p < 0.05.

Results: 17 fragments (mean 1.7±2.11/sample) were identified and characterized on 7 out of 10 human kidney samples. The result was significant (p.value 0.041) compared with controls (mean 0.33±0.49/blank). 9 fragments were identified and characterized on 7 out of 10 human urine sample (mean 1.28±0.49/sample) highly significant (p.value 0.0002). Spectra analyzed by microRaman showed the presence polymers, polymers additives and pigments associated to polymers such as: hematite, Cu-phthalocyanine blue, Cerulean Blue, Polystyrene, Styrene-Isoprene and polyethylene.

Conclusion: We first demonstrated the presence of MPs in human kidneys, and we also confirm their presence in urine assuming the presence of a kidney clearance mechanism. Using Raman Microspectroscopy, it was also possible to determine the nature and quantity of MPs. The remarkable relevance of this identification, potentially concern much of the humans, deserve a widespread attention of the medical community for its potential implications. Further studies are urgently needed to investigate the possible nephrotoxicity of MPs, mechanisms of kidney clearance and tissue accumulation.

**ESTIMATED GLOMERULAR FILTRATION RATE BY FIVE DIFFERING MEASURES, RACE, GENETIC RISK AND PREDICTION OF CARDIOVASCULAR DISEASE AND MORTALITY**

Lei Tang, Xiaoxi Zeng and Ping Fu

West China Hospital, Sichuan University, Division of Nephrology, Kidney Research Institute, Chengdu, P.R. China

**Background and Aims:** Estimated glomerular filtration rate (eGFR), a significant measurement of chronic kidney disease (CKD), is associated with adverse health outcomes in the general population but whether its utility differs by race and genetic risk remains unclear. The current study aims to investigate the performance of CKD staging and risk prediction in cardiovascular disease and mortality based on five eGFR measures among people of different ethnic groups and genetic background.

**Method:** In this prospective cohort study, we included 431,126 participants from the UK Biobank, deriving hazard ratios and 95% confidence intervals from multivariable adjusted Cox proportional hazards models. C statistic and net reclassification improvement (NRI) were utilized for comparing the predictive benefit of eGFR measures when added to the traditional cardiovascular risk factors.

**Results:** Over a median of 13.4 (IQR 12.7-14.9) years of follow-up, 27,757 (6.4%) participants died from any cause, of which 3272 (0.8%) died primarily from CVD. 39,522 (9.2%) incident composite CVD hospitalization and 911 (0.2%) ESRD occurred. Two new eGFR equations refitted without race provided lower estimates in Black population but higher in other ethnic backgrounds than the corresponding old ones. The relative risk of adverse outcomes was generally greater in Blacks and participants with low genetic susceptibility to impaired kidney function. The superiority of cystatin C-based eGFR measures in risk prediction did not differ by race and genetic risk.

**Conclusion:** Eliminating the use of racial categories in eGFR calculation help enhance the access to specialist care and intervention at the early stage of CKD for Black population. Cystatin C-based eGFR measures can be extensively used in risk assessment in clinical practice.

**INTEGRATED KIDNEY MARKERS AND CARDIOVASCULAR MORTALITY: A SURVIVAL ANALYSIS IN UK BIOBANK**

Ryosuke Fujii1,2, Roberto Melotti1 and Cristian Pattaro1

1Eurac Research, Bolzano, Italy, 2Fujita Health University, Toyoake, Japan and 3Nagoya University, Nagoya, Japan

**Background and Aims:** The estimated glomerular filtration rate (eGFR) and other kidney function markers are associated with cardiovascular disease (CVD) mortality [1]. It remains unclear whether integrating multiple kidney markers together can improve CVD mortality risk prediction and what would be an appropriate method of integration. In a small general population sample, we recently showed that confirmatory factor analysis (CFA) may predict CVD risk better than single markers, but it did not outperform cystatin C-based eGFR (eGFRcys) [2]. To assess whether our findings were context-dependent and to which extent they may extend to mortality risk assessment, we applied CFA and exploratory factor analysis (EFA), integrating five kidney function markers in the UK Biobank (UKBB) study, comparing risk discrimination for CVD mortality and renal failure mortality versus established eGFR formulas.

**Method:** We analyzed data from 366,758 UKBB participants (mean age 56.6 years; females 53.7%) without clinical history of kidney failure at baseline. Information on participants’ mortality was collected from the National Health System registry, using ICD-10 codes I00-I99 and N17-N19 to identify CVD mortality and renal failure mortality. We applied CFA and EFA to creatinine- and cystatin C-based estimated glomerular filtration rate (eGFRcre), eGFRcys, blood urea nitrogen (BUN), uric acid (UA), and serum albumin (Alb). EFA was fitted using maximum likelihood. Promax rotation was then applied. We fitted Cox regression models to examine the associations of mortality with kidney markers: CFA-based kidney index [CFA]; 1st EFA-based kidney index [EFA1]; 2nd EFA-based kidney index [EFA2]; eGFRcrecys; eGFRcys, and creatinine- and cystatin C-based eGFR (eGFRcyscrecs). Models were adjusted for sex, age, body mass index, education, self-reported ancestry, hypertension, diabetes, and tobacco smoking. The receiver operating characteristics (ROC) curve and the DeLong test were used to compare discriminatory ability of each index.

Background and Aims: Anemia in chronic kidney disease (CKD) has been repeatedly associated with increased cardiovascular and all-cause morbidity and mortality. Most observational studies have focused on one single measurement of hemoglobin, but very few have investigated the trajectory of hemoglobin over time. Our aim was to identify, in moderate to severe CKD, typical profiles of hemoglobin trajectories, and to estimate their associated risk of major adverse cardiovascular event (MACE).

Method: We used data from the CKD-REIN cohort, which included 3033 patients with moderate to severe CKD from 40 nationally representative nephrology clinics in France between 2013 and 2016. A minimum of one hemoglobin measurement was necessary to be included. The primary endpoint was MACE defined as the first event among cardio-vascular death, myocardial infarction, stroke or hospitalization for acute heart failure. Secondary events included initiation of kidney replacement therapy (KRT) and death. A joint latent class mixed model was used to identify classes of hemoglobin trajectory and estimate the risk of each event. Once the model had identified classes and assigned participants in their class, we described the characteristics of patients in each class a posteriori. We also performed a posterior analysis to describe the course of estimated glomerular filtration rate (eGFR) in each class.

Results: A total of 3011 subjects were included in the analysis: 66% were men, median age at inclusion was 69 years. A total of 33874 hemoglobin measurements have been analyzed (median of 10 per patient). A total of 460 MACE, 522 KRT before MACE and 216 deaths before MACE or KRT, were recorded over a median follow-up of 4.3 years (Interquartile Range IQR 2.3-5.0). Five distinct classes were identified with a predominant one, Class-1 (‘constant’) including 63% (n = 1885) of the studied population with an overall stable trajectory surrounding a hemoglobin concentration of 13 g/dl. (See figure below). For this class, risks of events were very low throughout the follow-up. Patients in this class had fewer cardiovascular risk factors, lower eGFR, and less often increased proteinuria at baseline than in other classes.

Class-2 trajectory (late strong decline, n = 75, 2.5%) had an abrupt decline at 2 years of follow-up; concomitantly risks of KRT and death before MACE emerged but the risk of MACE remained low over the follow-up. Patients classified in this class had more often tubulo-interstitial or unknown nephropathy than in other classes. Classes 3 (late moderate decline, n = 438, 14.6%) and 4 (early moderate decline, n = 356, 11.8%) exhibited more
Figure 1: Trajectories of hemoglobin and associated risk of MACE, KRT before MACE or death before KRT or MACE, n = 3011, CKD-REIN study.

A moderate decline of hemoglobin level occurring on average at 3 and 1 year of follow-up, respectively. For these two classes, the risk of KRT before MACE increased from the start of these declines but their risks of MACE increased from the cohort entry. Class-5 (early strong decline, n = 257, 8.5%) had a collapsing trajectory right from the entry into the cohort, and had a risk of MACE increasing rapidly in the very first year. Patients from Class-3 and Class-5, who had the highest risk of MACE, also had a worse cardiovascular profile at baseline. The average eGFR trajectories estimated in each of the 5 identified classes of hemoglobin showed similar patterns as those for hemoglobin.

Conclusion: In patients with CKD under nephrology care, most of patients have normal and stable hemoglobin values over time. In about one third of patients, 4 profiles of hemoglobin decline were observed, likely matching those of eGFR decline. These 4 classes with declining profiles had different levels of MACE risk and a strong increased risk of KRT after hemoglobin decline. This study suggests that more attention should be paid to dynamic changes of hemoglobin in the management of CKD.

PREVALENCE OF UNRECOGNIZED CHRONIC KIDNEY DISEASE IN THE LOLLAND-FALSTER HEALTH STUDY: A POPULATION-BASED STUDY IN A RURAL-PROVINCIAL AREA OF DENMARK
Ebba Mannheimer1, Morten Jørgensen4, Kristine Hommel5, Anne Lise Kamper1, Bo Feldt-Rasmussen1 and Mads Hornum1
1Rigshospitalet, København, Denmark and 2Holbæk Hospital, Holbæk, Denmark

Background and Aims: In order to improve renal and cardiovascular outcome in patients with chronic kidney disease (CKD), it is important to identify patients with CKD in early stages of the disease. Given the asymptomatic nature of early-stage CKD, the majority of the CKD patients are living with an unrecognized condition. There is limited knowledge about the Danish prevalence of CKD stage 1-4. Moreover, previous studies have shown association between CKD and low socio-economic status. This study aims to increase the insights into prevalence and risk factors of CKD in a population living in a part of Denmark where income and life expectancy is below the national average.

Method: Data was derived from The Lolland-Falster Health Study (LOFUS) which is a population and household-based prospective cohort study at Lolland-Falster, a mixed rural-provincial area in Denmark. Data was obtained between 2016 and 2020 from questionnaires, clinical- and paraclinical evaluation. CKD was defined according to KDIGO classification (single test) as urinary albumin-to-creatinine ratio (UACR) >30 mg/g and/or estimated glomerular filtration rate (eGFR) <60 ml/min/1.73 m2. Univariate and multiple logistic regression models were used to evaluate potential risk factors for CKD.

Results: The study included 16,142 adult individuals. Characteristics of the population are reported in Table 1. The median age was 58.6 years (IQR 44.7-68.6) and 53% of the population were women. The overall CKD prevalence was 17.7% and was higher in women than in men (19.2% versus 16.0%, p-value < 0.001). Of the 2856 participants with CKD, 71.1% had CKD based on elevated UACR, 19.0% had CKD based on reduced eGFR and 9.9% had CKD based on reduced eGFR combined with elevated UACR. Among the participants with CKD, 31.8% had CKD stage 1, 39.2% had stage 2, 28.0% stage 3, and 1.1% had CKD stage 4-5. Less than 2% (n = 207) of the total population had a self-reported kidney-related diagnosis which correspond to only 4.5% of the individuals with CKD identified in the study. Among those with CKD stage 3-5, more than 27% did not report any kidney-related diagnosis. In univariate analyses, female sex (OR 1.25, 95% CI 1.15 – 1.35), age above 55 years (OR 3.55, 95% CI 3.01 – 4.20), BMI > 25 kg/m² (OR 1.02, 95% CI 1.02 – 1.03), diabetes (OR 3.38, 95% CI 2.89 – 3.95), hypertension (OR 3.34, 95% CI 3.06 – 3.65) and low income (OR 1.24, 95% CI 1.12 – 1.37) were associated with CKD.

**DAPRODUSTAT VERSUS RECOMBINANT HUMAN ERYTHROPOIETIN FOR TREATING ANAEMIA OF CHRONIC KIDNEY DISEASE: COST EFFECTIVENESS MODEL METHODOLOGY AND FINDINGS**

Alfred Sackeyfio¹, Yevgeniy Samyshkin², Justin Riemer¹, Michelle Blake³, Simbarashe Mhishi³, Marie Prett⁴, Laura Elliot⁴ and Rodrigo Refoios Camejo²

¹GSK, Stevenage, Hertfordshire, United Kingdom, ²GSK, Brentford, London, United Kingdom, ³GSK, Mississauga, ON, Canada and ⁴FIECON, St Albans, United Kingdom

**Background and Aims:** Anaemia is a common manifestation in patients with chronic kidney disease (CKD). Daprodustat, a hypoxia-inducible factor prolyl hydroxyylase inhibitor, offers an alternative to conventional treatment with recombinant human erythropoietins (rhEPOs). This study reports the development of a cost-effectiveness analysis to support reimbursement discussions for daprodustat in Canada.

**Method:** A Markov model was developed to conduct a cost-utility analysis to compare expected costs and outcomes associated with daprodustat, vs two rhEPO treatment comparators (darbepoetin alfa [DA] or epoetin alfa [EA]), which represent standard of care. The model used a lifetime time horizon, and a publicly funded Canadian healthcare payer perspective for adults with anaemia of CKD (on/not on dialysis). Clinical inputs for the model were obtained from two Phase 3 clinical trials: ASCEND-D¹ (daprodustat vs DA or EA in 2964 dialysis patients) and ASCEND-ND² (daprodustat vs DA in 3872 non-dialysis patients). Efficacy and adverse event profiles of both rhEPOs were assumed equal. Patients entering the model (Figure) receive daprodustat, DA or EA. The model includes five health states informed by ASCEND-D and ASCEND-ND: non-dialysis, dialysis, kidney transplant, post-transplantation and terminal care. While in the dialysis or non-dialysis health state, costs and utilities are assigned based on three haemoglobin (Hb) levels: <10g/dL, 10–11.5g/dL or >11.5g/dL. A monthly cycle length is utilised and aligned with the ASCEND study visits and observations up to Week 52. Hb concentrations from ASCEND-D and ASCEND-ND are used to estimate proportions of patients in the target Hb range of 10–11.5g/dL, and non-target Hb levels. They were assumed to have different utility values. Patients could transition from non-dialysis to dialysis; in the latter state, patients could die or receive a kidney transplant, and transition to a post-transplantation state. Transition probabilities were derived from ASCEND-D and ASCEND-ND data and the literature. The median follow-up durations in ASCEND-D and ASCEND-ND were 2.5 and 1.9 years, respectively, necessitating extrapolation to the model time horizon; increases over time in the transition probabilities were applied. It is assumed that patients cannot transition back to non-dialysis from the dialysis state. Patients may transition to death from any health state, with mortality risks informed by the ASCEND trials and Canadian all-cause mortality data. Costs in the model included treatment acquisition and administration, cold-chain storage, dialysis, kidney transplant, transfusions of red blood cells and iron, and adverse events (AEs). All costs were sourced from fee schedules (2022 SCAd) or the literature. Utilities for health states and HB levels were obtained from the ASCEND trials; AE-associated utility decrements could not be estimated from ASCEND data due to low event rates – hence, disutilities were sourced from the literature.

**Results:** In the probabilistic reference case analysis, daprodustat was less costly (comparison with DA: -$8763; EA: -$13,864) and produced more quality-adjusted life years (DA: +0.012; EA: +0.018; Table). The incremental savings with daprodustat versus DA and EA were -$860 and -$1033, respectively, in the non-dialysis state, and -$7904 and -$12,831 in the dialysis state. Contributors to the cost savings with daprodustat include an absence of cold-chain storage costs and reduced administration costs.

**Conclusion:** This study indicates that daprodustat is less costly and originates more QALYs than DA and EA in the treatment of anaemia due to CKD. In this setting, daprodustat may provide cost savings from a Canadian public payer perspective. The model described here could be adapted to other perspectives, including European countries.

HEMOGLOBIN VARIABILITY AND ADVERSE CLINICAL EVENTS IN PATIENTS WITH NON-DIALYSIS-DEPENDENT CHRONIC KIDNEY DISEASE AND ANEMIA IN CONTINUOUS CARE
Kuragano Takahiro1, Suguru Okami2, Sachiko Tanaka3,4, Hidetoshi Uenaka4, Takeshi Kimura4, Yosuke Ishida2, Glen James5 and Takanori Hayasaki2

Ltd., Research and Analytics Department, Kyoto, Japan and 5Bayer AG, Integrated Evidence Generation & Business Innovation, Reading, United Kingdom

Background and Aims: Anemia management in non-dialysis dependent chronic kidney disease (NDD-CKD) patients has attracted attention with the introduction of new treatment options, such as prolyl hydroxylase domain enzyme inhibitors (HIF-PHI). However, studies reporting comprehensive information on anemia management in NDD-CKD patients are limited. While previous studies reported increased risks of adverse clinical events associated with hemoglobin (Hb) fluctuation in hemodialysis patients, limited information is available in NDD-CKD patients.

Method: A retrospective cohort study was performed using a Japanese nationwide electronic medical record-based hospital database. Patients with...
stage ≥3a NDD-CKD, aged ≥18 years, and at least one recorded Hb <11 g/dL between January 1st 2013 and April 30th 2021 were included. Patients already receiving any anemia treatment (erythropoiesis stimulating agent (ESA), iron, or HIF-PHI) were excluded. Hb levels were collected at the index date (the date of the first recorded Hb <11 g/dL) and during the follow-up period. Clinical events included all-cause death, cardiovascular (CV) events (myocardial infarction, unstable angina pectoris, stroke, or hospitalization for heart failure), dialysis introduction, and red-blood-cell transfusion. Time-dependent Cox proportional hazard models, adjusted by clinically relevant variables were applied to assess the risk of clinical events associated with transitioning Hb fluctuation patterns, categorized into six groups: within the target Hb range (11–13 g/dL); consistently below the target (low); consistently above the target (high); low-amplitude fluctuation around the upper limit of the target (LAH); low-amplitude fluctuation around the lower limit of the target (LAL); and, high amplitude fluctuation across the target (HA).

**Results:** Of 162,170 patients with CKD, 26,626 (16.4%) NDD-CKD patients with Hb <11 g/dL were identified (median follow-up length, 1.9 years). The mean age was 75.9 years, and 37.8% were female. In overall patients, the mean (±SD) Hb levels at index and at 3, 6, and 12 months of follow up were 9.9±1.2 g/dL, 10.6±1.5 g/dL, 10.8±1.6 g/dL, and 10.9±1.6 g/dL, respectively. The proportion of patients with Hb <10 g/dL at index and at 12 months were 34.3% and 23.9%, respectively. In the subgroup of patients treated with ESA or HIF-PHI (n = 8,876), the mean Hb (±SD) levels had increased from 9.3±1.3 g/dL to 10.3±1.5 g/dL at 3 months, 10.5±1.5 g/dL at 6 months, and 10.6±1.5 g/dL at 12 months after treatment initiation. In this subgroup, the proportion of patients with Hb <10 g/dL had decreased from 70.0% to 30.1% at 12 months. Fig. 1 shows the Hb levels and proportions of patients with Hb <10 g/dL by treatment type. During the follow-up period, 5,991 (22.5%) deaths, 3,545 (13.3%) CV events, 4,231 (15.9%) dialysis introductions, and 5,561 (20.9%) red-blood-cell transfusions were observed. The risks of clinical events were significantly higher in the low and LAL Hb groups than in the target Hb group (Fig. 2). The hazard ratios (95% CIs) for death, CV events, dialysis introduction, and red-blood-cell transfusion in the low Hb group, compared to the target Hb group were 1.35 (1.20–1.52), 1.90 (1.58–2.27), 1.75 (1.39–2.20), and 2.80 (2.28–3.43), respectively, and in the LAL Hb group were 1.28 (1.14–1.43), 1.71 (1.43–2.04), 1.85 (1.48–2.33), and 1.64 (1.33–2.02), respectively. In HA Hb group, significantly higher risks for dialysis introduction and red-blood-cell transfusion were observed.

**Conclusion:** This study reports comprehensive information on anemia management in NDD-CKD patients in clinical practice. Despite treatment for Hb correction, 20–30% of patients persistently remained at low Hb levels. The increased risk of adverse clinical events associated with Hb fluctuations suggest that stable Hb control within the target range is important to reduce the risk of mortality and morbidity in patients with NDD-CKD and anemia.

EVALUATION OF HAEMOGLOBIN RESPONSE IN PATIENTS WITH CKD-RELATED ANAEMIA NOT ON DIALYSIS RECEIVING DAPRODUSTAT OR CONTROL IN ASCEND-ND

Sapna Shah1, Sergio Godoy2, Stavros Patsalas1, Sung Gyun Kim3, Jo Dole4, Purav Bhatt6, Allison Blackorby6, Amy Meadowcroft6 and Vivekanand Jha7

1 King’s College Hospital NHS Trust, London, United Kingdom, 2 George Clinical, Pilar, Argentina, 3 Nephrosis Dialysis Unit, Efkarpia Thessaloniki, Greece, 4 Hallym University Sacred Heart Hospital, Hallym University College of Medicine, Chuncheon, Gangwon, Korea, Rep. of South, 5 GSK, Collegeville, PA, United States of America, 6 GSK, Durham, NC, United States of America and 7 The George Institute for Global Health, New Delhi, India

**Background and Aims:** Daprodustat (Dapro) is a novel hypoxia-inducible factor prolyl hydroxylase inhibitor being investigated in anaemia of chronic kidney disease (CKD). ASCEND-ND achieved non-inferiority (NI) for Dapro vs darbepoetin alfa (Darbe) in both coprimary endpoints, mean change in haemoglobin (Hb) levels from baseline to the evaluation period (EP; Week [Wk] 28–Wk 52) and first occurrence of a composite major adverse cardiovascular event, in patients (pts) with anaemia of CKD not on dialysis. Here, we present key Hb efficacy data and evaluate differences in Hb response within ASCEND-ND subgroups.

**Method:** Pts with Stages 3–5 CKD (not on erythropoiesis stimulating agents [ESAs]; Hb 8–10g/dL; on ESAs: Hb 8–11g/dL) were randomised 1:1 to Dapro or Darbe. Statistical analysis methods for the coprimary endpoint have been published.1 Secondary endpoints evaluated during the EP included: 1) the percentage of Hb responders (pts with mean evaluable Hb within the analysis range [10–11.5g/dL]); 2) the percentage of time Hb was within the analysis range; 3) analysis of Hb change from baseline to Wk 52. Secondary endpoints were analysed as follows: 1) Cochran-Mantel-Haenszel test adjusted for ESA use and region; 2) Rosendaal method (evaluable Hb values) and Hodges-Lehmann and stratified Mann-Whitney estimates of treatment effect, analysed with a van Elteren’s test stratified by ESA use and region; 3) mixed model repeated measures analysis (on-/off-treatment, observed Hb values from Wks 28–52) with factors for ESA use, region, baseline Hb (by time), treatment by time interactions. Secondary and subgroup analyses were not multiplicity adjusted.

**Results:** Of 3872 pts in ASCEND-ND (Dapro n = 1937; Darbe n = 1935), mean baseline Hb levels were similar for both treatment arms and mean change in the EP Hb level for Dapro and Darbe met the prespecified NI margin of –0.75 g/dL (difference = 0.08g/dL; 95% confidence interval [CI] = 0.03, 0.13).1 Subgroup analyses were consistent with coprimary analyses (Table), with little or no heterogeneity between most groups: 7/22 subgroups (ethnicity, high-level race, region, ESA use at randomisation, pre-ESA dose group, history of stroke, and hospitalisation 6 months prior to screening) had interaction p values <0.1; however, all subgroups met the NI criterion with between-group differences that were not clinically meaningful. Proportions of pts within the Hb analysis range were higher for Dapro than Darbe in the EP overall and regardless of baseline ESA use and similar for region (Table). The median (interquartile range) percentage of time Hb was in the analysis range during the EP was 70.5% (45.3%–93.2%) for Dapro vs 63.2% (33.7%–88.9%) for Darbe. Daproduction was associated with a nominally NI (margin of –15%) and significant increase in percentage time in analysis range during the EP (estimate of median difference [95% CI] = 4.57% [2.04%, 7.11%; one-sided p <0.0001]). The estimate (95% CI) for the probability that Dapro had a greater percentage of time Hb within the analysis range than Darbe was 0.55 (0.53, 0.57); the lower boundary of the 95% CI exceeded 0.50, representing equal probability between the two treatment arms. Results by region were similar for Dapro vs Darbe (treatment effect): Asia Pacific = 0.56; Eastern Europe/South Africa = 0.51; Western Europe/Canada/Australia/New Zealand/Israel, 0.58; Latin America, 0.58; USA, 0.55). In mixed-model repeated measures analysis, g/dL Hb change (standard error) at Wk 52 was 0.76 (0.029) with Dapro and 0.73 (0.029) with Darbe (difference [95% CI] = 0.03 [−0.05, 0.11]). Hb efficacy was similar regardless of ESA use (Figure).

**Conclusion:** Daprodustat was effective and NI to Darbe for maintaining Hb in non-dialysis pts with anaemia of CKD, and results of subgroup analyses were consistent with the coprimary analyses. Additionally, Daprodustat raised and maintained Hb within the analysis range regardless of baseline ESA use or region. These preliminary analyses indicated a nominal NI showcasing greater Hb time in range with Daprodustat vs Darbe; further analyses will be presented to fully characterise this interaction.
Note: Error bars indicate Confidence Interval. Baseline and visits on or before Day 1 include only pre-treatment values. Post-randomisation values include observed on and off treatment values. The horizontal reference lines in the figures represent the Hb analysis range (10-11.5 g/dL). The Hb target range for dose changes 10–11 g/dL. The dashed vertical lines represent the evaluation period (Week 28 to Week 52).

Dapro, daprodustat; Darbe, darbepoetin alfa; ESA, erythropoiesis stimulating agent; Hb, haemoglobin; SCR, screening.

CAROTID PLAQUE THICKNESS PREDICTS CARDIOVASCULAR EVENTS AND DEATH IN PATIENTS WITH CHRONIC KIDNEY DISEASE

Sasha Saurbrey Bjergfelt 1,2, Ida Maria Hjelm Soerensen 1, Klaus F. Kofoed 3,4, Bo Feldt-Rasmussen 1,4, Henrik Sillesen 5, Christina Christoffersen 2,6 and Susanne Bro 1

1Rigshospitalet, Department of Nephrology, Copenhagen Ø, Denmark, 2University of Copenhagen, Department of Biomedical Sciences, Copenhagen N, Denmark, 3Rigshospitalet, Department of Cardiology, Copenhagen, Denmark, 4University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark, 5Rigshospitalet, Department of Vascular Surgery, Copenhagen, Denmark and 6Rigshospitalet, Department of Clinical Biochemistry, Copenhagen, Denmark

Background and Aims: Classical risk scoring systems highly underestimate the elevated risk of cardiovascular (CV) disease in chronic kidney disease (CKD) (1). Coronary artery calcification score (CACS) has improved prediction of CV events in patients with CKD (2). Recently, ultrasound examination of the carotid arteries with measurement of maximal carotid plaque thickness (cPTmax) has demonstrated similar predictive value as CACS in the general population (3). This is the first study to investigate whether cPTmax can predict CV events in patients with CKD. We also compared the predictive value of cPTmax and CACS.

Method: Two hundred patients with CKD stage 3 from the Copenhagen CKD Cohort underwent ultrasound scanning of the carotid arteries in 2016 to 2017. The assessment consisted of finding areas with plaque, if there were any, and measuring the thickest part of the plaque, cPTmax, defined as the radial distance from the media–adventitia interface to the intima–lumen interface towards the center of the arterial lumen. For the statistical analysis only the anatomical side with the highest cPTmax was used. The intra-observer coefficient of variation was 9%. Based on the distribution of cPTmax, the subjects were divided into 3 groups: No plaques, cPTmax 1.0-1.9 mm and cPTmax > 1.9 mm (the median cPTmax in the group was 1.9 mm). One hundred and seventy-five of the patients underwent a non-contrast CT scan of the coronary arteries, which was used to measure CACS. The patients were divided into the following categories: no calcification, CACS = 1-100, CACS = 101-400 and CACS > 400. The follow-up time was time elapsed from the ultrasound scan and until a predefined end-date or the time of first event, which was defined as a composite of major CV events or death of any cause (MACE). CV events included: myocardial infarction, percutaneous coronary intervention, coronary bypass surgery, ischemic stroke, carotid endarterectomy or stenting, non-traumatic lower limb amputation, lower limb artery bypass graft, percutaneous transluminal angioplasty of a lower limb.

Results: The average follow-up time was 5.4 years. Twenty patients (10%) experienced a CV event and 28 patients died (14%). In a crude absolute risk plot (Figure), patients with no plaque at baseline showed the lowest risk of MACE, whereas patients with cPTmax 1.0-1.9 mm showed an intermediate risk, and patients with cPTmax >1.9 mm the highest risk (log rank test, p<0.0001). When using the group of patients with no plaque as the reference in an unadjusted Cox-regression analysis, the hazard ratio (HR) of MACE was significantly increased in patients with cPTmax 1.0-1.9 mm (HR = 3.8 (CI: 1.5 - 9.9), p<0.01) and in patients with cPTmax >1.9 mm (HR = 8.4 (CI: 3.4 – 20.8), p<0.0001). After adjustment for age, sex, diabetes, smoking, hypertension, and hypercholesterolemia, only patients with cPTmax >1.9 mm showed a significantly increased HR of MACE (HR 3.2, CI 1.1-9.3), p<0.05. We applied C-statistics to assess which imaging technique had the best predictive value of MACE in this cohort. The differences in C-statistics were similar for the two imaging methods: cPTmax (0.21, p<0.0001) and CACS (0.21, p<0.0001).

Conclusion: Our results indicate that measurement of cPTmax may be a useful method for prediction of MACE in CKD.

In the present small study, cPTmax and CACS showed equal potential for predicting MACE. Ultrasound imaging is more convenient, more widely available, and without radiation exposure. To further assess the value of cPTmax in predicting CV risk in CKD, a larger study of patients with all CKD stages is needed.

THE ROLE AND MECHANISM OF EZH2 IN VASCULAR CALCIFICATION ASSOCIATED WITH CHRONIC KIDNEY DISEASE
Lin Pinglan, Chaoyang Ye and Ming Wu
Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Department of Nephrology, TCM Institute of Kidney Disease of Shanghai University of Traditional Chinese Medicine, P.R. China

Background and Aims: Vascular calcification (VC) is a prevalent complication in chronic kidney disease and contributes to increased cardiovascular morbidity and mortality. EZH2 (Enhancer of zeste 2 homolog-2) is reported as a key epigenetic regulator involved in various kidney diseases such as acute kidney injury, renal fibrosis, diabetic nephropathy, and lupus nephritis. In this study, we aimed to investigate the role of EZH2 in chronic kidney disease associated vascular calcification.

Method:
1. Patients and Radial Artery Analysis
Radial arteries with or without calcification from patients with end-stage renal disease that underwent arterial venous fistular operation were collected for Von Kossa staining and immunohistochemical (IHC) staining.

2. Animal model of Chronic renal failure-Vascular Calcification (CRF-VC) (in vivo)
An adenine and phosphate (1.2%) diet-induced CRF mouse model was designed following an 8-week program. The thoracoabdominal arteries of mice and rats were dissected to assay Ca deposition and histological analysis. Plasma levels of Alkaline phosphate (ALP), and phosphate (Pi) were measured. The transcription level of EZH2 and Runt-related transcription factor 2 (Runx2) were measured by real-time PCR and IHC staining.

3. Aortic ring calcification (ex vivo)
Thoracic aortas were dissected from SD rat. To induce calcification, Pi (NaH₂PO₄/Na₂HPO₄ [pH = 7.4]) was added to HG-DMEM at a final concentration of 2.6 mmol/l. After the indicated incubation periods (3, 5, 7 days), samples were taken for Calcium deposition assay, Western blotting and histological analysis.

4. Cell culture and treatment (in vitro)
Calcification of rat smooth muscle embryonic thoracic aorta cell line A7r5 (VSMC) was induced by incubation in calcifying media. 3-deazaneplanocin A (3-DZNeP), a carbocyclic analog of adenosine was added right after Pi to block EZH2 activation. After the indicated incubation periods, samples were collected for Calcium deposition assay and Western blotting analysis.

Results:
1. In vivo, EZH2 protein level was increased in calcified radial arteries from patients with end-stage renal disease that underwent arterial venous fistular operation. In CRF-VC mice model, the aortic calcium deposition markedly aggravated in the group induced by adenine diet. Severe vascular calcification was also induced as shown by increased intensity of von Kossa. Moreover, IHC and q-PCR results showed that the protein and transcriptional levels of EZH2 expression were upregulated in calcified aortas of CRF mice, in paralleled with the increased expression Runx2 in protein and transcriptional levels.

2. Ex vivo, histological analysis revealed significant medial vascular calcification in the aortic ring culture with this calcifying medium for 7 days. Similarly, WB results showed that the expression of EZH2 and its downstream, methylation of Histone H3 at lysine 27 (H3K27me3), were significantly enhanced after high Pi medium stimulation while the osteogenic markers Runx2, Osteopontin (OPN) and Msh homeobox 2 (Msx2) protein levels were upregulated and the expression of VSMC differentiation markers α-SMA, Calponin (CNN) and Smooth muscle protein 22 (SM22) were downregulated.

3. In vitro, the osteogenic markers Runx2, OPN and Msx2 were significantly upregulated in high Pi treated VSMCs compared to control VSMCs. Moreover, the epigenetic markers EZH2 and H3K27me3a were markedly repressed in calcifying VSMCs by time.
4. 3-DZNep treatment reduced the calcium deposition in a concentration dependent manner. Western blotting showed that 3-DZNep treatment blocked the increased expression of osteogenic markers Runx2, Bone morphogenetic protein 2 (BMP2) as well as epigenetic markers EZH2 and H3K27me3a by high Pi treatment, indicating that inhibition of EZH2 attenuates VSMCs Calcification.

**Conclusion:** Our study revealed that EZH2 is highly expressed in calcified vascular tissues of CRF patients and CRF mice, rat aorta culture and VSMCs calcification models, and EZH2 inhibitor 3-DZNep attenuated calcification of VSMCs. EZH2 could be a promising target for treatment of vascular calcification in CRF patients.
Figure 2. A. 10- to 12-week-old male mice were fed with chow diet or adenine diet of various concentration for 8 weeks. B-F. The levels of serum creatinine (Scr; C), blood urea nitrogen (BUN; D), uric acid (UA; E), phosphate (Pi; E) and alkaline phosphate (ALP; F) were measured. G. Quantification of calcium deposition in aortas of mice fed with chow diet or adenine diet for 8 weeks. H. Representative von Kossa staining and Runx2, EZH2 staining. I. Quantitative PCR analysis of mRNA levels of Runx2 and EZH2. Data represent mean ± SE.
Figure 3. EZH2 promotes aortic ring calcification with high phosphate (ex vivo study). A. Histological analysis of aortic rings with Von kossa staining (Bar=100μm). B. Time course analysis of vascular calcification induced by phosphate stimulation. C. Representative Western blot analysis and quantification of EZH2, H3k27me and osteogenic genes (Runx2, Mx2, OPN) and VSMC differentiation markers (α-SMA, CNN and SM22) protein levels. At least 3 independent experiments were performed. *P<0.05 by one-way ANOVA followed by the Student-Newman-Keuls test for post-hoc comparison.
Figure 4: EZH2 promotes VSMC calcification in vitro. A-B. Quantification of calcium (Ca) deposition and Alizarin Red staining in A7r5 cells under Pi stimulation for 3, 5, 7 days. The data presented as the means±SEM from at least 3 independent experiments in triplicate. *P<0.05 by two-way ANOVA followed by the Bonferroni test. C. Representative Western blot analysis and quantification of EZH2, H3k27me and osteogenic genes (Runx2, Msx2, OPN) protein levels β-GP stimulation for 1-3 days (D).
EFFICACY OF PAXLOVID WITHIN 5 DAYS VERSUS 5 DAYS AFTER DIAGNOSIS IN COVID-19 PATIENTS WITH CHRONIC KIDNEY DISEASE

Wenjuan Yu, Xiaozhang, Sha Fu, Ting Shu, Junzhe Chen and Ying Tang

The Third Affiliated hospital of Southern Medical University, Department of Nephrology, GuangZhou, P.R. China

Background
Paxlovid is a commonly used antiviral drug for patients with COVID-19. There are few studies in patients with CKD. Therefore, we conducted a retrospective cohort study to compare the drug efficacy of Paxlovid in patients with CKD at different time points after COVID-19 infection.

Methods
70 CKD patients
4 weeks follow-up

Results
Use Paxlovid
After 5 days

Conclusion
Early use of Paxlovid to inhibit virus replication has a good therapeutic effect on CKD patients.
Background and Aims: With the liberalization of COVID-19 control policies in mainland China, the majority of the Chinese population has experienced Omicron infection since mid-December 2022. Paxlovid is a commonly used antiviral drug for patients with COVID-19, but there are few studies in patients with chronic kidney disease (CKD). Therefore, we conducted a retrospective cohort study to explore the drug efficacy of Paxlovid in patients with CKD at different time points after COVID-19 infection.

Method: 70 CKD patients who were admitted to the Department of Nephrology, the Third Affiliated Hospital of Southern Medical University before January 07, 2023 and diagnosed with COVID-19 were included. The patients were divided into three groups: No Paxlovid group, Paxlovid group within 5 days of diagnosis, Paxlovid group after 5 days of diagnosis, each patient was followed-up for at least 4 weeks. The primary outcome measures included all-cause mortality, length of hospital stay, PCR positive duration and the aggravation of the disease requires ICU admission or mechanical ventilation, or the initiation of renal replacement therapy, and re-hospitalization. The t test or non-parametric test was used to compare the quantitative data, the chi-square test was used to compare the rates, and the K-M curve and Cox regression model were used for survival analysis.

Results: Among the 70 patients (mean age 65.8±15.90 years, male sex 67.7%), Paxlovid was not used in 35 patients (50%), used in 16 patients (22.9%) within 5 days of diagnosis, Paxlovid group after 5 days of diagnosis, each patient was followed-up for at least 4 weeks. The primary outcome measures included all-cause mortality, length of hospital stay, PCR positive duration and the aggravation of the disease requires ICU admission or mechanical ventilation, or the initiation of renal replacement therapy, and re-hospitalization. The t test or non-parametric test was used to compare the quantitative data, the chi-square test was used to compare the rates, and the K-M curve and Cox regression model were used for survival analysis.

Results: Among the 70 patients (mean age 65.8±15.90 years, male sex 67.7%), Paxlovid was not used in 35 patients (50%), used in 16 patients (22.9%) within 5 days of diagnosis, and in 19 patients (27.1%) after 5 days. At the start of follow-up, there were no significant differences in age, gender, eGFR, comorbidities, COVID-19 severity and laboratory parameters between patients who used Paxlovid within 5 days and after 5 days of diagnosis. However, patients who used Paxlovid had more severe disease than those who did not use Paxlovid (P<0.001), and patients were more likely to use glucocorticoids (74.3% vs 17.1%, P< 0.001), as well as lower lymphocyte count (0.54*10^9/L vs 0.85*10^9/L, P = 0.016) and percentage (9.5% vs 14.2%, P = 0.009). Higher levels of IL-6 (68.57 pg/ml vs 14.66 pg/ml, P = 0.015) and CRP (113.36 mg/L vs 24.57 mg/L, P = 0.001). After a median follow-up of 45 days, we found that patients used Paxlovid had significantly longer hospital stays and higher rehospitalization rates, with subgroup analysis finding that the increased length of stay and rehospitalization rates were mainly attributable to Paxlovid use after 5 days of diagnosis. Patients who used Paxlovid after 5 days had longer nucleic acid positive time (25 days vs 7 days, P = 0.001) and longer hospital stay (16 days vs 10 days, P = 0.008) compared with those who used Paxlovid earlier. At the end of follow-up, a total of nine patients had died. The K-M survival curve was drawn after the exclusion of mild patients, which showed that patients who used Paxlovid within 5 days had the lowest risk of death, those who did not use Paxlovid had the highest risk of death, and those who used Paxlovid after 5 days fell in between. However, due to the small sample size, the difference was not statistically significant (P = 0.155). The Cox regression analysis showed that IL-6 (HR 1.009; 95% CI: 1.004-1.014, P = 0.001) was the best predictor of death risk in COVID-19 patients with CKD after adjusting other factors.

Conclusion: The risk of death in CKD patients infected with COVID-19 is significantly higher than that in the general population. Early use of Paxlovid to inhibit virus replication has a good therapeutic effect on these patients, which can greatly reduce the risk of death, admission to ICU or emergency renal replacement therapy. Delayed use of Paxlovid may increase the time of nucleic acid positive and the length of hospital stay.

EFFECTS OF EMPAGLIFLOZIN ON KIDNEY AND CARDIAC MRI MEASURES IN PATIENTS WITH CHRONIC KIDNEY DISEASE
Parminder Judge and on behalf of the EMPA-KIDNEY collaborative group
University of Oxford, Oxford, United Kingdom

Background and Aims: EMPA-KIDNEY demonstrated empagliflozin reduced the risk of kidney disease progression or cardiovascular death in patients with CKD at risk of progression, but the mechanisms of benefit are uncertain. MRI was used to assess whether empagliflozin modified the structure and function of the kidneys and heart at around 18 months after randomization.

Method: Randomized participants from 8 sites in UK and Germany without a contraindication to MRI scanning, were eligible and invited to participate in this substudy. MRI scans were performed using a standardized protocol. Renal T1 mapping (MOLLI 5[3]3 scheme which measures fibrosis and inflammation) was computed by first segmenting MOLLI data using a U-net and then applying the masks to both kidneys. Cardiac MRI included cine steady-state free precession imaging to assess biventricular volumes, mass and function, and T1 mapping to assess myocardial inflammation and fibrosis. The primary outcome was kidney cortical T1 mapping measured by MOLLI. Secondary outcomes included LV ejection fraction, myocardial T1 MOLLI and LV mass index. Differences in MRI measurements between treatment groups were analysed using linear regression adjusted for baseline age, sex, eGFR, UACR and diabetes status. 172 participants were required to provide 90% power at 2p = 0.05 to detect a 50 ms difference in T1.

Results: 172 participants had an MRI scan around 18 months after randomization. 93 (54%) were allocated empagliflozin and 79 (46%) placebo. Mean (SD) age was 60 (16) years, 26% were female and 23% had diabetes. Mean eGFR was 37 (14) ml/min/1.73m² and geometric mean (95% CI) UACR was 242 (182-322) mg/g (Table 1). Adjusted mean (SE) cortical T1 mapping by MOLLI was 1623 (10) ms in those allocated empagliflozin versus 1634 (11) ms in those allocated placebo, difference in means (95% CI) −11 (−41 to 18), P = 0.45 (Table 2). Medullary T1 MOLLI scores were similar. Empagliflozin had no significant effect on cardiac MRI measures: difference (95% CI) in LV ejection fraction 1% (−1 to 4); myocardial T1 MOLLI −3 ms (−16 to 10); LV mass index −3 g/m² (−5 to 0) (Table 2).

Conclusion: Empagliflozin had no significant effect on MRI-based measures of fibrosis within the kidney cortex or myocardium in people with CKD at risk of progression. There was no effect of treatment on measures of cardiac structure or function. Further MRI measures will be available for presentation by the time of the ERA congress.

Funding: Boehringer Ingelheim, Eli Lilly and others; Clinicaltrials.gov:NCT03594110.

**EFFECTS OF EMPAGLIFLOZIN ON FLUID OVERLOAD IN CHRONIC KIDNEY DISEASE: AN EMPA-KIDNEY BIOIMPEDANCE SUBSTUDY**

Kaitlin Mayne¹,²

¹Nuffield Department of Population Health, University of Oxford, Clinical Trial Service Unit and Epidemiological Studies Unit, Oxford, United Kingdom and ²University of Glasgow, School of Cardiovascular & Metabolic Health, Glasgow, United Kingdom

**Background and Aims:** The EMPA-KIDNEY trial showed that, compared to placebo, empagliflozin 10 mg once daily reduced the risk of kidney disease progression or cardiovascular death in 6609 patients with chronic kidney disease at risk of progression. We aimed to assess effects of empagliflozin on bioimpedance-measured fluid overload and adiposity in a subset to better understand the mechanisms of cardiovascular benefits of sodium glucose co-transporter-2 inhibitors.

**Method:** This EMPA-KIDNEY substudy added Body Composition Monitor (BCM) measurements at randomization and the 2 and 18 month follow-up visits to the trial’s main protocol-specified procedures. The primary outcome was Absolute Fluid Overload (a parameter reflecting overhydration, derived from extracellular and intracellular resistance). Pre-specified subgroup analyses of the primary outcome were by sex, diabetes status, estimated glomerular filtration rate (eGFR) and N-terminal pro-brain-type natriuretic peptide (NT-proBNP) at baseline. The key secondary analysis was a composite of death from heart failure, heart failure hospitalisation or development of new moderate (>7%, ≤15%) or severe (>15%) BCM-measured Relative Fluid Overload. Tertiary outcomes included weight, anthropometry, and other BCM-measurements of body water and adiposity. The primary outcome was analysed using mixed-model repeated measures (MMRM) methods. The key secondary outcome used time-to-first event methods.

**Results:** A total of 660 EMPA-KIDNEY participants were recruited into this substudy. Mean age was 64 years, 205 (31%) were female and 245 (37%) had diabetes. Mean (SD) eGFR was 36 (12) ml/min/1.73m² and median (Q1-Q3) NTpro-BNP was 211 (93-581) ng/L. Mean (SD) Absolute Fluid Overload at baseline was 0.4 (1.6) L, 19% had moderate fluid overload and 5% fulfilled criteria for severe fluid overload at baseline. Compared to placebo, the mean study average absolute difference in Absolute Fluid Overload was -0.24L (95% CI -0.38, -0.11), with similar differences at 2 months and 18 months (Figure 1). This difference was similar in men and women, in people with and without diabetes, and across the spectrum of eGFR and NT-proBNP studied (Figure 2). The number of key secondary outcomes was low and there was no significant difference in the risk of this outcome between treatment groups (35/332 [10%] vs 38/328 [12%], hazard ratio 0.91 [95% CI 0.57, 1.45], p = 0.69).

**Conclusion:** In patients with chronic kidney disease, empagliflozin reduced bioimpedance-measured fluid overload irrespective of diabetes status or level of eGFR. This effect persisted for at least 18 months with no evidence of attenuation over time.

**Funding:** Boehringer Ingelheim, Eli Lilly and others; Clinicaltrials.gov:NCT03594110.
Figure 1: Effect of Empagliflozin versus Placebo on Mean Absolute Fluid Overload by Time. Mean Absolute Fluid Overload in litres at randomization is plotted separately for empagliflozin and placebo groups at time 0. The estimated marginal means (and standard errors) for the Absolute Fluid Overload value (from the MMRM model) within the time window surrounding the 2-month and 18-month follow-up visits are plotted at the median follow-up day in each treatment group. The estimated means are adjusted for baseline Absolute Fluid Overload and for any differences in key baseline characteristics (age, sex, diabetes, eGFR and uACR) between treatment groups.

Figure 2: Effect of Empagliflozin versus Placebo on Mean Absolute Fluid Overload (in Litres) By Pre-specified Subgroups. Analyses using MMRM methods excluded 40 consenting participants with no valid follow-up measurements (3 deaths before first follow-up measurement, 28 with no measurement performed and 9 excluded due to inadequate data quality as pre-specified in the Data Analysis Plan).
BIO-CONDUCTIVITY MEASUREMENTS ENABLE PORTABLE AND SELF-ADMINISTERED CHRONIC KIDNEY DISEASE SCREENING AND MONITORING

Pak To Cheung1, Fedi Zouari1, Adrien Touboul1, Cheuk Man Ho1, Venice Sin1, Eddie C. Wong1,2, Iris Zhou3, Desmond Yap1,4 and Russell Chan1

1Genes Technologies Ltd, Hong Kong, Hong Kong, Hong Kong, P.R. China, 2Li Ka Shing Faculty of Medicine, Department of Medicine, Hong Kong, P.R. China, 3Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Boston, United States of America and 4Queen Mary Hospital, Division of Nephrology, Hong Kong, P.R. China

Background and Aims: Chronic kidney disease (CKD) is an escalating health concern. The identification of CKD during mass public screening by laboratory tests constitutes important resource implications. Home-based and self-administered approach to screen and monitor disease severity in both healthy and CKD subjects are eagerly awaited. Frequency-difference electrical impedance tomography (fDEIT) reconstructs the interior of a body by measuring the electrical responses to a small alternating current applied at the surface of the subject at various frequencies. Kidney fibrosis is a cardinal feature of CKD, which is associated with alterations in renal molecular composition and hence electrical conductivity. Therefore, this study aims to investigate the feasibility of a portable, self-administered approach to assess CKD severity using fDEIT in the kidney region.

Method: Clinical subjects are recruited at Queen Mary Hospital, Hong Kong. EIT data was collected via a PVC belt acting as an electrode holder placed circumferentially on the upper abdominal region of the subject. The belt was connected to a portable console to collect EIT data. 24 frequencies ranging from 10KHz to 300KHz are used to stimulate electrical responses in the body. (Figure 1A) Paired blood and urine samples were collected for measured of eGFR. Group source separation was implemented to extract the kidney region of interest (ROI) and extract conductivity features (Figure 1A); these features, together with the age of the subject, are then input into a regression model to estimate the eGFR and the CKD stage of the subject according to the following classification scheme: stage 1 CKD (eGFR > 90) as healthy subjects, stages 3, 4, 5 CKD (eGFR < 60) as unhealthy subjects, stage 2 CKD (60 < eGFR < 90) as borderline cases.

Results: 75 subjects were recruited (54 with CKD and 21 were healthy volunteers). We obtained an eGFR estimation model with R2 score of 0.40. We also obtained a CKD stage classifier with sensitivity of 87.5% and specificity of more than 99.9%. (Figure 1C) The mean conductivity in the extracted kidney signal comprises 40% weighting in the regression model (Figure 1B), showing comparable importance as the age in predicting the eGFR.

Conclusion: The results demonstrate that measuring bio-conductivity anomalies through fDEIT is highly accurate and non-invasive, and can be developed into a portable and self-administrable device to screen and monitor CKD

FINERENONE ADDED TO RAS/SGLT2 BLOCKADE FOR NON-DIABETIC CHRONIC KIDNEY DISEASE: RESULTS OF A PRECLINICAL DOUBLE-BLINDED RANDOMIZED CONTROLLED TRIAL

Zhizhi Zhu1, Yoshihiro Kusunoki1, Karoline Rosenkranz1, Chenyu Li1, Martin Klaus1, Oliver Gross2, Maria Lucia Angelotti1, Luigi Cirillo3, Paola Romagnani3, Roman David Bü low4, Peter Boor5 and Hans-Joachim Anders1

1Hospital of the Ludwig-Maximilians University, Division of Nephrology, Department of Medicine IV, Munich, Germany, 2University Medical Centre Goettingen, Clinic of Nephrology and Rheumatology, Goettingen, Germany, 3University of Florence, Department of Biomedical Experimental and Clinical Sciences “Maria Serio”, Florence, Italy and 4RWTH University Hospital Aachen, Institute of Pathology, Aachen, Germany

Background and Aims: Inhibitors of the renin-angiotensin system (RAS), sodium-glucose transporter (SGLT)-2, and the mineralocorticoid receptor (MR) have all demonstrated renoprotective effects in large clinical trials of diabetes-related CKD. Furthermore, dual RAS/SGLT2 blockade showed additive renoprotective effects also in non-diabetic CKD. We hypothesized that triple RAS/SGLT2/MR blockade would be even superior to dual RAS/SGLT2 blockade in non-diabetic CKD.

Method: We performed a “no touch” preclinical randomized controlled trial in Col4a3-deficient mice with spontaneous and progressive CKD (registry ID: PCTE0000266). Treatments were administered as food admix from 6-14 weeks of age at the following estimated doses: 10 mg/kg ramipril, 30 mg/kg empagliflozin, 10 mg/kg finerenone. The prespecified primary endpoint was total lifespan up to uremic death. Ancillary studies addressed baseline histology, and mechanistic studies on a subset of mice after 2.5 weeks of treatment.

Results: At the time of randomization, Col4a3−/− mice had albuminuria, elevated serum creatinine, glomerulosclerosis, tubular atrophy, and interstitial fibrosis. Total lifespan was 63.7 ± 9.99 days (vehicle), 77.25 ± 5.34 days (ramipril), 80.3 ± 10.98 days (ramipril+empagliflozin), and 103.05 ± 20.28 days (triple therapy), respectively. Artificial intelligence-based histopathology and RNA sequencing analysis documented a potent anti-sclerotic, -inflammation and -fibrotic effect of the triple combination.

Conclusion: Adding finerenone to dual RAS/SGLT2 blockade significantly prolongs uremia-free lifespan even when started at an advanced stage of Alport nephropathy. Triple RAS/SGLT2/MR blockade could be a potent treatment strategy to prolong uremia-free lifespan in patients with CKD related to Alport syndrome and possibly other progressive kidney disorders.
Figure 1: Finereone added to a dual RAS/SGLT2 inhibition substantially prolongs lifespan of Col4a3-/- mice with progressive CKD due to Alport nephropathy. (A) Kaplan-Meier graph of survival. (B) Effects of RASi, RASi/SGLT2i, and RASi/SGLT2i/MRA treatments on kidney function (GFR) in Col4a3-/- mice. All quantitative data are means ± SD.

#3382 REASONS FOR DIALYSIS INITIATION AND SAFETY OF DAPAGLIFLOZIN AMONG DIALYSIS PARTICIPANTS: NEW INSIGHTS FROM DAPA-CKD

Hiddo Lambers Heerspink1, David C. Wheeler2, Niels Jong3, Ricardo Correa-Rotter4, Peter Rossing5, Ronald Gansevoort6,7, John McMurray8, Anna Maria Langkilde9, Robert Toto10 and Glenn Chertow11

1University of Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, Netherlands, 2University College London, Department of Renal Medicine, London, United Kingdom, 3University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, Netherlands, 4The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico, 5Steno Diabetes Center, Copenhagen, Herlev, Denmark, 6University Medical Center Groningen, Department of Internal Medicine, Groningen, Netherlands, 7University of Groningen, Department of Internal Medicine, Groningen, Netherlands, 8University of Glasgow, Institute of Cardiovascular and Medical Sciences, Glasgow, United Kingdom, 9AstraZeneca, BioPharmaceuticals R&D, Gothenburg, Sweden, 10UT Southwestern Medical Center, Department of Internal Medicine, Dallas, United States of America and 11Stanford University School Medicine, Department of Medicine, Stanford, United States of America

Background and Aims: The DAPA-CKD trial demonstrated that dapagliflozin reduced the risk of kidney failure in patients with chronic kidney disease (CKD) with or without type 2 diabetes. In contrast to most other trials, participants who reached dialysis were allowed to continue study medication with dapagliflozin or placebo. In this pre-specified analysis of the DAPA-CKD trial, we assessed reasons for dialysis initiation and serious adverse events (SAEs) among participants who initiated dialysis and continued the study medication.

Method: The DAPA-CKD trial randomized 4304 patients with CKD (estimated glomerular filtration rate [eGFR] 25–75 mL/min/1.73m²) and albuminuria (urinary albumin-to-creatinine ratio 200–5000 mg/g) to dapagliflozin 10 mg daily or placebo in addition to standard of care. Chronic dialysis was defined as the need for dialysis for at least 28 days. Investigator reported reasons for dialysis and SAEs were summarized by treatment groups.

Results: During median 2.4 years follow-up, 68/2152 (3.2%) and 99/2152 (4.6%) participants in the dapagliflozin and placebo groups respectively required chronic dialysis. Reasons for dialysis initiation are shown in the Table below, with volume overload being the most frequently reported. Roughly one-third of patients in both groups had discontinued study drug in advance of dialysis initiation; in the dapagliflozin and placebo groups, 25/68 (37%) and
41/99 (41%) continued the blinded study medication while receiving chronic dialysis. Among these, SAEs were reported in 8/25 (32%) and 11/41 (27%), respectively.

**Conclusion**: Participants who continued dapagliflozin or placebo after dialysis initiation experienced similar rates of SAEs. To determine whether dapagliflozin provides cardiovascular or other benefits to patients with kidney failure on chronic dialysis, will require a dedicated prospective trial. Based on our prespecified exploratory analysis, we observed no safety concerns that might discourage the conduct of such a trial.

**Funding**: This study was funded by AstraZeneca

**EFFECTS OF FERRIC CITRATE HYDRATE ON FIBROBLAST GROWTH FACTOR 23 AND PLATELET COUNT IN CKD AND NON-CKD PATIENTS WITH IRON DEFICIENCY ANAEMIA**

**Kyoko Ito**, **Kojo Arita**, **Yuko Mitobe**, **Tadao Akizawa** and **Norio Komatsu**

1 Torii Pharmaceutical Co., Ltd., Medical Affairs Department, Tokyo, Japan, 2Japan Tobacco Inc., Pharmaceutical Division, Tokyo, Japan, 3Showa University School of Medicine, Division of Nephrology, Department of Medicine, Tokyo, Japan and 4Juntendo University School of Medicine, Department of Haematology, Tokyo, Japan

**Background and Aims**: Iron deficiency increases the transcription and cleavage of the peptide hormone, fibroblast growth factor 23 (FGF23). Elevated FGF23 has been associated with increased risk of cardiovascular events and mortality. Iron deficiency also increases platelet count (PLT) in part, and higher levels PLT are associated with arterial thrombosis in the brain. Ferric citrate hydrate (FC, Riona®, Torii Pharmaceutical Co., Ltd. Tokyo, Japan) is an oral iron-based phosphate binder for patients with chronic kidney disease (CKD) and also an iron preparation approved for treatment of iron deficiency anaemia (IDA) in Japan. A phase 3 study was conducted to investigate the efficacy and safety of FC in CKD and non-CKD patients with IDA. This study aimed to evaluate the effects of FC on intact FGF23 and c-terminal FGF23 levels, and the proportion of patients with high PLT (exceeding upper limit: >35.2 × 10^4/μL).

**Method**: A randomized, open-label, multicentre, uncontrolled, 24-week study was conducted at 31 centres in Japan from July 2018 to December 2019 (JapicCTI-184000) in CKD and non-CKD patients with IDA (Hb: < 8.0 g/dL and < 11.0 g/dL, serum ferritin < 50 ng/mL in CKD (eGFRcre < 60 mL/min/1.73 m^2) and < 12 ng/mL in non-CKD). CKD patients scheduled to initiate maintenance dialysis were excluded. Dynamic allocation was used to randomise subjects (CKD and non-CKD with Hb at baseline) to the FC-low group (500 mg [approximately 120 mg elemental iron]/day) or FC-high group (1000 mg [approximately 240 mg elemental iron]/day) (1:1). Notably, if investigators determined that sufficient iron replacement had been achieved from week 8 onwards, the study treatment was completed. For this reason, changes from baseline to week 8 were evaluated.

**Results**: Of 73 patients (CKD n = 42, non-CKD n = 31), 36 were allocated to the FC-low group (CKD n = 21, non-CKD n = 15) and 37 to the FC-high group (CKD n = 21, non-CKD n = 16). Baseline levels of serum ferritin, transferrin saturation (TSAT), c-terminal FGF23, intact FGF23, and PLT are shown in Table 1. Regardless of CKD status, serum ferritin and TSAT increased. After FC-low treatment, mean changes from baseline to week 8 (95% CI) in serum ferritin and TSAT were 18.8 (13.3, 24.2) ng/mL and 8.1 (4.4, 11.8) % in CKD, 17.5 (13.8, 21.3) ng/mL and 13.8 (8.7, 18.9) % in non-CKD, they were 28.1 (13.4, 42.7) ng/mL and 8.8 (5.4, 12.1) % in CKD, 15.9 (12.1, 19.8) ng/mL and 19.9 (9.8, 30.1) % in non-CKD. After administration of FC, in both groups, intact FGF23 levels did not change, whereas c-terminal FGF23 levels decreased. Median changes (interquartile range) from baseline to week 8 of c-terminal FGF23 were -58.00 (-227.50, -12.25) RU/mL in CKD and -725.00 (-1124.00, -168.50) RU/mL in non-CKD, and -66.00 (-265.70, -27.00) RU/mL in CKD and -649.50 (-1127.00, -326.65) RU/mL in non-CKD. Serum phosphate did not change regardless of CKD status. At baseline, high PLT was observed in all these patients, PLT reduction to below 35.2 × 10^4/μL was observed until week 8.

**Conclusion**: In patients with IDA, administration of FC increased serum ferritin and TSAT, decreased c-terminal FGF23, and normalized PLT in patients with high PLT at baseline regardless of CKD status. FC may decrease the potential risk of cardiovascular events in CKD or non-CKD patients with IDA.

CAN A BLOOD TEST FOR MIDDLE MOLECULES BE USED TO MEASURE RESIDUAL kidney FUNCTION TO PERFORM INCREMENTAL DIALYSIS?

Usama Butt, Enric Vilar, Sivakumar Sridharan and Kenneth Farrington
Lister Hospital, Department of Renal Medicine, Stevenage, United Kingdom

Background and Aims: Incremental dialysis involves combining residual kidney functions (RFK) with dialysis dose to individualise treatment, increasing the dialysis dose as RFK falls. Potential benefits include quality of life benefits, less treatment burden and health economic benefits. Kidney Disease Outcome Quality Initiative (KDOQI) recommends incremental haemodialysis may be performed when renal urea clearance (KRU) is > = 2 ml/min. To avoid underdialysis, incremental approach requires frequent interdialytic urine collections to monitor RFK, which can be inconvenient.

An easier assessment of RFK would likely increase the uptake of incremental dialysis. Blood levels of middle molecules (e.g Beta 2 Microglobulin (Beta2M) and Beta Trace Protein (BTP)) have been studied as predictors of RFK. However, their role in identifying patients for incremental dialysis have not been tested. There are a few published methods of predicting RFK using middle molecules. A proposed simple method is identification of patients with KRU > = 2 ml/min, based on having a blood middle molecule level below a certain cut-off. Alternatively direct prediction of KRU from middle molecule levels can be performed with an algorithm/equation.

We set out to establish if these methods may identify patients with significant RFK who can benefit from incremental dialysis.

Method: We conducted a retrospective analysis on the data from a multicentre feasibility randomised controlled trial to assess the impact of incremental versus conventional haemodialysis initiation. As a part of this trial 55 participants were followed up for up to 12 months with monthly RFK measurement using interdialytic urine collections. Monthly Beta2M and BTP measurements were also performed. We used (1) a published middle molecules-based KRU equation (2) published Beta2M cut-off levels, to predict RFK. We, then, compared the predicted RFK with conventionally measured RFK from urine collection. The focus was to establish reliability of these methods in identifying patients with KRU > = 2 ml/min, which is the recommended cut-off for incremental dialysis, and to identify where underdialysis might occur if these methods were used in clinical practice.

Results: The middle molecules-based KRU equation had 62% sensitivity and 84% specificity to identify those with KRU > = 2, whereas a beta2M cut-off level of < 19.15 mg/L had 78% sensitivity and 82% specificity. 6/55 (10.9%) participants would have had underdialysis whilst performing incremental dialysis guided by a middle molecules-based KRU equation and 7/55 (12.7%) would underdialyse using the Beta2M cut-off level to predict KRU. The predicted mean underdialysis that would occur using these methods was 0.2 – 0.3 standard kt/v units. Combining these methods with urine volume improved specificity and sensitivity. Beta2M level of < 19.15 mg/L and Urine volume of > 0.5 litre/day combined predicted KRU > = 2 with 70% sensitivity and 98% specificity. In other words, only 1/55 (1.8%) patients would have had underdialysis if incremental dialysis were performed based on a combination of Beta2M cut-off and urine volume.

Conclusion: Blood Beta2M level, when combined with urine volume assessment reliably predicts adequate RFK to perform incremental dialysis safely. If dialysis patients can reliably estimate or measure their urine volume, this tool can potentially replace the need for cumbersome interdialytic urine collection to determine RFK and offer an easy way to perform incremental dialysis.

FIBROBLAST GROWTH FACTOR 21 PREDICTS ARTERIOVENOUS FISTULA FUNCTIONAL PATENCY LOSS AND MORTALITY IN PATIENTS UNDERGOING MAINTENANCE HEMODIALYSIS

Xinhui Hu, Qing Wei, Bin Wang and Hong Liu
Zhongda Hospital, Southeast University School of Medicine, Institute of Nephrology, Nanjing, P.R. China

Background and Aims: Arteriovenous fistula (AVF) dysfunction is a common complication in patients undergoing maintenance hemodialysis (MHD). Elevated serum level of fibroblast growth factor 21 (FGF21) was associated with atherosclerosis and cardiovascular mortality. However, its association with vascular access outcomes remains elusive. In this study, we aimed to evaluate the relationship of serum FGF21 levels with AVF dysfunction and all-cause mortality in patients undergoing MHD.

Method: We performed a study of patients undergoing MHD who received AVF creation at a tertiary medical center in China from January 2018 to December 2019. Serum FGF21 concentration was detected by enzyme-linked immunosorbent assay (ELISA). Patients were followed-up to record two clinical outcomes, including AVF functional patency loss and all-cause mortality. The follow-up period ended at April 30, 2022. Kaplan-Meier curves were used to analyze AVF dysfunction events and mortality. Univariate and multivariate Cox proportional risk model analyses were used to calculate risk ratios (HR) and 95% CI and independent prognostic factors. The receiver operating characteristic (ROC) curve and area under the curve (AUC) were used to analyze the predictive value of FGF21 in AVF functional patency loss and all-cause mortality.

Results: Among 147 patients, the mean age was 58.49 ± 14.41 years, and 58.50% of them were males. The median serum level of FGF21 was 150.15 (70.57-318.01) pg/ml. During median follow-up period of 40.83 months, the serum level of FGF21 was an independent predictor for AVF functional patency loss (per 1 pg/ml increase, HR 1.002 [95% CI: 1.001-1.003, P = 0.003]), and all-cause mortality. The follow-up period ended at April 30, 2022. Kaplan-Meier curves were used to analyze AVF dysfunction events and mortality. Univariate and multivariate Cox proportional risk model analyses were used to calculate risk ratios (HR) and 95% CI and independent prognostic factors. The receiver operating characteristic (ROC) curve and area under the curve (AUC) were used to analyze the predictive value of FGF21 in AVF functional patency loss and all-cause mortality.

Conclusion: Serum FGF21 level was an independent risk factor and predictor for AVF functional patency loss and all-cause mortality in patients undergoing MHD.
Figure 1: Kaplan-Meier estimate of AVF functional patency in patients undergoing maintenance hemodialysis with low levels of serum FGF21 ($\leq 150.15 \text{pg/ml}$) and high levels of serum FGF21 ($>150.15 \text{pg/ml}$) ($P < 0.001$; log-rank test).
Figure 2: Kaplan-Meier estimate of overall survival in patients undergoing maintenance with low levels of serum FGF21 ($\leq$150.15pg/ml) and high levels of serum FGF21 (>150.15pg/ml) ($P = 0.016$; log-rank test).

ARTERIOVENOUS FISTULA BLOOD FLOW ESTIMATION THROUGH AI MODEL EXPLOITING THE PATIENT'S ROUTINELY COLLECTED DATA
Francesco Bellocchio¹, Mario Garbelli¹, Len Usvay², Stefano Stuard¹ and Luca Neri¹

¹Fresenius Medical Care Italia SpA, Italy, ²Fresenius Medical Care, United States of America and ³Fresenius Medical Care Deutschland GmbH, Germany

Background and Aims: Clinical monitoring and surveillance are key pillars of Arteriovenous Fistula (AVF) management in hemodialysis patients. They are aimed at limiting the risk of suboptimal dialysis dose and Vascular Access (VA) failure. AVF blood flow (Qa) is commonly used to assess VA function. Several methods have been proposed for the measurement of Qa including doppler
Abstracts

Confusion matrix (CM) of the estimation. The diagonal elements of CM represent the number of right matches between predicted and actual (true) label, while off-diagonal elements are those that are mislabeled. The CM values are normalized over actual label (by row).

ultrasound, and Body Thermal Monitor, among others. All these diagnostic tests are, in general, time-consuming for clinical staff, operator dependent, and costly for healthcare providers. To overcome limitations in the uptake of current Qa measurement techniques, we used data automatically recorded by dialysis machine sensors and medical information captured in electronic charts to estimate Qa using a machine learning technique.

**Method:** For this historical cohort study, we analyzed electronic health records (EHR) of adult patients from four different European countries (Czech Republic, Portugal, Slovakia, and Spain), receiving in-center hemodialysis therapy in Fresenius Medical Care dialysis clinics between January 1st, 2015 and June 30th, 2022 registered in the European Clinical Database (EuClinD®). All patients consented their pseudo-anonymized data be used for secondary data analysis. The input dataset included 49 variables representing the health status of the patients, functional parameters of AVF function and the HD treatment parameters. The input variables were collected in the 90 days before the Qa measure. We constructed metrics representing the 90-day average and trend of each functional and medical parameter. Qa was classified in three levels: < 525 ml/h (very low), 525 ml/h - 925 ml/h (low), > 925 ml/h (normal).

We estimated Qa as ordinal classification problem. Therefore, we used 2 binary classifiers based on the XGBoost algorithm. The estimation of the first-class, P(Qa ≥ 525), is given by the first classifier and the estimation of the third class, P(Qa ≥ 925), is given by the second classifier. The probability of the middle class is computed as P(Qa ≥ 525) - P(Qa ≥ 925). The Qa estimation accuracy was assessed computing mean absolute error (MAE), precision and recall, F1-score and confusion matrix.

**Results:** Our dataset included 46,292 Qa measurements referred to 5,940 different hemodialysis patients. We obtained an overall precision of 0.77, a recall of 0.76, a F1-score of 0.76, a MAE of 0.27. The same metrics for each class are shown in Table 1. The model was able to detect fistula with “very low flow” with a precision of 0.9 and 16% of the missed “very low flow” AVFs are predicted as “low flow” and 4.7% are predicted as normal flow. The Confusion Matrix for each class is shown in Figure 1.

**Conclusion:** In this study we showed that clinically relevant Qa classes can be accurately predicted by resorting to routinely collected clinical data extracted from an electronic health record without any additional effort from healthcare professionals, training or instrumentation. Qa assessment is an important parameter in the evaluation of AVF function. Our algorithm accurately

discriminated patients with “very low flow” that may be referred to vascular surgeon evaluation. It might help the AVF surveillance process, without adding time-consuming procedures for clinical staff or costs for healthcare provider.

**#3408 A META-ANALYSIS OF VASCULAR ACCESS OUTCOMES IN HEMODIALYSIS PATIENTS OVER 75 YEARS OF AGE**

Alexandra Ntemka1, Christos Argyriou2, Parthena Kyriklidou1, Miltiadis Lazaridis2 and Georgios Georgiadis2

1 General Hospital Of Thessaloniki “Papageorgiou”, Thessaloniki, Greece and 2 University Hospital of Alexandroupolis, Greece

**Background and Aims:** The age of patients with end-stage renal disease is constantly growing, but evidence for the best vascular access for hemodialysis is scarce and controversial for elderly. A meta-analysis was performed in hemodialysis patients over 75 years old to compare the outcomes of different vascular access procedures in the sub-group of elderly ESRD patients ≥ 75 years of age.

**Method:** A literature search was performed using the electronic databases MEDLINE and SCOPUS up to October 2021. Twelve eligible articles fulfilled the inclusion criteria and were finally selected in the meta-analysis (Table). Three of these studies including ESRD patients >70 years of age were exceptionally included as the mean age was well above 75 years. First step analysis was focused on studies that reported the primary patency rates of autologous vs. prosthetic vascular accesses (5 studies). Second step analysis was focused on articles comparing the results of primary and secondary patency rates of distal (forearm) vs. proximal (upper arm) fistulas in elderly patients (8 studies). All these studies were retrospective cohort studies, none was randomized controlled trial.

**Results:** Regarding the first step analysis, primary failure rate at 24 months was in favor of AVFs (OR: 0.56, 95% CI: 0.38-0.83, p = 0.003, Fig. 1). Although several studies have shown that AVG patency is not affected by age, this meta-analysis showed patency benefit of AVF in this subgroup of elderly patients ≥ 75 years of age. In a second step, the 12-month primary failure rate was by far in favor of proximal AVFs (OR: 2.14, 95% CI: 1.53-2.78; p <.00001, Fig. 2). The 12-month secondary patency rate of the forearm AVFs was also inferior compared to the proximal AVF (OR: 1.76, 95% CI: 1.12-2.78; p <.01, Fig. 3). These findings favor the use of proximal AVFs as first choice access in this subgroup of elderly patients, especially when they are late referrals or have low life expectancy.

**Conclusion:** The question of the right access in elderly ESRD patients does not have an easy answer. The present study shows that patients ≥75 years old should not be excluded from creation of an autologous access, with proximal AVFs having better patency rates.
Table 1: The included studies in meta-analysis.

THE CHANGING HAEMODIALYSIS POPULATION IN A SINGLE UK CENTRE: A POST PANDEMIC PHENOMENON?
Joanna Mckinnell1, Zoe Pottman1, Kirsty Swinscoe1, Nahedh Abdulifa1, Liberty Berino1 and Nick Selby1,2
1University Hospitals Derby and Burton NHS Foundation Trust, Renal, Derby, United Kingdom and 2University of Nottingham, Nottingham, United Kingdom

Background and Aims: Following the Covid-19 pandemic, UK dialysis centres have seen a sharp increase in numbers of patients requiring renal replacement therapy (RRT) particularly haemodialysis (HD). This has resulted in pressures on dialysis capacity and staffing. There may also have been negative effects on other aspects of quality of care, such as a fall in the proportion of patients dialysing via an Arterio-venous fistula (AVF) or worsening anaemia. To study this further, we conducted a retrospective observational study to describe the incident and prevalent HD populations in the post-Covid pandemic period and compare these against pre-pandemic patterns, in a single UK dialysis centre.

Method: We reviewed data on prevalent HD patient numbers across our service. We specifically collected data from all patients commencing HD between January 2021 and December 2022 using electronic medical records. We collected information on time known to renal prior to starting dialysis, clinic data including which types of clinic attended, documentation of pre-dialysis decisions about modality as well as vascular access referrals, vascular access clinics and vascular access surgery as well as haemoglobin (Hb) at first dialysis. We compared figures with published pre-pandemic data from the 23rd annual UK Renal Registry report on data collected to December 2019 for our centre. We defined a planned start to dialysis as patients who were known to renal >90 days. This aligns with the registry definition. We compared proportional data using the chi square test.

Results: Comparing prevalent data in Dec. 2022 with Dec 2019, there was a 17% increase in the prevalent HD population from 298 to 349. The proportion of patients dialysing via an AVF fell from 88% to 80% (p = 0.006). The spread across different types of HD in Dec.2022 remained static at 71% In-Centre HD (72% in Dec 2019), 11% Satellite HD (9% in 2019) and 17% HDHD (18% 2019) with overall numbers rising across all HD modalities (p for trend = 0.37). PD numbers also rose from 58 to 71 keeping the total percentage on home therapies stable at 31% in our unit. From Jan. 2021- Dec. 2022 inclusive 147 people commenced HD of whom 115 (78%) had planned starts. This compares to 58 starting HD in 2019 and 79% planned (p = 0.85). There was a significant fall in the proportion of planned start HD patients who commenced dialysis with an AVF/AVG, from 81% in 2019 to 56% in 2021-22 (p = 0.003). Themes emerged in planned starters who did not start HD with an AVF/AVG and are detailed in Figure 1. Median Hb level of planned starts on HD was lower at only 94 AVF/AVG, from 81% in 2019 to 56% in 2021-22 (p = 0.003). Using the electronic patient records, we identified patients with significant vascular access events (thrombosis, angiographic stenosis requiring angioplasty or doppler with > 50% stenosis) without vascular access event. Information for clinically detected malfunctioning fistula was retrieved from the last clinic letter and the last vascular access multidisciplinary meeting notes prior to the vascular event. For the event positive patients, we included in the analysis the Vasc-alert data 2 months prior to the event. For the negative group, we included Vasc-alert data for 5 consecutive months with 1 month follow up. For the analysis we used the number of events per patient for the Vasc-alert data 2 months prior to the event. For the negative group, we included Vasc-alert data for 5 consecutive months with 1 month follow up. For the analysis we considered HRS positive if ≥ 2 HRS were generated.

Results: Out of 141 patients with available Vasc-alert data there were 60 patients dialyzing via a tunneled line. Amongst 81 patients with arteriovenous fistula or graft, 58 had available Vasc-alert data for ≥ 2 months. Out of 12 event positive (4 patients with thrombosed access, 6 patients with stenosis requiring angioplasty and 2 patients with < 50% doppler referred and awaiting fistulogram),10 (83%) had ≥ 2 HRS generated 2 months prior to the vascular event (Median 8, IQR 6.75-8). Out of the 46 patients without vascular events, 15 patients (32.6%) had ≥ 2 HRS and 2 patients had only one HRS score.

Patient characteristics by vascular event are presented in Table 1. The sensitivity and specificity of HRS ≥ 2 for detecting future vascular events were 83.3% and 67.4%, respectively. The positive and negative predictive value of HRS ≥ 2 were 40% and 93.9% respectively. History of prior access stenosis and clinically detected malfunctioning fistula were significantly associated with vascular access events (P value 0.002, < 0.001 respectively), and HRS > 200 discrete values (P value 0.007 and 0.005 respectively). Within the patients with thrombosed access, 2 patients (50%) detected by HRS were not detected with clinical monitoring.

Conclusion: Our results suggest that vascular access risk score can be a useful screening tool to assist clinical decision making for VA risk stratification. Prospective studies are required to evaluate its utility in the VA surveillance pathway.

PSYCHOSOCIAL ASSESSMENTS AND HOSPITAL ADMISSION RATES IN ELEVATED OR HIGH ACUITY HEMODIALYSIS PATIENTS
Joanna Willetts¹, Sceetl Chaudhuri¹, Len Usavat², Kathleen Belmonte², Felicia Speed², Anna Rutherford² and Jeffrey Hymes³
Background and Aims: Using data routinely captured in electronic medical records of a large dialysis organization (LDO) in close collaboration with social workers (MSW), we developed a weekly patient acuity score to identify the level of need for psychosocial support in hemodialysis patients to help social workers optimize visits to deliver timely personalized care. We evaluated how interventions by a MSW affected future hospital admission rate in in-center hemodialysis (ICHD) patients with Elevated or High acuity in an LDO.

Method: Using data from prevalent (vintage >90 days) ICHD patients from Mar-2022 through Dec-2022, a weekly acuity score was computed using 95 routinely captured variables considered critical (e.g., psychosocial, cognitive, clinical, treatment, hospitalization). Each variable was assigned points based on a priori criteria which were summed and categorized based on population distribution for each week. Patient acuity was assigned as Low, Moderate, Elevated, or High based upon percentile distribution. We defined MSW interventions as the number of assessments completed (0, <1, 1, or >1 per month) during the baseline period (BL, Mar-2022 through May 2022). Next, we compared hospital admission rate in the BL period to that in a follow-up period (FU, June 2022 through Dec 2022) for patients whose acuity at start of BL was Elevated or High (E/H), stratified by monthly MSW assessment exposure. This analysis focuses on prevalent ICHD patients in the Elevated and High acuity categories at baseline (BL, March 2022 through May 2022) as they were expected to have been prioritized for MSW assessment.

Results: We identified 29,665 prevalent ICHD patients whose acuity was E/H at the start of BL; 8.2%, 24.8%, 20.9%, and 46.2% had 0, <1, 1, and >1 MSW assessments per month during BL, respectively. As expected, hospital admission rate was generally high for patients with E/H acuity. Likewise, for patients with E/H acuity, hospital admission rate increases as the number of monthly interventions in BL increases (Figure 1). For patients with E/H acuity, in each category of BL MSW assessment exposure, the hospital admission rate in FU is lower than in the BL period and the magnitude of the decrease is larger when there are more MSW assessments in the BL period; for 0, <1, 1, and >1 respective MSW assessments, the respective rate ratios were 0.99, 0.99, 0.98, and 0.90, and rate ratio was significantly lower for patients with >1 MSW assessment in BL.

Conclusion: Our results suggest that acuity is helping MSW to identify patients with requiring more psychosocial and other needs as 46.2% of patients with E/H acuity had >1 MSW assessment. Our results also suggest that >1 MSW assessments in E/H acuity patients results in a larger magnitude in the decrease of hospital admission rates compared to other levels of MSW assessment exposure. Future analyses are needed to confirm these results.

Determination of Predictors of Outcomes Following Vascular Access Conversion: Which Patients Benefit Most?
Amun Hofmann1, Suman Lama2, Hanjie Zhang3, Ashin Assadian4, Murat Sor5, Peter Kotanko1 and Jochen Raimann6

Method: We studied prevalent incident HD patients undergoing conversion from CVC to non-CVC, between Jan. 2016 and Dec. 2019. Predictors included demographic and clinical variables such as comorbidities, drug history, and lab parameters. First, feature importance was assessed to separate weak from strong predictors using the Boruta algorithm. Second, important and tentative features were utilized in a subsequent machine learning workflow. Our main outcome was the predictive performance of different machine learning classification algorithms to predict re-conversion to central venous catheter and mortality within 1 year after conversion. Performance was quantified as accuracy, sensitivity, and AUC ROC. We compared insights from Machine learning algorithms to multivariate logistic regression models with selected inputs based on published literature (sex, age, BMI, diabetes, inflammation, blood pressure).

Results: After exclusions of patients with missing data, 38,151 out of 73,031 incident HD patients were studied. Of these, 25,470 (66.8%) experienced no major adverse outcome within 1 year after access conversion, 3,683 (9.7%) underwent re-conversion, and 7,779 (20.4%) did not survive the observational period, and 1,219 (3.2%) required re-conversion and did not survive the follow-up period. Post HD systolic blood pressure, history of a previous non-CVC that failed, and anthropometric characteristics (height, weight) had most weight in

The prediction of re-conversion to CVC, according to the Boruta algorithm. Ethnicity and age were found to be the most important predictors of mortality. Classification based on the absence/presence of any major adverse outcomes resulted in a predictive accuracy between 0.70 and 0.54, depending on the respective algorithm. Sensitivity and ROCAUC had maxima of 0.58 and 0.69, respectively. However, information gain by including all additional values had no remarkable effect on the predictive qualities (Table 1).

Logistic regression for re-conversion in survivors only resulted in an accuracy of 0.78 and sensitivity of 0.29. Limiting predictors to 6 published predictors of our studied outcomes in the context resulted in an accuracy of 0.77 and sensitivity of 0.22 (Figure 1a and b).

**Conclusion:** Prediction of re-conversion and mortality within 1 year after catheter-to-arteriovenous access conversion is accurately feasible based on demographic and clinical features but discrimination of those benefiting most comes with low predictive accuracy. It remains reasonable to assume that not all patients will truly benefit from conversion, the inability to identify those that do not based on retrospective medical records data, again emphasizes “Fistula first” (if surgically feasible) and the need for investigation into molecular and genetic risk determinants.

**IMPACT OF DYSMAGNESEMIA ON ATRIAL FIBRILLATION IN MAINTENANCE HAEMODIALYSIS PATIENTS: A NATIONWIDE STUDY**

Tatsunori Toida, Noriaki Kurita, Abe Masanori, Norio Hanafusa and Nobuhiko Joki

1 Kyushu University of Health and Welfare, School of Pharmaceutical Sciences, Nobeoka city, Japan, 2 Fukushima Medical University, Department of Clinical Epidemiology, Graduate School of Medicine, Fukushima city, Japan, 3 Fukushima Medical University Hospital, Department of Innovative Research and Education for Clinicians and Trainees (DiRECT), F, Japan, 4 The Japanese Society for Dialysis Therapy, The Committee of Renal Data Registry, Tokyo, Japan, 5 Nihon University School of Medicine, Divisions of Nephrology, Hypertension and Endocrinology, Department of Internal Medicine, Tokyo, Japan, 6 Tokyo Women’s Medical University, Department of Blood Purification, Tokyo, Japan and 7 Toho University Ohashi Medical Center, Division of Nephrology, Tokyo, Japan
BACKGROUND AND AIMS: The dose-response relationship between serum magnesium (sMg) and atrial fibrillation (AF) and the contribution of dysmagnesemia to AF remain unknown among haemodialysis patients.

METHOD: This was a nationwide cross-sectional study on the Japanese Society for Dialysis Therapy registry as of the end of 2019. Eligible participants were adult patients undergoing haemodialysis thrice a week. The main exposure was sMg, categorised into seven categories (<1.5, 1.5–<2, ≥2–<2.5, ≥2.5–<3, ≥3–<3.5, ≥3.5–<4, and ≥4.0 mg/dL). The outcome was AF reported by dialysis facilities. The independent contribution to AF was assessed via logistic regression to generate population-attributable fractions, assuming a causal relationship between sMg and AF.

RESULTS: A total of 165,926 patients from 2,549 facilities were analyzed. The prevalence of AF was 7.9%. Compared with the reference (>2.5–≤3 mg/dL), lower sMg was associated with increased AF (adjusted ORs [95%CI] of 1.49 [1.19–1.83], 1.24 [1.17–1.32], and 1.11 [1.05–1.16] for sMg of <1.5, 1.5–<2.0, and >2.5 mg/dL, respectively). The slightly high sMg was associated with fewer AF (adjusted OR 0.87 [95%CI 0.79–0.96] for sMg of >3.0–≤3.5 mg/dL). The adjusted population-attributable fraction of lower sMg and higher and lower sMg for AF was 7.4% and 6.9%, respectively.

CONCLUSION: An association does indeed exist between lower sMg and AF, with the fewest percentages of AF at sMg levels above the reference range for the general population. Dysmagnesemia may be an important contributor to AF among adult haemodialysis patients. Further longitudinal studies are warranted to determine whether correction of sMg reduces the incidence of AF.

EFFECT OF COMORBIDITIES ON HEALTHCARE EXPENDITURES FOR PATIENTS ON KIDNEY REPLACEMENT THERAPY IN A FRENCH COHORT

Isabella Vanorio Vega1,2, Panayotis Constantinou1, Victor Brett1, Stephanie Gentile3, Patrik Finne4, Bénédicte Sautenet5, Philippe Tuppin2 and Cécile Couchoud1

1Agence de la biomédecine, REIN registry, Saint Denis La Plaine, France, 2Caisse nationale de l'assurance maladie, Direction de la stratégie des études et des statistiques, Paris, France, 3APHM, Service d'évaluation médicale, Marseille, France, 4University of Helsinki, Helsinki, Finland and 5Centre Hospitalier Régional Universitaire de TOURS, Service de néphrologie-hypertension artérielle, dialyses, transplantation rénale, Tours, France

BACKGROUND AND AIMS: End stage kidney disease (ESKD) is associated with a substantial economic burden. In France, the cost of care for such patients represents 2.5% of the total French healthcare expenditures, but serves less than 1% of the population. These patients’ healthcare expenditures are high because of the specialized and complex treatment needed as well as the presence of multiple comorbidities. This study aims to describe and assess the effect of comorbidities on healthcare expenditures (direct medical cost and non-medical costs including transportation and compensatory allowances) for patients with ESKD in France, while considering the modality and duration of renal replacement therapy (RRT).

METHOD: This retrospective observational study included adults who started RRT for the first time between 2012 and 2014 in France and were followed for 5 years. Linear models were built to predict mean monthly cost (MMC) by integrating first the time duration in the cohort, then patient characteristics and finally the duration of use of each treatment modalities. A complementary analysis stratified on age group was also performed. The variables included in these analyses were: body mass index, age, sex, RRT modality, time in the cohort, coronary artery disease, heart failure, chronic respiratory disease, active cancer, diabetes, lower-limb arterial disease, HIV/AIDS, abdominal aneurism, rhythm disorders, stroke or transient ischemic attack, liver disease, mobility limitations. All RRT modalities available in France were also included: renal transplant (RT), hemodialysis (HD) in center, HD in self-care unit, HD in out-center, HD at home, assisted continuous ambulatory peritoneal dialysis (aCAPD), non-assisted continuous ambulatory dialysis (naCAPD), assisted automated peritoneal dialysis (aAPD), non-assisted automated peritoneal dialysis (naAPD).

RESULTS: A total of 22,506 patients were included in the study. The mean MMC was 6,391€ (95% CI 6,345–6,438 €). The comorbidities with the highest effect on MMC were inability to walk (95% CI 291–291 €), HIV positivity (95% CI 594–594 €), and diabetes (95% CI 1,434–1,434 €), followed by the presence of diabetes, cancer, and respiratory disease, which had a great impact on MMC in younger patients.

CONCLUSION: This study confirms the importance of considering patient characteristics, comorbidities and type of RRT when assessing healthcare expenditures for patients with ESKD. Better care of comorbidities prior to RRT could reduce cost for individual patients as well as potentially reduce the incidence of patients in ESKD. Even though the Euro value is specific to France, other countries might benefit from evaluating and anticipating healthcare costs for patients in RRT by assessing patient comorbidities.
RISK OF MAJOR ADVERSE CARDIOVASCULAR EVENTS ACROSS DIALYSIS MODALITY
Wisam Bitar, Jaako Helve, Mikko Haapio, Virpi Rauta, Eero Olavi Honkanen and Patrik Finne
University of Helsinki, and Helsinki University Central Hospital, Department of Nephrology, Helsinki, Finland

Background and Aims: Among dialysis patients, cardiovascular events are the leading cause of death. Little is known about difference in the frequency of cardiovascular events between various dialysis modalities. Glucose load may contribute to a metabolic burden in peritoneal dialysis (PD). On the other hand, hemodialysis can cause intradialytic hypotension, cardiac stunning, and arrhythmias, which are associated with increased risk of death. We compared risk of major cardiovascular events in patients who started continuous ambulatory PD (CAPD), automated PD (APD) and home HD with in-center HD patients.

Method: We included 968 patients who entered dialysis in the Helsinki-Uusimaa healthcare district in Finland from 2004 to 2017, of whom 162 were on CAPD, 229 on APD, 145 on home HD and 432 on in-center HD at day 90 from the start of dialysis. Patients were followed up for 5 years or until the end of 2019. Major adverse cardiovascular event (MACE) was defined as acute myocardial infarction, stroke or death due to cardiovascular disease. The cumulative incidence of the first MACE was calculated by taking other causes of death into account as competing risk events and censoring at time of kidney transplantation. Cox regression was used to compare risk of MACE between dialysis modalities with adjustment for age, gender, primary renal disease, prior comorbidities (coronary heart disease, left ventricular hypertrophy, heart failure and stroke), and laboratory data (plasma albumin, phosphate and ionized calcium). Imputation was performed to replace missing values of comorbidities and laboratory data.

Results: Of all 968 patients, 195 (20%) experienced a MACE during the entire follow-up and 62 (6.4%) during the first year of follow-up. The cumulative incidence of first MACE was similar in in-center HD and CAPD patients and higher than that in APD and home HD patients (Figure 1). Without adjustments, the hazard ratio of MACE was 0.83 [95% CI 0.56–1.2] for CAPD, 0.49 [95% CI 0.31–0.77] for APD and 0.42 [95% CI 0.23–0.78] for home HD in comparison to in-center HD. After adjustment for possible confounders, the hazard ratio of MACE was 1.1 [95% CI 0.70–1.6] for CAPD, 0.88 [95% CI 0.53–1.5] for APD and 0.80 [95% CI 0.41–1.6] for home HD and not statistically significantly different in comparison to in-center HD.

Conclusion: We observed a lower risk of MACE among patients who entered APD or home hemodialysis compared to in-center hemodialysis, but after adjusting for potential confounding factors, the difference diminished and was no longer statistically significant.

Figure 1: Cumulative incidence of the first MACE according to dialysis modality.
components to patients’ risk, we included both DCa and serum calcium level (SCa) in the models. We observed significant associations with all outcomes and SCa, but not with DCa and the interaction between them. In a subgroup analysis of patients with iPTH levels below 130 pg/ml (n = 7,438), we did not find any significant association between DCa and the outcomes.

**Conclusion:** In this observational study, no differences in all-cause or cardiovascular mortality were observed with the prescription of DCa 1.50 as compared to 1.25 after adjustment for confounders, whereas the risk of SCD appeared to be lower in the group of DCa 1.50. The association between the SCa-DCa gradient and outcomes appears to be predominantly related to the effect of SCa.

ASSOCIATION OF PROLONGED QT INTERVALS WITH MORTALITY IN HEMODIALYSIS PATIENTS: A NATIONWIDE RETROSPECTIVE COHORT STUDY

Sho Sasaki1, Kiichiro Fujisaki2, Masato Nishimura3, Toshiaki Nakano4 and Nobuhiko Joki5

1Kyoto University Hospital, Section of Education for Clinical Research, Kyoto University, Japan, 2Iizuka Hospital, Department of Nephrology, Iizuka, Japan, 3Tojinbo Hospital, Kyoto, 4Graduate School of Medical Sciences, Kyushu University, Department of Medical and Clinical Science, Fukuoka, Japan and 5Toho University Ohashi Medical Center, Division of Nephrology, Meguro City, Japan

**Background and Aims:** The prevalence of prolonged QT intervals is known to be prevalent among hemodialysis patients. In the general population, prolonged QT intervals are linked to increased mortality, however, the correlation between prolonged QT intervals and prognosis in hemodialysis patients remains uncertain. The objective of this study was to investigate the association between prolonged QT intervals and mortality and cardiac death among hemodialysis patients.

**Method:** We conducted a retrospective cohort study using the JSDR2019-2020, a nationwide registry of hemodialysis patients in Japan. We excluded from these subjects those younger than 18 years, with QT interval deficit, dialysis less than 3 times a week, atrial fibrillation, peritoneal dialysis, and home dialysis. In 2019, we collected data on various factors and basic patient information, and subsequently monitored outcomes in 2020. QT intervals were corrected using Bazett’s formula. Our primary and secondary outcomes were death and cardiac death which we defined as a composite of heart failure, pulmonary edema, arrhythmia, ischemic heart disease, and acute myocardial infarction, respectively. We performed univariate and multivariate analyses of the relationship between QT interval categories and outcomes using logistic regression models, adjusting for age, gender, cause of end-stage renal failure, serum concentrations of iron, potassium, magnesium, calcium, and phosphorus, history of dialysis, and history of cardiovascular disease. We also created a restricted cubic spline to visualize the relationship between QT intervals and outcomes. We employed multivariate imputation by chained equations to complement missing values. We set the significance level at 5%.

**Results:** Of the 332,599 patients in the database, 198,624 were included in the analysis of this study. The mean (standard deviation: SD), median (quartiles), and actual number (%) of subjects were: age 69.8 (12.4), 130,735 (65.8) male, 101,988 (51.3) with diabetes, and 66.0 (29.0, 128.0) months of dialysis history. The mean QT interval (SD) was 450.7 msec (30.5). During the 1-year observation period, there were 29,705 deaths, 7,247 cardiac deaths, and 12,166 new cases of ischemic heart disease. The odds ratios (95% confidence intervals: 95%CI, p value) for death within 1 year in the three QT interval categories (<460 [reference], 460 < = & <500, 500 < ) were 1(−), 1.58 (1.52-1.64, p<0.001), and 2.49 (2.35-2.62, p<0.001), respectively. In multivariate analysis, the adjusted odds ratios for death within 1 year in each QT interval category were 1(−), 1.44 (1.37-1.21, p<0.001), and 1.98 (1.87-2.09, P <0.001), respectively. Our analysis of cardiac death as an outcome also revealed a statistically significant increase in cardiac death with increasing QT intervals.

**Conclusion:** QT intervals were prolonged in hemodialysis patients, and prolonged QT intervals were significantly associated with increased mortality and cardiac death.
**Figure 1:** Association between QT intervals and death. The model was adjusted for age, gender, cause of end-stage renal failure, serum concentrations of iron, potassium, magnesium, calcium, and phosphorus, history of dialysis, and history of cardiovascular disease.

**AUTOPHAGY PATHWAY ACTIVATION IN IMMUNE-INFLAMMATORY CELLS OF PERITONEAL DIALYSIS PATIENTS**

Simona Granata¹, Maurizio Bruschi², Paola Pontrelli¹, Giovanni Candiano², Giovanni Stallone¹, Loreto Gesualdo³ and Gianluigi Zaza¹

¹University of Foggia, Department of Medical and Surgical Sciences, Foggia, Italy, ²Gaslini Hospital, Genova, Italy and ³University of Bari, Bari, Italy

**Background and Aims:** The better understanding of the biological pathways related to chronic kidney disease (CKD) may be useful for the identification of new therapeutic targets to improve the management of CKD patients. High-throughput technologies with innovative bioinformatics approaches for data analysis are very useful to achieve this objective.

**Method:** We reinterrogated our previous gene expression microarray data obtained from peripheral mononuclear cells (PBMCs) of 5 healthy subjects (HS), 9 chronic kidney disease patients with KDOQI stage II-III (CKD) and 10 CKD patients undergoing peritoneal dialysis treatment (PD). Advanced statistical and machine learning methods, including support vector machine learning and partial least squares discriminant analysis, were used for bioinformatics. Western blot and flow cytometry, then, was used to validate these results in an independent study group (10 HS, 10 CKD and 15 PD).

**Results:** Statistical analysis revealed that the transcriptomic profile of PD was significantly different from HS and CKD. Instead, no significant differences were observed between HS and CKD. A total of 348 genes (p < 0.0001, FDR < 5%) were able to differentiate PD patients from the other two study groups. Autophagy resulted one of the most up-regulated pathways in PD and the autophagy related 5 (ATG5), a gene encoding for a key protein involved in autophagic vesicle formation, was the top discriminative transcript (as demonstrated also by the VIP score). Western blot for ATG5 and LC3BII, main phagosome proteins, performed on the validation cohort, confirmed the activation of autophagy pathway only in PBMC of PD patients.

**Conclusion:** Our high-throughput data demonstrated, for the first time, that the autophagy pathway is activated in immune-cells of PD patients. This condition may significantly impact their immune-response and -homeostasis and, probably, it represents the last attempt of these circulating cells to avoid apoptosis.

**VITAMIN D AND PARATHYROID HORMONE PREDICT INCIDENT MAJOR ADVERSE CARDIAC EVENTS IN PATIENTS STARTING HAEMODIALYSIS: A REAL-WORLD ANALYSIS**

Garry Mcdowell¹²³, Robert Downey², Benjamin Buckley⁴, Philip Austin⁵, Gregory Lip⁵⁶ and Anirudh Rao²³

¹Liverpool John Moores University, Pharmacy and Biomolecular Sciences, Liverpool, United Kingdom, ²University of Liverpool, Liverpool Centre for Cardiovascular Science, Liverpool, United Kingdom, ³Royal Liverpool University Hospital, Nephrology and Transplantation, Liverpool, United Kingdom, ⁴Liverpool John Moores University, School of Sport and Exercise Science, Liverpool, United Kingdom, ⁵TriNetX, London, United Kingdom and ⁶Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

**Background and Aims:** Despite its advantages, haemodialysis (HD) is associated with increased cardiovascular mortality and morbidity, with some studies reporting 48% higher mortality, within 2 years of starting treatment. HD patients are known to suffer from vitamin D deficiency which has been linked to excess CV mortality and morbidity. We aimed to investigate the prognostic significance of vitamin D in predicting incident Major Adverse Cardiovascular Events (MACE) within 5 years of commencing HD.

**Method:** A retrospective cohort study was performed using electronic medical records from a global federated research network from the US (TriNetX). The TriNetX network was searched on 31st January 2023. The cohorts commenced HD post-diagnosis of End-Stage Kidney Disease. Data censoring for MACE was invoked prior to the index event of HD. Vitamin D (25-hydroxyvitamin D and 1,25 dihydroxy Vitamin D) concentrations were the first reported result within 3 months of starting HD. Cohorts were grouped according to biomarker-specific thresholds and 1:1 propensity-score matched for age, gender, and co-morbidities (hypertension, diabetes mellitus and smoking status). Logistical regression produced odds ratios with 95% CI for 5-year MACE. MACE was defined, a priori, as a composite of ischaemic heart disease, angina pectoris, acute myocardial infarction, heart failure, AF, stroke, and all-cause mortality. All statistical analysis was performed on the TriNetX online platform.

**Results:** The results are shown below. There was no association between outcome and PTH at 55 pg/ml threshold. Only results that reached statistical significance (p<0.05) are shown. Patients with a 25-OH Vitamin D
concentration <24 ng/ml or 1,25-diOH Vitamin D at <35 pg/ml had significantly more events, as shown below.

**Conclusion:** Circulating plasma levels of cholecalciferol and calcitriol are predictive of CV outcomes in patients commencing HD; however, the risk profile is different between low levels of active and inactive vitamin D. As the incident HD population are at increased risk of CV mortality and morbidity, cholecalciferol and calcitriol should be included in assessing overall risk.

C. S. R. L., Italy and 8Seconda Università degli Studi di Napoli, Caserta, Italy

**Background and Aims:** Peritoneal dialysis (PD) is a renal replacement therapy that enables metabolic waste products and excess fluids to be eliminated through the peritoneal membrane. Exposure to conventional dialysates at high glucose concentrations is considered critical for the pathogenesis of peritoneal fibrosis, angiogenesis, and epithelial-mesenchymal transition (EMT). These events largely contribute to peritoneal membrane aging, resulting in ultrafiltration failure. Preclinical research in this field suffers from the lack of valid and reproducible *in vivo* systems and so far has been limited to *in vitro* systems of mesothelial or endothelial cell lines. *In vitro* studies on mesothelial cell monolayers have validated the significant protective effects of dialysates with alternative osmo-metabolic agents. With their better biocompatibility these novel formulations could provide a valid substitute for conventional solutions (1,2). The method proposed, based on multi-photon microscopy, aims to study the physiology of the peritoneal membrane during dialysis exchange and to validate the effects of biocompatible dialysates in animal models of fibrosis as observed in the course of dialysis treatment.

**Method:** We have implemented a surgical procedure to optimize the stability of a flap of parietal peritoneum to allow direct microscope observation. The innovative technology of multi-photon microscopy enables one to observe the vessels of microcirculation *in vivo* and provides a 3D rendering of the peritoneal membrane, giving an overview of all the single layers without the use of specific markers (Figure 1). One may also assess specific phenomena induced by the fibrotic process, such as the thickening of the sub-mesothelial interstitium, exploiting the autofluorescence signal from excited collagen fibers caused by the physical phenomenon of Second Harmonic generation. *In vivo* microscopy evaluation of peritoneal membrane senescence parameters was conducted in rats subjected to one daily intraperitoneal injection (10 mL/day) for 15 days with one of the following PD solutions: a commercially available glucose-based neutral-pH, low-GDP, PD solution (Physioneal 3.86%, Baxter Healthcare, Italy), and a new single-chamber low glucose PD solution containing osmo-metabolic agents such as L-carnitine and xylitol (XyloCore HS, Galenica Senese, Italy). XyloCore HS is a lactate-buffered PD solution with glucose (1.5%), L-carnitine (0.02%) and xylitol (2.0%). The osmotic strength of the two PD solutions tested was comparable.

**Results:** Treatment with XyloCore HS was associated with a significant reduction in thickness of the sub-mesothelial interstitium (p = 0.013), the density of collagen fibers (p = 0.012) and the vascular composition (p = 0.006), as well as the number of branch points (p = 0.0335), when compared to rats treated with a commercial glucose-based PD solution, Physioneal. Figure 2 shows the different thicknesses of sub-mesothelial strata upon treatment with the PD solutions under investigation.

**Conclusion:** Previous *in vitro* studies have shown that XyloCore (1,2), a novel glucose-sparing PD solution currently in Phase III clinical development (ELIXIR - NCT03994471), is able to counteract the glucotoxic effects on the peritoneal membrane induced by conventional dialysates. Our pre-clinical *in vivo* methodology not only confirms our previous *in vitro* findings, but also

**PERITONEAL DIFFUSE PODOPLANIN EXPRESSION IS ASSOCIATED WITH SEVERE ARTERIOLOPATHY IN CHILDREN ON PERITONEAL DIALYSIS**

Maria Bartosova¹, Conghui Zhang¹, Fabian Eibensteiner², Rebecca Herzog¹, Iva Marinovic¹, Bettina Schaefer¹, Zhiwei Du¹, Sotirios Zarogiannis¹,², Klaus Kratochwill¹ and Claus Peter Schmitt¹

¹University Hospital Heidelberg, Heidelberg, Germany, ²Medical University of Vienna, Vienna, Austria

**Background and Aims:** Podoplanin is a transmembrane glycoprotein binding chemokines and modulating inflammatory reactions. In healthy peritoneum, it is expressed in mesothelial cells and in lymphatic endothelium, expression beyond these structures (diffuse podoplanin staining, DPS) has been observed in adult patients with encapsulating peritoneal sclerosis (EPS).

**Method:** Parietal peritoneal tissues from 71 children on PD fluids with low glucose degradation product (GDP) content underwent digital histomorphometry. DPS and pathomechanisms of peritoneal membrane transformation and vasculopathy were hierarchically clustered. A panel of 13 peritoneal cell markers was selected and tissue sections were stained with metal conjugated markers to evaluate podoplanin signals. Single-cell analysis was used to characterize peritoneal cells with positive podoplanin signals.

**Results:** DPS was present in 22% of the PD patients, all devoid of any clinical, radiological or histological feature of EPS. DPS positive patients were younger, had higher dialytic glucose exposure (median 103 vs. 154 g/m²/day, p = 0.002), and lower peritoneal arteriolar lumen to vessel (L/V) ratio, i.e. exhibited more arteriolar lumen narrowing. PD duration [median 20 (14.5, 48) months] and peritonitis incidence were similar as in non-DPS patients. In multivariable analysis, glucose exposure, PD duration, epithelial-to-mesenchymal transformed (EMT) cells and lower patient body surface area (BSA) independently predicted the presence of DPS. DPS and lower mesothelial surface coverage predicted lower arteriolar L/V ratio. In subgroups matched for BSA, PD duration and dialytic glucose exposure, DPS patients had a lower L/V ratio, (0.44 ± 0.13 vs. 0.31 ± 0.18, p = 0.003) and higher submesothelial CD45 leucocyte, CD68 macrophage and EMT cell count. Submesothelial lipopolysaccharide and hyaluronic acid receptor CD44 were increased in DPS positive patients, hyaluronan synthase 1 and 2 were similar. Among DPS positive patients, DPS intensity grade was higher in those with history of bacterial or fungal peritonitis (7 out of 15). Two patients had three and four peritonitis episodes respectively, their PD pattern did not differ from patients with history of only one peritonitis episode. Hierarchical clustering demonstrated highest similarity of DPS positive areas with CD68 positive areas. In IMC analysis of DPS positive areas, highest podoplanin signals were derived from M2 classified macrophages (CD68+CD163+) and fibroblastic cells [αSMA positive/non-endothelial/non-macrophage (αSMA+PROX1-CD31-CD68-CD163-)], signals derived from M1 classified macrophages (CD68+CD163-) were lowest.

**Conclusion:** Peritoneal DPS in pediatric patients on low-GDP PD is associated with lower BSA, higher dialytic glucose exposure, history of infectious peritonitis and peritoneal inflammatory and EMT cell invasion, and predicts obliterating peritoneal vasculopathy. We identified M2 macrophages as major source of extra-lymphatic peritoneal podoplanin accumulation, suggesting their role in severe peritoneal transformation.

**PERITONEAL DIALYSIS ADDITIVE REDUCES TRANSPERITONEAL LOSS OF BLOOD MICROPARTICLE AND EXTRACELLULAR MATRIX PROTEINS IN A CONTROLLED CROSSOVER TRIAL**

Fabian Eibensteiner¹,², Rebecca Herzog¹,², Andreas Vychytíl¹, Christoph Aufricht¹ and Klaus Kratochwill¹,²

¹Division of Pediatric Nephrology and Gastroenterology, Department of Pediatrics and Adolescent Medicine, Comprehensive Center for Pediatrics, Medical University of Vienna, Vienna, Austria, ²Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical University of Vienna, Vienna, Austria

**Background and Aims:** About 11% of patients requiring dialysis worldwide are treated with peritoneal dialysis (PD). With each PD exchange high amounts of protein are removed from the peritoneal cavity stemming from the systemic circulation (reflecting toxin removal, loss of serum proteins, inflammatory processes) and local inflammatory processes. Thereby, the clinically measured peritoneal protein loss (PPL) is the result of transperitoneal serum loss, lymphatic drainage, transmesothelial reabsorption, local production, and cellular components. Although high PPL has been found to be predictive of mortality and cardiovascular morbidity, the pathophysiological concept is still poorly understood.

**Method:** Peritoneal dialysis effluent (PDE) samples were obtained from peritoneal equilibrium tests during a prospective, multicenter, double-blinded, controlled, randomized, dual-period, 2-treatment, crossover, phase II, proof-of-concept study in Austria. PDE samples were submitted to proteomic analysis by tandem mass tag (TMT) labeling and 2D reversed phase liquid chromatography mass spectrometry. To disentangle transmembrane serum protein loss from local protein production we developed a novel and unique analytical approach. Briefly, partitioning around medoids and proximity in the Euclidean space for between visit (non-treatment visits only) single-protein kinetics was utilized to achieve this separation. A multivariate mixed-effects model was calculated to identify treatment (intraperitoneal alanyl-glutamine administration) effects.
Results: We identified 2,624 different proteins within the PDE of 12 patients across two time-points. A large cluster of proteins with stable abundance in collinearity with well-established clinical characteristics of transperitoneal transport (e.g., dialysate-to-plasma-albumin) in accordance with the three-pore-model was identified. After clustering and separation, the proteins resembling similar time-course kinetics to clinical transperitoneal membrane transport characteristics (one of five clusters) were all identified to be able to theoretically traverse through the small peritoneal pore (< 4-6 nm). Of these 549 proteins lost from the systemic circulation via transperitoneal small pore diffusion, the appearance of 51 in the PD effluent was significantly reduced by intraperitoneal administration of alanyl-glutamine. The affected proteins are mainly involved in extracellular matrix organization, part of extracellular exosome signaling and blood microparticles, e.g., high density lipoprotein (HDL) formation (Apollipoprotein A1).

Conclusion: PPL is an important but poorly understood undesired effect of PD associated with cardiovascular morbidity and mortality. Our novel analytical approach enables us to disentangle the complexity of transperitoneal serum protein loss and local protein production on single-protein level across the peritoneal proteome. Furthermore, we were able to delineate the potential beneficial effects of intraperitoneal alanyl-glutamine treatment on PPL and peritoneal health which might even suggest potential beneficial effects on cardiovascular morbidity (e.g., HDL formation).

GRAPHICAL ABSTRACT

Extended validation of the iBox in real-life settings, different transplant systems and clinical trials: the iBox extended trial

Background

The iBox is a validated prognostication system predicting long-term kidney allograft failure. It received regulatory endorsement by EMA, for surrogate endpoint for clinical trials. As the iBox system was primarily built using a deep phenotyped cohort, there is a need for proof-of-principle in extended clinical scenarios, geographically diverse centers, national and international transplant allocation systems.

Methods

- 10,851 transplant recipients
- 17 academic medical centers
- Europe, North America and South America

Results

Destination cohort: 6,000 recipients
- Banff with donor risk index (MDRD186, MDRD175, CKD-Epi)0.81; 2) iBox + structural (absence of histology); 3) iBox + functional (without DSA measurements); 4) iBox to risk evaluation, functional parameters (eGFR, proteinuria), allograft histological lesions (IFTA, g+ptc, i+t, cg Banff scores), and circulating anti-HLA DSA. We stratified the performances of the iBox according to several real-life scenarios, including: 1) iBox + different eGFR formulas (MDRD186, MDRD175, CKD-Epi); 2) iBox + urinary dipstick; 3) iBox Functional + Structural (absence of DSA measurements); 4) iBox functional + Immunological (absence of histology); 5) iBox in response to treatment in T-cell mediated rejection (TCMR); 6) iBox for in response to treatment antibody mediated rejection (ABMR) clinical trials. The performances of the iBox system were assessed with the discrimination (C-index) and calibration.

Results: The derivation cohort included 4,000 recipients from Europe (France, Belgium, Spain, Germany, Finland n = 4,643), the United States (n = 1,537) and South America (Brazil, Argentina n = 671). The mean recipient age was 50.26 years (14.05) with a median follow-up after evaluations of 5.41 years [IQR: 3.26 to 7.13]. 1336 patients (12.3%) lost their graft during the study follow-up. The performances of the iBox were confirmed in the different real-life setting with the following C-Index: 1) iBox + different eGFR formulas (MDRD186, MDRD175, CKD-Epi): 0.81; 2) iBox + urinary dipstick: 0.80; 3) iBox Functional + Structural (histology): 0.80 (derivation) and 0.84 (validation); 4) iBox functional + Immunological: 0.80 (derivation) and 0.83 (validation); 5) iBox in response to treatment in T-cell mediated rejection: 0.81; 6) iBox for in response to treatment antibody mediated rejection trials 0.81. The score showed an accurate calibration in every scenario.

Conclusion: The iBox extended trial confirms in various medicos-economic settings the performances transportability and surrogacy of the iBox system, further reinforcing its use as a surrogate end point for clinical trials including TCMR and ABMR.

GRAPHICAL ABSTRACT

Racial disparity and kidney function in living kidney donors

Background

Kidney disease disproportionately affects some races and ethnicities. Whether this disparity exists in living kidney donors is unknown. We aimed to evaluate the association between racial/ethnic and kidney function after living kidney donation.

Methods

- (OPTN/SRDB, January 1977–Aug 2022)
- 166,845 living kidney donors

Results

- Age (1% to 99%)
- race (AA, CA, NH)
- race (AA, CA, NH)

Conclusion

- Kidney donors disproportionately affect some races and ethnicities. Whether this disparity exists in living kidney donors is unknown. We aimed to evaluate the association between racial/ethnic and kidney function after living kidney donation.
Method: A retrospective cohort study utilizing Organ Procurement and Transplantation Network (OPTN) and Scientific Registry of Transplant Recipients (SRTR) database includes living kidney donors undergoing donation between June 1972 and September 2022. Time-to-event of >35% rising post-donation serum creatinine from pre-donation serum creatinine among different races and ethnicities was examined by multiple Cox proportional hazard regression analyses.

Results: Of 136,814 living kidney donors, the mean ± SD age was 42 ± 12 years and 61% were female. The majority were White (70%) followed by Hispanic (14%), Black (11%), Asian (4%), multiracial (0.61%), American Indian/Alaska Native (0.47%), and native Hawaiian/other Pacific islander (0.25%). Among 103,938 living kidney donors with post-donation serum creatinine, 78,344 (75%) living kidney donors had the event over a median time to follow-up of 6.27 months (interquartile range 4.07, 8.67). The incidence rate of the event was 0.09 person-months. Mean pre-donation serum creatinine was 0.85 ± 0.19 mg/dL and post-donation serum creatinine during routine follow-up visits at 6, 12, and 24 months were 1.22 ± 0.30, 1.194 ± 0.30, and 1.16 ± 0.27 mg/dL, respectively (Figure 1A). Mean percentage of elevated serum creatinine from pre-donation serum creatinine were 46, 43, and 41%, respectively (Figure 1B). Compared to White, Blacks had a significantly higher; while Hispanics and multi-racial groups had a significantly lower risk of increased post-donation serum creatinine >35% (hazard ratio (HR) Black 1.03, 95% confidence interval (CI) 1.01, 1.06, P = 0.008; HR Hispanic 0.95, 95% CI 0.93, 0.97, P < 0.0001; HR Multiracial 0.92, 95% CI 0.84, 0.99, P = 0.049; Figure 2). After adjusting for age, gender, U.S. citizenship, education level, pre-donation body mass index, systolic blood pressure, diastolic blood pressure, serum creatinine, post-donation proteinuria, history of pre-donation hypertension, and the interaction term between race/ethnicity and age (<70 or ≥70), Black remained at greater risk for the event and Asians still had a lower the risk (HR Black 1.22, 95% CI 1.13, 1.31, P < 0.001; HR Asian 0.88, 95% CI 0.83, 0.94, P < 0.001). Other races/ethnic had no significant difference in the risk. Age was an effect modifier with attenuated risk for increased serum creatinine >35% observed in older Hispanic, Asian, and multiracial groups (P interaction 0.037, 0.001, and 0.006, respectively).

Conclusion: Blacks are at risk of increased post-donation serum creatinine >35%; while Asian is protective compared to White independent of pre- and post-donation factors. Elderly Hispanic, Asian, and multiracial living kidney donors do not have worsened kidney outcome compared to their younger living kidney donors with the same races/ethnicities.
Next Generation Sequencing: From Banff Score Molecular Signatures and Classifiers to Predicted Histological Archetypes of Kidney Biopsies

Background and Aims: To improve risk stratification in kidney transplantation, molecular diagnostic tools are increasingly investigated for their feasibility and gain in diagnostic power. Nonetheless, previously published studies focused on sequencing technologies and gene panels with limited vision of the transcriptome (pathogenesis-based transcripts [PBTs], Banff Human Organ Transplant [BHOT] panel). The EU-TRAIN consortium was built to discover new predictive and informative biomarkers for kidney transplant histology and rejection diagnoses, leveraging a next generation sequencing technology.

Method: EU-TRAIN (NCT03652402) is a prospective multicentric study including unselected kidney transplant cohorts from 11 centres from 4 countries (France, Spain, Germany, Switzerland). We performed a bulk RNA sequencing on the polyadenylated probes of 770 kidney biopsies (n = 540 kidney recipients) collected between 2018 and 2021. Differential gene expression analyses were computed to obtain a molecular signature for all Banff score lesions. We then derived three different feature selections by either i) training an ElasticNet model on all differentially-expressed genes (DEGs), or by taking the top 30 ii) overall DEGs or iii) the top 30 DEGs focusing on transcripts included in the BHOT gene panel. From them, we trained four machine learning (ML) classifiers through a 10-times repeated 3-fold cross-validation. Models’ performances were assessed on a hold-out test.
set accounting for 30% of the total samples. Finally, we derived prototypic histological profiles using an archetypal analysis on the samples’ predicted Banff score probabilities from the best classifier. 

**Results:** The ElasticNet feature selection lowered the number of DEGs to be predicted accurately the Banff score lesions and 8 profiles were identified among these predictions. External validation and archetypes’ association with graft loss will be addressed in the future.

**Conclusion:** In addition to the previously described factors usually related to worse evolution of IgA nephropathy in the native kidney and after post-transplant recurrence, we observed that cellular inflammation influences worse evolution after rIgAN. We suggest to considering the Banff criteria for acute cellular inflammation to better understand the subsequent evolution of patients with rIgAN.

**PROGNOSTIC VALUE OF A POSITIVE CROSSMATCH BEFORE DESENSITIZATION IN A COHORT OF HIGHLY-SENSITIZED PATIENTS**

Johan Noble1, Paolo Malvezzi1, Thomas Jouve1, Beatrice Bardy1, Lionel Rostaing2 and Celine Dard2

1CHU Grenoble-Alpes, Nephrology and kidney transplantation, Grenoble, France and 2Etablissement Français du Sang, HLA Department, Grenoble, France

**GRAPHICAL ABSTRACT**

**Prognostic value of a positive crossmatch before desensitization in a cohort of highly-sensitized patients**

**Background:** Human Leukocyte antigen (HLA) sensitization in patients is a barrier for Kidney Transplantation (KT) access, and highly-sensitized patients remain on the waiting list longer than other patients which results in a higher morbidity and mortality. Desensitization may be an option to increase their access to KT. All patients transplanted in this context have a negative Complement-Dependent Cytotoxicity crossmatch (CDC-CM) the day of KT. However, the stratification of the long-term risk of graft loss according to flow cytometry crossmatch (FC-CM) and to CDC-CM during the desensitization period remains unknown.

**Method:** In this retrospective study, all highly-sensitized patients (Panel Reactive Antibigen (PRA) ≥ 85) in our center were included. CDC-CM and FC-CM were performed on samples before and during the desensitization period and clinical follow-up data were retrieved. Pre-KT desensitization strategy consisted in two Rituximab infusions (375mg/m²) and a variable number of apheresis (mostly semi-specific immunoadsorption) associated with a classical immunosuppression-based regimen (tacrolimus, mycophenolate and steroids).

**Results:** A total of 183 highly-sensitized recipients received a KT between 2014 and 2022. Of these, 23 were desensitized prior to KT and among them 18 had a positive FC-CM before KT and 5 had no positive FC-CM on all assessed serum samples. Mean age was 52.9 ± 13 years. Mean follow-up was 5.2±4 and 3±2 years for non-desensitized and desensitized patients respectively. PRA before desensitization was higher in desensitized patients (98%) versus non-desensitized patients (95%) and the mean time on the waiting list was 5.8±4 versus 7.5±4 years respectively. Death-censored graft survival and patient’s survival, using cox-survival analysis, were not statistically different between the desensitized kidney transplanted patients and the highly-sensitized patients without desensitization (p = 0.77 and p = 0.57 respectively). In sub-group analyses, the positivity of FC and/or CDC-CM did not add an additional risk of graft loss or patient mortality.

**INFLUENCE OF CELLULAR INFLAMMATION ON THE OUTCOME OF KIDNEY TRANSPLANTATION AFTER RECURRENT OF IgA NEPHROPATHY**

Teresa Vázquez1, Emilio Rodrigo2, Luis Fernando Quintana Porras3, Ana Sanchez Fructuoso4, Jose María Gomez-Ortega1, Ana Buxeda5, Eva Gavela5, Maria Isabel Beneyto Castello6, Maria Ovidia Lopez Oliva3 and Domingo Hernández1

1Hospital Universitario Regional de Málaga, IBIMA, RD21/0005/0012, Nephrology, Málaga, Spain, 2Hospital Universitario Marqués de Valdecilla, Nephrology, Santander, Spain, 3Hospital Clinic, Nephrology, Barcelona, Spain, 4Hospital Clínic San Carlos, Nephrology, Madrid, Spain, 5Hospital Universitario Marqués de Valdecilla, Pathology, Santander, Spain, 6Hospital del Mar, Nephrology, Barcelona, Spain, 7Hospital Universitario Dr. Peset, Nephrology, Valencia, Spain, 8Hospital La Fe, Nephrology, Valencia, Spain and 9Hospital Universitario La Paz, Nephrology, Madrid, Spain

**Background and Aims:** The recurrence of IgA nephropathy (rIgAN) worsens the prognosis of renal transplantation, representing the third cause of loss in these recipients. Several variables at the time of recurrence, such as worse renal function, greater proteinuria, previous steroid withdrawal, and MEST-C histological findings have been associated with a higher risk of graft loss after recurrence. The presence of clinical or subclinical inflammation has been associated with a higher risk of kidney graft loss, but it is not precisely known how it influences the outcome of patients with rIgAN.

**Method:** A multicenter retrospective study was carried out including renal transplant recipients with biopsy-proven IgA nephropathy as the underlying disease in which the recurrence of the primary disease had been verified by means of graft biopsy and in which the Banff criteria were available or could be reviewed. Cellular inflammation was defined according to Banff scores as “t” or “i” ≥ 2. The main endpoint was progression to CKD stage 5 or death censored-graft loss (DCGL).

**Results:** 118 kidney transplant recipients were included with an age of 47 ± 14 years at recurrence, 80% male, with a mean time to biopsy of 65 ± 69 months and a post-transplant follow-up of 118 ± 70 months. After recurrence, 34 (28.8%) transplants were lost after 35 ± 28 months, excluding death. Using univariate Cox regression, the factors related to CKD stage 5 or graft loss were systolic blood pressure (HR 1.039, 95% CI 1.016-1.064, p = 0.001), glomerular filtration rate (HR 0.948, 95% CI 0.922-0.974, p < 0.001), the logarithm of proteinuria (HR 15.836, 95% CI 5.504-45.565, p < 0.001), Oxford-C score (HR 3.490, 95% CI 2.137-5.699, p < 0.001), interstitial fibrosis (HR 2.173, 95% CI 1.362-3.468, p = 0.001) and cellular inflammation (HR 2.458, 95% CI 1.237-4.884, p = 0.010). After multivariate analysis, cellular inflammation remained significantly related to CKD stage 5 or DCGL (HR 2.338, 95% CI 1.077-5.075, p = 0.032), independently of systolic blood pressure, glomerular filtration rate, the logarithm of proteinuria and Oxford-C score.

**Conclusion:** There is a significant impact of cellular inflammation on the adverse evolution of rIgAN in the native kidney and in the post-transplantation period. This finding is important to better understand the evolution and make accurate decisions regarding the treatment strategy in these patients.
Conclusion: Desensitization allows highly-sensitized patients to access KT with an HLA-incompatible graft (with a positive CDC or FC-CM on the serum collected prior to desensitization), with the same graft survival as similarly sensitized patients transplanted with an HLA-compatible graft without desensitization.

Background and Aims: We previously reported excellent efficacy and improved safety aspects of rapid steroid withdrawal in the randomized controlled one year “Harmony” trial with 587 predominantly deceased-donor kidney transplant recipients randomized either to basiliximab or rabbit antithymocyte globulin induction therapy and compared to standard immunosuppressive therapy consisting of basiliximab, low tacrolimus once daily, mycophenolate mofetil, and corticosteroids. The five-year post-trial follow-up (FU) data reported here were obtained in an observational manner to evaluate, how these excellent short-term surrogate parameters will translate into hard long-term outcome parameters like patient death/graft loss.

Method: The five-year post-trial follow-up data were obtained in an observational manner at a three and a five-year visit for patients who consented to participate and covered clinical events that occurred from the second year onwards.

Results: Biopsy-proven acute rejection and death-censored graft loss rates remained low and independent of rapid steroid withdrawal (see Figure 1). Rapid steroid withdrawal was an independent positive factor for patient survival (adjusted hazard ratio 0.554, 95 % confidence interval 0.314 to 0.976; p = 0.041, see Table 1). The reduced incidence of post-transplantation diabetes mellitus in rapid steroid withdrawal patients during the original one-year study period was not compensated by later incidences during follow-up. Incidences of other important outcome parameters such as opportunistic infections, malignancies, cardiovascular morbidity/risk factors, donor specific antibody formation, or kidney function did not differ during follow-up period.

Abstracts
Belatacept outcomes in pediatric kidney transplantation: An international multicenter study

Belatacept is a co-stimulation blocker associated with better long-term outcomes in adult patients compared to CNI based regimens. Data on its use in older children and young adults are lacking. We are the 1st to report outcomes for 45 pediatric kidney transplant recipients converted to belatacept.

Method: 45 patients were included from 4 centers (USA and France) between 05/2018 and 12/2021. Patients received an induction with basiliximab (n = 39) or ATG (n = 6). Maintenance immunosuppression included CNI, MMF +/- steroids. Patients' viral status (EBV, CMV) were monitored monthly to report outcomes for 45 pediatric kidney transplant recipients converted to belatacept. All patients were EBV viral at the time of conversion (4 were EBV+ at the time of conversion). 6 patients because of delayed graft function and 1 to avoid CNI toxicity. 38/45 patients were converted after a median of 4.1 years post-transplant (IQR 1.7-6.0). GFR was stable or improved over a median follow-up time of 1.6 years (IQR 1.1-2.4), Fig 1 A. Rejection episodes were observed in 10/45 patients (22%) after a median of 10.2 months (IQR 6.1-15.8) and included 7 TCMR, 2 ABMR and 1 mixed rejection. None of these patients were converted early (<3 m), 5 had been converted for non-adherence, 4 had pre-existing DSA and 4 had prior history of rejection. Evolution of GFR in rejectors is shown in Fig 1 B. CNI were reintroduced for 6/10 and belatacept stopped for 3/10. Regarding viral complications, 1 severe BKV nephropathy required the discontinuation of belatacept. All patients were EBV+ at conversion (4 were EBV- at the time of transplantation). No EBV replication was observed.

Conclusion: Selected pediatric kidney recipients benefit from long-term CNI toxicity avoidance, but selection criteria need to be refined to avoid rejection under costimulation blockade.

**IMPACT OF DARATUMUMAB AND BELATACEPT ON HLA ANTIBODIES IN KIDNEY TRANSPLANT CANDIDATES WITH 100% CPRA: EARLY RESULTS OF ATTAIN (ITN090ST)**

Flavio Vincenti1,1, Sindhu Chandran2, Rajalingam Raja1, Kristen Mason3, Shreya Mall1, Stalinraja Maruthamuthu1, Thomas Martin1, Cynthia Breeden4 and Juliete Silva4

1 University of California San Francisco Parnassus Campus, San Francisco, United States of America, 2 UCSF Immune Tolerance Network, San Francisco, United States of America, 3 Rho Inc, Durham, United States of America and 4 Immune Tolerance Network, Atlanta, United States of America

**Background and Aims:** Despite high allocation priority, <10% of kidney transplant candidates with cPRA 100% can find a compatible donor. Current desensitization strategies are ineffective due to antibody rebound. Adding costimulation blockade to plasma cell (PC) depletion prevents antibody rebound in nonhuman primates by countering nodal B cell and Tfh expansion.

**Method:** ATTAIN is a pilot, phase I/II trial of daratumumab, a CD38 mAb used in multiple myeloma, plus belatacept, a high affinity CTLA4-Ig, to desensitize kidney transplant candidates with cPRA ≥99.9%. Enrolled subjects receive daratumumab (6 doses: 8 mg/kg) and belatacept (4 doses: 10 mg/kg) over 10 weeks with bone marrow and blood assessments pre- and post-treatment. The primary efficacy endpoint (PE) is a composite of (1) elimination of ≥1 HLA antibody specificity, (2) ≥50% reduction in the MFI of ≥3 HLA antibody specificities, or (3) kidney transplant from a previously incompatible donor. Target accrual is 15, enrolled in 2 cohorts (5+10).

**Results:** Cohort 1 (n = 5, mean age 44, 60% with previous transplant) has been enrolled and treated, with 5-31 weeks follow-up to date. The treatment was tolerated well in all 5 patients who showed a significant reduction in most HLA antibodies after treatment without manifestation of rebound. 3 of 5 participants reached the PE and 5 of 5 had >50% bone marrow (BM) PC depletion. One patient received a kidney transplant from a previously incompatible deceased donor and is doing well at 7 months post-transplant without rejection or rebound of HLA antibody. Treatment was temporarily paused in 3 subjects due to AEs (acute cholecystitis and COVID, upper GI bleed, fevers); no cases of opportunistic infection or malignancy occurred.

**Conclusion:** A novel HLA desensitization regimen consisting of PC depletion with Daratumumab and costimulatory blockade with Belatacept appears safe and successful in the ongoing ATTAIN clinical trial. In the initial subject, this regimen led to transplant without HLA antibody rebound or acute rejection. Longer follow-up and additional subjects are needed to confirm these promising results. ATTAIN (NCT04827979) is a trial conducted by the Immune Tolerance Network and sponsored by NIAID (award UM1AI109565).

---

DONOR-DERIVED CELL-FREE DNA (DD-CfDNA) AS A NON-INVASIVE BIOMARKER OF KIDNEY ALLOGRAFT REJECTION IN PEDIATRIC KIDNEY TRANSPLANTATION

Julien Hogan¹, Roshan George², Pamela Winterberg², Carissa Hayes³, Chris Fan³, Margret Kamel² and Rouba Garro²

¹Robert Debré Hospital, APHP, Pediatric Nephrology department, Paris, France and ²Emory University School of Medicine, Pediatric Nephrology department, Atlanta, United States of America

Background and Aims: Rejection remains the first cause of allograft loss in pediatric kidney transplant (pKTx) recipients. Detection of rejection currently relies on KTx biopsies performed either because of allograft dysfunction with the risk of late diagnosis or per surveillance protocols allowing early detection of subclinical rejection but resulting in many unnecessary biopsies. Dd-cfDNA was reported as a new non-invasive biomarker with the potential to improve rejection detection and guide biopsy indications. We aim to assess the association of dd-cfDNA levels with biopsy results in a large cohort of pediatric KTx recipients.

Method: All pediatric KTx patients with at least one dd-cfDNA assessment at the time of a biopsy at a single pediatric transplant center were included. Clinical, biological and histological data were collected from medical reports. Dd-cfDNA were retrospectively measured from plasma samples biobanked at the time of allograft biopsy between 2015 and 2020 or collected in patients who received regular dd-cfDNA testing as part as clinical care between 2021 and 2022.

Results: 170 cfDNA measurements in 132 pKTx recipients were available at the time of a biopsy, including 100 performed for surveillance. Mean age at biopsy was 16 years with a median time from KTx of 21 [11;38] months. Median eGFR was 62 [48;83] mL/min/1.73 m², median UPCR 0.21 [0.14;0.36] g/g, and 20% had DSA at the time of the biopsy. Biopsy findings included: 109 normal, 30 borderline, 15 TCMR, 11 AMR and 5 mixed rejections. Median cfDNA level was 0.64 [0.31;1.80] %. We found a strong association between cfDNA levels and active tubule-interstitial and microvascular Banff lesions (Figure 1). cfDNA levels were significantly increased in cases with rejection (Figure 2).

Using the proposed cut-off of 0.5%, performances of the test to detect rejection were Se 84%, Spe 51%, PPV 33%, NPV 92%. Among the borderline cases, 17 (57%) had cfDNA >0.5%.

Conclusion: We confirm in the largest pediatric KTx cohort to date, the association of dd-cfDNA levels with allograft rejection and its potential interest as a non-invasive biomarker in children. Further studies are needed to assess the added value of dd-cfDNA monitoring to the current standard of care and its ability to reduce unnecessary surveillance biopsies and improve outcomes.

Figure 1: Association between dd-cfDNA levels and active tubule-interstitial and microvascular Banff lesions.
Background and Aims: Antibody induction therapy is frequently used as an adjunct to the maintenance immunosuppression in adult kidney transplant recipients (KTRs). There are few comparisons of antibody induction therapy allowing early glucocorticoid withdrawal in KTRs. The purpose of the present study was to compare induction therapy involving tocilizumab with the most commonly used induction regimens in patient populations at either high immunologic risk or low immunologic risk.

Method: In this prospective study, we randomly assigned patients to receive tocilizumab or conventional induction therapy such as basiliximab. Patients were stratified according to acute rejection risk, with a high risk defined by a repeat transplant, a peak or current value of panel-reactive antibodies of 30% or more. The 102 high-risk patients received tocilizumab (one dose of 8 mg/kg, in 52 patients) or basiliximab (a total of 40 mg over 4 days, in 50 patients). The 113 low-risk patients received tocilizumab (one dose of 8 mg/kg, in 62 patients) or basiliximab (a total of 40 mg over 4 days, in 51 patients). All patients received tacrolimus and mycophenolate mofetil and underwent a 10-days glucocorticoid (prednisone) taper in a regimen of early steroid withdrawal. The primary endpoint was biopsy-confirmed acute rejection at 6 months and 12 months. Patients were followed for 2 years for safety and efficacy endpoints.

Results: The rate of biopsy-confirmed acute rejection was significantly lower in the tocilizumab group than in the basiliximab group at both 6 months (5.3% vs. 10.9%, P<0.01) and 12 months (7.9% vs. 12.9%, P<0.01). At 2 years, the rate of biopsy-confirmed acute rejection in low-risk patients was lower with tocilizumab than with basiliximab (9.7% vs. 17.7%, P<0.05), but among high-risk patients, no significant difference was seen between tocilizumab and basiliximab (19.2% vs. 16.0%, P = 0.68). Adverse-event rates were similar among all four treatment groups.

Conclusion: By the first year after transplantation, biopsy-confirmed acute rejection was less frequent with tocilizumab than with conventional therapy. The apparent superiority of tocilizumab with respect to early biopsy-confirmed acute rejection was restricted to patients at low risk for transplant rejection; among high-risk patients, tocilizumab and basiliximab had similar efficacy. Further randomized and controlled studies are needed to support these results.
Circulating nephrin autoantibodies could be a possible candidate for CF in the specimens were observed in all 14 patients with post-transplant recurrent punctate deposition of IgG colocalized with nephrin in grafted kidney biopsy

**Conclusion:** The autoantibodies to nephrin in plasma samples and the deposition of IgG colocalized with nephrin in all 14 recurrent patients. The IF staining of graft biopsy specimens showed punctate

**HEPATITIS B VIRUS REACTIVATION IN KIDNEY TRANSPLANT RECIPIENTS TREATED WITH BELATACEPT**

Chloe Schwarz1, Antoine Morel2, Marie Matignon3, Philippe Grimmel3, Eric Rondeau4, Nacer Ouali5, Helene Francois4, Laurent Mesnard4, Camille Petit-Hoang4, Cédric Rafat4, Karine Dahan4 and Yusou Luque4

1Tenon Hospital, Paris, France, 2Henri-Mondor University Hospital, Créteil, France and 3Sorbonne Université, Paris, France

**Background and Aims:** Hepatitis B virus (HBV) reactivation in kidney transplant recipients may be associated with liver failure and graft loss, especially in anti-HBc antibody (HBcAb)-positive HBs antigen (HBsAg)-negative patients. Belatacept, a selective costimulation blocker, has been used in kidney transplantation for some time and has been associated with reactivation of other viruses as BK or CMV. However, there are few data on HBV reactivation among kidney recipients treated with belatacept.

**Method:** We performed a retrospective study in two French kidney transplantation centres including all transplant recipients receiving belatacept. Among HBcAb-positive patients, we analyzed HBV reactivation rate, outcomes and risks factors.

**Results:** 135 patients treated with belatacept were included, and 32 were HBcAb-positive. Seven patients reactivated HBV (21.9% of HBcAb-positive patients), including 5 HBsAg-negative patients (16.7%); reactivation occurred 54.8 (±70.9) months after transplantation. There was no significant difference in survival between patients that reactivated HBV and patients that did not: 5-year patient survival of 100% (28.6; 100) and 83.4% (67.6; 100), respectively (p = 0.363) and 5-year graft survival of 100% (28.6; 100) and 79.8% (61.7; 100), respectively (p = 0.335). No factor, including HBsAb positivity and antiviral prophylaxis, was statistically associated with the risk of HBV reactivation.

**Conclusion:** Compared to the few studies that exist in this area, the HBV reactivation rate was high in patients treated with belatacept in our study. Our findings suggest that systematic antiviral prophylaxis for anti-HBc antibody (HBcAb)-positive HBs antigen (HBsAg)-negative patients should be considered and that there should be close monitoring of HBV serology and viral load in these patients to detect early HBV reactivation.

**Background and Aims:** Diabetic nephropathy (DN), which is one of the most common systemic microvascular complications of diabetes mellitus, is extremely harmful to the patients' health. There were some studies had shown that the disturbance of lipid metabolism was connected with the progression of DN. Therefore, the purpose of our study was to find the lipid metabolism-related hub genes in DN and provide a better reference for the diagnosis of DN.

**Method:** The Gene Expression Omnibus (GEO) database was used to download the gene expression profile data of DN and healthy samples (GSE142153), and we obtained the lipid metabolism-related genes from the Molecular Signatures Database (MSigDB). Differentially expressed genes (DEGs) between DN and healthy samples were analyzed and the weighted gene co-expression network analysis (WGCNA) was performed to examine the connection between genes and clinical traits and screen the key module genes in DN. Next, we utilized the Venn Diagram R package to identify the lipid metabolism-related genes in DN, and the Protein-Protein Interaction (PPI) of these genes was constructed. Then we carried out the Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses. Moreover, the hub genes were identified using two machine learning algorithms, and the Gene Set Enrichment Analysis (GSEA) was used to analyze the functions of the hub genes. Furthermore, the immune infiltration discrepancies between DN and healthy samples and the correlation between the immune cells and hub genes were estimated. Finally, quantitative reverse transcription-PCR (qRT-PCR) experiment verified the expression of key genes.

**Results:** A total of 1445 DEGs were found in DN samples compared to healthy samples, and 694 DN-related genes in yellow and turquoise modules were identified by WGCNA. Next, we used the Venn Diagram R package to further identify 17 genes that were related to lipid metabolism and constructed a PPI network. Then GO analysis revealed that these 17 genes were significantly correlated with 'phospholipid biosynthetic process' and 'cholesterol biosynthetic process', while the KEGG analysis showed these lipid metabolism-related genes were enriched in 'glycerophospholipid metabolism' and 'fatty acid degradation'. Moreover, SAMD8 and CYP51A1 were identified through the intersections of two machine learning algorithms. The results of GSEA analysis revealed that the 'mitochondrial matrix' and 'GTPase activity' were the significantly enriched GO terms in SAMD8 and CYP51A1, and the KEGG pathways of them were mainly concentrated in 'pathways of neurodegeneration - multiple sclerosis'. Immune infiltration analysis suggested that there were 9 immune cells expressed differently in DN and healthy samples, and both SAMD8 and CYP51A1 were significantly correlated with activated B cell and effector memory CD8 T cell. Finally, qRT-PCR confirmed the expression of SAMD8 and CYP51A1 in DN was high.

**Conclusion:** In summary, the lipid metabolism-related genes SAMD8 and CYP51A1 may play key roles in DN.

EXPLORATION OF PROGNOSTIC FACTORS IN DIABETIC NEPHROPATHY WITH NODULAR LESION USING TRANSCRIPTOME ANALYSIS OF HUMAN KIDNEY TISSUES

Toshiyuki Imasawa¹, Hiroyuki Unoki-Kubota², Daishi Hirano³, Hiroshi Kitamura⁴ and Yasushi Kaburagi⁵

¹National Hospital Organization Chiba-Higashi National Hospital, Department of Nephrology, Chiba, Japan, ²Research Institute, National Center for Global Health and Medicine, Department of Diabetic Complications, Diabetes Research Center, Tokyo, Japan, ³The Jikei University School of Medicine, Department of Pediatrics, Tokyo, Japan and ⁴National Hospital Organization Chiba-Higashi National Hospital, Department of Pathology, Chiba, Japan

Background and Aims: Although the speed of eGFR decline is usually rapid in patients with diabetic nephropathy (DMN) and a nodular lesion (NL), some patients with NL experience a slow eGFR decline. The factors associated with the difference in prognosis remain unknown. In this study, we aimed to explore prognostic factors by performing transcriptome analysis on preserved residual renal biopsy specimens from patients with pathologically diagnosed and prognostically known DMN with nodules.

Method: Patients who had an annual eGFR drop rate > 5 mL/min/1.73 m² were defined as rapid decliners (RD) and the others as slow decliners (SD). Twelve patients (RD = 6 and SD = 6) who underwent kidney biopsy, had no other renal comorbidities, and had been followed up for at least one year were included. Total RNA was isolated from renal biopsy tissues in formalin-fixed, paraffin-embedded blocks, and microarray analysis was done.

Results: At the time of renal biopsy, the eGFR, urine protein, and rate of sclerotic glomeruli were not statistically different between the RD and SD groups, at 49.7±10.1 mL/min/1.73 m² and 57.5±12.4 mL/min/1.73 m² (p = 0.258), 7.5±4.2 g/gCre and 4.0±2.7 g/gCre (p = 0.123), and 19.2±13.4% and 25.5±14.4% (p = 0.450), respectively. In microarray analyses (total 58,341 gene probes), genes with little expression (raw signals <50) and with little differences between RD and SD (processed signals <0.3) were excluded, leaving 14,227 genes for further analysis. A total of 1,496 differentially expressed genes (DEGs) were selected with p-values <0.05 and fold change ≥2 between the RD and SD group for further bioinformatic analysis. Using the Ingenuity Pathway Analysis system, 15 canonical pathways and 9 diseases or functions annotations were found to be enriched. In addition, upstream regulator analysis identified 73 upstream regulators. Among them, only two regulators, CBX5 and CCN5, showed p <0.05 and absolute z-score > 2 as activated and inhibited regulators, respectively, in the RD group. We next performed regulator effects analysis, indicating one regulator network which identified the key upstream regulator CCN5. The regulator network also showed a small number of genes involved in the viral infection, which included CDH1, CD24, and ESR1. Additionally, IPA showed 25 interaction networks ranging from 11 to 38. The fifth-ranked network was associated with Cancer, Organismal Injury, and Abnormalities (score = 32), in which CD24 and ESR1 were included. We, therefore, performed qRT-PCR to compare the expression levels of CDH1, CD24, and ESR1 in the RD group with those in the SD group.

The expression levels of CD24 and ESR1 in the RD group were downregulated compared with those in the SD group (p = 0.004 and p = 0.022, respectively) although there was little difference in the level of CDH1 between them (p = 0.638).

Conclusion: Transcriptomic analysis using renal biopsied tissue revealed that ESR1 and CD24 might be candidates for renoprotective factors in DMN with NL.

AMINOPEPTIDASE A REGULATES ACUTE ANGIOTENSIN DEPENDENT HYPERTENSION

Peter Forster¹², Yasemin Abedini¹, Tilman Müller¹, Minghao Ye¹, Jan Wysocki¹ and Daniel Battle¹

¹Northwestern University Feinberg School of Medicine, Department of Nephrology and Hypertension, Chicago, United States of America and ²Charité – Universitätsmedizin Berlin, Berlin, Germany

Background and Aims: Aminopeptidase A (APA) is an enzyme that cleaves a single aspartate residue from the amino-terminus of several renin-angiotensin systems (RAS) peptides. We have shown that genetic deficiency of APA was associated with increased blood pressure and ultrastructural glomerular pathology in mice. Here we studied the effect of this Aminopeptidase on different peptides of the RAS and its effect on acute hypertension.

Method: We developed an in vitro assay based on Aspartate formation by APA to detect which Angiotensin (Ang) peptides are the substrate of this enzyme. The identified Ang peptides were injected to determine their relative effects on systolic blood pressure (SBP) in anesthetized WT mice. The effect of recombinant Aminopeptidase A on Ang I, Ang II and Ang 1-12 mediated SBP increase was further assessed in APA deficiency using global knockout mice (KO), and after systemic injection of recombinant APA.

Results: In the in vitro assay, the rAPA showed significant cleavage activities for Ang II (22427±3353, n = 12), Ang I (21883±1692, n = 3). Ang I-7 (15833±3395, n = 3), Ang-9 (15773±3395, n = 3) and Ang-1-12 (13170±220, n = 3) as evidenced by the formation of aspartate measured as a readout of enzymatic cleavage. When the five angiotensin peptides were injected into WT mice, only Ang I, Ang II and Ang 1-12 caused a substantial increase in SBP (Figure 1, left). In APA KO mice the bolus administration of Ang II showed an exaggerated increase in SBP compared to WT mice (Figure 1, right). The effect of Ang I and Ang 1-12 in APA KO appeared similar (not shown). When Ang I, Ang II and Ang 1-12 were administrated in WT mice preinjected with APA the increase in SBP was markedly reduced (p<0.001, p = 0.0024 and p = 0.0063, respectively).

Conclusion: Aminopeptidase A can cleave the N-terminal aspartate from Ang II as well as from other RAS peptides upstream [Ang 1-12, Ang I (1-10) and Ang I-9] and downstream of Ang II (Ang 1-7). Aminopeptidase A deficiency is associated with exaggerated SBP response to Ang I, Ang II and Ang 1-12 whereas the recombinant enzyme restores the effect on acute hypertension caused by infusion of these peptides. This suggests that APA could be used to treat hypertension due to RAS overactivity.
URINARY OROSOMUCOID IS ASSOCIATED WITH ALL-CAUSE MORTALITY IN THE GENERAL POPULATION
Runa Marie Andreassen1,2, Karl Marius Brobak2,3, Toralf Melsom2,3, Bjørn Odvar Eriksen2,3 and Marit Dahl Solbu2,3
1Helgelandssykehuset Sandnessjøen, Norway, Internal medicine, Sandnessjøen, Norway, 2UT The Arctic University of Norway, Metabolic and Renal Research Group, Tromsø, Norway and 3University Hospital of North Norway HF, Section of Nephrology, Tromsø, Norway

Background and Aims: Urinary albumin excretion (UAE) is considered a risk factor for cardiovascular (CV) disease and all-cause mortality, but the pathophysiological mechanisms are not known, and studies are not consistent with regards to the effect of pharmacological UAE reduction on endpoints. Another protein, orosomucoid (41-43kDa), is a non-specific acute inflammatory protein and is a part of the glycolax that covers the endothelium. Under normal conditions the concentration in urine is low, but a marked increase is demonstrated under both acute and chronic inflammation and in cardiovascular disease. In patients with diabetes urinary orosomucoid excretion (UOE), was an independent predictor of all-cause and cardiovascular mortality even in normoalbuminuric patients. In this longitudinal study, our aim was to study both UAE and UOE in a middle-aged cohort from the general population. We hypothesized that UOE, but not UAE, is an independent predictor for all-cause mortality.

Method: The Tromsø Study is a population-based, prospective study with repeated health surveys of inhabitants of Tromsø (Northern Norway), and the first took place in 1974. From the sixth wave (Tromsø6, 2007/2008) we included all participants with urinary samples. Follow-up time was assigned from the attendance date of Tromsø6 until 31.08.2022. The associations between urinary markers and all-cause mortality were assessed by Cox regression analysis.

Results: The cohort included 7180 subjects (4094 women and 3086 men) with a mean (SD) age 63.5 (±9.2) years. Median urinary orosomucoid to creatinine ratio (UOCR) was 0.44 g/g, median albumin to creatinine ratio (UACR) was 0.36 mg/mmol, mean (SD) eGFR was 88.1 (±14.0) ml/min/1.73m² and 1689 died during follow-up. UOCR was independently associated with all-cause mortality (hazard ratio (HR) per g/g increase 1.02, 95% CI 1.01, 1.03, p < 0.001) adjusted for sex, age, UAE, eGFR and CV risk factors (diabetes, hypertension, smoke, cholesterol, BMI). The HR for UOCR above vs. below median adjusted for the same variables was 1.13 (95% CI 1.01, 1.27, p = 0.032). UACR above median with the same adjustments was not associated to all-cause mortality (hazard ratio 1.04, 95% CI 0.93, 1.15, p = 0.484).

Conclusion: In this study, we showed for the first time that UOE, but not UAE, was an independent predictor of all-cause mortality in a large cohort from the general population. Thus, UOE may be an earlier marker of vascular damage
than UAE. Whether UOE is clinically useful as an early marker of CV disease should be further studied.

EFFICACY AND SAFETY OF COTADUTIDE, A DUAL GLP1-GLUCAGON RECEPTOR AGONIST, IN PATIENTS WITH CHRONIC KIDNEY DISEASE AND T2DM

Yi-Ting Chang2 and Victoria Parker 1

≥

2AstraZeneca, Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, Cambridge, United Kingdom, 1AstraZeneca, Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, Gaithersburg, United States of America and 3AstraZeneca, Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, Mölndal, Sweden

Background and Aims: Cotadutide is a dual GLP1-glucagon receptor agonist under development for NASH and CKD with T2DM. Incretin-based therapies have been shown to promote improvements in albuminuria while the addition of glucagon has been suggested to provide hepatic benefits; the renal benefits of dual GLP1-glucagon receptor agonism are unknown but kidney and liver are the organs with highest expression of glucagon receptor. We sought to evaluate the efficacy and safety of cotadutide in patients with CKD and T2DM.

Method: In this randomised, double-blind, phase 2b study, patients with T2DM and CKD on insulin and/or oral therapy including ≥40% treated with SGLT-2i (HbA1c ≥ 6.5 and < 10.5%), eGFR ≥ 20 and < 90 ml/min/1.73m² and BMI ≥ 25 (23 in Japan) kg/m² were treated for 26 weeks. Participants were randomised (n = 45 per arm) to receive once-daily SC cotadutide titrated up to 100, 300 or 600 μg, or placebo. The primary endpoint was percentage change in albumin creatinine ratio (UACR) at 26 weeks. Safety and tolerability. Changes in renal function was evaluated as an exploratory endpoint.

Results: A total of 248 Participants were randomised. Approximately 47% were on SGLT-2i and 97% were on ACE inhibitors or ARBs at baseline. The primary endpoint was met. Dose dependent reductions in UACR from baseline were observed after 26 weeks treatment with 300 and 600 μg of cotadutide, -39.9% (95 CI -52.5, -23.9) and -46.0% (95% CI -57.1, -32.1) vs placebo (P <0.001). In patients on background SGLT2i therapy, similar reductions in UACR from baseline were observed after 26 weeks treatment with 300 and 600 μg of cotadutide, -31.2% (95% CI -51.9, -1.5) and -48.7% (95% CI -64.1, -26.6) vs placebo (P = 0.01 and <0.001 respectively). There was no observed change in eGFR early in dosing. At 26 weeks, an increase in eGFR (+5.5 ml/min/1.73m²) was observed with 600 μg of cotadutide (p = 0.028). A statistically significant, modest reduction in serum uric acid was observed as an exploratory endpoint at 26 weeks in the 100 and 600 μg arms (-0.54 mg/dL, p = 0.03 and 0.76 mg/dL, p = 0.001 respectively) but not the 300 μg arm (-0.32 mg/dL, p = 0.17). No significant changes in urine KIM-1 were observed. A significant increase in pulse rate was observed (+4.8 bpm), alongside a numerical reduction in systolic BP (-8.3 mmHg) at 600 μg on office-based measures. SAEs were balanced across all arms and there were fewer AE-related discontinuations at 100 and 300 μg versus placebo, but more discontinuations at 600 μg.

Conclusion: In patients with CKD with T2DM, cotadutide promoted clinically important effects on UACR on top of standard of care with an acceptable tolerability profile. The results suggest cotadutide has potential to provide benefit to patients with CKD and T2DM. Larger studies will be required to evaluate this.

IS GFR DECLINE INDUCED BY SGLT-2 INHIBITOR OF CLINICAL IMPORTANCE?

Merve Guenes-Alta1, Agnes Bosch1, Kristina Striepe1, Mario Schiffer1, Peter Bramlage2, Roland E. Schmieder 1 and Dennis Kannenkeril1

1University Hospital Erlangen, Department of Nephrology and Hypertension, Erlangen, Germany and 2Institute for Pharmacology and Preventive Medicine, Cloppenburg, Germany

Background and Aims: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) are associated with better cardiovascular outcome and with nephroprotection independent of diabetes status. However, the use of SGLT2i often cause an initial decline in estimated glomerular filtration rate (eGFR). This study addresses the question whether there is a relationship between vascular improvement and GFR dipping.

Method: We measured GFR (mGFR) and calculated GFR (eGFR) in 65 patients with T2D at baseline and after 12 weeks of treatment with either a combination of Empagliflozin (E) + Linaagliptin (L) (n = 34) or Metformin (M) + Insulin (I) (n = 31). mGFR was measured using the gold standard clearance technique by infusion of inulin. In addition, pulse wave velocity (PWV) was obtained at office and under ambulatory conditions. We splitted the study cohort according to the median change of mGFR after 12 weeks and compared the baseline characteristics.

Results: mGFR and eGFR decreased significantly with E-L and with M+I (Ott C et al. Cardiavasc Diabetol. 2021). However, no correlation was noticed between the change of mGFR and change of eGFR for either treatment cohorts (E-L: p = 0.404; M+I: p = 0.460). We found a significant decrease in office PWV in the E-L group only (8.2±1.6 to 7.8±1.5, p = 0.028) without any change in 24-h PWV. The change of office PWV correlated with the change of mGFR (p = 0.009) in E-L group only and remained significant after adjustment for the change of office systolic BP (p = 0.018). In addition, we observed a correlation between the change of high sensitive C reactive protein (hsCRP) and change in mGFR (p = 0.031). We identified patients with higher albumin excretion (p = 0.044), higher fasting plasma glucose (p = 0.014) and high hsCRP (p = 0.057) to have a greater decline in mGFR with E-L.

Conclusion: First, eGFR may not be an appropriate parameter to assess the true change in renal function after receiving E-L in a single patient. Second, after E-L medication a high decrease in mGFR goes in parallel with vascular improvement and less inflammation thereby reflecting the pleiotropic pharmacologic effects of SGLT 2 inhibitors.
Background and Aims: Immunosenescence, or aging process of the immune system, leads to either defective immune response or increased systemic inflammation. Previous studies have shown that kidney immune system may coordinate the process of kidney inflammation, resolution, or progressive fibrosis in kidney diseases. However, the exact role of individual immune cell type has not been systematically characterized, especially in the context of ageing kidneys.

Method: Firstly, we induced acute and chronic aristolochic acid nephropathy (AAN) in 15-month-old mice. At different stages of AAN (Steady state, acute inflammation, recovery from acute injury, and chronic fibrosis), mice were then sacrificed, and kidneys were harvested for further processing. We flow-sorted kidney CD45+ immune cells (live cells) and applied to 10 x Genomics platform for single cell isolation and cDNA library construction. Illumina NovaSeq 6000 system was used for RNA sequencing. Finally, we performed downstream bioinformatics analysis through CellRanger and Seurat pipelines.

Results: Utilizing AAN mouse model, we successfully conducted flow sorted kidney immune cells single-cell RNA sequencing (scRNAseq) from 15 M/O kidneys with AKI and CKD. We clearly identified 25 distinctive immune cell types, representing distinctive lymphoid and myeloid populations (Figure 1a). We showed dynamic change of immune cell compositions upon different phases of AAN (i.e., CCR2+ monocytes and proliferative macrophages increased during acute inflammation, activated T cells expanded during recovery phase, CD206+CCL8+ macrophages enriched within the fibrotic kidneys) (Figure 1b). By analysis of differentially expressed genes (DEG), we identified 30 top-ranked genes, which uniquely enriched in specific cell subset (Figure 1c).

Conclusion: We have successfully unveiled the immune cell landscape in ageing kidneys with AKI and CKD. Our preliminary data has demonstrated that distinct immune cell subsets at different phases of injury may have unique roles. Future work will focus on the cell-cell interactions and immune cell activation/differentiation.
Figure 1: (1a) UMAP plot of 25 kidney immune cell clusters were performed. Total 45,005 cells were analyzed using 10x CellRanger and Seurat pipelines. (1b) UMAP plot of 25 kidney immune cell clusters, split into “steady state”, “acute inflammation”, “recovery”, and “fibrosis”. Notably, we found that CCR2+ monocytes and proliferative macrophages increased during acute inflammation, activated T cells expanded during recovery phase, and CD206+CCL8+ macrophages enriched within the fibrotic kidneys. (1c) Dot plot showing top 30 differentially expressed genes, enriched in specific kidney immune cell types. Data were analyzed by Seurat package.
RECOMBINANT HIGH-DENSITY LIPOPROTEIN MODULATES INFLAMMATORY RESPONSE AND RENAL DYSFUNCTION IN A SWINE MODEL OF SEPSIS-INDUCED ACUTE KIDNEY INJURY

Alessandra Stasi1, Rossana Franzin1, Marco Fiorentino1, Francesco Staffieri2, Rosa Losapio1, Maria Teresa Cimiraglui1, Alberto Crovace2, Luca Lacitignola3, Francesco Murgolo4, Giuseppe Castellano4, Fabio Sallustio1, Salvatore Grasso1, Paola Pontrelli1, Antonio Crovace2 and Loreto Gesualdo1

Background and Aims: Sepsis is a severe and dysregulated inflammatory disease that often precedes the development of acute kidney injury (AKI) with consequent worsening outcome. Although clinical data demonstrate that high-density lipoprotein (HDL) levels drop in septic patients with a poor prognosis, little is known about the molecular basis of HDL’s role in systemic inflammation and renal function. Here we investigate the possible effects of a novel engineered HDL-mimetic (CER-001) in a swine model of lipopolysaccharide (LPS)-induced AKI.

Method: Sepsis was induced by intravenous infusion of a saline solution containing 300 μg/kg of LPS in a porcine model. The animals were randomized into three groups: LPS (endotoxemic pigs, n=6), CER20 (endotoxemic pigs treated with a single dose of CER-001 20mg/kg; n=6), and CER20 × 2 (endotoxemic pigs treated with two doses of CER001 20mg/kg; n=6). Animals were sacrificed after 24h from the start of experimental procedure. Renal histologic and biochemical changes were analyzed. Endothelial dysfunction biomarkers, circulating pro-inflammatory mediators, LPS and Apolipoprotein A-I (Apo A-I) levels were quantified with ELISA assay. Systemic complement activation was evaluated by Wieslab kit.

Results: Untreated animals were highly susceptible to LPS challenge and usually succumbed before completing the study protocol (LPS group 16.7%). CER-001 treatment increased the survival rate of endotoxemic pigs, compared to the LPS group (CER20, 50%; CER20 × 2, 66.7%). Furthermore, as shown in Figure 1A, LPS injection led to a time-dependent increase of IL-6 in endotoxemic animals respect to basal condition (T0). CER-001 treatment was able to reverse LPS effects. In particular, the second infusion of CER-001 three hours after the first dose (T3) strongly reduced IL-6 serum levels back to basal level (LPS p < 0.05). Similarly, we found high levels of TNF-α and MCP-1 in endotoxemic pigs that were significantly decreased in both CER-001 treatment arms (T24, CER20 × 2 vs LPS group, IL-6, p = 0.0086; TNF-α, p < 0.0001; MCP-1, p = 0.0009). In addition, CER-001 treatment ameliorated systemic endothelial dysfunction by reducing VCAM and ICAM serum levels. A significant activation of classical and alternative complement pathway (vs T0 p < 0.05) was observed at 1h, 3h and 24h after LPS infusion. CER001 treatment significantly prevented systemic complement activation in both treated groups (vs LPS p < 0.05). We also investigated whether CER001 infusions significantly prevented renal tissue damage. Endotoxemic pigs presented oliguric AKI with increased tubulo-interstitial infiltrate, extensive collagen deposition, and glomerular thrombi; CER-001 treatment preserved renal parenchyma, recovered urine output, decreased creatine levels, and reduced the biomarkers of tubular damage, Cystatin C and KIM-1, both in serum and urine samples. Considering that HDL has a very high affinity for LPS, we evaluated the circulating LPS concentration in treated animals. We observed that LPS levels were greatly reduced in treated animals and the effects are more evident after the second infusion of CER-001(Figure 1B). Therefore, we also examined LPS levels in bile samples and we observed a dose-dependent increasing amount of endotoxin in the CER001 treated septic pigs.

Conclusion: This preclinical data indicates that CER001 treatment prevents systemic inflammation thereby limiting renal damage. The mechanism of action is two-fold consisting of both the scavenging of endotoxin and a direct anti-inflammatory effect of CER-001.

**SHORT-CHAIN FATTY ACIDS, PROPIONATE AND BUTYRATE, RESEMBLE THE BENEFICIAL EFFECTS OF VITAMIN D DURING ACUTE KIDNEY DAMAGE**

Viviana Corte-Iglesias1,2, Maria Laura Saiz1,2, Cristian Ruiz Bernet1, Paula Diaz-Bulnes1, Aida Bernardo Florez1, Cristina Martín Martin1,2, Carlos Lopez-Larrea1,2 and Beatriz Suarez-Alvarez1,2

1Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Laboratorio de Inmunología Traslacional, Oviedo, Spain and 2Instituto de Salud Carlos III, Madrid, Spain, Red de Investigación Renal (RICORS2040), Spain

**Background and Aims:** The vitamin D receptor (VDR) is a nuclear receptor that acts as a ligand-induced transcription factor regulating the renal expression of numerous genes with anti-inflammatory and anti-fibrotic effects, among others. For that, VDR requires the binding of its ligand, 1,25(OH)2D3, to further heterodimerize with its co-activator, RXR, and translocate into the nucleus. Vitamin D deficiency in patients with renal disease leads to a decrease in VDR-mediated signaling and, consequently, of its beneficial functions. Additionally, these patients have intestinal dysbiosis, which leads to alterations in the production of microbial metabolites. Short-chain fatty acids (SCFAs) are metabolites with a clear anti-inflammatory and immunoregulatory role. Until now, some studies have studied their role as regulators of the inflammation and oxidative stress during the renal damage.1,2 However, their role in the VDR-mediated signaling in the kidney and the potential consequences to prevent the progression of the disease have not yet been explored in detail.

**Method:** The tubular epithelial cell line, HK2, was used to analyze the effect of the SCFAs, Propionate (Prop, 1-15mM) and Butyrate (But, 0.5-3 mM), in the VDR expression and their target-genes. In vitro treatment with histone deacetylases (HDACs) inhibitors and specific HDAC1 and HDAC3 siRNAs were used to determine the role of both SCFAs as epigenetic remodelers. The binding of VDR to HDAC1/3 and RXR was determined by ChIP and co-immunoprecipitation assays. The in vivo effect of these SCFAs was evaluated in an acute kidney injury mice model induced by folic acid (250 mg/kg) and administration of Prop (200mg/kg) or But (500mg/kg) at different time points. The expression of VDR and its target genes, inflammatory cell infiltration, renal damage markers and renal function parameters were evaluated at shorter (24h) and longer times (40 days).

**Results:** Treatment of tubular cells with Prop and But induces, in a dose-dependent manner, the VDR gene transcription. This effect is similar to the one obtained by using specific inhibitors and siRNA treatments against HDAC1/3. We determine using ChIP assay, that HDAC1/3 are recruited to the promoter regions of the VDR gene, blocking its expression. In presence of Prop and But, these HDACs are displaced, increasing the acetylation levels and VDR transcription. Moreover, Prop and But prevent the degradation of VDR by the proteasome, increasing its stability and enhancing VDR protein levels. In the presence of both SCFAs, VDR dimerizes with RXR initiating its translocation to the nucleus and allowing the transcription of its dependent genes, such as Cyp24a1 and E-cadherin. Of note, VDR activation by Prop and But is additive to the effect achieved by the vitamin D alone. In vivo studies reported that administration of Prop or But prevents the loss of VDR expression 24h after induction of the damage, leading to its activation and to the expression of its target genes. Additionally, a decrease in the recruitment of neutrophils to the kidney was observed associated to a reduced expression of IL-6. These changes are accompanied by a decrease of the kidney damage markers (KIM-1 and NGAL) and a significant reduction of the creatinine and blood urea nitrogen serum levels. In a second model of AKI-to CKD transition, administration of both SCFAs shows a decrease in the inflammatory (Cd20, Cd12, Lifi, Lth, C52SF2, Ifn, C515, Tief-a) and pro-fibrotic markers (Fip1, a-Sma, Coll1a1, Fn1) and a partial recovery of the glomerular filtration rate at long term.

**Conclusion:** Propionate and Butyrate, not only induce the VDR gene transcription in renal tubular cells but are also able to stabilize and activate the VDR protein. Accordingly, both metabolites are able to restore the loosened expression and activation of VDR due to induced renal damage, reduce the infiltration of immune cells, and partially recover the renal function. Thus, strategies aimed to increase the propionate and butyrate levels with postbiotics could be useful to ameliorate the AKI renal damage and CKD transition.

CYCLIN D1 AMELIORATES ACUTE KIDNEY INJURY BY IMPROVING FATTY ACID OXIDATION VIA AMPK PATHWAY
Yuliang Huang, Junzhe Chen, Xiaofei Shao, Jinxiang Li and Ying Tang
The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, China, P.R. China.

Background and Aims: Acute Kidney Injury (AKI) is a critical condition that is caused by the absence of oxygen during the acute ischemic phase, leading to energy metabolism disturbance and kidney tubular epithelial cell damage. Fatty Acid Oxidation (FAO) is the main source of energy production of renal proximal tubular epithelial cells. Timely promoting FAO, increasing supplies of energy, and promoting cell proliferation are essential to improve kidney injury. However, there is no clinically recognized effective treatment for this. Cyclin D1 (CCND1), a member of the cell cycle family, plays a vital role in cell proliferation. Our previous study showed that CCND1 improved AKI by increasing FAO. This study aimed to investigate the role and molecular basis of CCND1 involvement in fatty acid oxidation of AKI.

Method: CCND1 was evaluated in human kidney proximal tubular epithelial cells (HK-2 cells) and in male C57BL/6J mice (wild type). We investigated the protective role of CCND1 in AKI using a mouse model of ischemia-reperfusion injury, which was treated by transferring CCND1-expressing plasmids in male C57BL/6J mice (wild type) by ultrasound and microbubble-mediated delivery. Eight-week-old male C57BL/6J mice (wild type) were subjected to bilateral renal artery occlusion for 30min followed by 24h of reperfusion. We evaluated FAO, proliferation, and autophagy in vitro and in vivo. In addition, we evaluated the concentrations of blood urea nitrogen and creatinine, evaluated kidney ultrastructure and so on.

Results: In vivo studies showed that activation of CCND1 prevented AKI-induced lipid accumulation, kidney tubule injury and kidney function declined after ischemia-reperfusion injury. Compared to test control, the treatment significantly (p < 0.05) reduced the concentrations of blood urea nitrogen and creatinine. Kidney-specific overexpression of CCND1 increased FAO, promoted proliferation and reduced apoptosis. Mechanistically, CCND1 activated the AMPK pathway, which increased the expression of phosphorylation AMP activated protein kinase (p-AMPK) and upregulated FAO. On the other hand, inhibiting the expression of CCND1 worsened the impairment of FAO and disturbed energy metabolism.

Conclusion: CCND1 improved FAO and reduced lipid accumulation through the active AMPK pathway in kidney proximal tubular epithelial cells (PTECs). Hence, restoring of the expression of CCND1 may offer a novel therapeutic strategy for treating AKI.
MICROPLASTICS: FIRST EXTENDED PROTEOMIC ANALYSIS ON KIDNEY TUBULAR CELLS

Background and Aims: Several studies have shown the ubiquitous presence of microplastics (plastic fragments between 5 mm and 1 μm in diameter) and nanoparticles (<1 μm) in the environment and their toxicity. Furthermore, microplastics (MPs) absorb a lot of environmental pollutants, such as bisphenol A (BPA), and release them into tissues increasing their toxicity; this is the so-called “Trojan Horse” effect. Recent studies have also proved their presence in human blood and human tissues of healthy people, such as placenta and lung, and in cirrhotic liver. Most frequent biological effects of MPs are inflammation, oxidative stress and alteration of metabolic pathways. In this study proteomic analysis was performed to evaluate the toxicity of polyethylene (PE) and bisphenol-A (BPA) MPs on renal tubular cells (HK2) in vitro. This is the first extended proteomic study on human cells.

Method: HK-2 cultures were exposed for 5-24-48 hours to BPA, PE Microspheres (PE-MP) and MP combined with BPA. Then it was performed a proteomic analysis by mass spectrometry (MS). MS data were obtain by Orbitrap Fusion Tribrid mass spectrometer (ThermoScientific). Analysis of data were performed using unsupervised hierarchical clustering using multidimensional scaling, non-linear support vector machine (SVM) learning, and partial least squares discriminant analysis. In SVM learning, a fourfold cross-validation approach was applied to estimate the prediction and classification accuracy.

Results: The proteomic analysis showed a clear differentiation of the HK2 proteome based on conditioning and identified a “core” of proteins, significant at ANOVA and above the 95th percentile for “fold increase” and significant at T-test compared with controls, highly discriminatory between groups. Finally, among these, a final set of 6 proteins was selected to be validated for distinguishing features: Nephronectin, GDF15, Vasorin, IGFBP7, Midkine, Tissue factor-F3. Nephronectin is a structural membrane's protein involved in cellular adhesion. GDF15, tissue factor F3 and midkine are markers of stress conditions, including inflammation and oxidative stress. IGFBP7 is a biomarker of acute kidney damage. Vasorin is a transmembrane glycoprotein that protects against apoptosis and fibrosis.

Conclusion: MP and BPA significantly modify the protein expression in renal tubular cells. These findings highlight the urgent need for additional research into the toxic effects of plastic debris on human kidneys and the eventual link to kidney diseases.

2Germans Trias i Pujol Research Institute (IGTP), Badalona, Spain

GRAPHICAL ABSTRACT

Background and Aims: Acute kidney injury (AKI) is a common complication in the critically ill and non-critically ill patient. There is currently no specific treatment for patients who develop AKI, so early recognition may help prevent progression to more advanced stages and the need for kidney replacement therapies (KRT). Electronic Alert Systems (EAS) emerge as a useful tool in different clinical scenarios to alert the clinician to potentially harmful situations. One of the utilities of the EAS is the AKI scenario, in which the clinician can be alerted early to serum creatinine (SCr) changes in real time and thus establish early intervention protocols to avoid the poor outcomes described above. The aim of the present study is to analyze the incidence of AKI in a tertiary hospital using an EAS based on SCr changes (Electronic Creatinine Alert System -ECAS-).

Method: Retrospective study conducted in a tertiary referral hospital. All discharges of patients over 18 years of age, which were issued from 1 January 2019 to 31 December 2021, were analyzed. Exclusion criteria were: discharges from critical care units, patients admitted to the emergency room, patients with AKI criteria on admission, patients admitted to the nephrology department and patients with CKD G5 or on KRT. The ECAS was developed with the aim of alerting patients with an increase of ≥ 0.3mg/dL of SCr or an elevation of ≥ 1.5 times the baseline creatinine value, based on AKI SCr from the KDIGO guidelines. The aims of the present study were: 1. Number of hospitals discharges that activated the ECAS, as well as the severity of AKI; 2. Categorize the departments in which ECAS was common; and 3. Assessing length of hospital stay, survival and kidney recovery during admission defined as SCr less than 1.5 times baseline.

Results: A total of 69,002 discharges were analyzed over 3 years. Finally, 46,149 discharges were included in the analysis, of which 5,593 (13.5%) discharges activated the ECAS. The distribution by year in which the ECAS was activated was 1,788 (11.8%) of all discharges in 2019, 1,860 (12.4%) in 2020 and 1,945 (12.1%) in 2021. The median age was 75 years (65 – 83), 62% were male. The 5 departments with the highest number of ECAS activations were: Geriatric (14.2%), Cardiology (11.9%), General Surgery (9.9%), Infectious Diseases (9.2%) and Cardiac Surgery (7.6%). Baseline SCr was 1.12mg/dL (0.80-1.79), maximum SCr was 1.99mg/dL (1.40 - 3.19) and SCr at discharge was 1.39 (0.96 - 2.23). 69.7% of patients had AKI stage 1, 21.3% had AKI stage 2 and finally 9% had AKI stage 3. Length of hospital stay was significantly elevated in patients who activated the ECAS [6 days (3-11) vs. 13 (8 - 22); p: <0.001], the survival distributions for the ECAS activation were statistically different, X² (2) = 5.522, p: 0.019. Finally, kidney recovery at discharge was significantly lower in AKI.
2 (18.5%) and AKI 3 (8.5%) patients compared to AKI 1 patients (73%) (p: <0.001 for all).

Conclusion: The ECAS is a suitable electronic alert system that allows rapid identification of patients with AKI. The activation of ECAS is associated with poor outcomes. This study led to the adoption of a nephrology rapid response team for early detection of AKI before creatinine elevation using among others Point-of-care ultrasonography and acute kidney stress biomarkers.

ACCURACY OF PLATELET INDICES AS PREDICTOR OF IN-HOSPITAL MORTALITY IN PATIENTS WITH ACUTE KIDNEY INJURY REQUIRING RENAL REPLACEMENT THERAPY
Melvy June Balasa
Chong Hua Hospital, Internal Medicine, Cebu City, The Philippines

Background and Aims: Acute kidney injury (AKI) is a major medical complication associated with a markedly increased risk of death, particularly in patients admitted to the ICU where in-hospital mortality exceeds 50%. This study aimed to determine the accuracy of MPV, platelet count, and PDW as predictors of adverse outcomes in patients with AKI who received initiation renal replacement therapy (RRT).

Method: A retrospective cohort single-center study was done in a local private tertiary hospital in Cebu. Four hundred ninety-one patients with AKI who underwent RRT between January 2018 and December 2021 were enrolled. A retrieval of data on demographic and clinical parameters during the initiation of RRT was done. The impact of mortality-related factors were identified using univariate and multivariate logistic regression analysis. Determination of optimal cut-off values of platelet indices for in-hospital mortality was done.

Results: This study showed that the in-hospital mortality of patients was 58.45%, with a mean age of 68.6 ± 16.28 years among non-survivors. Among the platelet indices, platelet count and PDW were good predictors of in-hospital mortality in patients who received initiation renal replacement therapy. The optimal cut-off value of platelet count was 173 × 10^3/uL (sensitivity 56.45%, specificity 62.25%, PPV 67.78%, NPV 50.40%, AUC 0.604). The optimal cut-off value of PDW was 16.45% (sensitivity 50.87%, specificity 71.57%, PPV 71.57%, NPV 50.87%, AUC 0.611).

Conclusion: Platelet indices are feasible parameters that can be used as prognostic markers for mortality in patients with AKI requiring RRT. The in-hospital mortality of patients with AKI requiring initiation RRT is high (58.45%). Low platelet counts, high MPV values, and high PDW values are associated with poorer outcomes and higher mortality risk as compared to patients with normal indices.
ACUTE KIDNEY INJURY DURATION AND 20-YEAR RISK OF CHRONIC KIDNEY DISEASE AND CARDIOVASCULAR DISEASE: A POPULATION-BASED COHORT STUDY
Simon Kok Jensen1,2, Uffe Heide-Jørgensen1,8, Henrik Gammelager3, Henrik Birn1,8 and Christian Fynbo Christiansen1,8

1 Aarhus University, Department of Clinical Medicine, Aarhus N, Denmark, 2 Aarhus University Hospital, Department of Clinical Epidemiology, Aarhus N, Denmark, 3 Aarhus University Hospital, Department of Intensive Care Medicine, Aarhus N, Denmark, 4 Aarhus University Hospital, Department of Renal Medicine, Aarhus N, Denmark and 5 Aarhus University Hospital, Department of Renal Medicine, Aarhus N, Denmark

Background and Aims: Acute kidney injury (AKI) is associated with increased risks of chronic kidney disease (CKD) and cardiovascular disease (CVD). The duration of AKI may be an important clinical marker of individuals at high risk of adverse outcomes; however, the potential links between AKI duration and CKD and CVD remain unresolved. Therefore, we examined the associations between AKI duration and CKD and CVD in a population-based setting.

Method: Using population-based plasma creatinine (pCr) data, we identified individuals with first-time AKI in Denmark from 1 January 1990 to 31 December 2018. AKI was defined in accordance with the Kidney Disease: Improving Global Outcomes (KDIGO) creatinine criteria. To allow for assessment of baseline kidney function and AKI duration, analyses were restricted to individuals with an assessment of baseline kidney function by pCr within the prior year and evaluation of AKI duration by pCr within seven days after AKI onset. In accordance with the Acute Disease Quality Initiative (ADQI) 16 Workgroup criteria, AKI duration was categorized as “rapid reversal” if a pCr test within two days after AKI onset did not fulfill the AKI definition, as “persistent” if a pCr test between two and seven days after onset did not fulfill the AKI definition, and otherwise as “acute kidney disease” (AKD). CKD was defined by in- or outpatient hospital diagnoses codes or as ≥2 outpatient eGFR <60 ml/min/1.73 m² separated by at least 90 days. CVD was defined by diagnosis codes and evaluated overall and as individual conditions including atrial fibrillation or flutter, ischemic heart disease, heart failure, stroke, and hypertension. When examining CKD, overall CVD, and specific CVDs only individuals without the condition were included in the analyses. Twenty-year cumulative risks and hazard ratios (HRs) were computed and compared across the three AKI duration groups.

Results: We identified 165,334 individuals with first-time AKI and with an assessment of baseline kidney function and AKI duration. Among these 36,514 (22%) had rapid reversal AKI, 22,619 (13%) had persistent AKI, and 110,499 (65%) had AKD. The median age was 72 years (interquartile range (IQR), 62-80) and 52% were females. The most common comorbidities were CKD (37%) and hypertension (43%). Among the 106,916 individuals without prevalent CKD, the 20-year risks of CKD were 18.9% (95% confidence interval (CI), 18.2-19.6) for rapid reversal AKI, 23.2% (95% CI, 22.1-24.2) for persistent AKI, and 22.0% (95% CI, 21.6-22.5) for AKD. The adjusted HRs for CKD were 1.23 (1.17-1.30) for persistent AKI and 1.33 (1.28-1.39) for AKD when compared with rapid reversal AKI. Among the 59,949 individuals without prevalent CVD, the overall 20-year risks of CVD were 36.0% (95% CI, 34.0-38.0) for rapid reversal AKI, 33.2% (95% CI, 31.6-34.9) for persistent AKI, and 32.2% (95% CI, 31.4-33.0) for AKD. This corresponded to adjusted HRs of 1.02 (95% CI, 0.96-1.09) for persistent AKI and 0.97 (95% CI, 0.93-1.02) for AKD when compared with rapid reversal AKI. Findings were consistent across outcomes of atrial fibrillation or flutter, stroke, and hypertension. For ischemic heart disease and heart failure, persistent AKI was associated with adjusted HRs of 1.10 (95% CI, 1.01-1.20) and 1.13 (95% CI, 1.05-1.20), respectively, and AKD with adjusted HRs of 1.08 (95% CI, 1.02-1.15) and 1.08 (95% CI, 1.02-1.13), respectively, compared with rapid reversal AKI.

Conclusion: In conclusion, longer AKI durations were associated with increased long-term risks of CKD. AKI duration was not associated with rates of overall CVD; however, rates of ischemic heart disease and heart failure increased with longer AKI durations. The distinct increase in rates of CKD and specific CVDs with longer AKI durations illustrates the potential for using AKI duration as a risk marker when planning nephrology follow-up after AKI. Further studies examining whether interventions to shorten AKI duration prevent outcomes are warranted.

REGIONAL VARIATION OF ACUTE KIDNEY INJURY IN COVID-19 IN ENGLAND
Nitin Kolhe1, Richard Fluck2 and Maarten Taal2,3

1 University Hospital of Derby and Burton, Department of Renal Medicine, Derby, United Kingdom, 2 University Hospital of Derby and Burton, Renal Medicine, Derby, United Kingdom and 3 University of Nottingham - Derby Campus, Medicine, Derby, United Kingdom

Background and Aims: The recent worldwide COVID-19 pandemic has identified acute kidney injury (AKI) as a serious complication of COVID-19. Previous reports suggest that AKI associated with COVID-19 has higher morbidity and mortality compared to AKI due to other causes. Limited data has suggested that regional variation in COVID-19 incidence is related to population density. However, little is known about the effect of region, SARS-CoV-2 strains, steroid treatment and other determinants on incidence and mortality in patients with COVID-19 complicated by AKI. The aim of this study was to determine the regional variation of COVID-19 AKI and predictors of mortality in these patients.
**Method:** This retrospective cohort study used hospital episode statistics. Data were collected from all adult hospitalised patients with COVID-19 infection and AKI (diagnostic code U07.1 and N17 in any of the 20 diagnoses codes) between 1st March 2020 and 31st March 2021 until discharge. We also extracted all available secondary diagnoses and procedure codes. Patients with codes for chronic dialysis were excluded. We divided the observation period as per the dominant SARS CoV-2 variant and in relation to publication of the RECOVERY trial. SARS CoV-2 "Other" strain was prevalent between 1st March 2020 and 21st December 2020, "Alfa" between 22nd December 2020 to 17th May 2021. The end date of each phase was based on more than 50% decline in each variant.

**Results:** We extracted 749,844 unique admission spells in 337,029 patients with U071 code in any of the 20 diagnostic codes from 3,324,748 FCEs and admitted during the study period. We excluded patients not resident in England, multiple and duplicate FCEs within a spell. Out of 749,844 admissions, 63,147 patients had 227,268 admissions with AKI. Population incidence of AKI was highest in London at 6316 pmp and lowest in South West 2394 pmp. Mean length of stay was lowest in North East at 15.6 ± 15.9 days and highest in South West at 19.3 ± 18.3 days. London had highest proportion of patients with Asian (15.1%) and Black ethnicity (16.1%). Proportion of AKI patients dialysed varied from 2.5% in North West to 6.5% in London. Unadjusted mortality was highest in North West at 31.8% and lowest in London at 25.4%. In multivariable analysis, increasing age (OR 1.04, 95%CI 1.04, 1.04), Asian ethnicity (OR 1.13, 95%CI 1.08, 1.17), emergency admissions (OR 1.7, 95%CI 1.51, 1.9), and transfers (OR 1.18, 95%CI 1.03, 1.34), ITU admission (OR 5.16, 95%CI 4.98, 5.34) and acute dialysis (OR 2.74, 95%CI 2.6, 2.89) had higher odds of death (Figure 1a). All regions had higher adjusted odds of death as compared to London (Figure 1b). Post RECOVERY trial, the odds of death was lower with prevalent "Other" SARS CoV-2 (OR 0.78, 95%CI (0.76, 0.8)) and "alfa" variant (OR 0.80, 95%CI 0.78, 0.82).

**Conclusion:** In this large national study of COVID AKI, London had lowest adjusted odds of death despite a higher proportion of patients receiving dialysis. The odds of death were lower after the publication of RECOVERY trial which may have resulted in practice pattern change.
SECONDARY BACTERIAL AND FUNGAL INFECTIONS IN COVID-19 PATIENTS WITH ACUTE KIDNEY INJURY AND RELATION WITH CYTOKINE STORM SYNDROME

Radulescu Daniela1,2, Cristiana David1,2, Elena Cuiban1,2, Simona-Daniela Onofrei1, Feier Larisa Florina3, Flavia Liliana Turcu1,2 and Ileana Adela Vacaroiu1,2

1 Carol Davila’ University of Medicine and Pharmacy Bucharest, Clinical Department no.3, Nephrology, Bucharest, Romania and 2’Sf. Ioan’ Emergency Clinical Hospital, Bucharest, Nephrology and Dialysis, Bucharest, Romania

Background and Aims: Both COVID-19 and acute kidney injury (AKI) are associated with impaired host immunity. Virus-induced immunosuppression, overuse of antibiotics and corticosteroids are COVID-19 related factors, while dysregulation of the inflammatory response, increased volemia, hemodialysis catheters are AKI-related factors which favor secondary infections. We aimed to search the relation between markers of cytokine storm syndrome (interleukin-6 – IL-6; ferritin; C-reactive protein – CRP) and incidence of secondary infections and to identify the microorganisms involved in secondary infections in patients admitted with acute kidney injury and COVID-19 patients.

Method: Patients with both COVID-19 and AKI admitted in the 2nd and 3rd waves of the COVID-19 pandemic (May-December 2021) in an COVID-only hospital were included in this retrospective analysis. Diagnosis of AKI was established according to KDIGO creatinine-based criteria. Obstructive AKI cases were excluded. AKI was classified as A-AKI when it was diagnosed at the moment of admission and HA-AKI when it developed during hospitalization. Bacterial and/or fungal infections and the sites of positive cultures were registered in all patients. Colonizations with nonpathogenic microorganisms were excluded. Median values of IL-6, ferritin and CRP (maximum levels recorded during hospitalization) were compared between infected and non-infected patients.

Results: A total of 247 patients with AKI+COVID-19 were included in the study: 146 had A-AKI and 101 had HA-AKI. Secondary bacterial and fungal infections were registered in 111 patients (44.93%) cumulating 161 positive urine, blood, hemodialysis catheter tip, sputum, wounds, feces and tracheal intubation tubes cultures. Secondary infections were noted significantly more frequent in HA-AKI cases than in A-AKI cases: 61.38% (62 patients) vs 33.56% (49 patients) – Fischer exact test, p<0.001. The responsible microorganisms and the sites of positive culture are presented in Table 1. Median values of IL-6, ferritin and CRP (maximum levels recorded during hospitalization) were significantly higher in infected patients than in non-infected patients (Table 2) in the entire study group. IL-6 was significantly higher in infected HA-AKI patients when compared with infected A-AKI (231.40 pg/mL vs 124 pg/mL; p = 0.015), but no significant difference was found between the two subgroups of infected AKI patients regarding median ferritin levels (2481.5 ng/mL vs 1785 ng/mL; p = 0.324) or regarding median CRP values (206.27 mg/L vs 179.59 mg/L; p = 0.546).

Conclusion: Incidence of secondary bacterial and/or fungal infections in patients admitted with AKI and COVID-19 was very high in our study and it was associated with more severe altered markers of cytokine storm syndrome. Secondary infections in COVID-19 patients are important drivers of hospital-acquired AKI or they can aggravate its evolution.
Method: explored. We here aimed to evaluate the association between developing AKI whether developing AKI associates with the risk of dementia is not well (AKI) leads to biochemical and pathological changes in the brain. However, Background and Aims: Division of Nephrology, Department of Clinical Sciences, Sweden and Caring Sciences, Sweden and 6 Karolinska Institutet, Danderyd Hospital, Division of Nephrology, Department of Clinical Sciences, Sweden.

Results: we included all adults with age ≥65 years, free from dementia. We here aimed to evaluate the association between developing AKI and the subsequent risk of dementia in general population.

Method: we included all adults with age ≥65 years, free from dementia diagnosis and with known kidney function in Stockholm during 2006-2019. The exposure was AKI (time varying): prevalent history of AKI was ascertained by clinical diagnoses, and new/ incidental AKI events during observation by both criteria. The outcome was dementia diagnosis, first via confirmed cases in clinical diagnosis and with known kidney function, history of hypertension, diabetes, and cardiovascular disease. Conclusion: In this region-representative cohort, participants who experienced AKI were at increased risk of receiving a diagnosis of dementia.

#5352 INCIDENT ACUTE KIDNEY INJURY AND THE RISK OF DEMENTIA: IN THE STOCKHOLM CREATININE MEASUREMENTS (SCREAM) PROJECT

Hong Xu1, Yang Xu2, Sara Garcia-Ptacek3,4*, Annette Bruchfeld4,5, Maria Eriksdotter1,3 and Juan Jesus Carrero 2,6

1 Karolinska Institutet, Department of Neurobiology, Care Sciences and Society, Huddinge, Sweden, 2 Karolinska Institutet, Department of Medical Epidemiology and Biostatistics (MEB), Solna, Sweden, 3 Karolinska University Hospital, Theme Inflammation and Aging, Sweden, 4 Karolinska Institutet, Division of Nephrology, Department of Clinical Science, Intervention and Technology, Sweden, 5 Linköping University, Department of Health, Medicine and Caring Sciences, Sweden and 6 Karolinska Institutet, Danderyd Hospital, Division of Nephrology, Department of Clinical Sciences, Sweden.

Background and Aims: Preclinical studies suggest that acute kidney injury (AKI) leads to biochemical and pathological changes in the brain. However, whether developing AKI associates with the risk of dementia is not well explored. We here aimed to evaluate the association between developing AKI and the subsequent risk of dementia in general population.

Method: We included all adults with age ≥65 years, free from dementia diagnosis and with known kidney function in Stockholm during 2006-2019. The exposure was AKI (time varying): prevalent history of AKI was ascertained by clinical diagnoses, and new/incident AKI events during observation by both clinical diagnoses and transient creatinine elevations according to KDIGO criteria. The outcome was dementia diagnosis, first via confirmed cases in the Swedish registry of cognitive/dementia disorders (SweDem) and enriched with cases identified by two issued diagnoses of dementia in outpatient care or initiation of specific anti-dementia medications. We considered death, migration, and end of follow-up as censoring events and also explored risk associations with specific dementia subtypes. The association between developing AKI and study outcomes was evaluated through time-varying multivariate Cox regression, accounting for recurring AKI events under the assumption that the lowest sCr would represent baseline kidney function, history of hypertension, diabetes, and cardiovascular disease.

Results: In the selected patients, we defined and graded AKI according to the KDIGO criteria, by comparing the peak sCr to the lowest sCr during hospitalization under the assumption that the lowest sCr would represent baseline kidney function. Then, we divided this cohort into 3 groups: 1) patients with no AKI at all, 2) AKI calculated by sCr changes and formally codified in HDF (diagnosed AKI), 3) AKI calculated by sCr changes but not codified in HDF (i.e., undiagnosed AKI). Finally, we compared the clinical characteristics and outcomes of these groups.

Results: We included 56,820 pts. The incidence of AKI was 24.5% (n = 13,920), evaluating the distribution among the 3 groups, we noticed that a small percentage of AKI was reported in HDF, while in the emergency department, AKI was formally reported in HDF, while in the emergency department, AKI was diagnosed in 78% of cases. Compared with No AKI patients, those with AKI (both diagnosed and undiagnosed) had a higher prevalence of comorbidities (diabetes mellitus, heart failure, atrial fibrillation) and incidence of myocardial ischemia and sepsis (Table 1). Moreover, patients with AKI had a significantly longer hospitalization and major mortality risk, at cox regression (HR 2.6, IC 2.4-2.8, p<0.000) and Kaplan Meier (Fig. 2). The mortality risk augmented in all patients with AKI analyzed by both logistic regression univariate (OR 7.1, IC 6.7-7.6, p<0.001) and multivariate analysis corrected by age, gender, and comorbidities (OR 4.5, IC 4.2-4.9, p<0.001). Interestingly, these findings...

* In 2,529 pts (57%) of diagnosed AKI the diagnosis was made considering previous sCr not available for the evaluation of AKI stage.

The results were confirmed also considering only the group of patients with undiagnosed AKI (univariate: OR 5.9, IC 4.2-4.9, p<0.001; multivariate: OR 4.6, IC 4.2-4.9, p<0.001).

Conclusion: Undiagnosed AKI is still very common in hospitalized patients, even if it identifies a category of patients with a high risk of complications and mortality. Proper recognition of H-AKI remains a problem to face.
Background and Aims: COVID-19 has been a significant public health concern for the last three years; however, not much is known about the mechanisms that lead to severe kidney outcomes in patients hospitalized with COVID-19. In this multicenter study, we combine isobaric TMT-tagged urinary proteomics and machine learning to predict severe kidney outcomes in hospitalized COVID-19 patients.

Method: Urine samples from hospitalized COVID-19 patients in two medical centers (Mount Sinai Hospital and University of Michigan) were used in this study in adherence with proper consenting protocols. Urine samples were prepared for LC-MS/MS analysis as previously reported [1]. The obtained spectra were analyzed using Proteome discoverer software and matched against Uniprot human database. For constructing the ML algorithm, the samples were randomly divided into discovery and validation set at a 2:1 ratio. Severe outcomes were defined as ICU admission, mechanical ventilation, acute kidney injury (AKI), death, or length of stay more than 21 days. Limma test was used on the discovery set to identify differentially expressed proteins and then features were selected using Boruta feature selection method. 10-fold cross validation on a random forest model was then applied to obtain receiver operating characteristic (ROC) curves.

Results: Urine samples from 120 PCR-positive COVID-19 patients from two different medical centers were collected within one week of hospitalization. More than 3,000 unique urinary proteins were identified using TMT-tagged mass spectrometry. For constructing a predictive algorithm, patients were stratified into severe and mild outcomes. Using Limma test on the discovery set, we identified differentially expressed proteins (DEPs) in severe outcome cohort vs the mild outcome cohort (Figure 1A). A set of 12 top features were identified using Boruta feature selection method and used for random forest model construction within the discovery set with 10-fold cross validation (Figure 1B). The generated ROC curves show that the algorithm demonstrated good predictive power for both discovery and validation set with 87% and 79% accuracy, respectively and close to 90% specificity (Figure 1C, D). On average, major adverse kidney events were observed in patients within 5-13 days after hospitalization. Enrichment analysis of DEP in COVID-19 patients compared to healthy patients showed significant upregulation of immune related processes and downregulation of proteolytic and metabolic processes. Enrichment analysis of DEPs in severe COVID-19 patients compared to mild COVID-19 patients showed significant upregulation of exocytosis and some immune related processes and downregulation of cell adhesion and extracellular matrix organization related processes (Figure 2A, B). Upregulated proteins were associated with kidney proximal tubular cells in addition to pulmonary alveolar cells (Figure 2C). Downregulated proteins were associated strongly with kidney cells such as podocytes and mesangial cells in addition to endothelial cells (Figure 2D).

Conclusion: Here, we developed an algorithm for prediction of severity in COVID-19 patients within 5-13 days after hospitalization. We further delineate potential mechanisms that drive severe outcomes in COVID-19 patients. Learnings from this study can be used for developing therapeutic options for long COVID, in addition to better preparedness in the event of other respiratory illnesses in the future.

TACROLIMUS BUT NOT VOCLOSPORIN INHIBITS KIDNEY TUBULAR CALCIUM AND MAGNESIUM REABSORPTION IN RATS AT CLINICALLY THERAPEUTIC DOSES
Kuang-Yu Wei1, Martijn H van Heugten1, Hester van Willigenburg1, A. H. Jan Danser1, Linda M. Rehaume2, Jennifer L. Cross2, John J. Viel2, Jeroen de Baaij3 and Ewout Hoorn1

1Erasmus Medical Center, Department of Internal Medicine, Netherlands, 2Aurinia Pharmaceuticals Inc., Victoria, BC, Canada and 3Radboud University Medical Center, Department of Physiology, Netherlands

Background and Aims: Clinically, the calcineurin inhibitor tacrolimus frequently causes hypercalciuria and hypomagnesemia by inhibiting kidney tubular calcium and magnesium reabsorption. Voclosporin, a novel calcineurin inhibitor approved in the USA and Europe for the treatment of adults with active lupus nephritis, has fewer side-effects including less hypomagnesemia. However, the differences between the kidney tubular effects of tacrolimus and voclosporin are unknown. To address this, we compared the effects of tacrolimus, voclosporin, and vehicle in rats.

Method: Tacrolimus (0.5 mg/kg) and voclosporin (0.5 mg/kg) were administrated by daily intraperitoneal injections in male Wistar rats and were compared against vehicle (Cremophor EL: 95% ethanol:saline (5:5:90, v:v:v)) for 28 days (n = 8–9/group). Dosages were determined based on pharmacokinetic studies in rats and aimed to achieve the area under the concentration-time curve observed in clinical studies. At day 18, blood and 24h urine were collected to measure trough levels of the drugs and to analyze the fractional excretions of calcium and magnesium. At sacrifice, kidneys were harvested for immunoblotting of tubular proteins.

Results: Both tacrolimus and voclosporin reached clinically therapeutic doses with trough levels of 2.4 μg/L ± 0.6 μg/L and 25.8 μg/L ± 9.6 μg/L, respectively. Compared to vehicle, tacrolimus caused significantly higher fractional excretions of calcium (+348% ± 127%, P < 0.001) and magnesium (+60% ± 38%, P < 0.01) and also caused hypomagnesemia (plasma magnesium 0.65 mmol/L ± 0.04 mmol/L vs. 0.81 mmol/L ± 0.02 mmol/L, P < 0.001). Compared to vehicle, voclosporin only caused a slight, but non-statistically significant, increase in fractional calcium excretion (+44% ± 38%, P = 0.08) and did not cause higher fractional magnesium excretion (+5% ± 30%, P = 0.96) or hypomagnesemia (plasma magnesium 0.8 mmol/L ± 0.04 mmol/L, P = 0.9). Compared to vehicle, tacrolimus caused an 11-fold decrease in the protein abundance of the cytosolic calcium-binding protein calbindin-D28K and a 2-fold decrease in the abundance of the sodium-chloride cotransporter (NCC). In contrast, voclosporin did not decrease the protein abundances of calbindin-D28K and NCC. No differences were observed between vehicle, tacrolimus, and voclosporin in the calcium channel TRPV5 and magnesium channel TRPM6 (Figure 1).

Conclusion: In contrast to the calcineurin inhibitor tacrolimus, voclosporin does not inhibit the kidney tubular reabsorption of calcium and magnesium and therefore does not cause hypercalciuria or hypomagnesemia. A possible explanation for this difference is that tacrolimus but not voclosporin affects tubular transport in the distal convoluted tubule, which was further supported by the selective inhibition of calbindin-D28K and NCC by tacrolimus. Our data show that tubulotoxicity of tacrolimus is not apparent with voclosporin treatment, at clinically relevant doses.
Figure 1: Effects of tacrolimus and voclosporin on kidney transporters (A) Immunoblotting of whole kidney homogenates in vehicle, tacrolimus and voclosporin groups. (B) Densitometric analysis of immunoblots. Band intensities are normalized to the mean intensity of the vehicle group defined as 1.0. Values displayed under respective blots are mean ± SD (n = 8 rats per group; ** P < 0.01 vs. vehicle; *** P < 0.001 vs. vehicle; & P < 0.001 vs. tacrolimus; ns, non-significant; one-way ANOVA with Dunnett’s post hoc test).
IDENTIFICATION OF DIFFERENTIALLY EXPRESSED GENES AND PATHWAYS IN NON-DIABETIC CKD AND DIABETIC CKD BY INTEGRATED BIOINFORMATICS ANALYSIS

Clara Barrios1, Jan Julia2, Jessica Gomez2, Eva Marquez1, Andres Ribas1, Laia Sans1, Eva Rodríguez Garcia1, Marta Crespo1 and Marta Riera1

1 Hospital del Mar, Institut Mar d'Investigacions Mediques, Nephrology, Barcelona, Spain and 2 Anaxomic Biotech, Barcelona, Spain

Background and Aims: Chronic kidney disease (CKD) is a complex genetic-based disease with multiple unclarified molecular pathways involved. Dapagliflozin has shown a clear improvement in the progress of renal function in diabetic and nondiabetic populations. However, we do not really know the molecular pathways that this drug modulates. To overcome this global objective we have first seek similarities and differences in genes and molecular pathways implicated in Non-diabetic (Non-DM) CKD (considering Autoimmune-CKD and Hypertension-CKD) and type2 diabetic nephropathy (DN).

Method: Expression datasets were compiled from databases (ArrayExpress and Gene Expression Omnibus). Differential expression analysis (DEA) and Gene Set Enrichment Analysis (GSEA) were carried out; each cohort was compared with controls, and between them as direct comparison (Non-DM CKD vs. DN).

Results: Non-DM CKD and DN share many similarities when compared to controls. However, some quantitative differences come up in terms of genes and pathways (see Figure 1 for examples). (1) Hypertension-CKD is clearly closer to DN than Autoimmune-CKD in both glomeruli and tubulointerstitium both in gene and pathway analysis. (2) Extracellular matrix remodelling and immune system activation (innate and adaptive) are processes involved in Non-DM CKD and Hypertension-CKD and type2 diabetic nephropathy (DN). (3) Metabolic modulations, regarding metabolic acidosis, reprograming and dyslipidaemia, are more present in DN tubulointerstitium than Non-DM CKD subcohorts, tubulointerstitium specifically. (4) Genes related to complement activation are found overexpressed in DN glomeruli compared to CKD/subcohorts, which then translate to a complement system activation rise in the GSEA analysis.

Conclusion: We raise a series of core genes that may be potential targets for the study of Dapagliflozin mechanism of action.
NOVEL DOMINANT ALG5 VARIANT IN TWO UNRELATED FAMILIES WITH LATE-ONSET ADPKD AND ATYPICAL TUBULOINTERSTITIAL CHANGES

Elhussein Elhassan1,2, Tereza Kmochova3, Katherine Benson4, Kendrah Kidd5, Neil Fennelly6, Anthony Dorman6, Aleš Hnízda3, Anthony Bleyer5, Martina Zivna3, Stanislav Kmoch3 and Peter Conlon1,2

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is a monogenic disorder renowned for its clinical and genetic heterogeneity. Recently, variants in the ALG5 gene have been described as a cause of atypical ADPKD and interstitial fibrosis through the disruption of polycystin 1 maturation and trafficking via underglycosylation. In this report, we investigated genetic cause of the disease in two unrelated Irish families displaying late-onset ADPKD phenotype with atypical tubulointerstitial changes.

Method: Routine clinical and radiological evaluations were carried out. Available kidney biopsy specimens were reassessed. Genetic testing was performed on probands and all relatives with cystic kidneys. First, a custom-targeted gene panel of 227 genes associated with kidney disease was used, but the causal variant was not identified. Then reading frame-changing variants in variable number tandem repeats region of MUC1 were excluded by single-molecule real-time sequencing. Whole exome sequencing revealed a variant in the ALG5 gene, which is not included in the initial custom gene panel. By targeted Sanger sequencing, segregation of the variant with the disease phenotype was confirmed in both investigated families. Multiple bioinformatic tools were employed to predict the effect on protein structure and functions.

Results: The clinical diagnosis was consistent in most of the 20 affected individuals with non-enlarged cystic kidneys and few or no liver cysts. All but 1 individual underwent radiological assessment; 7 had kidney and liver cysts, 7 had only kidney cysts, and 5 had no kidney cysts at ages 68.6±14.4, 55.1±15.8, 46.8±15.6 years, respectively. Polycystic liver phenotype (>20 cysts) was present in two individuals. Biopsy-proven extensive kidney interstitial fibrosis and cystic tubular dilation were evident in four affected individuals with available kidney samples. Of the 20 genetically-defined individuals, 4 had end-stage kidney failure at a mean age of 70.25±3.1 years. Ten individuals were CKD stage 3 or greater, while 6 were CKD stage 4 or lower at ages 43.2±12.6 and 63.1±7.5 years (P value 0.004). A novel heterozygous missense variant in the ALG5 gene (NM_013338.5, c.235C>T, p.Arg79Trp) was identified in affected members from investigated families. Genetic screening of 20 affected and 10 unaffected individuals from both pedigrees revealed segregation of the variant with the disease phenotype. The novel ALG5 variant was classified as likely pathogenic as it was absent in the Genome Aggregation Database (gnomAD), is located in a conserved region and is predicted to be deleterious on protein stability.

Conclusion: This study expands the clinical and genetic spectrum of the identified range of ADPKD, considering the pathogenic ALG5 variants. Establishing a precise diagnosis of atypical cystic and interstitial kidney disease is crucial, with essential implications including follow-up, genetic counselling, prognostication, and therapeutic interventions.

Figure 1: Scattered distribution plot of two families with novel monoallelic ALG5 variant and their renal progression at last follow-up. Solid triangles indicate subjects with monoallelic ALG5 variant identified (p.Arg79Trp). Hallow circles indicate wild-type ALG5, none of whom developed chronic kidney disease. Most affected individuals developed chronic kidney disease stage 3 (horizontal line) after 50 years (vertical line). Four individuals had reached end-stage kidney disease, as depicted with an eGFR value of 5ml/min at various ages (x-axis).
THE KETONE BODY BETA-HYDROXYBUTYRATE IS ASSOCIATED WITH BETTER KIDNEY FUNCTION OUTCOME IN PATIENTS WITH ADPKD: RESULTS OF THE DIAPAK COHORT

Martine Knol1, Thomas Bais1, Paul Geertsema1, Margery A. Connolly2, Stephan J.L. Bakker3, Ron T. Gansevoort1 and Maatje Van Gastel1

1University Medical Center Groningen, Internal Medicine, Nephrology, Groningen, Netherlands and 2Laboratory Corporation of America (LACO) Holdings (Labcorp), Morristown, United States of America

Background and Aims: A dysregulated energy metabolism is a key feature of Autosomal Dominant Polycystic Kidney Disease (ADPKD), characterized by cystic cells being dependent on glucose and poorly able to use other energy sources such as ketone bodies. Besides providing energy, ketone bodies, especially beta-hydroxybutyrate, can act as signaling metabolites and reduce inflammation and oxidative stress. In experimental studies, raising ketone body concentration reduced disease progression. Therefore, we hypothesized that higher endogenous serum beta-hydroxybutyrate concentration reduces disease progression in patients with ADPKD.

Method: We analyzed data from the DIAPAK cohort, a prospective observational cohort study that included 670 patients with ADPKD. Beta-hydroxybutyrate was measured at baseline using nuclear magnetic resonance spectroscopy. We excluded participants with type 2 diabetes, who used disease-modifying drugs (e.g., tolvaptan, somatostatin analogs), were not fasting, or had missing beta-hydroxybutyrate, leaving 521 participants for the analyses. Linear regression analyses were used to study cross-sectional associations and linear mixed-effect modeling for longitudinal associations.

Results: The median concentration of beta-hydroxybutyrate was 94 (IQR 68–147) μmol/L. Of the participants, 61% were female, the mean age was 47.3 ± 11.8 years, and the mean estimated glomerular filtration rate (eGFR) was 63.3 ± 28.9 mL/min/1.73 m². Cross-sectionally, beta-hydroxybutyrate was neither associated with eGFR nor with kidney volume. Longitudinally, beta-hydroxybutyrate was positively associated with the eGFR slope (B = 0.37% (95% CI 0.11 to 0.62), p = 0.005) but not with kidney growth. After adjustment for potential confounders, every doubling in beta-hydroxybutyrate concentration reduced the annual rate of eGFR loss by 0.34 (95% CI 0.10 to 0.58, p = 0.005) mL/min/1.73 m².

Conclusion: These analyses support the hypothesis that raising the beta-hydroxybutyrate concentration, one of the ketone bodies, reduces the rate of kidney function decline in patients with ADPKD.

GLOMERULAR & TUBULO-INTERSTITIAL DISEASES

B1 - BASIC SCIENCE, EXPERIMENTAL & RENAL PATHOLOGY

SELECTIVE RENAL DISPOSITION OF THE CALCINEURIN INHIBITORS VOCRLOSPORIN, CYCLOSPORINE, AND TACROLIMUS

Simon Zhou1, Krishani Kumari Rajanayake2, Miao He1, Bo Wen2, Anika Lkhagva2, Ernie Yap1, Duxin Sun3, Jennifer L. Cross1, Kory Engelke1 and Robert B. Huizinga1

1Auria Pharmaceuticals, Victoria, Canada and 2University of Michigan, Ann Arbor, United States of America

Background and Aims: The calcineurin inhibitors (CNI) cyclosporine (CSA) and tacrolimus (TAC) were revolutionary immunosuppressants when first introduced for solid organ transplantation in the 1980s. Voclosporin (VCS), a novel CNI, recently became the first oral therapy approved in the United States, Great Britain, and Europe for the treatment of active lupus nephritis based on positive results from Phase 2 and 3 clinical trials. Unlike CSA and TAC, VCS has demonstrated a consistent pharmacokinetic and pharmacodynamic profile, eliminating the need for therapeutic drug monitoring. Further, VCS is associated with a more favorable metabolic profile and has not been associated with electrolyte disturbances. Emerging evidence indicates small molecule therapeutics may display differential disposition within organ tissues. This suggests that CNIs may be differentially distributed and retained in the kidney, potentially explaining the difference in their efficacy and safety profiles. To evaluate renal disposition of CSA, TAC, and VCS, we assessed in mice and humans the disposition of each CNI in the kidney relative to its systemic drug exposure.

Method: Single 30 mg/kg doses of CSA, TAC and VCS were administered intravenously to mice. Following intravenous administration, kidneys were collected at 15 minutes, 30 minutes, 1 hour and 2 hours, flash frozen in liquid nitrogen, and stored at −20 °C until sectioning. Sections of 10 μm kidney tissue were mounted on indium tin oxide coated glass slides. Matrix of 10 mg/mL α-Cyano-4-hydroxycinnamic acid in 85% acetonitrile/13% ethanol + 2% water + 0.1% trifluoroacetic acid was sprayed on the tissue using an HTX tissue sprayer, dried for 10 minutes in the vacuum, and subjected to Matrix-assisted Laser

CL, clearance; CL/F, renal clearance; fu, bioavailability; GFR, glomerular filtration rate; NA, not applicable

Desorption and Ionization Mass Spectrometry Imaging (MALDI-MSI). The systemic and renal clearance in humans of CSA and TAC were obtained from the literature; pharmacokinetic data on VCS was obtained from data on file. Renal secretion of each drug was compared to its expected passive filtration based on glomerular filtration rate (GFR), fraction unbound in plasma (fu), and respective systemic drug exposure.

Results: MALDI-MSI demonstrated significantly higher concentrations of drug and more diffuse tissue disposition of CSA in mouse kidney compared to VCS (Figure 1). CSA was retained in all kidney tissues up to 2 hours post-administration. Higher concentrations and more diffuse disposition of TAC was also noted compared to VCS at 15 and 30 minutes; TAC was distinctively retained in the cortex and medulla. VCS had moderate distribution in the cortex and was rapidly excreted with low levels of drug present in the kidney after 1 hour. According to published data, CSA has a measured renal clearance of 1.48 mL/min in healthy human subjects, representing approximately 10% of expected passive filtration of 12.5 mL/min (Table 1). TAC has a renal clearance of 0.014 mL/min representing <2% of expected passive filtration of 1.25 mL/min. VCS has a renal clearance of 7.82 mL/min representing approximately 200% of its expected passive filtration rate of 3.75 mL/min.

Conclusion: MALDI-MSI revealed differential retention and distribution of CSA, TAC and VCS in mice, consistent with their respective renal clearances in humans. Higher drug exposure and ~90% renal reabsorption was observed for both CSA and TAC in this study, whereas the renal handling of VCS suggested a significant component of tubular secretion. The higher rate of secretion and lower overall exposure of kidney tissue to VCS may be associated with an improved safety profile when compared to the more diffuse distribution and greater renal retention of CSA and TAC.

MODELIZATION OF THE GUT-RENAL AXIS OF IGA NEPHROPATHY BY DEVELOPING (A1KI+/+ PIGR−−) GENOTYPE IN MICE

Jade Majorel1, Grégoire Bon1, Perrine Jullien1, Stéphane Paul2, Anne Druihne2, Michel Cogne2 and Nicolas Maillard1

1CIRI, Gimap, Saint-Priest-en-Jarez, France and 2CNRS UMR 7276 / INSERM U 1262, Cribl, Limoges, France

Background and Aims: IgA nephropathy is the most frequent primary glomerulonephritis worldwide, responsible for end stage renal disease within 20 years after diagnosis. The origin of the nephritogenic IgA1 in plasma remains poorly understood, but elements accumulate to suspect a mucosal origin after abnormal immune regulation. Herein, we propose a mouse model of IgA nephropathy, based on the modification of mucosal IgA synthesis and transport which drives an excess of polymeric forms of IgA1 in plasma. This model is based on (i) the presence of an IgA1 repertoire produced by mucosal plasma cells (A1KI+/+ mice) and (ii) the absence of mucosal transcytosis of IgA allowed by the knockout of PIGR (PIGR−−). This study aimed at describing the phenotype of such a mouse model which is supposed to
circulate increased polymeric IgA1 derouted from a mucosal origin, which is a key feature of the human IgAN. The present study is aimed at describing the phenotype of this model (A1KI+/+ PIGR−/−) through a mucosa-plasma-kidney axis, in comparison to wild type controls (WT), and A1KI+/+ PIGR+/+.

**Method:** Tissue fragments were used for immunofluorescence. Antibodies anti-IgA humain (Igah) FITC, antibodies anti-IgA mice (IgAm) HRP, antibodies goat anti-IgG alexa fluor and antibodies goat anti mice C3 FITC are used. To determine the concentration of murine IgA in the mice studied, ELISA tests were performed with anti-IgAm antibodies not conjugated or conjugated with HRP. The determination of IgAh in mice, anti-IgAh rabbit antibodies and antibody IgAh AP were used. Electrophoresis was performed in non-reducing conditions on polyacrylamide gel, transferred to a blot and revealed using anti-mouse IgA or anti-human IgA.

**Results:** At mucosal level, the observation of ileal slices of (A1KI+/+ PIGR−/−) mice, revealed that both IgAh and IgAm were strongly localized in the subepithelial chorion of villi and lamina propria, much more than in WT and the A1KI+/+ PIGR−/− conditions (figure 1). In serum, human IgA concentration was higher in sera issued from (A1KI+/+ PIGR−/−) mice than serum from A1KI+/+PIGR+/+ and WT mice (figure 2A). The difference was even more striking for murine IgA with a 2log10 gap (figure 2B). The western blot revealed a marked accumulation of circulating polymeric forms of human IgA1 and murine IgA, mostly dimeric and trimeric (figure 2C). In kidney, immunofluorescence shows the presence of human IgA1, C3 and IgG deposit in renal glomeruli in (A1KI+/+ PIGR−/−) mice (figure 3), with less IgA and C3 in A1KI+/+PIGR+/+ and no deposit in glomeruli of WT mice. It is noticeable that IgG can codeposit with human IgG in both A1KI+/+ conditions.

**Conclusion:** This double genetically altered mouse model of IgA nephropathy (A1KI+/+ PIGR−/−) display the mucosal-kidney axis of the human disease, by derouting polymeric IgA1 from a mucosal origin. Those IgA1 accumulate at a subepithelial stage, increase in serum with marked proportion of polymeric forms and deposit in kidney as pIgA1-IgG-C3 immune complexes. So this new murine model of IgA nephropathy could be helpful to investigate some potential therapeutic targets and increases the conviction of the role of mucosa to drive the pathogeny of the disease.

(Concentration log10). (C) Discriminant and not reducing conditions. Electrophoresis allows the visualization of IgAm and IgA1h monomeric and polymeric.
PROTECTIVE ROLE OF THE PODOCYTE IL-15 / STAT5 PATHWAY IN EXPERIMENTAL FOCAL AND SEGMENTAL GLOMERULOSCLEROSIS

Aissata Niasse¹, Kevin Louis¹, Olivia Lenoir², Laurent Mesnard¹, Juliette Hadchouel¹ and Yosu Luque³

¹Inserm, CoRaKid UMR_S1155, Paris, France, ²Paris Research Center Cardiovascular - Inserm University Paris City, Paris, France and ³Sorbonne Université, AP-HP Néphrologie Hôpital Tenon, Paris, France

Background and Aims: During glomerular diseases, podocyte-specific pathways can modulate the intensity of histological disease and prognosis. The therapeutic targeting of these pathways could thus improve the management and prognosis of kidney diseases. The Janus Kinase/ Signal Transducer and Activator of Transcription (JAK/STAT) pathway, classically described in immune cells, has been recently detailed in intrinsic kidney cells. We previously evidenced a protective role for a podocyte-expressed immune receptor such as the common gamma chain (γC) during glomerulonephritis (1). We also found that STAT5, a transcriptional factor classically described and activated downstream γC in T cells is upregulated in podocytes during glomerulonephritis.

Method: Using a mice model with a podocyte-specific deletion of Stat5, we analyzed the role of STAT5 in two experimental models of glomerular diseases.

Results: Here, we show, for the first time, that STAT5 is activated in human podocytes in focal and segmental glomerulosclerosis (FSGS). Additionally, podocyte-specific Stat5 inactivation aggravates the structural and functional alterations in a mouse model of FSGS (Figure 1). This could be due, at least in part, to an inhibition of autophagic flux and an alteration of mitochondrial function. Finally, Interleukin 15 (IL-15), a classical activator of STAT5 in immune cells, increases STAT5 phosphorylation in human podocytes and its administration alleviates glomerular injury in vivo by maintaining autophagic flux in podocytes.

Conclusion: In conclusion, activating podocyte STAT5 with commercially available IL-15 represents a potential new therapeutic avenue for FSGS.

A MODULAR INTRACELLULAR HIERARCHICAL-RESPONSIVE NANO CARRIER ENABLES DUAL TARGETING FOR HIGH THERAPEUTIC EFFICACY IN KIDNEY DISEASE
Tao Zeng and Aiqing Li
National Clinical Research Center for Kidney Disease, State Key Laboratory of Organ Failure Research, Nanfang Hospital, Southern Medical University, Division of Nephrology, Guangzhou, P.R. China

**Background and Aims:** Single-loaded nanocarrier that can improve targeting capability and drug toxicity compared with free drugs demonstrates a promising strategy for disease treatment. Due to the heterogeneity of the injured cells during the disease progression, dose-induced drug resistance, and instability of nanocarriers in the blood circulation, it is challenging to achieve dual targeting to different injured cell subsets as well as reducing drug dosage but obtaining efficient treatment. In addition, developing nanocarriers is a complex and time-consuming process; there is a desire to develop a universal nanocarrier for various diseases, especially complex ones. Here, we have successfully designed a modular nanocarrier capable of co-delivery drugs. Meanwhile, the effective dosage was reduced to one-tenth of single-loaded nanocarriers.

**Method:** The dual-loaded drug-targeting nanoparticles consist of four main modules, including a chemical material, an antibody, and two drugs. First, we constructed a mesoscale spherical nanoparticle with a particle size of 400 nm from PLGA and wrapped drug A inside it. Next, the foot cell-specific antibody Nephrin is used as the target material and modified on the nanoparticle surface by the ph-sensitive short peptide. Finally, drug B is coupled to the antibody to obtain the final dual-targeting dual-drug nanoparticles. The dual-targeting dual-drug nanoparticles were injected into mice via the tail vein to evaluate their toxicity to organs and the immune system and compared with free drug. We explored the targeting and mechanisms of dual-targeting nanoparticles by organ imaging, Immunofluorescence, and other experimental methods. In mice, we established the model of acute kidney injury, puromycin aminonucleoside nephropathy (PAN), and ccRCC to compare the protective effects and mechanisms of dual-targeting nanoparticles in different concentrations.

**Results:** Dual targeting nanoparticles loaded with different drugs demonstrated the ability of dual targeting of glomeruli and tubules. In treating acute kidney injury, the nanocarriers were encapsulated with rapamycin and dexamethasone acetate; for puromycin nephropathy, the drugs were changed to rapamycin and captopril; and in the treatment of kidney cancer models, gefitinib and glutathione were chosen as targeted antitumor drugs. For different diseases, the lesions were treated significantly with different drug combinations. We observed a reduction of tubular injury in the acute kidney injury model, a recovery of the foot process of podocytes in the puromycin nephropathy model, and a reduction of cancer foci in the renal cancer model. These results show that dual drug-loaded nanomaterials have an excellent ability to cope with complex situations.

**Conclusion:** Dual drug delivery system can flexibly adapt the treatment of various diseases by changing particle size, surface antibodies, and drugs.

TRANSPLANTATION OF MESENCHY MAL STEM CELLS - NEW FOCUS OF IMMUNE CORRECTION IN TREATMENT OF LUPUS NEPHRITIS
Natalya Krivoruchko, Lina Zaripova, Manarbek Askarov, Abay Baigenzhin, Temirlan Karibekov, Galiya Shaimardanova and Saltanat Bekturganova
National Scientific Medical Center, Astana, Kazakhstan

**Background and Aims:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disease characterised by the production of organ-specific autoantibodies to components of cell nucleus, immune complex lesions of the connective tissue, and the development of irreversible damage of internal organs. Chronic relapsing course of SLE, resistance to steroid and immunosuppressive therapy, toxic effects of drugs determine the need of search for new therapeutic approaches.

**Objective:** To evaluate the efficacy and safety of bone marrow mesenchymal stem cell (MSC) transplantation with high-dose immunosuppressive therapy (HIST) in SLE patients.

**Method:** A total amount of 15 patients with a diagnosis of SLE (ACR criteria) refractory to classical immunosuppressive therapy was examined. Patients were divided into 2 groups: patients from the main group underwent MSCs transplantation with HIST (n = 10), while the control group was observed on the background of traditional immunosuppressive therapy without cell transplantation (n = 5). Both groups were comparable in age, gender of patients, duration and severity of the disease. The SELENA-SLEDAI was used to determine SLE activity. Cytokines were examined by ELISA (IL-1B, IL-4, IL-10, TNF-A), antibodies to double-stranded DNA (anti-dsDNA) and anti-nuclear antibodies (ANA) by indirect immunofluorescence. Morphological examination of kidney included Masson-trichrome histochemistry for collagen fibers, silvering reaction for elastic and reticulin fibers, immunofluorescent and immunohistochemical methods. The safety assessment included registration of various adverse events during and after transplantation. Statistical analysis was carried out by Kruskal-Wallis test using STATISTICA 6.1.

REFERENCE
Results: Monitoring the effectiveness of autologous stem cell transplantation in SLE patients showed a significant 2-fold decrease in activity by SELENA-SLEDAI score from 14.67 ± 1.15 to 7.33 ± 1.15 points after 12 months (p = 0.03). In the control group, this indicator remained unchanged and amounted to 15.0 ± 0.87 points despite ongoing immunosuppressive therapy. Clinical efficacy was noted in all patients receiving HIST and MSC transplantation, which was confirmed by a significant decrease in daily proteinuria from 2.48 ± 0.77 to 1.06 ± 0.56 g/l, a decrease in the value of antibodies to DNA (from 443.28 ± 547.53 to 187.8 ± 146.60) and blood cytokines (significantly for TNF-Α), and an increase in the level of complement (though insignificantly). According to kidney biopsy data, after MSC transplantation with HIST, positive dynamics consisted in an increase in the number of reticulin fibers in the vascular loops of the glomeruli, as well as a decrease in the immune inflammatory process in the vascular loops of the glomeruli by immunofluorescence analysis for the spectrum of antibodies (Figure 1). In most patients of the main group, the doses of methylprednisolone and immune suppressants were reduced. Chills during transplantation was registered in one patient; no other unwanted adverse events were identified. Conclusion: MSC transplantation in combination with HIST is significantly more effective than traditional immunosuppressive therapy in SLE according to clinical and laboratory data. The method is safe, allows decreasing signs of autoimmune aggression and can be used in cases of refractoriness, low efficiency or intolerance of standard therapy for SLE.

Figure 1: An immunofluorescence of a kidney biopsy demonstrated a decrease in the immune inflammatory process in the vascular loops of the glomeruli: the intensity of IgG, kappa, and C1q staining decreased.

**MOLECULAR FEATURES OF CIRCULATORY B CELLS AND RENAL CELLS AT THE SINGLE-CELL LEVEL IN AUTOANTIBODY-NEGATIVE PRIMARY MEMBRANOUS NEPHROPATHY PATIENTS**

Qilin Chen1,2, Xiaojian Fung1,2, Jinjie Zhong1,2, Yaru Jiang1,2, Huimin Jiang1,2, Liping Peng2, Junli Wan1,2, Mo Wang1,2, Haiping Yang1,2, and Qiu Li1,2

1Children's Hospital of Chongqing Medical University, Department of Nephrology, Chongqing, China; 2National Clinical Research Center for Child Health and Disorders, Ministry of Education Key Laboratory of Child Development and Disorders, P.R. China and 3Chongqing Key Laboratory of Pediatrics, P.R. China

**Background and Aims:** Primary membranous nephropathy (PMN) is an organ-specific autoimmune disease that is the most common cause of idiopathic nephrotic syndrome in adults. Furthermore, the incidence of PMN is increasing, especially in young adults and children. The landmark discovery of nephritogenic autoantibodies against podocyte antigens such as M-type phospholipase A2 receptor (PLA2R) and thrombospondin type-1 domain-containing protein 7A (THSD7A) has provided a paradigm shift in diagnosis and treatment of PMN. However, there are still few patients with negative serum and renal tissue autoantibodies. This study aims to explore the molecular features of antibody-negative PMN.

**Method:** We sorted CD19+ cells from the peripheral blood of a pediatric patient with seven nephritogenic autoantibodies-negative PMN (NEG) by flow cytometry and performed single-cell transcriptome sequencing (scRNA-seq) and single-cell B cell receptor sequencing (scBCR-seq). Meanwhile, scRNA-seq was performed on renal biopsy tissues from the same patient. In addition, we included the scRNA-seq data of renal from anti-PLA2R antibody positive patients (POS) and healthy controls (CTRL), and the scBCR-seq data of B cell from CTRL for integrative analysis.

**Results:** The NEG patient showed typical nephrotic syndrome and was diagnosed as stage III membranous nephropathy by renal biopsy. There was no evidence of anti-PLA2R or anti-THSD7A antibodies in peripheral blood and seven nephritogenic autoantibodies such as anti-PLA2R antibodies in renal tissue. After excluding secondary factors, the patient was diagnosed with PMN. Through scRNA-seq of CD19+ cells, we found that the number, characteristic gene, function and clonotype of naïve B cells and memory B cells in NEG were significantly changed. Expanded CD38+- naïve B cells in NEG had the molecular characteristics of CD19+CD24-CD27-CD38+, defined as transitional B cells. This group of cells had distinct function features of cell activation, and its up-regulated genes were involved in multiple aspects of the BCR signaling pathway. Pseudotime trajectory analysis suggested CD38+- naïve B cells were highly enriched in the beginning of B cell differentiation. There was a preference in the use of VJ gene segments of B cells between NEG and CTRL, especially an increase of the IGHV3-23 and IGLV2-14 in NEG. The stronger pairing frequencies, IGLV2-14/IGLJ3 and IGK2V2-29/IGK2, were identified in NEG. We identified 14 distinct kidney cell types by marker genes. Through re-clustering of glomerular parietal epithelial cells (PECs), the patients were clearly distinct from their control counterparts, indicating a major shift in gene expression for this cell type. PECs in NEG showed significant up-regulation of cellular communication network factor-related genes (CCN1, CCN2), phospholipase A and acyltransferase-related genes (PLA2TA, PLA2TA), and seiptin protein-related genes (SEPTN2, SEPTN7), accompanied by significant down-regulation of podocyte-related genes. In addition, there are clearly distinct cellular functions and pseudotime trajectory in PECs from NEG and POS, and genes such as CCN2, PLAT4, SEPTN2 might drive the special trajectory of PECs in NEG. For the podocytes, the genes related with extracellular matrix and cell adhesion were significantly enhanced in NEG, which consisted with the functional enrichment analysis of the differentially expressed genes and gene set-based scores. We calculated the gene set-based scores including genes encoding lumen-to-blood sodium transporters. Results indicated the enhanced expression of sodium transporters in distal nephrons of MIN patients. More surprisingly, a group of proximal tubule epithelial cells showed significantly higher expression levels of sodium transporters. Among them, the expression of SLC5A12 encoding SMCT2 increased significantly.

**Conclusion:** We have systematically revealed the cell-type specific molecular features of PMN patients from circulation to renal tissue. Our research provides valuable evidence for the molecular diagnosis of PMN in children and insights into pathogenic mechanism of classical nephritogenic autoantibody-negative PMN.

**RITUXIMAB FOR MAINTENANCE OF REMISSION IN ADULT MINIMAL CHANGE DISEASE**

Stathis Tsiaakis, Ioannis Theodoridis, Elemi Kapsia, Chrysanthi Skalioti, Ioannis Boletis and Smaragdi Marinaki

National and Kapodistrian University of Athens Medical School, Laiko General Hospital, Department of Nephrology and Renal Transplantation, Athens, Greece

**Background and Aims:** Maintaining remission in a minority of adult patients with minimal change disease remains challenging. Prolonged corticosteroid use is associated with severe adverse effects. A limited number of observational studies suggest that rituximab may be an alternative therapeutic option for remission maintenance, allowing steroid withdrawal.

**Method:** We retrospectively analysed the data of all adult patients with minimal change disease, who received rituximab in our centre between 2017 and 2022.

**Results:** A total of 14 adults with minimal change disease were treated with rituximab, six of whom had childhood-onset nephrotic syndrome. Six patients were steroid dependent. The median number of relapses was 6.5 (IQR 4.5-15.2) prior to rituximab. Thirteen patients had received at least ≥ 2 different immunosuppressive agents during their disease. Corticosteroid-related adverse events, including osteopenia, hypertension, cataract and diabetes mellitus were observed in 10 subjects. Rituximab was administered in a median time of 10.6 years (IQR 4.5-16.3) after diagnosis. All patients received 2 doses of 1g rituximab 2 weeks apart. The median age at rituximab administration was 31 years (IQR 18.7-49.0); all patients were in remission. Besides corticosteroids, concomitant immunosuppressive therapy included calcineurin inhibitors (n = 6) and mycophenolate mofetil analogues (n = 1). The median follow-up time after the first dose of rituximab was 44 months (IQR 9.5-67.2). Relapses occurred in 6/14 patients in a median time of 17.5 months (IQR 10.2-26.5). The number of relapses per year decreased to 0.27 from 0.87 (p < 0.001) after rituximab. Six patients received a repeat course of rituximab. One patient developed Pneumocystis jirovecii pneumonia, that was successfully treated with cotrimoxazole. At the last follow-up visit, corticosteroids were discontinued in 8 out of 14 patients and calcineurin inhibitors in 3 out of 7 patients.

**Conclusion:** Rituximab is a reasonable therapeutic approach for maintaining remission and avoiding steroid toxicity in adult minimal change disease. Randomized controlled studies are needed to further evaluate the safety and efficacy of rituximab in these patients.

**ASSOCIATION BETWEEN LOSS OF IMMUNE CHECKPOINT PROGRAMMED CELL DEATH PROTEIN 1 AND ACTIVE ANCA-ASSOCIATED RENAL VASCULITIS**

Björn Tampe

University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany

**Background and Aims:** Immune checkpoint inhibitors (ICIs) have made an important contribution on the survival of patients with certain cancers. ICIs interrupt co-inhibitory signalling pathways mediated by programmed cell death protein 1 (PD-1), programmed cell death protein-ligand 1 (PD-L1), and cytotoxic T lymphocyte-associated antigen (CTLA-4) that result in the elimination of cancer cells by stimulating the immune system. Immune-related adverse events have also been described and attributed to an enhanced immune system activation. Recent observations have suggested dysregulation of immune checkpoints in active antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Therefore, we here aimed to analyze abundance of immune checkpoint molecules PD-1/PD-L1 and its implications in ANCA-associated renal vasculitis.

**Method:** We here analyzed intrarenal PD-1 and PD-L1, and cytotoxic T lymphocyte-associated antigen (CTLA-4) that result in the elimination of cancer cells by stimulating the immune system. Immune-related adverse events have also been described and attributed to an enhanced immune system activation. Recent observations have suggested dysregulation of immune checkpoints in active antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Therefore, we here aimed to analyze abundance of immune checkpoint molecules PD-1/PD-L1 and its implications in ANCA-associated renal vasculitis.

**Results:** We here observed a predominant tubulointerstitial expression of PD-1 that is decreased in ANCA-associated renal vasculitis. Moreover, loss of tubulointerstitial PD-1 correlated with active ANCA-associated renal vasculitis. Consistent to the observed association with active glomerular and tubulointerstitial lesions. For independent validation, publicly available datasets were analyzed for PD-1 expression (encoded by PDCD1).
tubulointerstitial lesions. We identified that interstitial PD-1 correlated with tubular and/or glomerular PD-L1 positivity. Finally, PD-1 was associated with decreased local synthesis of complement factor B. Interestingly, we did not observe a correlation between PD-1 and complement C5 or its C5a receptor. Combined with our observations, this may implicate a link between im-paired PD-1/PD-L1 signalling, complement factor B, and active ANCA-associated renal vasculitis.

Conclusion: These findings could be of relevance because experimental data have already been described that PD-1 agonism can be used therapeutically to attenuate autoimmunity in multiple disease models. Furthermore, targeted therapy against complement C5/C5a receptor and factor B are both available and currently evolving in the treatment of AAV. Therefore, this pilot study expands our current knowledge and describes a potential interplay between immune checkpoints and the alternative complement pathway in active ANCA-associated renal vasculitis.

COULD MESANGIAL C3 DEPOSITION BE AN INDEPENDENT PROGNOSTIC MARKER IN IMMUNOGLOBULIN ANEPHROPATHY? Hakki Çetinkaya1, Meltem Gursu2, Halil Yazici3, Egemen Cebecli4, Necmi Eren5, Mehmet Riza Atilpamak6, Omer Faruk Akca7, Gültrar Manga Sahin8, Taner Basturk9, Kadır Gökhan Atilgan10, Nihal Aydemir11, Kenan Turgutalp12, Hamad Dheir13, MÜreyt Yilmaz13, Semahat Karahisar Sirali14, Erhan Tatlar15, Saïde Elif Gullulu Boz16, Nephrology, Istanbul University, Istanbul, Turkey, 4Haseki Training and Research Hospital, Nephrology, Istanbul, Turkey, 9Diskapi Training and Research Hospital, Nephrology, Istanbul, Turkey, 53Bakirkoy Sadi Konuk Training and Research Hospital, Nephrology, Istanbul, Turkey, 16Medical Faculty, Nephrology, Necmettin Erbakan University, Konya, Turkey, 21Medical Faculty, Ankara University, Nephrology, Ankara, Turkey, 22Medical Faculty, Nephrology, Trakya University, Edirne, Turkey and 23Haydarpaşa Numune Training and Research Hospital, Nephrology, Istanbul, Turkey

Background and Aims: Immunoglobulin A nephropathy (IgAN) is a common primary glomerulonephropathy and the role of complement activation in the pathogenesis has not been fully clarified. There is evidence that mesangial C3 deposition plays a role in the development of the disease. The aim of this study was to examine the effect of C3 deposition on the prognosis of IgAN patients.

Method: The study included 1135 patients with IgAN confirmed by biopsy using the database of the Turkish Nephrology Association Glomerular Diseases Working Group (TSN-GOLD). Patients were excluded from the study if they were aged <18 or >75 years, or if C3 staining had not been performed in the immunofluorescent analysis. C3 deposition was defined as immunofluorescent staining within the mesangium as 1+ positive and no staining, and 2+ and 3+ positive intensity staining (<2+ and ≥2+). Evaluation was also made according to the Oxford MEST-C classification. The primary endpoint was the development of end-stage renal failure (ESRF), and kidney transplantation, and an increase of 30% in glomerular filtration rate (GFR) compared to the basal value, or an elevation in proteinuria to a nephrotic level (3.5 g/day) were accepted as poor prognosis.

Results: Mesangial C3 deposition was determined in 603 (53.1%) patients. In the evaluation of basal values between the groups with and without deposition, no statistically significant difference was determined in respect of age, gender, BMI, proteinuria level, or the presence of hypertension. In the follow-up period of mean 78 months survival, no significant difference was determined between the two groups in respect of the primary endpoint (C3+:53.1% vs. C3-:46.9%, p = 0.43). A significant correlation was determined between C3 deposition and segmental glomerulosclerosis (S1) according to the Oxford MEST-C classification (p = 0.001).

Conclusion: Although a correlation was seen between mesangial C3 deposition and the S1 MEST-C classification, the use of these alone or together as a prognostic factor in IgAN is not appropriate.

OUTCOMES IN SRNS (FSGS) PATIENTS IN THE UK RADAR IDIOPATHIC NEPHROTIC SYNDROME REGISTRY AND THEIR RELATIONSHIP WITH TIME-AVERAGED PROTEINURIA

David Pitcher1, Jonathan Barratt2,3,4, Fiona Braddon1, Bruce Hendry1, Alex Mercer5, Kate Osmaston1, Margaretha Steenkamp1, Andrew Neil Turner6, Daniel Gale7 and Moin A. Saleem8,9

1The UK Kidney Association, Filton, United Kingdom, 2University of Leicester, United Kingdom, 3Leicester General Hospital, United Kingdom, 4Travere Therapeutics, Inc., San Diego, United States of America, 5JAMCO Pharma Consulting, Enskede, Sweden, 6University of Edinburgh, United Kingdom, 7University College London, Department of Renal Medicine, United Kingdom, 8University of Bristol, United Kingdom and 9Bristol Royal Hospital for Children, United Kingdom

Background and Aims: Idiopathic Steroid Resistant Nephrotic Syndrome, SRNS (incorporating FSGS) is an important cause of proteinuric renal disease leading to kidney failure. Here we describe the outcomes of SRNS using the UK National Registry of Rare Kidney Diseases Idiopathic Nephrotic Syndrome (RaDaR-INS) Cohort, including retrospective and prospective data from 4274 patients with nephrotic syndrome (NS) not attributable to glomerulonephritis or systemic disorders, recruited from 107 adult and paediatric kidney units across the UK since 2010. In patients with FSGS, severity of proteinuria at onset and during follow up is associated with renal failure. In this study, we tested for associations between defined proteinuria endpoints with both eGFR slope and renal survival, in children and adults.

Method: Participants included those with renal biopsy diagnosis of FSGS or minimal change disease (MCD), or monogenic NS. Patients with no proteinuria measurement ≥1.0 g/g >6 months after disease onset were excluded as likely fully steroid-sensitive. Patients with kidney failure (KF) (CKD stage 5 or on renal replacement therapy) at or prior to first proteinuria measurement after baseline were excluded. Disease onset was defined as time of renal biopsy; primary renal diagnosis (PRD) date if no biopsy date recorded, and first proteinuria ≥1 g/g if neither biopsy/PRD date was available. Baseline was defined as first proteinuria ≥1 g/g >6 months after disease onset. Kaplan-Meier methods were used to analyze renal survival, defined as absence of KF or death with survival time calculated from baseline to last follow up. eGFR slope was measured from 6 months after baseline for the duration of follow up.

Results: Of 612 MCD and FSGS patients meeting eligibility, median time from disease onset to baseline was 1.2 years (IQR 0.6-4.4). Median baseline age was 38 years (IQR 21–56) with paediatric patients representing 21% of the study population. Median proteinuria at baseline was 3.4 g/g (IQR 1.9-6.2), while mean eGFR was 89 mL/min/1.73 m² (SD 39). Mean rate of loss of eGFR over follow-up was 4.4mL/min/1.73 m²/year (SD 10.9). Complete proteinuria remission (CR) and FSGS partial remission (FPR) were defined as shown in Table 1 using values of time-averaged proteinuria (TA-PU) over months 6–24 from baseline. For patients achieving CR or FPR, the rate of loss of eGFR was slower (Table 1), with a higher probability of survival from KF/death (Table 1 & Figure 1), than patients failing to achieve CR or FPR.

Conclusion: This is a study of proteinuria and outcomes in a population of patients with FSGS or steroid-resistant MCD. We regard the latter group as likely also to have FSGS. In this population of patients with overt proteinuria, achieving partial or complete remission of proteinuria is associated with slower disease progression and reduced risk of KF/death.

Background and Aims: Rituximab is the first-line treatment for patients with primary membranous nephropathy (MN) and nephrotic syndrome (NS) at high risk of progression to end-stage kidney disease. However, this drug is effective only in approximately two thirds of treated patients, and repeated rituximab infusions may be complicated by hypersensitivity reactions, which contraindicate retreatment. Ofatumumab, a fully human anti-CD20 antibody, could overcome these limitations.

Method: We retrospectively evaluated the response to a single 50–300 mg dose of intravenous ofatumumab in 17 MN patients referred to our institution who either experienced hypersensitivity reactions (rituximab-intolerant, n = 5) or failed to achieve NS remission after rituximab infusion (rituximab-resistant, n = 12).

Results: Over a median [IQR] follow-up of 5.0 [3.0-9.8] months, ten (58.8%) patients—five rituximab-resistant (41.7%) and all five rituximab-intolerant—achieved complete or partial NS remission, defined as proteinuria <0.3 g/day or proteinuria <3.5 g/day with ≥50% reduction from baseline, respectively. Ofatumumab infusion induced a progressive reduction in 24-hour urinary protein and IgG excretion, and a sharp increase in serum albumin and IgG levels. Peripheral B cells were depleted in all patients and started reconstituting by 3 months from baseline. Seven of the 12 subjects with PLA2R-related disease (i.e. with baseline anti-PLA2R antibody levels >2.7 RU/mL by ELISA) achieved antibody depletion during the follow-up (half of rituximab-resistant and all rituximab-intolerant). There were 14 non-serious infusion-related adverse events in nine patients, all of which completely resolved with temporary interruption of ofatumumab infusion.

Conclusion: Ofatumumab may be an effective and safe treatment option for all rituximab-intolerant and a substantial proportion of rituximab-resistant MN patients.

Background and Aims: Response to calcineurin inhibitors (CNI) is associated with a significant improvement in long-term kidney survival of children with non-genetic steroid resistant nephrotic syndrome (SRNS). On the contrary, these agents are considered non-efficacious in monogenic SRNS and are contraindicated according to the latest International Pediatric Nephrology Association (IPNA) Clinical Practice Recommendations for SRNS. However, there is evidence suggesting that remission with CNI therapy in this subgroup of children with SRNS is possible, but no studies to date have assessed this question in a systematic way. We aimed to study the incidence of response to CNI in children with monogenic SRNS, factors predictive of remission and the effect of treatment on kidney survival.

Method: Retrospective cohort study of children 0–18 years with genetically confirmed SRNS treated with a CNI for at least 3 months. Demographic, clinical, genetic, biochemical, histopathologic and treatment data were collected at various time points: at clinical diagnosis, 6, 12, 24 months from CNI onset, and last available follow-up. Pathogenicity of all reported variants was assessed by a dedicated geneticist according to the American College of Medical Genetics guidelines and only patients with a pathogenic genotype were included in the analysis[1]. Patients were classified according to their response to CNI as complete, partial or non-responders based on the IPNA Clinical Practice Recommendations for SRNS[2].

Figure 1: (A) Cumulative incidence of complete and partial remission in rituximab-intolerant and rituximab-resistant patients, (B) % change in proteinuria and serum albumin, (C) B cell kinetics and (D) % change in anti-PLA2R levels after ofatumumab infusion.
#4286 ACCUMULATION OF MALADAPTIVE TUBULAR EPITHELIAL CELLS (TECs) IS UBIQUITOUS IN CKD AND REPRESENTS A COMMON INITIATING MECHANISM OF DISEASE PROGRESSION

Eric Olson1, Tobias Bohnenpoll2, Johannes Pospiech3, Niklas Michel3, Mark Mcconnell1, Jennifer Cox4, Jay Ko1, Olivier Radresa5, Andrew King4 and Uwe Andag4

1Chinook Therapeutics, Seattle, United States of America and 2Evotec International GmbH, Göttingen, Germany

**Background and Aims:** Intestinal fibrosis, tubular atrophy and inflammation are common final pathways to end-stage kidney disease (ESKD), contributing to progressive nephron loss and functional decline in most chronic kidney diseases (CKD), including those considered to be glomerular in origin. Disease-associated maladaptive TECs have been described in rodent models and are characterized by a failed repair phenotype that contributes to tubulointerstitial fibrosis and inflammation. The contribution of equivalent maladaptive cell states to human CKD progression remains poorly described. The aim of this study was to characterize maladaptive TECs in the NURIteRe CKD cohort to assess their abundance and potential role in initiating inflammation and fibrosis in a large and heterogeneous patient population.

**Method:** Human maladaptive TECs were identified in an scRNA-Seq dataset (GSE171314) from IgA nephropathy patients by scoring cells with a TNF activation and a mouse proximal tubule failed repair (FR) gene signature[1]. The results were validated in a scRNA-Seq dataset (GSE171488) from patients with membranous nephropathy. Marker genes for these human maladaptive TEC clusters were derived using the Seurat R package and the top 50 candidates were combined into cell state-specific signatures. Single-sample signature scores were calculated for 310 kidney biopsy transcriptomes from various CKD etiologies in the NURIteRe cohort. Signature scores were correlated with eGFR and used in a time-to-event analysis (40% decline in eGFR or occurrence of ESRD) to predict renal event-free survival.

**Results:** Analysis of independent human scRNA-Seq datasets and scoring with TNF activation and mouse proximal tubule FR gene signatures revealed two distinct maladaptive TEC states associated with different tubular segments. A cluster of cells (FR-PT) with increased TNF activation and mouse FR signature expression were identified that clustered adjacent to proximal TECs, suggesting a lineage relationship. A second cluster of cells (DT2) with increased TNF activation was clustered adjacent to thick ascending limb (TAL) cells, suggesting distal tubule lineage. Maladaptive TEC clusters were detected at low levels in healthy controls but increased in CKD. FR-PT and DT2 cells are characterized by a pro-fibrotic and pro-inflammatory gene expression and likely represent a source of signalling molecules mediating stromal crosstalk in the kidney fibrotic microenvironment. To investigate their abundance in CKD, signature expression in NURIteRe kidney biopsy transcriptomes was summarized into a sample-level score. Signature scores for FR-PT and DT2 cells were generally elevated in all CKD etiologies with substantial variation within disease groups. Inverse correlation of eGFR with the scores suggested an accumulation of maladaptive TECs with kidney function decline, largely independent of primary diagnosis (Fig. 1). Pseudotime analysis revealed that this accumulation accompanied or preceded increases in myofibroblast and immune cell gene expression, suggesting a mechanism that may be driving disease initiation and progression. Importantly, high expression of the FR and DT2 signatures was associated with a decrease in renal event-free survival (Fig. 2), further supporting their relevance to human disease progression.

##5399 VONAFEXOR AS A NOVEL THERAPY FOR CHRONIC KIDNEY DISEASE

Jufiang Yang1, Florence Vasseur2, Martine Burtin1, Clement Nguyen1, Michele Pelosi2, Serge Garbay3, Pierre Mallinjoud3, Benoît De Chassy4, Jacky Vonderscher2, Raphael Dartell2, Marco Pontoglio1 and Fabiola Terzi1

1Institute Necker Enfants Malades–Inserm University Paris City, Paris, France and 2ENYO Pharma, Lyon, France

**Background and Aims:** Chronic kidney diseases (CKD) are characterized by the progressive loss of renal function. The molecular mechanisms underlying this progression are still poorly characterized and probably multifactorial. Therefore, there is a real need to expand the very limited number of therapies able to slow down the rate of CKD progression. Recent findings indicate that NR1H4, a druggable nuclear receptor, might play an important role in CKD. The aim of this study was to investigate the benefit of Vonafexor, a novel small molecule and specific NR1H4 agonist in acquired and genetic models of CKD.

**Method:** Two complementary experimental models of CKD (the 75% excision of total renal mass (Subtotal Nephrectomy; Nx) and the Col4a3−/− mice, a model of Alport disease) were studied. NR1H4 and the expression of some of its downstream targets were evaluated by quantitative RT-PCR, western blot and immunohistochemistry. In the Nx model, mice were treated with Vonafexor by daily oral gavage from 5 to 8 weeks after the surgery. The possible beneficial effect was compared to that of Losartan and other NR1H4 agonists.

In the Alport model, mice were treated by Vonafexor from 5 to 8 weeks after birth. In both models, group of mice were sacrificed at 5 weeks to evaluate the extent of renal lesions at baseline. Renal lesions were quantified using imaging J. Renal inflammation, myofibroblast activation and podocyte number were quantified after specific staining. Human biopsies were also studied. RNAseq was performed using Illumina NovaSeq6000.

**Results:** We observed that NR1H4 expression and OSTa and OSTb, two downstream targets of NR1H4, were significantly reduced in remnant kidneys of Nx FVB/N mice compared to sham-operated animals 8 weeks after surgery. Co-localization staining revealed that NR1H4 is mainly expressed in proximal tubules and, to a minor extent, in Henle loops. Renal lesions were already present at 5 weeks in both experimental models. Remarkably, Vonafexor showed beneficial effects in terms of glomerulosclerosis and tubular dilatations and, more importantly, induced a reduction of interstitial fibrosis 8 weeks after nephrectomy as compared to the 5-week baseline. Lymphocytes and macrophage infiltration, as well as activated myofibroblasts, were also significantly reduced. Similarly, podocyte loss was stopped by Vonafexor treatment. Of note, the beneficial effect of Vonafexor was unique compared to other classes of NR1H4 agonists and also higher than that of Losartan. The same beneficial effect was found in Col4a3−/− mice. RT-PCR confirmed the activation of several NR1H4 downstream targets in mice treated with Vonafexor, while RNAseq analysis revealed that Vonafexor impacted the pathological activation of pathways involved in cell cycle, cell signaling and metabolism. These results may be relevant to humans, since NR1H4 expression was significantly reduced in biopsies from patients with CKD of different etiologies as compared to control kidneys.

**Conclusion:** Altogether our results identified Vonafexor a novel key drug to control CKD. This is consistent with recent results obtained in LIVIFY phase 2 clinical trial in which Vonafexor has already demonstrated beneficial effects on eGFR in NASH patients with mild to moderate CKD.

**Abstracts i121**
Conclusion: This study suggests an important role for an accumulation of maladaptive TECs in CKD progression. These cells are observed in every CKD etiology that was included in this study, suggesting that targeting these cells could be an effective strategy to preserve kidney function broadly in CKD. Identification of surrogate blood or urine biomarker would allow for the identification of patients with increased levels of these cells regardless of disease etiology.

THE SODIUM PHOSPHATE COTRANSPORTER NAPI-IIB IS UPREGULATED AND EXPRESSED DE NOVO IN KIDNEYS OF PATIENTS WITH CHRONIC KIDNEYS DISEASE
Rupert Busch1, Christoph Daniel2, Kerstin Amann3, Maja Lindenmeyer3, Nati Hernando1, Pedro Henrique Imenez Silva1 and Carsten Wagner1

1Institute of Physiology, University of Zurich, Zurich, Switzerland, 2Institute of Pathology, Friedrich-Alexander-University (FAU) Erlangen-Nürnberg, 3Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background and Aims: Renal reabsorption of phosphate is mediated by 3 main transporters located in the luminal brush border membrane of the proximal tubule, namely NaPi-IIa (SLC34A1), NaPi-IIc (SLC34A3), and Pit2 (SLC20A2). The expression of all three proteins has been shown to be reduced in animal models of kidney disease [1]. Recently, we demonstrated that NaPi-Iib, a paralogue of the SLC34 subfamily that is mostly expressed in small intestine and lungs, is also expressed in the loop of Henle. Its mRNA expression is enhanced in rodent models of kidney injury. However, the expression of NaPi-Iib has not been characterized in humans and it is unknown whether NaPi-Iib is also upregulated in chronic kidney disease (CKD).

Method: In this study, we examined the localization of NaPi-IIa, IIb, and IIc in kidneys of control healthy individuals (kidney donors) (eGFR: 111.6 ± 22.9 ml/min/1.73m²) and patients with diabetic nephropathy (eGFR: 31.9 ± 7.7 ml/min/1.73m²), anti-glomerular basement membrane nephritis (anti-GMB) (eGFR: 27.2 ± 22.6 ml/min/1.73m²), and hypertensive nephropathy (eGFR: 31.5 ± 5.3 ml/min/1.73m²) by immunofluorescence. Moreover, we analyzed data from various transcriptome data bases from healthy individuals and patients with CKD.

Results: In kidneys from healthy donors, NaPi-IIb staining was restricted to thin and thick limbs of the loop of Henle, while AQP1 was observed in proximal tubules and descending thin limbs. NaPi-IIc was abundantly found in proximal tubules and descending thin limbs. NaPi-Iic was abundantly found in...
proximal tubule cells. In biopsies from patients, NaPi-IIb signal was also found in addition to thin and thick limbs in cells of the collecting duct and in many proximal tubules. In contrast, the staining of NaPi-IIc was reduced in all groups of patients with CKD.

RNA expression data from the European Renal cDNA Bank (ERCB) confirmed our immunofluorescence findings. SLC34A2 (NaPi-IIb) mRNA was progressively more expressed in kidneys of patients with kidney disease of tubulointerstitial origin from CKD stages 1 to 5, while it was strongly upregulated from stage 4 onwards in CKD of glomerular origin. Single cell RNA sequencing data of patients with acute kidney injury and CKD [2] showed elevation of SLC34A2 expression in injured thick ascending limb, degenerative proximal tubule cells (14× higher, adj. p<0.0001) (de novo expression), and descending thin limb (3.7× higher, adj. p<0.0001). SLC34A1 (NaPi-IIa) expression levels were reduced in whole kidneys (ERCB data) and SLC34A1 and SLC34A3 expression also decreased in proximal tubule cells of patients with CKD.

Conclusion: The phosphate transporter NaPi-IIb is highly upregulated in kidneys from patients with various etiologies of CKD and its expression spreads to proximal tubule and collecting duct. In contrast, the expression of the main physiological phosphate transporters NaPi-IIa and NaPi-IIc is reduced in CKD. These findings may have implications for the development and maintenance of hyperphosphatemia in CKD patients and limit the use of specific NaPi-IIa and/or NaPi-IIc inhibitors in patients with CKD.

THE PROTECTIVE EFFECT OF INTERLEUKIN-1 RECEPTOR ANTAGONIST ON KIDNEY FUNCTION: A MENDELIAN RANDOMIZATION STUDY
Jeong Min Cho1, Kwon Wook Joo2, Jung-Hyun Kim3, Dong Ki Kim2 and Sehoon Park4
1Seoul National University Hospital, Department of Internal Medicine, Seoul, Korea, Rep. of South Korea, 2Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South Korea, 3PaiChai University, Home Economics Education, Daejeon, Korea, Rep. of South Korea and 4Seoul National University College of Medicine, Department of Internal Medicine, Seoul, Korea, Rep. of South Korea

Background and Aims: Interleukins (ILs), key cytokine family of inflammatory response, are closely associated with kidney function. However, the causal effect of various ILs on kidney function needs further investigation.

Method: We performed two-sample summary-level mendelian randomization (MR) analysis (Fig. 1). Genetic variants with strong association with serum IL levels were obtained from a previous genome-wide association study meta-analysis. Summary-level data for eGFR were obtained from CKDGen database. A replication analysis was performed in the independent UK Biobank data. As a main MR analysis, multiplicative random-effect inverse-variance weighted method was performed. Pleiotropy-robust MR analysis, including MR-Egger with bootstrapped error and weighed-median methods, were also implemented.

Results: We tested the causal estimates from nine ILs on eGFR traits. Among ILs, we found that genetically predicted serum IL-1ra level showed consistently significant association (P < 0.05) with eGFR, also supported by significant (P < 0.05) pleiotropy-robust MR results. Using 20 SNPs (18 of pQTL and 2 of eQTL SNPs), genetically predicted higher serum IL-1ra level was significantly associated (<0.05) with higher eGFR in multiplicative random effect IVW analysis (Fig. 2). In addition, the result was consistent towards eGFR decline phenotype of the outcome database. Otherwise, nonsignificant association was identified between other genetically predicted ILs and eGFR outcome (Fig. 3).

Conclusion: These findings support the clinical importance of IL-1 associated pathway in relation to kidney function in the general individuals, particularly highlighting the importance of IL-1ra.

**Using a Deep Learning Model to Evaluate Pathological Injury of Diabetic Kidney Disease**

Feng Yong Jin¹, Yang Huang¹, Yu Lin Huang¹, Qing Zhao¹, Qin Yi Wu¹ and Kun Ling Ma²

¹Institute of Nephrology, Southeast University, Nanjing City, P.R. China and ²Institute of Nephrology, Zhejiang University, Hang Zhou, P.R. China

**Background and Aims:** Early diagnosis and evaluation play an important role in preventing the progression of diabetic kidney disease (DKD). Renal biopsy is the gold standard of DKD diagnosis. In 2010, the Renal Pathology Society (RPS) developed a consensus classification for DKD, which classifies DKD glomerular lesions and scores for tubulointerstitial lesion. However, as the pathologic heterogeneity of DKD patients and unparallel relationship between pathology features and clinical symptoms, it remains controversial whether is reliable to use RPS classification for renal outcomes prediction. Besides, the inconsistence between pathologists might magnify the gap between prediction and outcome. More reliable methods for DKD pathology assessment are needed. The development of machine learning (ML) algorithms especially convolutional neural networks (CNNs) enables it possible, which can provide automatic and precise analysis for complicated images. Thus, this study aimed to construct a ML-based model to assist and provide automatic decision supports to clinical doctors.

**Method:** We examined 204 DKD renal biopsied whole-slide images (WSIs) of Periodic Acid Schiff staining from Southeast University Institute of Nephrology whose database came from more than 30 hospital centers. All the WSIs were randomly annotated by three pathologists. We established a consecutive CNNs framework: DKD pathology evaluation system (DPES). It consists of three parts: 1. Based on classic UNet architecture, we developed a segmentation model whose backbone is replaced by ResNet 50 architecture for detecting glomeruli. 2. According to RPS classification, a CNN added with channel attention mechanism is built to discriminate sclerotic glomeruli, glomeruli with K-W node, and glomeruli with mesangial expansion. Through this method, the entire WSIs were divided into RPS grades 1-IV. 3. For the analysis of tubulointerstitial lesion, we constructed a segmentation model as previous description to calculate the area of the atrophic tubule and its percentage of the total tubules.

**Results:** For glomerular assessment, compared with other ML networks, DPES achieved better performance in segmentation for glomeruli (Intersection over Union (IOU): 0.82, Precision: 0.89, Accuracy: 0.91) and tubulointerstitial (atrophy (TA): IOU: 0.9; Precision: 0.94; Accuracy: 0.95; non-tubular atrophy (NT): IOU: 0.84; Precision: 0.90; Accuracy: 0.93). Interstitial fibrosis and tubular atrophy (IFTA) from network compared with three pathologists didn’t show statistically difference.

**Conclusion:** Our findings demonstrated that the DPES achieved similar performance with three pathologists. It suggests that machine learning algorithms can generate reliable results and provide more supports for clinical decision.

**Effectiveness and Safety of Apixaban, Rivaroxaban and Warfarin in Patients with Advanced CKD and Atrial Fibrillation: A Nationwide US Cohort Study**

Edouard Fu¹, Rishi Desai¹, Julie Paik¹,², Dae Kim³,⁴, Yichi Zhang¹, Julianna Mastrorilli¹, Alexander Cervone¹ and Joshua Lin⁵,⁶

¹Brigham and Women's Hospital, Division of Pharmacoeconomics and Department of Medicine, Boston, United States of America, ²VA Boston Healthcare System, New England Geriatric Research Education and Clinical Center, Boston, United States of America, ³Brigham and Women's Hospital, Division of Renal Medicine, Department of Medicine, Boston, United States of America, ⁴Hebrew SeniorLife, Hinda and Arthur Marcus Institute for Aging Research, Boston, United States of America, ⁵Beth Israel Deaconess Medical Center, Division of Gerontology, Department of Medicine, Boston, United States of America and ⁶Massachusetts General Hospital, Division of General Internal Medicine, Department of Medicine, Boston, United States of America

**Background and Aims:** Head-to-head data comparing the effectiveness and safety of oral anticoagulants in patients with atrial fibrillation (AF) and advanced CKD or on dialysis are lacking. We compared the effectiveness and safety of apixaban, rivaroxaban and warfarin in patients with AF and CKD stages 3 to 5, including those on dialysis.

**Method:** We conducted a new-user, active-comparator, cohort study using data from two nationwide U.S. claims databases, Medicare and Optum Clinformatics. We included patients with nonvalvular AF and CKD who newly initiated warfarin vs. apixaban (N = 169,702), or rivaroxaban vs. apixaban (N = 129,396), CKD stages were determined based on a validated claims-based algorithm. The primary outcome was a composite of ischemic stroke or major bleeding to represent the net benefit of treatment. Secondary outcomes included the individual components of the primary outcome and all-cause death. We used 1:1 propensity score matching to adjust for 80 confounders. Adjusted hazard ratios (aHRs) were estimated with Cox regression analyses and absolute rate differences per 1000 person years (aRDs) with generalized linear regression in the propensity score matched sample.

**Results:** Compared with apixaban, warfarin and rivaroxaban were associated with a higher risk of the composite endpoint, regardless of CKD stage. Comparing warfarin vs. apixaban, the aHRs were 1.5 (1.3–1.6), 1.4 (1.0–1.9) and 1.3 (1.2–1.5) for CKD stages 3, 4, and dialysis, respectively (p-value for heterogeneity 0.16). Comparing rivaroxaban vs. apixaban, the aHRs were 1.5 (1.4–1.7), 1.7 (1.4–2.2) and 1.3 (0.9–1.8) (p-value for heterogeneity 0.38) for CKD stages 3, 4, and 5/dialysis, respectively; corresponding aRDs were 27.1 (12.3, 41.8), 32.9 (13.9, 40.5) and 20.7 (−28.9, 70.2) (p-value for heterogeneity 0.16). The higher rate of the primary endpoint for warfarin and rivaroxaban was driven by a higher risk of bleeding, with similar rates of ischemic stroke.

**Conclusion:** In patients with AF and CKD, apixaban was associated with a net benefit compared with rivaroxaban or warfarin, which was primarily driven by lower rates of bleeding. Benefits were consistent across severity of CKD.
Figure 1: Comparative effectiveness and safety of warfarin vs. apixaban or rivaroxaban vs. apixaban in patients with atrial fibrillation and CKD after 1:1 propensity score matching.
NON-ADHERENCE TO CARDIOMETABOLIC DRUGS AS ASSESSED BY LS-MS/MS IN URINE AND ITS ASSOCIATION WITH RENAL AND CARDIOVASCULAR OUTCOMES IN T2DM

Sara Denicolo¹, Vera Reinstadler², Felix Keller¹, Stefanie Thöni¹, Susanne Eder³, Hiddo Lambers Heerspink³, Laszlo Rosivall⁴, Andrzej Jan Wieck³, Patrick Mark⁶, Paul Perco¹, Johannes Leierer¹, Andreas Kronbhichler¹, Herbert Oberacher² and Gert Mayer¹

¹Medical University Innsbruck, Department of Internal Medicine IV (Nephrology and Hypertension), Innsbruck, Austria, ²Medical University Innsbruck, Institute of Legal Medicine and Core Facility Metabolomics, Innsbruck, Austria, ³University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, University of Groningen, Groningen, Netherlands, ⁴Semmelweis University, International Nephrology Research and Training Center, Institute of Translational Medicine, Budapest, Hungary, ⁵Medical University of Silesia, Department of Nephrology, Transplantation and Internal Medicine, Katowice, Poland and ⁶University of Glasgow, Institute of Cardiovascular & Medical Sciences, Glasgow, United Kingdom

Background and Aims: Cardiovascular and renal complications have a detrimental impact on the prognosis and quality of life of patients with type 2 diabetes mellitus (T2DM). Guidelines recommend combination drug therapy to prevent or delay these complications[1]. However, non-adherence to medication is common and a barrier to successful disease management[2]. Most previous studies on adherence and outcome used indirect methods to assess adherence[3]. In this study we used liquid chromatography-tandem mass spectrometry (LC-MS/MS), a direct and objective adherence measure, to assess adherence to cardiometabolic drugs in a large real-world cohort of individuals with T2DM and analyzed non-adherence in the context of cardiovascular and renal outcomes.

Method: 1125 eligible PROVALID participants were included. PROVALID is a prospective observational cohort study of patients with T2DM followed annually at the primary health care level. Urine samples from the PROVALID biobank were screened for 79 cardiometabolic drugs and metabolites thereof by LC-MS/MS. An individual was classified as fully adherent when markers for all prescribed drugs were detected, partially non-adherent when at least a marker for one drug was detected and totally non-adherent when no marker for any prescribed drug was detectable. In order to assess outcome by adherence we defined a cardiovascular (myocardial infarction, stroke, and cardiovascular death) and a renal (ESKD, renal death, sustained 40% reduction in eGFR to < 60 ml/min per 1.73 m², sustained progression of albuminuria) composite endpoint.

Results: The mean age was 64.2 (±8.9) years and 46.1% were female. The mean duration of T2DM was 11.4 (±7.9) years. The mean HbA1c was 7.1 (±1.1)%, the mean eGFR was 77.6 (±23.6) ml/min/1.73 m² and mean albuminuria 67.3 (±287.9) mg/g creatinine. Participants were prescribed 5.4 (±2.0) cardiometabolic drugs on average. Based on the results of LC-MS/MS measurements, 56.3% were totally adherent, 42.0% were partially adherent, and 1.7% were totally non-adherent to screened cardiometabolic drugs. Adherence was highest to antplatelet and glucose lowering drugs and lowest to lipid lowering drugs (totally adherent individuals 90.1%, 89.2% and...
70.7%, respectively). Non-adherent patients had a longer history of T2DM (12.3 ± 8.5 vs. 10.7 ± 7.5, p = 0.003) and a higher number of prescribed drugs (5.8 ± 2.1 vs. 5.1 ± 1.9, p < 0.001). Age per se had no influence on adherence, however the number of prescribed medications had more impact on adherence in younger patients (Fig. 1). Ex-smokers were more likely to be adherent than current or never-smokers (odds ratio 1.4, p-value = 0.014). Patients who were adherent to lipid lowering drugs had significantly lower LDL (82.4 ± 29.8 vs. 111.4 ± 39.7 mg/dl, p < 0.001). A trend for lower HbA1c with adherence to glucose-lowering drugs and lower systolic blood pressure with adherence to antihypertensive drugs could be observed, however these differences were not statistically significant. In the longitudinal analysis, worse cardiovascular prognosis was especially seen with non-adherence to antplatelet drugs and worse renal outcome especially with non-adherence to antihypertensive drugs (Fig. 2).

**Conclusion:** Our analysis confirms that non-adherence, especially partial non-adherence, to cardiometabolic drugs is common in T2DM. A higher incidence of cardiovascular events was observed with non-adherence to antplatelet drugs, whereas non-adherence to antihypertensive drugs was associated with a higher renal event rate.

KIDNEY FUNCTION TRAJECTORY BEFORE AND AFTER ARTERIOVENOUS ACCESS CREATION IN PATIENTS WITH PREDIALYSIS CKD

Abdel-Hay Tabcheh1, Raphael Coscas2, Oriane Lambert1, Benoîcie Stengel1, Luc Frimat3, Christian Combe4, Murilo Guedes5, Roberto Pecoits-Filho5, Julie Boucquemont1 and Natalia Alencar de Pinho1

1Centre for epidemiology and population health, Inserm, Clinical epidemiology team, Villejuif, France, 2Ambroise Paré University Hospital - APHP, Vascular Surgery, Boulogne-Billancourt, France, 3BRABOIS Hospitals - CHRU Nancy, Nephrology, Vandoeuvre-les-nancy, France, 4Bordeaux University Hospital - GH Pellegrin Tripode, Nephrology, Bordeaux, France and 5Arbor research collaborative for health, Dopps program, Ann Arbor, United States of America

Background and Aims: Timely arteriovenous (AV) access creation in view of starting hemodialysis is challenged by non-linear kidney function decline and the prospect of competing mortality. In addition, some studies have shown slower CKD progression following AV access creation in patients not on dialysis. While pathophysiological mechanisms, such as ischemic preconditioning and improved kidney perfusion, have been put forward to explain the apparent influence of AV access creation on estimated glomerular filtration rate (eGFR) trajectory, it cannot be ruled out that this finding resulted from an artefact induced by the use of models assuming linear (eGFR) decline before and after AV access creation. Our aim was to describe the kinetics of eGFR decline around the period of AV access creation and to identify different trajectory profiles using models relaxing this hypothesis.

Method: From 2013 through 2016, the CKD-REIN cohort included 3033 patients with CKD stages 3 to 5 from 40 nationally representative outpatient nephrology clinics in France. Participants were followed for 5 years or until initiation of kidney replacement therapy (KRT), death, or loss to follow-up, whichever came first. This study focused on patients who underwent their first AV access creation during follow-up. Linear mixed models with restricted cubic spline functions (two internal knots, one at AV access creation date, the other, one year before) were used to model a potential non-linear eGFR trajectory over time, based on routine labs. Random effects for the intercept and the spline function components allowed us to deal with individual variations in eGFR trajectory. Instantaneous rates of eGFR decline around AV access creation were then extracted. In addition, we performed latent class mixed models (LCMM) to identify distinct eGFR trajectories.

Results: During a median follow-up of 5.0 years (interquartile range [IQR], 4.6 to 5.2), 415 (14% of the total population) patients underwent a first AV access creation (32% women, 51% with diabetes). The median age at AV access creation was 69 years (IQR, 61 to 76), and the median eGFR, 13 ml/min/1.73 m² (IQR, 11 to 16). The median numbers of eGFR measurements before and after creation were 12 (IQR, 8 to 19) and 3 (IQR, 2 to 6) respectively. The average eGFR decline in the year before and after AV access creation, assuming constant slopes in each period, was 5.2 ml/min/1.73m² (95% confidence interval [CI], 4.8 to 5.5) and 3.4 ml/min/1.73 m² (95% CI, 3.1 to 3.7), respectively, with a mean difference of −1.8 ml/min/1.73m² (95% CI, −1.4 to −2.1). Analysis of instantaneous rates showed that the slowdown of eGFR decline began 8.3 months on average (95% CI, 7.8 to 8.6) before AV access creation.

Figure 1: Profiles of eGFR decline around the period of AV access creation in ml/min/1.73 m²/year.
creation. The LCMM identified two profiles of eGFR trajectories which mostly differed in the rate of eGFR decline (Figure). In both trajectories, the mean time to the slowdown of eGFR decline preceded time of AV access creation, by 9.1 and 7.2 months in the fastest and slowest eGFR decline trajectories, respectively.

Conclusion: In nondialysis patients, slowdown of kidney function decline appears to occur several months before AV access creation. Our findings do not support a causal biological effect of AV access creation on CKD progression, but favor alternative hypotheses including optimal management before AV access creation, greater uncertainty in eGFR estimation in advanced CKD due to muscle mass loss, or simply regression to the mean.

MODERATE AND SEVERE KIDNEY DYSFUNCTION ASSOCIATED WITH LEFT VENTRICLE DIASTOLIC DYSFUNCTION: A COHORT WITH DATA FROM ELECTRONIC HEALTHCARE RECORDS
Cindy P. Porras1,2, Michiel Bots2, Marianne Verhaar1 and Robin Vernooij1,2
1UMC Utrecht, Department of Nephrology and Hypertension, Utrecht, Netherlands and 2UMC Utrecht, Julius Center for Health Sciences and Primary Care, Utrecht, Netherlands

Background and Aims: Left ventricular diastolic dysfunction is observed in patients with chronic kidney disease (CKD) and may lead to heart failure with preserved ejection fraction (HFpEF). In this study, we investigate the association between kidney dysfunction and left ventricular diastolic dysfunction (LVDD) in a cohort using data from electronic healthcare records.

Method: We utilized electronic healthcare data from the Utrecht Patient Oriented Database (UPOD), including all patients treated at University Medical Center Utrecht (UMCU), a university teaching hospital. We extracted demographic patient data, admission data, medication orders, and laboratory results. All performed echocardiography from baseline (i.e., first visit to the hospital) to end of follow-up (i.e., death or censoring) were included. The estimated glomerular filtration rate (eGFR) was calculated using the creatinine formula without ethnicity. Participants were divided into four groups depending on their eGFR (mL/min/1.73 m²) as follows: normal kidney function (eGFR ≥ 90), mild kidney dysfunction (eGFR ≥ 60–89), moderate kidney dysfunction (eGFR ≥ 30–59), and severe kidney dysfunction (eGFR < 30). The association of eGFR with E/A and E/e’ ratio was tested by multivariable adjusted cox proportional hazards survival analysis, reporting hazard ratios (HR) and 95% confidence intervals (CI).

Results: We identified 6,216 participants who received echocardiography as part of their routine care between 2012 and 2022. The mean age was 66.9 years (SD: 12.04 years), and 41.7% of individuals were females. In total, 90.4% and 24.5% of the patients had, respectively, hypertension and diabetes. Twenty-six percent of participants had normal kidney function, 48.2% had mild kidney dysfunction, and 21.3% and 4% had moderate and severe kidney dysfunction, respectively. In total, 16,935 echocardiography were performed. The median time from the first to the final echocardiography was 7.08 (IQR: 2.89 years).

Adjusted multivariable analysis showed that patients with moderate (HR: 1.19; 95% CI: 1.09, 1.31) and severe kidney dysfunction (HR: 1.14, 95% CI: 1.14, 1.62) had higher probabilities of having E/A ratio < 0.75 or > 1.8 compared with those with normal kidney function. Similarly, for an E/e’ ratio > 14, participants with moderate and severe kidney dysfunction had higher probabilities, HR: 1.62 (95% CI: 1.49, 1.77) and 2.10 (95% CI: 1.83, 2.42), respectively, compared with participants with normal kidney function.

Conclusion: Moderate and severe kidney dysfunction are independently associated with LVDD. This association is independent of sex, age, hypertension, and diabetes status and is stronger for severe kidney dysfunction. Early recognition of LVDD in kidney dysfunction might help identify those at highest risk of developing HFpEF.

ALBUMINURIA AND THE RISK OF CANCER: THE STOCKHOLM CREATININE MEASUREMENTS (SCREAM) PROJECT

Li Luo1, Yuanhang Yang2, Lynne M. Kieneker1, Roemer J. Jans1, Alessandro Bosi2, Faizan Mazhar2, Rudolf A. de Boer4, Geertruida. H. de Bock5, Ron T. Gansevoort1 and Juan-Jesus Carrero6

1Department of Nephrology, University Medical Center Groningen, University of Groningen, The Netherlands, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, 3Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden; Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, The Netherlands, 4Department of Cardiology, Erasmus University Medical Center, Rotterdam, The Netherlands, 5Department of Epidemiology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands and 6Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden

Background and Aims: Studies investigating the association of chronic kidney disease and cancer have focused on estimated glomerular filtration (eGFR) rather than on albuminuria. The few studies focusing on albuminuria provide results that vary considerably, probably due to a lack of consideration of eGFR, their limited sample sizes, and that different albuminuria measurement techniques were used. This study therefore aimed to investigate the eGFR independent risk of cancer incidence associated with albuminuria measured as ACR as well as by dipstick in a large Swedish population.

Method: We included subjects of the Stockholm Creatinine Measurements (SCREAM) project without a history of cancer, 250,768 subjects with at least 1 urine albumin-creatinine ratio (ACR) test (primary cohort), and 433,850 subjects with at least 1 dipstick albuminuria test (secondary cohort). Albuminuria was quantified as KDIGO albuminuria stages. The primary outcome was overall cancer incidence. Secondary outcomes were site-specific cancer incidence rates. Multivariable Cox proportional hazards regression models were used to calculate hazard ratios (HRs, 95% CIs) crude, and additionally adjusted for confounders including baseline eGFR.

Results: During a median follow-up of 4.3 (IQR, 2.0-8.2) years, 21,901 subjects of the ACR cohort developed de novo cancer. In multivariable analyses, adjusting among others for eGFR, subjects with an ACR of 30–299 mg/g or ≥300 mg/g had a 23% (HR, 1.23; 95% CI, 1.19-1.28) and 40% (HR, 1.40; 95% CI, 1.31-1.50) higher risk of developing cancer, respectively, when compared to subjects with an ACR < 30 mg/g. This graded, independent association was also observed for urinary tract, gastrointestinal tract, lung, and hematological cancer incidence (all P < 0.05). No significant associations of albuminuria with the incidence of melanoma, breast, and prostate cancers were found. Results were similar in the dipstick albuminuria cohort, and were robust in several sensitivity analyses.

Conclusion: Albuminuria was associated with the risk of cancer independent of eGFR. This association was primarily driven by a higher risk of urinary tract, gastrointestinal tract, lung, and hematological cancers.
Method: We compared the performances of the CKD-EPI21 equation and the original creatinine-based eGFR equation assuming non-Black race (CKD-EPI09-NB) in patients >18 years of age with measured GFR ascertained by chromium-51-EDTA plasma clearance at Aarhus University Hospital in Denmark during 2010–2018. We examined bias, accuracy, precision (defined as the interquartile range of the absolute bias), and correct classification of chronic kidney disease (CKD) stages (GFR ≥ 60, 30–59, and <30 ml/min/1.73 m²) using the chromium-51-EDTA clearance as the reference standard. Furthermore, we assessed the performance of the equations in the total cohort while stratifying by CKD stage. We assessed the performance in the total cohort and in cohorts of cancer patients and potential living kidney donors.

Results: In this predominantly White population, the CKD-EPI21 equation performed slightly better than the CKD-EPI09-NB equation, both when examining the total cohort (N = 4,668) and when examining cohorts of cancer patients (N = 3,313) and living kidney donors (N = 239). In the total cohort, the CKD-EPI21 equation demonstrated lower median absolute bias (−0.2 versus −4.4 ml/min/1.73 m²), higher accuracy (72% versus 70%) as well as equal precision (25 versus 25 ml/min/1.73 m²) and correct classification of CKD stages (86% versus 85%) when compared with the CKD-EPI09-NB equation. When we stratified by CKD stage, the CKD-EPI09-NB equation performed slightly better than the CKD-EPI21 equation among patients with a GFR < 60 ml/min/1.73 m².

Conclusion: In a selected cohort of Danish patients with measured GFR, the CKD-EPI21 equation performed slightly better than the CKD-EPI09-NB equation except for patients with a GFR < 60 ml/min/1.73 m².
Conclusion: BP control in the NUTuRE-CKD cohort at baseline was suboptimal when compared to all three major guidelines. Subgroups at highest risk of adverse outcomes demonstrated poorer BP control. Given the importance of BP control in people with CKD, further research into BP management approaches and barriers to achieving optimal control is required. Priority should be given to developing a patient-centred approach to reduce BP more effectively.

#5661
EARLY COMPENSATORY INCREASE IN SINGLE-KIDNEY eGFR AFTER UNILATERAL NEPHRECTOMY IS ASSOCIATED WITH A LOWER LONG-TERM RISK OF eGFR DECLINE
Jessica Van Der Weijden 1, Faizan Mazhar 2, Edouard Fu 3, Marco Van Londen 1, Marie Evans 1, Stefan P. Berger 4, Martin de Borst 1 and Juan Jesus Carrero 2

1 University Medical Center Groningen, Internal Medicine, Division of Nephrology, Groningen, Netherlands, 2 Karolinska Institute, Medical Epidemiology and Biostatistics (MEB), Sweden and 3 Harvard University, Division of Pharmacoepidemiology and Pharmacoeconomics, Cambridge, United States of America

Background and Aims: The healthy kidney has reserve capacity, allowing for an increase in single-kidney GFR (Δsk-GFR) in the remaining kidney after nephrectomy. We evaluated whether higher Δsk-GFR, as a reflection of renal resilience, is associated with a lower long-term risk of eGFR decline in individuals undergoing unilateral nephrectomy.

Method: We included 1777 participants from the observational SREAM project who underwent radical unilateral nephrectomy in Stockholm during 2006–2021. We calculated the Δsk-GFR using the eGFR (CKD-EPI 2009) at 3 months post-nephrectomy eGFR minus 50% of the pre-nephrectomy eGFR and evaluated its pre-nephrectomy determinants (age, sex, eGFR, comorbidities) with multivariable linear regression. Follow-up started at 3-months post-nephrectomy, and Cox regression was used to explore the association between Δsk-GFR and the subsequent risk of CKD progression (defined as composite of a decline >30% relative to three months post-nephrectomy eGFR or initiation of kidney replacement therapy), adjusting for age, sex and pre-nephrectomy eGFR.

Results: Mean (SD) age was 68 ± 11 years, 40% of patients were female. 92% had a kidney cancer diagnosis and mean (SD) pre-nephrectomy eGFR was 75 ± 19 mL/min/1.73m². Median (IQR) Δsk-GFR was 11 (7–20) mL/min/1.73m². Pre-nephrectomy determinants of Δsk-GFR were age (StB = −0.20, P<0.001) and pre-nephrectomy eGFR (St.B = 0.14, P<0.001). During a median follow-up of 4 years (maximum 15 years), 178 participants developed CKD progression. The group with a Δsk-GFR above the median value (11 mL/min/1.73m²) had a 42% lower risk of CKD progression (adjusted HR: 0.58, 95% CI: 0.42 – 0.80), compared to those with a lower Δsk-GFR (Figure).

Conclusion: A larger compensatory increase in single-kidney eGFR early after unilateral nephrectomy, suggesting better renal resilience, was associated with a lower risk of CKD progression during long-term follow-up. Evaluation of Δsk-GFR could help identify patients at higher risk of progressive kidney function decline.

#6279
ESKD TREATMENTS: A DIFFICULT CHOICE TO ELDERLY PATIENTS?
Beatriz Mendes, António Inácio, Francisca Fonseca, Ana Piedade, Patrícia Domingues and Ana Farinha
Centro Hospitalar de Setúbal, Nefrologia, Setúbal, Portugal

Background and Aims: End stage kidney disease (ESKD) treatment choice may be very difficult mainly for elderly patients. Dialysis can be burdensome for the frail patients, offering more aggressive procedures and less quality of life. Conservative Care (CC) may shorten life in a fit patient. This study aimed to describe our elderly patients’ choices when it comes to CKD treatment options and reflect about them.

Method: We designed a single center retrospective observational, cross-sectional study regarding patients (pts) over 80 years old (yo) who attend the appointment of ESKD treatment modalities between July 2015 and and December 2021, since a Conservative Care Program is available in our hospital.

Results: During these 6,5 years, 113 pts over 80 yo were attended. Mean age was 85 yo (range 80–103). 66% were male and mean charlson comorbidity index (CMI) was 7 (sd ± 1,2). Mean seric creatinine was 3,69 mg/dl (sd 0,99; range 1,8-7,0). Mean estimated glomerular filtration rate was 17,41 (sd ±4,12) and 14,64 (sd ± 7,6) ml/min per 1.73 m² when calculated with BIS1 and CKD-EPI equation, respectively. Two patients were already on a regular program of dialysis. Regarding CKD etiology, 31,9% was from multifactorial origin, 27,4% was from undetermined origin, 10,6% was hypertensive, 8% was diabetic, 6,2% was from chronic pyelonephritis and 9,7% was in the context of cardiorenal syndrome. Regarding treatment options, 54% chose hemodialysis, 38,9% chose conservative care (CC), 2,7% chose peritoneal dialysis and 2,7% refused any treatment. We also observed a significant increase in the CC during these 6.5 years of study. Of those who chose hemodialysis, 22,95% (n = 14) died before starting on a regular program of dialysis, 62,3% (n = 38) actually started on a regular program and 14,75% (n = 9) still maintain follow-up in nephrology appointment. Regarding those who died before starting on dialysis treatment,
the mean time between choosing dialysis and death was 1.36 years (range 115 days to 3.46 years, median 1.36 years), and between starting on a regular program and death was 1.38 years (range 115 days to 4.9 years). The main cause of death was unknown (66%) (by lack of data), followed by infectious cause (26.6%). Considering those who chose CC, 31.8% (n = 14) died before starting the regular follow up, 54.5% (n = 24) are on a regular program of follow up, and 4.5% (n = 2) lately decided for dialysis. Regarding those who died before CC, the mean time between choosing it and death was approximately 1 year (range 29 days to 3.4 years), and between starting on a regular follow up and death was 0.68 years (range 14 days to 1.7 years). We didn’t find any statistical significance between CMI and the ESRD modality chosen (p = 0.709) or the occurrence of death (p = 0.496).

Conclusion: Even considering the poor prognosis and the high mortality rate, the majority of patients over 80 years old still chose dialysis over conservative kidney treatment. In our cohort, there was no survival benefit from those who choose dialysis instead of CC. CC should be offered as an alternative treatment to all the patients who may not benefit from dialysis. It is important to find tools who help us to guide patients in the best suitable choice in regard to ESKD treatments.

UNI-494 LOWERS URINARY B2-MICROGLOBULIN LEVELS IN RATS
Guru Reddy, Pramod Gupta, Atul Khare and Shalabh Gupta

Unicycive Therapeutics, Inc., Los Altos, United States of America

Background and Aims: Mitochondrial dysfunction in renal cells play a critical role in the pathophysiology of acute kidney injury (AKI) and chronic kidney disease (CKD). The proximal tubule is the primary sensor and effector in CKD progression and AKI. The measurement of urine B2-microglobulin (B2M) is a sensitive assay for proximal tubule injury. Nicorandil, a selective mitochondrial ATP-sensitive potassium channel activator, may be a promising AKI treatment, but its clinical use is limited by serious gastrointestinal side effects and rapid absorption and elimination. UNI-494, a novel nicorandil prodrug designed to improve its pharmacologic properties, may increase the short half-life and improve the safety profile of nicorandil. This study presents the efficacy data on the effects of UNI-494 in a rat ischemia-reperfusion (I/R) model, evaluating biomarkers of renal injury.

Method: 49 male Sprague-Dawley rats were randomly assigned to 4 groups to evaluate the in vivo efficacy of UNI-494 in a bilateral renal (I/R) model. Group 1, the Sham group, consisted of 10 subjects while groups 2–4 each had 13. Group 1 received no treatment, Group 2 a vehicle, Group 3 10mg/kg of UNI-494, and Group 4 20mg/kg of UNI-494. Treatments were administered as a single dose on Day 0, 1 hour prior to modeling. Body weights were measured on Days -1, 0, and 1. Urine B2M levels and urinary albumin-to-creatinine ratio (UACR) samples were collected within 24 hours after the surgery using the metabolic cages. Serum blood urea nitrogen (BUN) and creatinine samples were collected on Day -1 (pre-modeling) and 24 hours after modeling. T-tests were used to evaluate statistical differences between groups.

Results: B2M levels were significantly lower for the 20 mg/kg UNI-494 dose group compared to the vehicle group, and B2M content in both UNI-494 dose groups (10 and 20 mg/kg) was significantly lower compared to the vehicle group (Fig. 1). B2M levels and content were lower for the 20 mg/kg UNI-494 dose group than for the 10 mg/kg dose group (Fig. 1). There was no difference in body weight changes between the UNI-494 dose groups and the vehicle group. There were no statistically significant differences among all groups for serum creatinine and BUN pre-modeling and in UACR.

Conclusion: Lower levels of urine B2M levels in the higher UNI-494 dose group compared to the other groups indicate that UNI-494 may have a renoprotective effect. Additionally, the lower levels of B2M in the higher dose group compared to the lower dose group indicate a dose-response trend. Our study results are consistent with previously published data with nicorandil in a similar rat model of I/R. This potential renoprotective effect should be further investigated.

EXTRARENAL CYP27B1 ACTIVITY CONTRIBUTES TO THE CIRCULATING POOL OF 1,25(OH)2D

Hanne Joergensen1,2, Nele Peersman3,4, Jaak Billen3,4, Pieter Vermeersch3, Fiona Ivison5, Annemieke Heijboer6, Roger Bouillon4, Maarten Naeens2,7, Dirk Kuypers2,7 and Pieter Evenepoel2,7

1 Aarhus University Hospital, Department of Renal Medicine, Aarhus N, Denmark, 2 KULeuven, Department of Microbiology, Immunology and Transplantation; Nephrology and Renal Transplantation Research Group, Leuven, Belgium, 3 University Hospitals Leuven, Department of Laboratory Medicine, Leuven, Belgium, 4 KULeuven, Laboratory of Clinical and Experimental Endocrinology, Leuven, Belgium, 5 Manchester University NHS Foundation Trust, Department of Clinical Biochemistry, Manchester, United Kingdom, 6 Amsterdam UMC, University of Amsterdam, Department of Clinical Chemistry, Endocrine Laboratory, Amsterdam Gastroenterology Endocrinology & Metabolism, Amsterdam, Netherlands and 7 University Hospitals Leuven, Division of Nephrology, Leuven, Belgium

Background and Aims: Alterations of vitamin D metabolism are ubiquitous in patients with chronic kidney disease (CKD) and a key feature of the syndrome of CKD-mineral and bone disorder. A central paradigm in vitamin D metabolism is that the kidneys are the only relevant source of activation of vitamin D for systemic effects. However, various cells and tissues exhibit CYP27B1 activity and are capable of producing 1,25(OH)2D, which could contribute to the circulating pool [1]. This longitudinal, observational study challenges the dogma of the kidneys as the only source of 1,25(OH)2D, by investigating vitamin D metabolites in anephric patients free of active vitamin D therapy.

Method: Anephric patients free of active vitamin D therapy were included at time of kidney transplantation. A subset had a second study visit at 12 months post-transplant. Liquid chromatography–tandem mass spectrometry was used to measure 25(OH)D2/3, 1,25(OH)2D3 and 24,25(OH)2D3. Metabolic ratios of vitamin D metabolites over precursors were used as measures of CYP24A1 (24,25(OH)2D3/25(OH)D3) and CYP27B1 (1,25(OH)2D/25(OH)D3) activity. Biointact PTH (1-84) was measured by an in-house immunoradiometric assay [2] and FGF23 was measured by ELISA (Kainos Laboratories, Tokyo, Japan). Interleukin 6 (IL6), tumor necrosis factor-A (TNF- A) and interferon-γ (IFN-γ) were measured using an electrochemiluminescence multiplex immunoassay (Human Proinflammatory 1 V-plex, MSD, Maryland, US). Two independent laboratories performed confirmatory analyses of 1,25(OH)2D.

Results: All anephric patients (n = 38) had detectable (>2.5 pg/mL) levels of 1,25(OH)2D, with a median value of 13.5 pg/mL (range 3.9 to 35.7 pg/mL). There was a significant correlation between levels of 25(OH)D and 1,25(OH)2D (r = 0.583, p < 0.001), with 25(OH)D levels explaining 34% of the variation in 1,25(OH)2D (Fig. 1). 1,25(OH)2D levels were not significantly correlated to PTH (r = 0.279, p = 0.09) or FGF23 (r = 0.280, p = 0.09), nor to any of the inflammatory markers; IL6 (r = 0.068, p = 0.69), TNF- A (r = −0.264, p = 0.11), IFN-γ (r = −0.001, p = 0.99). To validate our findings, anonymized samples of 17 anephric patients and 17 CKD stage 5D with residual renal function were sent to two independent laboratories. The presence of 1,25(OH)2D was confirmed in all anephric patients. Twenty-five anephric patients underwent a successful kidney transplantation and were free of active vitamin D therapy at a study visit 12 months post-transplant. After kidney transplantation, 25(OH)D-level decreased, while levels of 1,25(OH)2D and 24,25(OH)2D substantially increased. The metabolic ratios expressing CYP24A1 and CYP27B1 activity both increased (Fig. 2). At 12 months post-transplant, 1,25(OH)2D-levels correlated with levels of biointact PTH (r = 0.603, p = 0.002), but not with levels of FGF23 (r = −0.262, p = 0.21).

Conclusion: Extrarenal CYP27B1 activity contributes to the circulating active vitamin D pool and may sustain low-normal levels of active vitamin D, even in anephric individuals. While renal CYP27B1 activity is hormonally regulated, extrarenal CYP27B1 activity seems to be mainly substrate dependent.

SAFETY OUTCOMES OF ORAL ANTICOAGULANT THERAPY IN PATIENTS WITH ATRIAL FIBRILLATION AND CHRONIC KIDNEY DISEASE

Ranokhon Igamberdieva and Sherzod Abdullaev
1Tashkent pediatric medical institute, Internal medicine, nephrology and hemodialysis, Asian (origins of Asia, East Asia or Southeast Asia), Uzbekistan and 2Republican Scientific and Practical Medical Center of Nephrology and Kidney Transplantation, Immunogenetics, Asian (origins of Asia, East Asia or Southeast Asia), Uzbekistan

Background and Aims: The comorbid conditions of atrial fibrillation (AF) and chronic kidney disease (CKD) leads to an increased risk of thromboembolic complications in AF. But with the deterioration of kidney function, the risk of hemorrhagic complications increases dramatically. This problem makes it difficult to choose an effective and safe oral anticoagulant therapy. Clinical data on the use of new oral anticoagulants (NOACs) in patients with AF and advanced CKD are limited, which determines the relevance of conducting studies in comparison with vitamin K antagonists. The aim of study was evaluation of safety parameters for the using of rivaroxaban in patients with stage 4 CKD with AF.

Method: The study included 109 patients over the age of 18 with a diagnosis of stage 4 CKD (eGFR < 15–29 ml/min/1.72 m²) and non-valvular AF. They were randomized in a 2:1 ratio to either rivaroxaban 15 mg (n = 73) or warfarin (n = 36). The mean follow-up period was 18 months. In the warfarin group, time in therapeutic range (TTR) >70% was achieved in 34 (94%) patients. Exclusion criteria were a history of bleeding that required hospitalization; decrease in hemoglobin level below 80 g/l, platelet count below 100 × 10⁹/l; indications for taking antiplatelet therapy; chronic use of drugs that increase the risk of bleeding. The analysis of the observed hemorrhagic events was carried out using the BARC and ISTH scales. Classification of anemia was carried out according to the recommendations of the World Health Organization.

Results: Patients taking warfarin were significantly more likely to develop minor bleeding according to the BARC scales and ISTH and all clinically significant bleeding on the ISTH scale. In patients with AF and CKD receiving warfarin therapy, minor bleeding (MB) according to the BARC scale was observed in 72.2% (n = 26), minor clinically significant bleeding (MCSB) in 8.33% (n = 3), major bleeding in 8.33% (n = 3) of cases; and in the group of patients treated with rivaroxaban, MB was observed in 42.4% (n = 31, p < 0.01), MCSB in 2.74% (n = 2, p = 0.32), major bleeding in 2.74% (n = 2, p = 0.32) of cases. When assessing bleeding on the ISTH scale during therapy with VKA, MB – 61.1% (n = 22), MCSB – 19.4% (n = 7), major bleeding – 8.33% (n = 3); against the background of NOACs therapy, MB – 36.9% (n = 27, p = 0.01), MCSB in 8.2% (n = 6, p = 0.06), major bleeding in 2.74% (n = 2, p = 0.32). All clinically significant hemorrhagic events according to the BARC scale in the warfarin group occurred more than 16.6% (n = 6) compared with the rivaroxaban group 5.4% (n = 4, p = 0.06); when analyzed according to the ISTH scale, the number of patients receiving VKA anticoagulant therapy 27.7% (n = 10) significantly prevailed over patients on the background of NOACs therapy, MB – 10.9% (n = 8, p = 0.03). Analysis of hemoglobin level did not reveal significant dynamics and significant differences between the groups: the median hemoglobin level at inclusion was 129 g/l in the rivaroxaban group and 123 g/l in the warfarin group (p = 0.3), after 18 months - 130 g/l and 121 g/l, respectively (p = 0.7).

Conclusion: Data suggesting a favorable safety profile for NOACs (rivaroxaban) compared with VKAs (warfarin) in patients with AF and advanced CKD was obtained in this study. Taking rivaroxaban was accompanied by a significantly lower number of hemorrhagic events, which may indicate a safe effect of the drug. No significant changes in hemoglobin levels were found in both groups. Confirmation of these data may be key in choosing an anticoagulant in patients with AF and advanced CKD.

CYSTATIN C-BASED ESTIMATED GLOMERULAR FILTRATION RATE AND RISK OF STROKE IN THE GENERAL POPULATION

Fei Xiao and Jinlan Liao
1Shantou University Medical College, Shantou, P.R. China and 2Peking University Shenzhen Hospital, Renal Division, Shenzhen, P.R. China

Background and Aims: Previous results on the association between estimated glomerular filtration rate (eGFR) and strokes are mixed. Most studies derived the eGFR from serum creatinine, which is affected by non-kidney determinants and possibly has biased the association with stroke risks. We hypothesized that eGFR was independently associated with the risk of stroke in the general population.

Method: We performed a population-based prospective cohort study of adults aged 40 years or older in a community-based setting. Participants were recruited from the community health service centers and the community medical centers. The primary outcome was incident stroke, defined as a first-ever non-fatal stroke or fatal stroke. Participants were followed for up to 10 years. The primary exposure was the eGFR, estimated using the Modification of Diet in Renal Disease (MDRD) formula. We used age, sex, smoking status, diabetes, hypertension, and systolic blood pressure in the initial model to adjust for potential confounding variables. We used a multivariable regression model to estimate the association between the eGFR and the risk of stroke.

Results: Among 20,000 participants, there were 1,000 incident strokes. The median eGFR was 90 ml/min/1.73 m². The eGFR was inversely associated with the risk of stroke (p < 0.01). The risk of stroke was 40% lower in the group with the highest eGFR compared with the group with the lowest eGFR (p < 0.01). In the multivariable regression model, the eGFR remained inversely associated with the risk of stroke (p < 0.01).

Conclusion: The eGFR was independently associated with the risk of stroke in the general population. These findings provide further evidence that renal function is a risk factor for stroke.
population. Herein, we investigated the linear and nonlinear associations of the cystatin C-based eGFR (eGFR$_{cys}$) with the risk of total stroke and its subtypes in the UK Biobank participants.

**Method:** In this cohort study, we included 462,307 UK Biobank participants (94.5% Whites, 54% women, aged 56±8 years) free of stroke at enrollment. The eGFR$_{cys}$ and eGFR$_{cr}$ were calculated with serum cystatin C and creatinine, respectively. Outcomes of interest were the incidences of total stroke and subtypes. We investigated the linear and nonlinear associations using Cox proportional hazards models and restricted cubic splines, corrected for regression dilution bias.

**Results:** During averaged follow-up of 10.11 years, 4,427 incident strokes occurred, among which 3,447 were ischemic and 1,163 were hemorrhagic. After adjustment of confounders, the regression dilution-corrected hazard ratios (95% confidence intervals) for every 10 ml/min/1.73 m$^2$ decrement in eGFR$_{cys}$ were 1.10 (1.06-1.12) for total stroke and 1.11 (1.08-1.15) for ischemic stroke. A similar pattern was observed with eGFR$_{cr}$ although the association was weaker. When either eGFR was below 75 ml/min/1.73 m$^2$, the risks of total and ischemic stroke increased exponentially as eGFR decreased. However, when eGFR$_{cys}$ was above 75 ml/min/1.73 m$^2$, the risks did not significantly differ but seemingly decreased as eGFR$_{cys}$ exceeded 105 ml/min/1.73 m$^2$. A U-shape relationship was witnessed if eGFR$_{cr}$ was used instead. There was null association between eGFR and hemorrhagic stroke.

**Conclusion:** The risks of total stroke and ischemic stroke increased exponentially when the eGFR fell below 75 ml/min/1.73 m$^2$.

**Background and Aims:** Apolipoprotein L1 (APOL1) toxic gain-of-function variants (G1 or G2) are genetic factors driving a broad spectrum of progressive, proteinuric nephropathies referred to as APOL1-mediated kidney disease (AMKD). APOL1 genotyping is not routinely performed in kidney disease care, and prevalence of APOL1 variants among persons with chronic kidney disease (CKD) in Europe is not well known. These variants are common in persons of recent African ancestry. We report interim data of a global study estimating the prevalence of APOL1 genotypes in participants of recent African ancestry and proteinuric CKD, with a focus on data from Europe.

**Method:** Enrollment in this ongoing study will include up to 2,500 participants across different geographies who are of recent African ancestry and have focal segmental glomerulosclerosis (FSGS) or other proteinuric nondiabetic kidney disease (NDKD). The study includes a single visit during which blood samples are collected from participants to determine their APOL1 genotype using a validated polymerase chain reaction (PCR)-based assay. The percent of participants with two APOL1 variants and percent of participants in each genotype category (e.g., G1/G1, G1/G2, G2/G2) are assessed; genetic counseling services are available to participants, if desired.

**Results:** This interim analysis included 1,256 participants of whom 174 (13.9%) were from Europe. As shown in the table, among the 88 participants with FSGS and 86 participants with proteinuric NDKD, 54 (61.4%) and 32 (37.2%) have two APOL1 variants, respectively.

**Conclusion:** Our study will generate one of the largest global APOL1 genotyping data sets in participants with proteinuric kidney disease. These data begin to address a critical knowledge gap and highlight the importance of APOL1 genotyping in kidney disease care to identify AMKD, potentially optimize disease management, and enable referral for interventional clinical trials evaluating targeted therapies for AMKD.

\textit{APOL1:} Apolipoprotein L1; \textit{FSGS:} focal segmental glomerulosclerosis; \textit{IA:} interim analysis; \textit{NDKD:} nondiabetic kidney disease; \textit{SD:} standard deviation

Notes: Eligible participants are at least 12 years of age and of African ancestry or geographic origin (Black, Caribbean, African American, Sub-Saharan African, Cuban, Mexican, Puerto Rican, South or Central American, or other Spanish culture/origin). For more information about the study, please see https://apol1program.com/. This table includes participants in the Full IA Set with a genotyping result as of 01 Dec 2022. Percentages were calculated based on the number of participants in the Full IA set, unless otherwise specified.

$^a$ Percentages were calculated based on the total number of participants in each region/country per disease state.
(CKD) and cardiovascular (CV) complications based on estimated glomerular filtration rate (eGFR) and urinary albumin:creatinine ratio (UACR). GLP-1-like peptide-1 receptor agonists (GLP-1RAs) are recommended by the KDIGO 2022 Clinical Practice Guidelines for Diabetes and CKD in patients with type 2 diabetes (T2D) and CKD who need better glycemic control or CV risk reduction. In patients with T2D, once-weekly (OW) semaglutide, a GLP-1RA, reduces albuminuria and may preserve eGFR compared with placebo, irrespective of baseline eGFR or UACR. The aim of this analysis was to assess the treatment effects on kidney outcomes of OW semaglutide by KDIGO risk category at baseline compared with placebo.

**Method:** In a post hoc analysis from the SUSTAIN 6 trial (NCT01720446), randomised patients with T2D (N = 3,297) treated with OW semaglutide (0.5 mg and 1.0 mg) or placebo were stratified by baseline KDIGO risk category (low, moderate, high, and very high). The median follow-up time was 2.1 years. The treatment effect on the adjudicated endpoint of time to first new or worsening nephropathy (a composite of macroalbuminuria onset, doubling of serum creatinine and eGFR <45 mL/min/1.73 m², need for kidney replacement therapy, or death due to kidney disease) across KDIGO categories was analysed using Cox regression. Analyses of treatment for eGFR slope and change in UACR (log-transformed) across KDIGO categories were performed using random slope modelling and mixed models adjusted for baseline UACR and UACR (log-transformed) across KDIGO categories were performed using Cox regression. Analyses of treatment for eGFR slope and change in UACR (log-transformed) across KDIGO categories were performed using random slope modelling and mixed models adjusted for baseline UACR and UACR (log-transformed) across KDIGO categories were performed using Cox regression. Analyses of treatment for eGFR slope and change in UACR (log-transformed) across KDIGO categories were performed using random slope modelling and mixed models adjusted for baseline UACR and UACR (log-transformed) across KDIGO categories were performed using Cox regression.

**Results:** Participants with baseline eGFR and UACR values (N = 3,238) were stratified in the low (n = 1,596 [49%]; 60% male; mean 64 years), moderate (n = 831 [26%]; 62% male; mean 65 years), high (n = 445 [14%]; 62% male; mean 66 years) and very high (n = 366 [11%]; 59% male; mean 67 years) KDIGO risk categories. Regardless of treatment group, participants in the moderate-, high- and very high-risk groups were more likely to experience new or worsening nephropathy endpoint vs participants in the low-risk group, as predicted by KDIGO risk category classification. The treatment effect of OW semaglutide vs placebo on risk of new or worsening nephropathy, eGFR slope and change in UACR was consistent across KDIGO risk categories. The ongoing FLOW kidney outcomes trial has a population with T2D and CKD that corresponds to the high- and very high-risk KDIGO categories, and it will provide primary outcome data on potential kidney-protective effects of OW semaglutide; results are anticipated in 2024.

#3664 EVALUATION OF THE INTRODUCTION OF NOVEL POTASSIUM BINDERS IN ROUTINE CARE: THE STOCKHOLM CREATININE MEASUREMENTS (SCREAM) PROJECT

Ailema González-Ortiz, Alessandro Bosi, Edouard Fu, Beatriz E Pérez-Guillén, Marie Evans, Catherine M. Clase, Carmine Zoccali and Juan Jesus Carrero

1 Karolinska Institutet, Department of Medical Epidemiology and Biostatistics, Stockholm, Sweden, 2 Instituto Nacional de Pediatría, Mexico City, Mexico, 3 Translational Research Center, Mexico City, Mexico, 4 Leiden University Medical Center, Department of Clinical Epidemiology, Leiden, Netherlands, 5 Brigham and Women’s Hospital and Harvard Medical School, Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Boston, United States of America, 6 Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden, 7 McMaster University, Department of Medicine, Hamilton, Ontario, Canada, 8 McMaster University, Department of Health Research and Methodology, Canada, 9 CNR-IFC, Clinical Epidemiology of Renal Diseases and Hypertension, Italy and 10 Department of Clinical Sciences, Karolinska Institutet, Danderyd Hospital, Sweden

**Background and Aims:** The pharmacological management of hyperkalemia has traditionally considered sodium polystyrene sulfonate (SPS) and, since late 2018, the novel potassium (K+) binders Patiromer and Sodium Zirconium Cyclosilicate (SZC). This study evaluated their patterns of use, duration of treatment and relative effectiveness in reducing plasma K+ levels in Stockholm’s contemporary routine care.

**Method:** Observational study of all adults who newly-filled a prescription for SPS, Patiromer or SZC during 2019–2021 in Stockholm, Sweden. Sweden offers universal healthcare and covers the cost of prescribed medications. We described patient characteristics of new initiators, including their comorbidities, medication use, eGFR and pre-treatment plasma K+ levels. We then quantified treatment duration by evaluating all subsequent dispensations. Lastly, we
compared their relative efficacy by evaluating post-treatment K+ during the following 60 days through multivariable logistic regression. Because the frequency and pattern of K+ monitoring differed per patient, we considered the K+ test closest to the end of 15-day intervals. Then, we estimated odds ratios and 95% confidence intervals of maintaining normokalemia (K+ < 5.1 and < 5.5 mmol/L) for the novel binders vs SPS.

**Results:** During 2019–2021, 1879 adults started treatment with SPS, and 147 with novel binders (41 with Patiromer and 106 with SZC). The median K+ at initiation for all three treatments was 5.7 mmol/L. Median eGFR was higher among Patiromer initiators (58 mL/min/1.73 m²) than initiators of SZC (31 mL/min/1.73 m²) or SPS (37 mL/min/1.73 m²). Patients on SPS stayed mean 61 days on treatment, and 14% filled three or more consecutive prescriptions suggesting chronic use. Patients on novel binders stayed mean 109 days on treatment, and 49% filled three or more prescriptions (Panel A). After 15 days of treatment, mean plasma K+ similarly decreased to 4.6 (4.3-5.1) and 4.8 (4.5-5.2) mmol/L in patients with SPS and novel binders, respectively, and this level was maintained during the 60 days post-treatment (Panel B). 76% of SPS users reached a potassium value < 5.1 mmol/L at day 15 versus 67% of patients in the novel binder group (between group difference 9%; 95% CI 0.92-2.57; p-value 0.07; Panel C). Furthermore, the proportion of patients with K+ < 5.5 mmol/L at day 15 was 91% for SPS and 85% for novel binders (Panel D). In multivariable logistic regression, the odds ratio for novel binders (vs SPS) in reaching K+ targets (K+ < 5.1 mmol/L) after 15 days was 0.68 (95% CI 0.42-1.17) and 0.78 (95% CI 0.42-1.44) after 30 days.

**Conclusion:** We observe modest use of novel K+ binders in Stockholm's contemporary practice, with longer treatment lengths than SPS. Both SPS and novel binders showed similar efficacy in achieving normal potassium values during the first 15 days of treatment and subsequent 2 months.
The present study aimed to characterize the performance of this feedback controller. 

**Methods:** We conducted a single-arm, prospective, interventional pilot study in subjects on chronic HD at three Avantus Renal Therapy dialysis centers in New York City. Subjects were treated with Fresenius 2008T HD machines. RBV was measured with the CLiC® device. CLiC® and HD machine data were fed into a research laptop running the UFR Feedback Controller software. The UFR recommendations (generated every 10 minutes) were evaluated by dialysis nurses, who then either implemented or disregarded them as they deemed clinically appropriate. The nurses were instructed to only override Controller recommendations if medically indicated, but not in an attempt to manage the subjects’ RBV trajectories themselves. RBV target range attainment with the UFR Feedback Controller was compared to standard of care treatments (data obtained retrospectively) in the same subjects.

**Results:** Fifteen subjects (58.9 ± 15.3 years, dialysis vintage 4.1 ± 2.4 years, baseline interdialytic weight gain 2.6 ± 0.8 L, treatment time 222 ± 28 min) were studied prospectively with the UFR Feedback Controller (63 study visits, 4.2 ± 1.9 visits per subject). Nine subjects contributed at least two complete treatments to each study period (Controller and standard of care, respectively) and were included in this analysis. The probabilities of achieving an RBV within the desired target range for each timepoint, stratified by study period (standard of care versus UFR Feedback Controller), are shown in the Figure. Use of the Controller was associated with a higher rate of RBV target range attainment for every timepoint. We confirmed these results with generalized linear mixed-effects models: Across all RBV target timepoints, use of the Controller was a significant predictor of better RBV target range attainment (P < 0.0001). Use of the UFR Feedback Controller was a significant predictor of better RBV target range attainment for timepoints 60, 90, 120, and 150 minutes, and a borderline significant predictor for timepoints 30 and 180 minutes.

**Conclusion:** Use of this UFR Feedback Controller was associated with a significant and clinically meaningful increase in RBV target range attainment. This technology individualizes the UFR to the patient’s plasma refill kinetics during the HD treatment and may assist clinicians with optimizing fluid management in their patients.

---

**NOVEL EXTRACORPOREAL TREATMENT FOR SEVERE NEONATAL JAUNDICE: A MATHEMATICAL MODELING STUDY WITH ALLO-HEMODIALYSIS**

Vaibhav Maheshwari¹, Maria Ferris², Guido Filler³ and Peter Kotanko¹, 4

¹Renal Research Institute, New York, United States of America, ²University of North Carolina at Chapel Hill, Chapel Hill, United States of America, ³Schulich School of Medicine and Dentistry, Department of Paediatrics, London, Canada and ⁴Icahn School of Medicine at Mount Sinai, New York, United States of America

**Background and Aims:** Neonate hyperbilirubinemia usually resolves within 3–5 days without complications however, severe neonatal jaundice (SNJ) is associated with long-term neurocognitive impairment, cerebral palsy, auditory neuropathy, deafness, or death. Globally, at least 481,000 term/near-term neonates are affected by SNJ annually, with 114,000 neonates dying and an additional 63,000 neonates surviving with kernicterus [1,2]. Phototherapy and exchange transfusions prevent/treat SNJ, but these modalities are scarce in some low and lower-middle income countries, where SNJ prevalence is increased due to higher prevalence of glucose-6-phosphate dehydrogenase deficiency, blood group incompatibilities, late referrals, and delayed diagnosis. We aimed to explore a model for allo-hemodialysis (alloHD), a novel potential modality to treat SNJ rapidly and effectively in neonates, possibly avoiding exchange transfusions.

**Method:** With alloHD, the neonate’s blood flows through hollow fibers of a 0.075 m² miniature low flux hemodialyzer (pore size 1.2 to 2.2 nm), while the blood of a healthy adult (“buddy”) flows counter-currently through the dialyzer, thus serving as the “dialysate”. Our mathematical model simulates the bilirubin kinetics in alloHD, with neonate and buddy blood flow rates at 15 and 30 mL/min, respectively. In the neonate model, bilirubin conjugation was assumed to be zero, resulting in excess unconjugated bilirubin that binds to albumin and causes SNJ. Bilirubin production rate in neonate and buddy were set to 6 and 3 mg/kg/day, respectively [3]. Buddy bilirubin conjugation rate was calculated to obtain normal steady state bilirubin levels.
We only simulated unconjugated bilirubin because the conjugated form is easily excreted. Simulations are performed with neonate and buddy albumin levels of 31 g/L and 43 g/L, respectively.

**Results:** Model simulations suggest that 3- to 6-hour alloHD session can reduce neonatal bilirubin levels by >30% (Fig. 1, left panel). Due to the high bilirubin conjugation capacity of an adult’s healthy liver, the buddy’s bilirubin level increases only transiently during the alloHD session (Fig. 1, right panel).

**Conclusion:** Our modeling suggests that a single alloHD session can lower bilirubin levels to 31 g/L and 43 g/L, respectively. Simulations are performed with neonate and buddy albumin levels effectively. In principle, this bilirubin reduction should lower the risks associated with SNJ, especially kernicterus and possibly avoiding exchange transfusions. Future modeling scenarios will incorporate the improved neonatal liver function over time and additional alloHD schedules.

**NON-INVASIVE OPTICAL ESTIMATION OF INTRADIALYTIC CONCENTRATIONS OF UREMIC TOXINS IN BLOOD OF HEMODIALYSIS PATIENTS**

Joosep Paats¹, Annika Adoberg², Jürgen Arund¹, Ivo Fridolin¹, Jana Holmar¹, Kai Lauri³, Liisi Leis³, Kristjan Pilt¹, Risto Tanner¹ and Merike Luman¹

¹Tallinn University of Technology, Department of Health Technologies, Tallinn, Estonia, ²North Estonia Medical Centre, Centre of Nephrology, Tallinn, Estonia and ³SYNLAB Eesti OÜ, Tallinn, Estonia

**Background and Aims:** Hemodialysis (HD) adequacy is generally estimated by the dialysis adequacy marker Kt/V urea that poorly describes removal of uremic toxins with different removal kinetics, such as protein bound or middle molecule uremic toxins, which have direct effect on morbidity and mortality of end stage kidney disease (ESKD) patients. We have recently shown the feasibility of estimating an alternative dialysis adequacy marker that can be applied to dialysis sessions with varying settings and different uremic toxins, intradialytic time average concentration (TAC) of uremic toxins, such as urea, uric acid (UA), indoxyl sulfate (IS) and beta-2-microglobulin in blood of ESKD patients, from spent dialysate concentrations determined by laboratory methods [1]. The aim of this retrospective observational study was to estimate intradialytic TAC of uremic toxins UA and IS non-invasively from spent dialysate concentrations determined by optical methods.

**Method:** Twenty-two ESKD patients on chronic HD were enrolled into the study. For each patient 4 midweek dialysis sessions with different treatment settings were included (1 HD: Qb = 200 mL/min, Qd = 300 mL/min, dialyzer 1.5 m²; 3 HDF: median (interquartile range) Qb = 298 (296–356) mL/min, Qd = 795 (500–800) mL/min, Vsubst. = 21.8 (15–24.5) L, dialyzers 1.8 m² and 2.2 m²). During each dialysis session, blood samples were taken at 0 min (start) and 240 min after the start from the arterial blood line and dialysate samples were taken at 7 min and 240 min after the start from the outlet of the dialysis machine. Concentrations of UA and IS in serum and spent dialysate samples were determined with HPLC. In addition, UV absorbance and fluorescence of the spent dialysate samples were measured with spectrophotometer UV-3600 and spectrofluorometer RF-6000 (both from Shimadzu Corp., Japan), after which concentrations of UA and IS in spent dialysate samples were determined based on the optical properties of samples. Stability of HD treatment settings were monitored online and dialysis sessions with unstable blood and dialysate flow rates were excluded. TAC of UA and IS were calculated from serum concentrations and evaluated from laboratory and optically estimated logarithmic mean concentrations (Mln D) of spent dialysate.

**Results:** Mean intradialytic serum TAC values of UA and IS were 198.4 ± 37.8 μmol/L and 69.5 ± 37.8 μmol/L and strongly correlated to those estimated from optically determined Mln D 198.0 ± 38.9 μmol/L (R² = 0.75) and 69.5 ± 37.8 μmol/L (R² = 0.81), respectively. Mln D of UA and IS in spent dialysate based on laboratory methods were 102.2 ± 22.8 μmol/L and 5.9 ± 3.5 μmol/L and strongly correlated with the optically determined concentrations of 102.7 ± 23.1 μmol/L (R² = 0.97) and 6.1 ± 3.4 μmol/L (R² = 0.97), respectively.

**Conclusion:** Intradialytic serum TAC of UA and IS can be estimated non-invasively with optical methods from their concentration in spent dialysate independent of treatment modality. Optical online monitoring of spent dialysate in real-time could therefore provide additional information about treatment adequacy regarding the removal of uremic toxins’ other than urea. In future, TAC estimation models should be optimized for each uremic toxin to establish higher accuracy, considering real-time treatment settings, recirculation etc.

TEMPORAL CHANGES IN PLASMA ENDOTHELIN-1 AND BLOOD PRESSURE DURING MAINTENANCE HAEMODIALYSIS

Leszek Pstras¹, Anika Singh²,³, Simon Correa⁴,⁵ and Finnian R. MC Causland²,³

¹Nalecz Institute of Biocybernetics and Biomedical Engineering, Polish Academy of Sciences, Warsaw, Poland, ²Brigham and Women’s Hospital, Renal Division, Department of Medicine, Boston, MA, United States of America, ³Harvard Medical School, Boston, MA, United States of America, ⁴Yale School of Medicine, Department of Internal Medicine, New Haven, CT, United States of America and ⁵Yale New Haven Hospital, New Haven, CT, United States of America

Background and Aims: Endothelin-1 (ET-1) is a potent endothelium-derived vasoconstrictor that plays an important role in the regulation of arterial blood pressure (BP). Elevated levels of plasma ET-1 have been reported in patients with end-stage renal disease (compared with controls), patients on dialysis (compared with non-dialyzed uremic patients), and patients on haemodialysis (compared with peritoneal dialysis). It has been suggested that ET-1 plays a role in BP response to HD; however, the temporal association of changes in ET-1 with changes in BP during the course of an HD session has not been well defined. Moreover, conflicting results have been reported as to the patterns of intradialytic ET-1 changes, with different studies reporting either a decrease, an increase, or no change in ET-1 during HD. The aim of this study was to investigate temporal changes in ET-1 in patients with different intradialytic BP profiles.

Methods: Data was obtained from a prospective cohort study of 50 maintenance, thrice-weekly HD patients admitted to Brigham and Women’s Hospital in Boston, MA, USA. BP was measured before, after, and every 15 min during dialysis using a calibrated ambulatory BP cuff. Blood samples were drawn before dialysis, at 30, 60, and 120 min into HD, and at the end of treatment. Following the exclusion of cases with missing data, shorter dialysis sessions, or very low pre-dialysis BP (below 85/55 mmHg), 42 patients were included in the analysis (17 females, median age 62 years, over 90% diagnosed with hypertension). One HD session was studied in each patient (median ultrafiltration 2.05 L, median duration 232 min). The patients were divided into three subgroups with different patterns of intradialytic systolic blood pressure (SBP): 1) patients with intradialytic hypotension (IDH) defined as: a) drop of...
SBP to or below 90 mmHg; or b) drop in SBP by at least 30 mmHg associated with at least two hypotension-related symptoms; or c) drop in SBP associated with multiple symptoms requiring intervention; 2) normotensive patients (NT) defined as patients in whom SBP remained between 90 and 130 mmHg for most of the HD session; 3) hypertensive patients (HT) defined as patients in whom the median intradialytic SBP was above 140 mmHg.

Results: 9 hypertensive patients (HT), 24 IDH patients, and 9 normotensive patients (NT) were identified. In the IDH group, at the end of HD, the median drop in SBP (from the pre-HD level) was 28 mmHg (25th – 75th percentile 10–45 mmHg). In HT and NT patients, SBP did not change significantly during HD. IDH patients had lower baseline ET-1 (2.2 pg/mL) compared with HT patients (3.4 pg/mL, P = 0.006) but similar compared with NT patients (2.3 pg/mL). ET-1 decreased over the course of dialysis in HT patients (P = 0.02) and NT patients (P = 0.008), whereas no change was observed in IDH patients (P = 0.30). At the end of HD, IDH patients had a similar ET-1 level (2.4 pg/mL) compared with HT patients (2.6 pg/mL) but higher compared with NT patients (1.4 pg/mL, P = 0.004). A moderate negative correlation was found between the dialysis-associated changes in ET-1 and SBP (r = -0.43, P = 0.005) as well as between the baseline ET-1 and baseline SBP in IDH patients (r = -0.42, P = 0.04).

Conclusions: HD patients may present various patterns of ET-1 changes during HD, which seem to be associated with BP response to HD. In particular, the patterns of ET-1 response to HD may vary among patients categorized as ‘hypertensive’ (the vast majority of patients in our study), who previously were observed to have an intradialytic increase in ET-1. Our results provide a possible explanation as to why previous studies that did not consider intradialytic BP patterns have yielded conflicting results regarding the direction of ET-1 changes during HD.

Results: At two weeks, survival and graft patency were 100%. Explant cellularity and collagen content were not significantly different between sham and CKD rats and were not influenced by SDF-1α. Endothelial cell coverage (RECA +) and smooth muscle cell presence (αSMA +) were visually similar irrespective of disease or bio-functionalization. Elastin+ (p = 0.11), pan-(CD68+, p = 0.08) and anti-inflammatory macrophage (CD163+, p = 0.52) surface area, as well as (anti)-inflammatory gene expression were not significantly different between groups. The twelve-week CKD-group was taken out of experiment prematurely due to rapid disease progression. In addition, preliminary death due to vascular rupture occurred in four animals (n = 2 pristine and n = 2 SDF-1α) in the twelve-week sham animals. While patent, all remaining sham explants at twelve weeks (n = 9) showed severe vascular dilatation and calcifications (von Kossa+). No differences in inflammatory and neo-tissue markers were found between twelve-week sham pristine and SDF-1α grafts or between explants over time.

Conclusion: CKD did not significantly alter inflammation or tissue formation of in situ tissue engineered vascular grafts. Additionally, SDF-1α bio-functionalization did not significantly alter cell engraftment or tissue formation. Mechanical stability of the graft appears to be the primary driver of neo-tissue formation. Future emphasis on in vitro to in vivo translation should be on the fine balance between tissue formation on one hand and fiber resorption on the other hand.

#4216 FEASIBILITY ANALYSIS OF AN ULTRASOUND-GUIDED PLACEMENT OF TUNNELED HEMODIALYSIS CATHETERS

Martin Kächele, Lucas Bettac, Christopher Hofmann, Hannes Herrmann, Amelie Brandt, Bernd Schroeppeel and Lena Schulte-Kemna

University Hospital of Ulm, Internal Medicine I - Section of Nephrology, Ulm, Germany

Background and Aims: Radiographic fluoroscopy (RAD) is the current standard for placement of tunneled central venous catheters (CVC) for hemodialysis. RAD requires structural and personnel infrastructure and exposes the patient to ionizing radiation. Here, we investigate the feasibility of solely ultrasound-guided placement of tunneled central venous dialysis catheters.

Method: We evaluated prospectively collected single center data of 134 consecutive patients who underwent CVC implantation between 2020 and 2021 regarding feasibility, safety, and catheter function. We used the inset guidewire to visualize the position of the catheter tip. In the case of inadequate visibility by ultrasound, we additionally used intracardiac ECG recording or agitated saline. A total of 1844 catheter days were assessed. As a historical control, we analyzed the position of 50 CVCs placed by RAD. Optimal CVC position was defined to be in between the cavalatrial junction (CAJ) and the right atrium (RA), according to the guidelines.

Results: The catheters were placed on the right side in 117 (87%) cases. The primary success rate for optimal position and function was 97.7% (n = 131). Placement solely by ultrasound was possible in 130 (97%) cases. There were no immediate procedure-associated complications related to the new technique. Effective blood flow averaged 292 ± 39 ml/min. Of all ultrasound-placed catheters, 6% were in the vena cava superior (RAD 24%), 70% in the CAJ (RAD 60%), and 24% in the RA (RAD 16%), resulting in a rate of 94% with optimal position.

Conclusion: Placement of CVCs for hemodialysis solely by ultrasound is an effective and safe alternative to fluoroscopy-assisted placement.
A COHORT OF DIALYSIS PATIENTS WITH LOW PREVALENCE OF UPPER ARM FISTULAS
Simona Cuna, Giulia Fonto, Luisa Lefons, Paolo Ria, Paolo Protopapa, Marcello Napoli and Silvia Barbarini

Ospedale “Vito Fazzi”, Lecce, Italy

Background and Aims: International guidelines encourage the use of distal native fistula (AVF) which is the best first-line vascular access (VA). But, despite these indications, all over the world, except for Japan, the prevalence of upper arm fistula (UAF) is dramatically increasing. Previous surveys in our department included about 50% of Haemodialysis patients (HP) and showed prevalence of UAFs less than 5%—very low, if compared with those of our country, reported by DOPPS 5 study. We decided to analyse 100% of HP in our department, in order to confirm or exclude the low prevalence of UAF.

Method: Puglia, southern east of Italy, has 1.4 millions inhabitants, of which 1365 need dialysis; 1295 on haemodialysis in 17 different centers and 70 on peritoneal dialysis. The department is organized on a Hub and Spoke model for VA management (Fig. 1). Hub performs simple and complex AVFs, Graft, PTA of non matured or stenotic fistulas, PTA of central stenosis, and surgical rescue of thrombosed or stenotic fistulas. Our four spokes perform mainly simple distal forearm fistula (DFF). In December 2021 we collected datas of VA prevalence of all 1295 HP. The AVFs were classified, according to their anatomical site, in DFF, mean-proximal forearm fistula (MPFF) and UAF.

Results: The average age of 1295 HP was 69 ± 14.65 yo (65% males and 21% diabetics) and 458 of them (35%) where more than 75 yo. The prevalence of DFF, MPFF, UAF, GRAFT and CVC was 63.5%, 10.1%, 3%, 0.7%, 22.5% respectively (fig. 2). Patients aged ≥75 years, women and diabetics showed a higher prevalence of CVC and a lower prevalence of DFF.

Conclusion: Data collected on all patients confirm the low prevalence of UAF detected in the previous surveys— which involved only a part of haemodialysis patients. Zero upper arm fistulas is an utopian goal, but it seems possible to reduce the prevalence of proximal fistulas to 5% or less as the Japanese experience has showed.
TAUROLIDINE HAVE A SIMILAR INFLAMMATORY PROFILE TO PATIENTS ON HD WITH CENTRAL CATHETERS LOCKED WITH TAUROLIDINE-CITRATE (CVC-Hep).

- P < 0.01 vs AVF; **Not significant vs AVF.

Conclusion: In patients under HD with cuffed tunneled CVC, the use of TCH lock solution after each HD session is associated with a significant gene expression level of IL-6 and TNF-alpha. After 3 months, gene expression levels of subjects with AVF compared to baseline, whereas in subjects with CVC-lock solution after each HD session is associated with IL-6 and TNF-alpha in peripheral blood mononuclear cells (PBMC) were measured at inclusion and after three months follow-up.

Results: Altogether eighty-five subjects (42 males and 43 females; mean age 61 ± 9 yrs; 39% diabetics) were initially included in the study. In 25 subjects the vascular access was AVF, while the rest used tunneled CVC; of these 31 used standard CVC-Hep and 29 used CVC-TCH. Five patients dropped out the study and thus 80 patients completed the 3-month follow-up and were finally evaluated. Inclusion, patients with CVC had significantly higher serum and expression levels of inflammatory markers compared to subjects with AVF.

Conclusion: In patients under HD with cuffed tunneled CVC, the use of TCH lock solution after each HD session is associated with a significant improvement in the inflammatory serum and gene expression state. Thus, the inflammatory profile of patients with CVC using TCH does not differ from that of patients with native AVF after at least three months of CVC-TCH use.

Abstracts
SAFETY AND EFFICACY OF VIRTUAL OUTPATIENT NEPHROLOGY CONSULTATION IN THE NORTHERN ALBERTA RENAL PROGRAM

Mark Courtney, Feng Ye and Aminu Bello

University of Alberta, Medicine, Edmonton, Canada

Background and Aims: There is a growing awareness among Canadian health care providers of the need to incorporate virtual consultations safely and effectively post pandemic. With the onset of the Covid-19 pandemic in March 2020, outpatient consultation in Northern Alberta Renal Program (NARP) was rapidly transitioned to virtual delivery (telephone or videoconferencing) in place of face-to-face visits. To scale up and sustain virtual consultation in kidney care programs, its safety and effectiveness in improving processes of care (reduced wait time and access to care) and patient-related outcomes must be established. Data establishing safety and effectiveness of virtual consultation in kidney care has been limited. We therefore aimed to evaluate the safety and effectiveness of virtual consultation in patients with advanced CKD or peritoneal dialysis (PD) being cared for in NARP.

Method: The study was conducted in NARP (one of the largest kidney care programs in Canada). The study populations comprised two categories of patients with kidney disease: 1) CKD (non-dialytic) being followed in the ambulatory care clinics and 2) chronic PD patients being followed up in a dedicated home dialysis clinic at 3-monthly intervals. Data were collected over two-time points, pre and post implementation of virtual kidney following the COVID-19 pandemic: March 2019-February 2020 (pre-implementation), and March 2020-February 2021 (post implementation). We were only allowed to collate data on the processes of care outcomes for CKD (clinic cancellations/no-shows, wait times to see a nephrologist from the point of referral and number of visits), and adverse clinical outcomes (peritonitis rates, all-cause hospitalizations, technique failure, defined as PD failure with transition to hemodialysis) for the patients on PD. Summary statistics and tests of associations applied as appropriate. Interrupted time series analyses were used to evaluate trends. All analyses were conducted using (STATA 15 software (Stata Corporation, 2017). The study was approved by the University of Alberta Research Ethics Board.

Results: In patients on PD, the studied outcome measures were not significantly impacted (no changes in the trend) pre and post virtual care implementation (Figs 1a-c). The absolute number of clinic visits in patients on PD did not change (data not shown). In the patients with CKD, there were significant reductions in the rate of clinic cancellations/no-show rates (Fig. 2a), and a reduction in wait time (by a median of two weeks) following virtual care implementation (Fig. 2b). The rates of clinic visits pre and post implementation did not change (Fig. 2c).

Conclusion: The implementation of virtual consultation with the onset of COVID-19 pandemic (and the attendant reduction in face-to-face contacts with patients) did not negatively impact the care of patients on PD regarding risk for adverse clinical outcomes (peritonitis rates, all-cause hospitalizations, and technique failure). In patients with CKD, implementation of virtual care
Figure 1c: All-cause hospitalization rates in peritoneal dialysis pre-and post-implementation of virtual care. (p = 0.52).

Figure 2a: Cancellation/ no-show rates in the patients with CKD pre-and post-implementation of virtual care. (P < 0.001).

Figure 2b: Changes in wait time to see a nephrologist for patients with CKD pre-and post-virtual care implementation. (P < 0.001).

Figure 2c: Nephrology visits by patients with CKD pre-and-post implementation of virtual care.

has led to significant improvements in the processes of care (reduction in wait times and enhanced access to care). These findings have implications in the design of sustainable virtual care programs for delivery of specialized kidney care in both dialysis and non-dialytic CKD in Canada and beyond.

ROLE OF CONTINUOUS GLUCOSE MONITORING OF BLOOD GLUCOSE CONTROL IN PATIENTS WITH DIABETES UNDERGOING HEMODIALYSIS: A PILOT STUDY

Sua Lee¹, Seokjinn Hwang², Seung Woo Heo³, Bo Sun Park², Soyoung Lee³, Kyeong Min Kim³ and Jong Ho Shin³

¹Daejeon Eulji Medical Center, Eulji University School of Medicine, Daejeon, Republic of Korea, Division of Nephrology, Department of Internal Medicine, Daejeon, Korea, Rep. of South Korea, ²Daejeon Eulji Medical Center, Eulji University School of Medicine, Daejeon, Republic of Korea, Department of Internal Medicine, Daejeon, Rep. of South Korea and ³Daejeon Eulji Medical Center, Eulji University School of Medicine, Daejeon, Republic of Korea, Division of Nephrology, Department of Internal Medicine, Daejeon, Rep. of South Korea

Background and Aims: End-stage kidney disease (ESKD) is a global health problem, with a steep increase in its prevalence. Diabetes is a major cause and common comorbidity in patients with ESKD. As already known, glycemic control is an important factor in preventing micro- and macrovascular complications in diabetes. Besides, glycemic variability has recently been considered an important factor in the treatment of diabetes. However, both hypoglycemia and hyperglycemia can frequently occur in patients with diabetes undergoing hemodialysis. This study aimed to determine the role of continuous glucose monitoring (CGM) for glycemic control and glycemic variability stabilization in patients with diabetes undergoing hemodialysis.

Method: Eighteen patients aged ≥18 years with type 1 or 2 diabetes and ≥3 months on hemodialysis at the Eulji Medical Center, Daejeon, Republic of Korea between November 2021 and May 2022 were included. Patients underwent 7-day CGM twice: the baseline study period (T0) and the follow-up study period (T1), at a 12-week interval. Physicians modified the treatment strategy according to the T0 results, and then patients conducted T1. iPro2 CGM (MMT-7745) and Enlite glucose sensors MMT-7008A (Medtronic Minimed, Northridge, CA, USA) were used to assess glycemic control. As indicators of glycemic control, the mean glucose levels and glycated hemoglobin A1c (HbA1c) were measured. As indicators of glycemic variability, standard deviation (SD) and % coefficient variation (%CV) were measured.

Results: Data from 18 patients were analyzed. The mean age was 62.0 ± 11.2 years, male/female ratio was 13 (72.2%) / 5 (27.8%). The mean dialysis duration was 5.2 ± 3.5 years. Among the 18 patients, only one had type 1 diabetes, and the mean diabetes duration was 22.9 ± 7.0 years. The mean glucose levels decreased from 179.1 ± 42.3 mg/dL during T0 to 153.2 ± 25.6 mg/dL during T1 (P = 0.001). HbA1c decreased from 7.4 ± 1.3% during T0 to 6.9 ± 1.2% during T1 (P = 0.023). SD improved from 55.7 ± 19.8 mg/dL during T0 to 42.6 ± 15.3 mg/dL during T1 (P = 0.001). %CV improved from 30.5 ± 7.3% during T0 to 25.5 ± 5.5% during T1 (P < 0.001). During T0, the mean glucose level was significantly lower on a day with hemodialysis than on a day without (P ≤ 0.05), and SD and %CV were significantly higher on a day with hemodialysis than on a day without (P ≤ 0.05). After the physicians modified the treatment according to the T0 results, the mean blood glucose levels decreased on both the hemodialysis-on and hemodialysis-off days, as compared to those values during T0 (from 174.7 ± 46.5 to 154.6 ± 29.7 mg/dL, and from 184.7 ± 50.5 to 156.3 ± 28.7 mg/dL, respectively), and consequently there were no statistically significant differences between the hemodialysis-on and hemodialysis-off days.

Figure 1: Changes in glycemic markers and continuous glucose monitoring (CGM) metrics.

Figure 2: Changes in continuous monitoring (CGM) metrics on days with or without hemodialysis session.
during T1 (P = 0.638). SD improved on both the hemodialysis-on and hemodialysis-off days compared to those values during T0 (from 46.9±21.5 to 33.2±14.6, and from 39.5±20.6 to 32.3±13.3, respectively), and consequently, there were no statistically significant differences between the hemodialysis-on and hemodialysis-off days during T1 (P = 0.384). %CV improved from 27.8±10.9 on the hemodialysis-on day during T0 to 21.4±9.2 on that during T1, and there was no statistically significant difference between the hemodialysis-on and hemodialysis-off days during T1 (P = 0.166).

Conclusion: CGM could be a promising tool for individualizing treatment strategies in patients with diabetes undergoing hemodialysis.

**BIOELECTRICAL IMPEDANCE PARAMETERS AS EARLIER PREDICTORS OF FRAILTY AND FUNCTIONAL IMPAIRMENT IN ECUADORIAN HEMODIALYSIS PATIENTS**

Santacruz Juan1, Kevin Armiño2, Vanessa Arévalo3, Angel Santacruz1, Ana Vásquez1 and Verónica Gavilanes2

1Clínica de los Riñones MENYDIAL, Medical, Quito, Ecuador, 2Clínica de los Riñones MENYDIAL, Nutrition, Quito, Ecuador and 3Clínica de los Riñones MENYDIAL, Statistic, Quito, Ecuador

**Background and Aims:** Functional impairment (FI) and frailty are highly prevalent in hemodialysis (HD) population and are associated with morbidity/mortality. Bioelectrical impedance analysis (BIA) is a non-invasive test to assess body composition and water distribution. Few is known about BIA parameters as predictors of frailty and FI. The aim of the study was to study BIA parameters associated with frailty and FI and to determine their prevalence among Ecuadorian adult patients on HD.

**Method:** Observational-prospective-cohort study performed between January/2021 and October/2022 in one HD center. Clinical Frailty Scale (CFS) score ≥4 determined frailty diagnosis, and FI was labeled with Barthel Index (BI) <70. ROC curves were performed to determine the best cut-off for Phase Angle (PA) and Extracellular/Intracellular water ratio (E/I ratio) to predict frailty and FI (Fig. A). Pearson’s correlation coefficient between PA and E/I ratio with CFS score and FI were calculated (Fig. B), and univariate logistic regression analysis was performed.

**Results:** A total of 115 patients were included. Baseline characteristics, findings and variables with statistical significance are resumed in Table 1. The AUC of PA to predict non-frailty patients and non-functional impaired patients was 0.87 (p<0.001) and 0.79 (p<0.001), which corresponds to PA values of ≥4.35° and ≥3.62°, respectively. The AUC for E/I ratio to predict frailty and FI was 0.83 (p<0.0001) and 0.74 (p<0.0001), which corresponds to E/I ratio values of ≥0.97 and ≥0.99 respectively. Moderate-to-strong-negative correlation was found between PA and CFS score (r = −0.61, p<0.0001) as well as moderate-positive correlation between PA and BI (r = 0.47, p<0.0001) was found. Moderate-positive correlation between E/I ratio and CFS score (r = −0.56, p<0.0001) and moderate-negative correlation between E/I ratio with BI (r = −0.45, p<0.0001) were found. Univariate logistic regression analysis revealed that factors independently associated with frailty were age (OR = 1.04, CI-95%:1.02-1.06) and PA (≥4.35°) (OR = 0.17, CI-95%:0.11-0.24).

**Conclusion:** PA and E/I ratio obtained in a single non-invasive BIA can be used as screening tool, with sensitivity >80%, for earlier prediction of FI and frailty in HD patients allowing premature identification and intervention in this group of patients.

Figure A: ROC curves of Phase Angle and E/I ratio for frailty and functional impairment diagnosis.

Figure B: Correlation between Phase Angle value and clinical frailty scale score.
Limited Pharmaceutical Literacy in Patients on Hemodialysis in the Netherlands as Assessed with the Ralph Interview Guide

Francesca van den Oever1,2, Erwin Vashinder1, Yvonne Schrama3, Ellen Koster4, Patricia Van den Bent5 and Teun Van Gelder2

1Franciscus Gasthuis and Vlietland, Clinical Pharmacy, Rotterdam, Netherlands, 2Leiden University Medical Center (LUMC), Clinical Pharmacology and Toxicology, Leiden, Netherlands, 3Franciscus Gasthuis & Vlietland, Internal Medicine, Rotterdam, Netherlands, 4Dutch Internists Association, Utrecht, Netherlands and 5University Medical Centre Groningen, Clinical Pharmacy and Pharmacology, Groningen, Netherlands

Background and Aims: Patients with advanced chronic kidney disease typically use 15 or more different drugs. Proper use of these drugs requires sufficient pharmaceutical literacy, which is defined as health literacy in the context of medication use. Until now, no data are available on the prevalence of limited pharmaceutical literacy in patients with CKD or on hemodialysis. Recently, the Ralph (Recognizing and Addressing Limited Pharmaceutical Literacy) interview guide was developed in the Netherlands to assess pharmaceutical literacy skills. The current study aims to provide data on the prevalence of limited pharmaceutical literacy, associated problems, and the domains in which these problems occur, in hemodialysis patients using phosphate-binding drugs in the Netherlands.

Method: This study was part of a prospective observational study in a teaching hospital in Rotterdam, investigating a complex adherence-improving intervention in hemodialysis patients using phosphate-binding drugs. One of the aims of the original study was to explore pharmaceutical literacy at baseline, using the RALPH interview guide. The RALPH consists of eleven multiple-choice questions and several open-ended questions in three health literacy domains. The functional domain assesses the basic skills of reading, writing, and calculating. The communicative domain assesses more advanced skills, namely finding and understanding information and applying this information to the own situation. The critical domain assesses the even more advanced skills of critically analyzing information and applying this information to different situations. Limited pharmaceutical literacy was defined as the presence of at least one problem in one or more of the domains of the RALPH. The primary outcome was the prevalence of limited pharmaceutical literacy. Secondary outcomes were the prevalence of one or more problems in the domains. Data were analyzed using descriptive statistics (SPSS version 28.0).

Results: A total of 63 patients were included in the study. Mean age was 66 years, 65% were male. The main primary renal diagnoses were hypertensive nephropathy (31%) and diabetic nephropathy (19.1%). Seventy-three percent of patients received their drugs in a weekly drug dispensing system. The prevalence of limited pharmaceutical literacy was 79%. Fifty-two percent of patients had at least one problem in the communicative domain, 46% in the functional domain, and 78% in the critical domain. Around 90% of patients could correctly reproduce user instructions for phosphate-binding drugs. The most prevalent problems were lack of knowledge about the indication (40%) in the functional domain and finding understandable information (51%) in the communicative domain. In the critical domain, the most frequently encountered problems were a lack of adequate judgment of both reliability and applicability of information (62% and 65%, respectively). Almost half of the patients did not search for information. Furthermore, 32% of patients did not engage in shared-decision making or found this difficult to do. Reasons for this were a profound trust in the nephrologist and the patient’s conviction that the nephrologist knew what was best.

Conclusion: Limited pharmaceutical literacy is frequent in patients on hemodialysis: the majority of patients have problems with finding understandable information and judging its applicability and reliability. Judging its applicability and reliability. The results of this study are in line with earlier findings studying pharmaceutical literacy in Dutch community pharmacies in the Netherlands. However, the current study found slightly higher percentages for problems with finding understandable information and judging the applicability of information. This was expected, as our population generally uses more drugs and has a more vulnerable health status. Recent data show that limited health literacy in general negatively affects certain aspects of self-management, such as adherence, communication, and knowledge. This is also apparent in our study. These data together underline the need for dialysis healthcare providers to individualize their communication and support to meet their patients’ needs.

Individualized Anemia Therapy Improves Hemoglobin Outcomes and Decreases Epoetin Beta Drug Exposure in Hemodialysis Patients

Doris Helene Fuertinger1, Lin-Chun Wang2, Lela Tisdale3, David Joerg3, Stephan Thijssen4, Sabrina Casper5, Alhaji Cherif6, Xiaoling (Janice) Ye2, Amrish Patel2 and Peter Kotanko2,3

1Fresenius Medical Care, Global Medical Office, Computational Medicine, Bad Homburg, Germany, 2Renal Research Institute, New York, United States of America and 3Icahn School of Medicine at Mount Sinai, New York, United States of America

Background and Aims: Anemia is a common complication in hemodialysis (HD) patients. Its treatment with erythropoiesis-stimulating agents (ESAs) is challenging due to a nonlinear dose-response relationship and time delays between ESA administration and hemoglobin (Hgb) response. Anemia treatment protocols are frequently used in clinical settings. However, high variability of patient-specific disease characteristics complicate attainment and maintenance of desired Hgb levels. We developed a novel fully personalized ESA dose recommendation tool and present clinical results of a multi-center, randomized controlled trial (RCT) using this software.

Method: We conducted an RCT in adult HD patients in six dialysis facilities in the US. Patients were randomized 1:1 and treated with our personalized ESA dose recommendation tool for twenty-six weeks (intervention group) or continued to be treated using an anemol protocol that was used as part of this study.
of standard of care in those clinics (control group). The recommendation tool utilized a physiology-based model of anemia to estimate patient-specific physiological key characteristics, such as red blood cell lifespan, to create a patient-individual model from recent routine clinical data (gender, height, weight, Hgb measurements, and ESA treatment). These key characteristics and model-based outcome predictions were used to generate patient-specific ESA dose recommendations to stabilize Hgb levels in a target window of 10–11 g/dL. Dose recommendations were disseminated to the anemia managers of patients enrolled in the study for evaluation and further decision-making (Figure 1). This procedure was repeated biweekly with updated clinical data.

**Results:** Ninety-six patients were enrolled in the RCT. Patients were included in the statistical analysis when they remained in the clinical study for at least 30 days (n = 45 control group, n = 46 intervention group). We evaluated outcome measures showing efficacy and efficiency of the treatment in achieving target Hgb levels. Hgb-related outcomes were significantly different between the two study groups, with an improved Hgb control in the intervention arm, manifesting in a reduction of the Hgb distance to target by more than 30%. Epoetin-beta utilization in the intervention group was decreased by over 20%, while iron-related parameters showed no difference between the two arms (Table 1). Acceptance rate of dose recommendations was high; roughly 95% of the recommendations were accepted and implemented by the clinical staff.

**Conclusion:** A therapy software for personalized anemia management was developed for use with epoetin beta. The model-based ESA dose recommendation tool was evaluated in a clinical RCT in HD patients. Hgb control improved significantly in the group using the novel software tool, while ESA usage decreased, thus providing more efficient anemia management for the individual patient while reducing epoetin-beta drug exposure.

**Figure 1:** Schematic of the framework to determine individualized dosing recommendations.

**Table 1:** Primary and secondary outcomes and iron related parameters. Clinical variables are reported as Median (Q1, Q3). Wilcoxon rank sum tests were performed to compare distributions between the two groups (*** p < 0.001, ** p < 0.01, * p < 0.05, n.s. p > 0.05).

EFFICACY OF SACUBITRIL/VALSARTAN IN MAINTENANCE HEMODIALYSIS PATIENTS WITH HEART FAILURE WITH PRESERVED EJECTION FRACTION

Sha Fu, Xiaohong Wang, Qirong Song, Junzhe Chen and Ying Tang

The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, P.R.China

Background and Aims: Growing evidences have confirmed the effect of Sacubitril/Valsartan (SV) on hypertension and heart failure espacially EFHF in general population. However, data on ARNI treatment in maintenance hemodialysis (MHD) patients with EFHF are lacking. The present study was conducted to assess the efficacy and safety of sacubitril-valsartan in patients with HFpEF undergoing MHD.

Method: End-stage kidney disease (ESKD) patients undergoing MHD for more than 3 months with New York Heart Association (NYHA) class II–IV heart failure ejection fraction of 50% or higher, and elevated levels of N-terminal pro–B-type natriuretic peptide (NT-proBNP) were assigned to receive sacubitril-valsartan. Patients were followed up regularly after medication treatment. The alterations in clinical and biochemical parameters before and after taking sacubitril-valsartan (generally 50–200mg b.i.d) were investigated, and safety was also assessed.

Results: 120 patients were recruited in this study. Compared with baseline levels, NT-proBNP levels [7540.5 (3575.7–18373.0) vs. 4649.0 (2259.0–8187.0), P<0.001], systolic blood pressure [(157.8 ± 20.5) vs. (141.5 ± 16.8), P<0.001], diastolic blood pressure [(85.2 ± 14.9) vs. (78.5 ± 10.2), P<0.001], heart rate[(78.1 ± 9.0) vs. (74.5 ± 6.9), P<0.001], total cholesterol [4.7 ± 1.1 vs. 3.9 ± 1.3, P = 0.01] and Low Density Lipoprotein [2.4 ± 0.9 vs. 2.2 ± 1.1, P = 0.04] were markedly decreased after treatment with sacubitril-valsartan. The results of KCCQ scores [53.4 ± 16.1vs. 61.4 ± 15.7, P<0.001] and NYHA classification [P=0.01] showed obviously improvement after a median follow-up of 13 months. None of the patients showed adverse drug reactions.

Conclusion: Sacubitril/valsartan treatment improves significantly quality of life, symptoms of heart failure, NT-ProBNP and NYHA functional class in patients with HFpEF undergoing hemodialysis. Sacubitril/valsartan was safe and well tolerated.

PERITONEAL DIALYSIS (PD) EFFLUENT DERIVED EXTACELLULAR VESICLES TO ESTABLISH PD-INDUCED PERITONEAL ALTERATIONS

Micky Karsten1,2, Dirk Pegetel3,4, Johan de Rooij4, Marc Vervloet2,5 and Lily Jakulj1,2,6

1 Amsterdam UMC, location University of Amsterdam, Nephrology, Amsterdam, Netherlands, 2 Amsterdam Cardiovascular Sciences, Diabetes & Metabolism, Amsterdam, Netherlands, 3 Amsterdam UMC, location Vrije Universiteit Amsterdam, Pathology, Amsterdam, Netherlands, 4 ExBiome BV, Amsterdam, Netherlands, 5 Amsterdam UMC, location Vrije Universiteit Amsterdam, Nephrology, Amsterdam, Netherlands and 6 Dianet Dialysis Center Amsterdam, Amsterdam, Netherlands

Background and Aims: Peritoneal dialysis (PD) is a life-saving kidney replacement treatment in patients with end-stage kidney disease (ESKD). Yet, long-term exposure of the peritoneal membrane to glucose and its degradation products results in fibrosis and loss of membrane function. At present, detection of early and specific peritoneal injury is challenging. With evolving therapies, biomarkers to assess peritoneal vitality and response to interventions mitigating peritoneal injury in PD-treated patients is mandatory. Extracellular vesicles (EVs) are nano-sized structures containing proteins, micro-RNAs (miRNAs) and lipids reflecting their cells of origin and have a role in intercellular communication. EVs have been widely investigated as potential easy-accessible and stable biomarkers, particularly in inflammatory conditions. Here, we describe a clinically applicable and robust technique to isolate and analyze the molecular cargo of peritoneal dialysis effluent (PDE) derived EVs (PDE-EVs).

Method: PDE was collected from adult patients treated with PD, excluding those with a recent peritonitis (<6 weeks). First, cell-free PDE was obtained by centrifugation. As a filtration and concentration quality control step celmiRNA39 packed in EV-sized liposomes was added to the cell-free PDE. PDE-EVs were isolated by subsequent filtration and size-exclusion chromatography (SEC). We used Western blot with the EV-markers Flotillin 1, 70 kilodalton heat shock protein (HSP70), and Syntenin to confirm the presence of EVs in the SEC-fractions. We used Calnexin as a marker of other intercellular membranes as an indication of purity. To confirm robustness of the filtration and concentration steps, exogenous cel-miRNA39 was quantified by qPCR. Endogenous miRNA21 and -10b were used to check if the PDE-EVs contain adequate amounts of small RNA for future analyses.

Results: PDE was collected from 13 patients (mean age 64.7 years (standard deviation 20.1 years); 62% female; 46% treated with APD; median PD-vintage 18 months (range 7–33 months)). Presence of PDE-EVs was confirmed by Western blot (Fig. 1). A weak staining was observed in PDE from a 1-hour dwell time. There was no difference in staining between 4-hour dwells, 24-hour PDE collection or a 10-hour dwell. No Calnexin staining was seen. Ct-values for exogenous cel-miRNA39 and endogenous miRNA21 and -10b, obtained by qPCR, showed robust signals for all types of PDE (Fig. 2). No relevant differences were seen between samples from different dwell duration or with different glucose concentrations of the instilled PD-fluids.

Conclusion: We present a reproducible and clinically applicable method to isolate and molecularly characterize PDE-derived EVs. Further characterization of the molecular cargo of PDE-EVs may serve as a novel means to monitor peritoneal changes over time during PD and as a potential future biomarker for risk stratification in terms of systemic (cardiovascular) sequelae by PD-induced inflammatory responses. This would fill two important caveats in contemporary PD-management.

Figure 1: Western blot confirming presence of extracellular vesicles (EV) in the peritoneal dialysis effluent with the EV-markers Flotillin 1, 70 kilodalton heat shock protein (HSP70) and Syntenin. POLY(I:C) INDUCES MORPHOLOGICAL CHANGES AND TYPE I INTERFERON-MEDIATED INFLAMMATORY RESPONSE IN MESOTHELIAL CELLS FROM PERITONEUM

Flavia Trionfetti1,2, Vanessa Marchant3,4, Michela Terri1,2, Giulio Bontemp1,2, Alessandro Domenici5, Paolo Mene5, Marta Ruiz-Ortega3,4 and Raffaele Strippoli1,2

Spallanzani, IRCCS, Department of Epidemiology, Preclinical Research and Advanced Diagnostics, Rome, Italy, 3TIS-Fundación Jiménez Díaz. Universidad Autónoma de Madrid, Cellular and Molecular Biology in Renal and Vascular Pathology Laboratory, Madrid, Spain, 4Instituto de Salud Carlos III, Ricord 2040, Madrid, Spain and 5Sant’Andrea University Hospital, Sapienza University of Rome, Renal Unit, Department of Clinical and Molecular Medicine, Rome, Italy

Background and Aims: Peritonitis is a major cause of morbidity and discontinuation of the therapy in peritoneal dialysis (PD) patients. Most of peritonitis episodes during PD may be imputed to bacterial infection, although in about 20% of the cases a viral origin may be hypothesized. Toll-like receptors (TLRs) play a critical role in innate immune responses by specifically recognizing molecular patterns from different microorganisms, including bacteria, fungi, and viruses. Polyinosinic-polycytidylic acid (Poly(I:C)) is a synthetic analogue of double-stranded RNA (dsRNA) that mimics the antiviral immune response by activating TLR3. Upon activation, TLR3 signaling pathway leads to the induction of NF-kB pathway and the interferon response (IRF3 activation). The aim of this work is to study the ex vivo and in vivo effect of Poly(I:C) treatment in primary human mesothelial cells (MCs) and mice peritoneum.

Methods: MCs were collected from effluent fluids of 8 clinically stable PD patients and amplified for ex vivo experiments. MCs were treated with Poly(I:C) (2 ng/μl) or TGFβ1 (2 ng/ml). After 48 hours of stimulation, samples were collected for RNA subsequent analysis. Poly(I:C) was intraperitoneally delivered to mice daily for 10 days, using two different doses: 30 mg/kg (n = 6) and 90 mg/kg (n = 4) of weight. Non-treated mice were used as control (n = 6). Mice were euthanized and peritoneal tissue was collected for the subsequent mRNA, protein, and histological experiments. Gene expression analyses of TLRs, interferon-stimulated genes (ISGs), and other inflammatory markers were performed by qPCR. Protein analysis from cell lysates was performed by western blot and cytokine and chemokine levels from cell supernatants were detected by ELISA assay.

Results: MCs from PD patients expressed a specific subset of TLRs, which were modulated by stimulation with Poly(I:C), being TLR3 the most induced receptor. Additionally, Poly(I:C) induced a bona fide mesothelial to mesenchymal transition (MMT), characterized by the acquisition of a spindle-like morphology, increased expression of mesenchymal markers such as SNAIL, TGFB1, FN1, MMP9, and MMP14, and decreased expression of the epithelial markers ECAD and CALB2. Moreover, Poly(I:C) increased mRNA and protein levels of several cytokines and chemokines, such as TNFα, IL-6, IL-1β, IFNβ, CXCL8, and CXCL9; and ISGs, including CXCL10, MX1, IFIT1, and IFITM1. In vivo, Poly(I:C) administration in mice induced peritoneal inflammation, characterized by increased gene expression of proinflammatory response-related factors, including Ccl5, Arg1, and the ISGs Cxcl10 and Ifit1, in a dose-dependent manner.

Conclusion: Treatment with Poly(I:C) is sufficient to induce a profibrotic/proinflammatory response in MCs in ex vivo and in vivo settings. These discoveries highlight the role of viral infections in peritoneum damage and may provide insight for further studies aimed at specifically counteracting the effect of viral infections in peritonitis in PD patients.
Carnaxide, Portugal and 3 Nova Medical School, Lisboa, Portugal

Detection and treatment. It's important to identify sarcopenic or at-risk patients in order to promote early intervention. It's also important to preserve renal function in PD patients. It's also important to preserve renal function in PD patients. We corroborate the association between age and frailty in the sarcopenic or at-risk patient. In multivariate analysis, age, higher CFS score, and residual urine output were related to probable sarcopenia. In the multivariable analysis, age (HR 1.135; 95% CI 1.015-1.269), CFS score (HR 2.637; 95% CI 1.008-6.900), and residual urine output were related to probable sarcopenia. We performed an exome-wide association study comparing proteinuria recipients and collected DNAs from 40 recipients of an allogeneic kidney transplant who maintained good graft function. The results of the study showed that proteinuria is a key factor in immunosuppression. The underlying mechanisms are unknown. We hypothesized that tolerance might be driven by inherited protein coding genetic variants with large effect, at least in some patients. We performed an exome-wide association study comparing the distribution of moderate to high impact variants in 36 tolerant patients, selected for genetic homogeneity using principal component analysis, and 192 controls, using an optimal sequence-kernel association test adjusted for small samples. We identified rare variants (allele frequency < 1%) of HOMER2 (3/36, FDR 0.0387), ICHQ (5/36, FDR 0.0362), and LCN2 (3/36, FDR 0.102) in 10 tolerant patients vs 0 controls. One patient carried a variant in both HOMER2 and LCN2. Furthermore, the three genes showed an identical variant in two patients each. The three genes are expressed at the primary cilium (p = 0.01), a key structure in innate immune responses. Both LCN2 variants were located 9 base pairs apart, in the 20 amino-acid long signal peptide of the encoded NGAL protein, suggesting the possibility of a shared functional effect.

Conclusions: Rare protein coding variants in a small set of primary cilium genes are associated with operational tolerance in a sizable portion of patients. Our findings have important implications for a better understanding of immune tolerance in transplantation and other fields of medicine.
INNATE IMMUNE MEMORY DETERMINES LONG-TERM KIDNEY ALLOGRAFT SURVIVAL

Inge Jonkman1, Maaike Jacobs1, Cansu Yanginlar1, Joost Martens2, Marijke Baltissen2, Mihai Netea3,4, Johan Van Der Vlag1, Luuk Hilbrands1, Nils Rother1 and Raphael Duivenvoorden1,5

1Radboud University Medical Center, Nephrology, Nijmegen, Netherlands, 2Radboud University Nijmegen, Molecular Biology, Nijmegen, Netherlands, 3Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands, 4University of Bonn, Immunology and Metabolism, Bonn, Germany and 5Icahn School of Medicine at Mount Sinai, BioMedical Engineering and Imaging Institute, New York, United States of America

Background and Aims: Historically, transplant medicine has focused primarily on the adaptive immune system, while the role of innate immune cells in the complex graft-reactive immune response has been understudied. The recently emerging concept of “trained immunity” is of particular interest in this regard. Trained immunity is a phenomenon in which innate immune cells develop a long-lasting memory in response to an initial stimulus, thereby re-programming cells for a stronger inflammatory response to future stimuli. We hypothesized that damage-associated molecular patterns (DAMPs), released during ischemia-reperfusion injury, and immunosuppressive medication can affect trained immunity, and investigated in a cohort of kidney transplant patients if trained immunity is associated with long-term allograft survival.

Method: An established in vitro trained immunity assay was used in which human peripheral blood mononuclear cells (PBMCs) were stimulated. After five days of rest, cells were restimulated with lipopolysaccharide (LPS), and IL-6 and TNF were measured in the supernatant as a readout of the trained immunity response (Fig. 1A). We tested a library of DAMPs, and immunosuppressive drugs commonly used in kidney transplantation, to determine their effect on trained immunity. Of 96 kidney transplant recipients, with a follow-up for graft survival >8 years, serum was obtained before- and one week after transplantation. Patient sera were used to stimulate healthy PBMCs in the trained immunity assay. The relationship between serum induced trained immunity and long-term allograft survival was analyzed by Kaplan-Meier and Cox regression analysis.

Results: We found that DAMPs can affect trained immunity, causing either an enhanced (HMGB1, histones, IL-1β) or suppressed (vimentin, ATP, and C1q) cytokine response after LPS restimulation (Fig. 1B). Prednisone and tacrolimus potently suppressed trained immunity (Fig. 1C). In the kidney transplant patient cohort, cells stimulated with patients’ serum showed considerable heterogeneity in the IL-6 and TNF production after LPS restimulation. The IL-6 and TNF response of cells stimulated with serum obtained one week post-transplantation was lower compared to cells stimulated with serum obtained before transplantation (Difference of 463 ± 428 pg/mL, p < 0.001 for IL-6; 1215 ± 1078 pg/mL, p < 0.001 for TNF). The trained immunity response to post-transplant obtained serum was strongly associated with long-term death-censored graft survival (p = 0.005 for IL-6 tertials, and p = 0.037 for TNF tertials in a Kaplan-Meier analysis), and remained significant after adjusting for potential confounders.

Conclusion: Trained immunity can be affected by stimulation with DAMPs, which are released during ischemia-reperfusion injury during transplantation, and by immunosuppressive drugs used in kidney transplantation. The net effect of patients’ serum taken one week after transplantation, containing a mixture of DAMPs and immunosuppressive drugs, has a suppressive effect on trained immunity compared with patients’ pre-transplant serum. Interestingly, the trained immunity response to post-transplant serum is strongly associated with long-term allograft survival. Thereby we have identified trained immunity as a novel and relevant immunological mechanism in organ transplantation.
Figure 1: DAMPs, immunosuppressive drugs, human serum and the relation with trained immunity. A. Schematic representation of the trained immunity assay. B. IL-6 cytokine production in the supernatant measured by ELISA (n = 6) Data are expressed as log2 fold change compared to untrained (RPMI) PBMCs. p-values were calculated using an unpaired t-test. C. IL-6 cytokine production in the supernatant measured by ELISA (n = 6) Data are expressed as log2 fold change compared to PBMCs trained with HKCA. p-values were calculated using an unpaired t-test. D. Kaplan-Meier survival analysis of serum-induced trained immunity and death-censored graft survival (green = low serum-induced trained immunity, red = high serum-induced trained immunity). P-values were calculated using the log-rank test and Breslow test.

**CHANGES IN ECHOCARDIOGRAPHIC INDICES FOLLOWING KIDNEY TRANSPLANTATION: A SYSTEMATIC REVIEW AND META-ANALYSIS**

Achilleas Betsikos¹, Marieta Theodorakopoulou¹, Maria Korogiannou², Smaragdi Marinaki¹, Aikaterini Papagianni¹, John Boletis¹, Costas Tsioufis² and Pantelis Sarafidis³

¹Aristotle University of Thessaloniki, Department of Nephrology, Hippokration Hospital, Thessaloniki, Greece. ²Medical School of Athens, Clinic of Nephrology and Renal Transplantation, Laiko General Hospital, Greece. ³National and Kapodistrian University of Athens, First Department of Cardiology, Hippokration General Hospital, Athens, Greece

**Background and Aims:** Cardiovascular disease is the leading cause of death in ESKD and uremic cardiomyopathy contributes significantly to the increased cardiovascular risk in these patients. Kidney transplantation is associated with improved survival compared to dialysis. This systematic review and meta-analysis (CRD42022371202) aims to assess the changes in echocardiographic indices in patients before and following kidney transplantation.

**Method:** We included studies in adult subjects with echocardiographic assessments before (baseline) and following kidney transplantation (>1 month follow-up). The primary outcome measure was left-ventricular mass index (LVMI). Literature search involved PubMed, Web-of-Science and Scopus databases, manual search of article references and grey literature.

**Results:** From 6463 records initially retrieved, 35 studies with a total of 2692 patients receiving kidney from living kidney donors (WMD; -76.90 g/m², 95%CI (-22.79, -10.49), I² = 88%, P < 0.001) and those on hemodialysis before (WMD; -21.16 g/m², 95%CI (-27.21, -15.12), I² = 88%, P < 0.001). In subgroup analysis, higher differences were evident among 6 studies (N = 163) evaluating LVMI <6 months after kidney transplantation (WMD -41.54 g/m², 95%CI (-51.51, -16.00), I² = 92% P < 0.001). In sensitivity analyses, patients receiving living donors (WMD; -76.90 g/m², 95%CI (-122.13, -31.67), I² = 88%, P < 0.001) and those on hemodialysis before KTx (WMD; -33.76 g/m², 95%CI (-51.51, -16.00), I² = 92% P < 0.001) presented higher LVMI reductions following transplantation.

**Conclusion:** Kidney transplantation is associated with significant reductions in LVMI compared to the pre-transplantation levels. This could be another factor contributing to the lower cardiovascular risk observed in KTRs compared to dialysis patients.

**MULTIDIMENSIONAL RISK ASSESSMENT OF KIDNEY ALLOGRAFT REJECTION USING DONOR DERIVED CELL-FREE DNA**

Cindy Ursule-Dufait¹, Olivier Aubert¹,², Romain Brousse¹, Juliette Gueguen¹, Maud Racapé¹, Christophe Legendre¹,², Dany Anglicheau¹,², Carmen Lefaucheur¹,² and Alexandre Loupy¹,²

¹Paris Institute for Transplantation and Organ Regeneration, Université Paris Cité, INSERM, U-970, AP-HP, Paris, France. ²Kidney Transplant Department, Necker Hospital, Paris, France and ³Kidney Transplant Department, Saint Louis Hospital, Paris, France

**Background and Aims:** Post-transplantation patient care requires development and validation of non-invasive biomarkers to improve allograft monitoring and prevention from unnecessary and costly biopsies. Reports have suggested the association of donor derived cell-free DNA (dd-cfDNA) with allograft rejection. However, there is no proof of its added value on standard of care in large, unsellected and deep phenotyped cohorts.

**Method:** We enrolled 1134 kidney transplant recipients having concomitant evaluation of allograft histology, anti-HLA DSA and functional parameters between April 2013 and June 2018 in the derivation cohort, representing 1415 biopsies. Dd-cfDNA was measured in plasma at the time of the biopsy. Diagnoses were performed using Banff 2019 criteria. 171 AMR, 34 TCMR and 17 mixed rejections occurred. Parameters associated with rejection were assessed using uni- and multivariable logistic regression. We then developed a risk model using the variables that were independently associated with kidney rejection. The validation cohort comprised 1929 evaluations including 499 evaluations in one Belgian center and 1430 evaluations in nine North American centers.

**Results:** Higher levels of dd-cfDNA were observed for AMR and TCMR or both compared to other diagnoses (Fig. 1A). Dd-cfDNA incrementally increased with Banff acute lesions without significant increase for chronic lesions. In multivariable analysis, the variables independently associated with rejection were anti-HLA DSA (P < 0.0001), dd-cfDNA (P < 0.0001), eGFR (P < 0.033), proteinuria (P = 0.016), and previous history of rejection (P < 0.0001). Dd-cfDNA remained independently associated with kidney allograft rejection in validation cohorts from Belgium (P = 0.0006) and North America (P < 0.0001). Discrimination of the model without dd-cfDNA was 0.777 and 0.821 with its inclusion, showing its added value (Fig. 1B). The good discrimination performances of the model with dd-cfDNA were also confirmed in the validation cohorts from Belgium (AUC: 0.815) and North America (AUC: 0.826).

**Conclusion:** We here demonstrate the independent and added value of dd-cfDNA in addition to conventional features to predict rejection. This first integrative system shows improved performance for patient monitoring and could help physicians in decision-making process.
Figure 1: dd-cfDNA results according to the diagnoses and ROC curve of the model with dd-cfDNA. 1A: Dd-cfDNA according to the diagnoses. 1B: ROC curves of the integrative model with dd-cfDNA and without dd-cfDNA.

GRAFT SURVIVAL IN MULTIPLE KIDNEY TRANSPLANT RECIPIENTS FROM CHILDHOOD TO ADULTHOOD: AN ERA STUDY FROM 1978 UNTIL 2019

Evgenia Preka 1,2, Marjolein Bonthuis 2,3, Stephen Marks 4,5, Anneke Kramer 3,6, Vianda Stel 1,6, Jerome Harambat 7 and Kitty JJager 3,6

1 Evelina London Children’s Hospital, Paediatric Nephrology, London, United Kingdom, 2 European Society for Pediatric Nephrology/European Renal Association (ESPN/ERA) Registry, Amsterdam UMC, location University of Amsterdam, Department of Medical Informatics, Amsterdam, Netherlands, 3 Amsterdam Public Health Research Institute, Quality of Care, Amsterdam, Netherlands, 4 Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom, Paediatric Nephrology, London, United Kingdom, 5 NIHR Great Ormond Street Hospital Biomedical Research Centre, University College London Great Ormond Street Institute of Child Health, London, United Kingdom, 6 ERA Registry, Amsterdam UMC location...
**Method:** Using ERA Registry data, we investigated all patients on kidney replacement therapy (KRT) who received their first kidney transplant (KT) before 20 years of age between 1978 and 2019. Graft survival after first, second and third KT were studied alongside their risk factors, using Kaplan-Meier survival analysis and multivariable Cox regression models.

**Results:** Among 10012 paediatric KT candidates, 8601, 1962 and 412 received at least one, two and three KT. Graft survival at 5 and 10 years was 80.6% and 65.7% for first KT, 71.3% and 53.7% for second KT and 67.1 and 49.5% for third KT. Factors associated with increased graft failure risk were having glomerulonephritis or a recurrent disease as cause of kidney failure for first KT recipients (aHR 1.24, 95%CI 1.12-1.37 and aHR 1.24, 95%CI 1.13-1.37, respectively). Patients whose first KT lifespan was between 0–30 days or more than 5 years presented lower graft failure risks regarding their second KT compared to patients whose KT survived between 1–5 years (aHR 0.79, 95%CI 0.64-0.98 and aHR 0.73, 95%CI 0.61-0.88, respectively). Similar results were found for third KT recipients whose second KT lived for more than 5 years (aHR 0.61, 95%CI 0.41-0.92).

Patients who were transplanted for the first and second time before 2000 presented a higher graft failure risk compared to patients who received their KT between 2000–2007 concerning the first KT; and aHR 1.69, 95%CI 1.15-2.65 and aHR 1.63 95%CI 1.29-2.06 for the transplantation era before 2000 and between 2000–2007 concerning the second KT). Pre-emptive KT presented less graft failure compared to patients who received dialysis > 1 year for first and second KT (aHR 0.89, 95%CI 0.81-0.98 and aHR 0.63, 95%CI 0.51-0.78, respectively). Patients having received a LD KT had less chances for graft failure for first and second KT (aHR 0.77, 95%CI 0.7-0.84 and aHR 0.71 (0.6-0.85, respectively). Having a second LD KT (no matter the donor type for first KT) was advantageous compared to having a second DD.

**Conclusion:** Graft outcomes after pediatric kidney (re)transplantation have improved significantly over time for all recipient subgroups, especially for patients with LD KT, longer previous KT lifespan and pre-emptive KT. Patients with GN and recurrent diseases as causes of their kidney failure showed the poorest outcomes, highlighting the need for continued progress in this field.

**Tubuloreticular Inclusions: A New Prognostic Biomarker in Kidney Transplantation**

Sarah Gleeson1,2, Jack Beadle1,2, Linda Moran3, Ted Fitzgerald1, Candice Roufous1,2 and Michelle Willicombe1,2

1Imperial College London, Department of immunology and inflammation, London, United Kingdom and 2Imperial College Healthcare NHS Trust, Centre for renal and transplantation, United Kingdom

**Background and Aims:** Tubuloreticular inclusions (TRIs) seen on electron microscopy (EM) are classically associated with lupus nephritis (LN) and systemic viral infections in native biopsies. Traditionally a marker for enhanced type I interferon expression, little is known about their significance post-transplant. We aimed to look at a large cohort of transplant biopsies showing TRIs to investigate associations and outcomes.

**Method:** A retrospective analysis was performed on two prospective databases; an in-centre transplant registry and a histopathology database holding data on all kidney biopsies performed at our centre. All patients biopsied since 2015, who had EM examination were included. Where patients had more than one biopsy showing a TRI the earliest one was included. Demographic, clinical and transplant data was collected from the laboratory records.

**Results:** 2283 kidney transplant biopsies were performed between January 2015 and November 2022; 1898 (83.1%) had EM performed. Of 1898 with EM, 176 (10.8%) had evidence of TRIs. Of 176 patients, 34% were female, the median age was 52.2 (38.9-59.4) years, 32% had underlying glomerulonephritis as their cause of ESKD, 65% were deceased donors and 75% were of non-white ethnicity. TRIs were associated with serological evidence of autoimmunity (16%), viral infections (26%) and donor specific antibodies (28%), with no association found in 41%. Rejection occurred in 49%, including 31% of patients with no recognised association with TRIs. Allograft outcomes were poor, with all-cause allograft survival and death-censored allograft survival of 66% and 60%, after a follow up of 1.9+/−1.8 years post index biopsy. A comparison with a matched control group is planned.

**Conclusion:** In extension to previous work, we show that TRIs appear to be associated with alloimmunity. In this regard they may be a useful biomarker especially in cases where the diagnosis is unclear or biopsy findings are 'subthreshold'. Irrespective of aetiology, TRIs are associated with poor outcomes and warrant further consideration.
Background and Aims: Chronic diarrhea in post-renal transplant recipients due to Cytomegalovirus (CMV) presents as Blood CMV PCR (polymerised chain reaction) positive chronic diarrhoea and Gut-invasive (rectal tissue PCR positive, blood PCR-negative) compartmentalised CMV. The available literature on compartmental gut CMV is scarce. The aim is to study the clinical presentation and outcome of patients with compartmentalized gut invasive CMV when compared with Blood CMV positive chronic diarrhoea in renal transplant recipients.

Method: This is a retrospective single-centre follow-up study of patients with CMV disease who were transplanted between 2000 and 2020. Diagnostic variables like blood CMV PCR (polymerised chain reaction) positivity with constitutional symptoms, presence or absence of chronic diarrhoea, tissue PCR positivity and site of tissue biopsy were given harmony codes and 6 syndromes were identified – CMV diarrhoea (Blood PCR positive, presence of diarrhoea), compartmentalized gut invasive CMV (Blood PCR negative, presence of diarrhoea, rectal tissue quantitative CMV PCR positive), Acute CMV syndrome, CMV Esophagitis, CMV nephropathy, CMV cystitis. Out of which patients presenting with diarrhoea (first two groups) were included for analysis. The baseline descriptive statistical measures were carried out using analysis of variance. The time to CMV disease from transplant was computed by identifying the pattern of distribution at 10%, 50% and 90% between groups using reliability models. The time to death from diagnosis was analyzed by identifying the pattern by parametric log-logistic distribution. Survival analysis was done by a parametric reliability model identifying location, scale and threshold parameters, from which month-wise prediction of probabilities was found for survival. The proportion of adverse outcomes (relapse, death and graft loss) between the two groups were analyzed by one-way ANOVA and Tukey pairwise comparison. All the patients were followed up till death or last follow-up.

Results: Out of 2208 renal transplants done between 2000 and 2020, 118 (5.3%), patients developed CMV disease. Chronic diarrhoea was the presentation in 88 (57%), of which 47 had manifestations of CMV diarrhoea, and 41 had compartmentalized gut CMV. Induction agents used (CMV diarrhoea Vs compartmentalized gut CMV) were basiliximab (51% Vs 56%), ATG (27% Vs 17%), Grafalon (0% Vs 2.4%) and no induction (21%, 24%). Only 31.9% and 26.8% received Valganciclovir prophylaxis for pre-specified indications respectively. The time to CMV diagnosis from transplant for 10%, 50% and 90% of patients (in months) was 12.63, 154 and 139 months for compartmentalized gut CMV. The mean duration (weeks) of diarrhoea was similar in both groups (7 Vs 7.3). Associated opportunistic infections causing diarrhoea were higher in compartmentalized gut CMV (28% Vs 46% p = 0.08); the commonest being cryptosporidium. Quantitative PCR in the blood ranged from 1245 to 2511345 copies/ml; whereas in gut tissue, it ranged from 1132 to 3517920/25 mg. The major histopathological finding in compartmentalized gut CMV was active inflammatory pathology in 34 (83%) patients. The probability of survival was significantly lower (72.6%; CI 60% to 83%) in CMV diarrhoea when compared with compartmentalized Gut CMV (87.2%; CI 76% to 94%) for initial 12 months (p<0.05); however at 5 years (56.2%, Vs 58.5%) and 10 years (48.5% Vs 42.7%) the survival was similar. Compartmentalized gut CMV was associated with a higher relapse rate (19.5%) when compared with CMV diarrhoea (6.4%) on follow-up (p = 0.06). The mortality (36% Vs 29%; p = 0.490) and graft loss (25% Vs 22%; p = 0.692) were similar between both the group.

Conclusion: Compartmentalized gut invasive CMV represents a larger proportion of chronic diarrheal illness with a higher relapse rate, which needs invasive gut tissue PCR analysis, despite negative blood PCR, for early diagnosis and management.

Background and Aims: Chronic kidney disease is a frequent complication of heart (HT) and lung transplant recipients and is associated with worse survival. Current literature shows that probably the best renal replacement therapy option for these patients is kidney transplantation (KT). The aim of our work is to assess the results of renal transplantation in HT recipients.

Method: Retrospective descriptive single-center study including all heart transplant recipients who received a kidney transplantation in our center between 1992 and 2022. Data on renal and overall vital survival as a well as the factors that could have influenced them and associated complications were analyzed.

Results: We included 14 patients, 66% men, with a mean age of 56 years at the time of the KT. A total of 30.8% received an anticipated KT. A total of 85.7% received a KT from a cadaveric donor. In 90% of the induction immunosuppression consisted of thymoglobulin, prednisone, mycophenolate, and differed tacrolimus. The mean time between heart and kidney transplantation was 15 years. Six months after KT the mean GFR was 40 ml/min/1.73 m², at 12 months 35 ml/min/1.73 m² and at 5 years 30 ml/min/1.73 m². Renal graft survival was 84% and patient survival was 93% at 10 years. Regarding complications, the most frequent were urological (38.5%) followed by infections (30.8%). The incidence of acute rejection was 18%. Conclusion: Our data confirms that kidney transplantation in heart transplant recipients has very positive results. It is necessary to promote collaboration between HT and KT units with the aim of identifying promptly those patients who are candidates for KT, being able to perform it in the best conditions (preemptive transplantation, possibility of living donor transplantation).
LONG-TERM VISIT TO VISIT VARIABILITY IN HBA1C AND KIDNEY RELATED OUTCOMES IN PERSONS WITH DIABETES

Yang Xu1,2, Shujie Dong3, Edouard L Fu2,4, Arvid Sjölander2, Morgan E Grams5, Elizabeth Selvin6 and Juan Jesus Carrero2,7

1Peking University Clinical Research Institute, Peking University First Hospital, Beijing, China, 2Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden, 3Department of Pharmacy, Peking University Third Hospital, Beijing, China, 4Division of Pharmacoepidemiology and Pharmacoeconomics, Department of Medicine, Brigham and Women’s Hospital and Harvard Medical School, U.S.A., 5Department of Medicine, New York University Grossman School of Medicine, New York, NY, U.S.A., 6Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD and 7Division of Nephrology, Department of Clinical Sciences, Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden

Background and Aims: Glycated hemoglobin (HbA1c) is central to the routine monitoring of glycemic control in persons with diabetes, and poor glycemic control is an established contributor to the occurrence and progression of CKD, but whether long-term visit-to-visit variability in glycemic control predicts kidney outcomes is not well studied.

Method: We included all adults with type 1 or type 2 diabetes in Stockholm, Sweden, during 2006–2019, who had at least one annual outpatient HbA1c test in three consecutive years. We evaluated associations between baseline and time-varying HbA1c variability score (HVS, the percentage of total HbA1c measures that vary by >0.5% [5.5 mmol/mol] during a 3-year window), with the risk of CKD progression (composite of >30% eGFR decline and kidney failure), acute kidney injury (AKI, by clinical diagnosis or increase in creatinine ≥0.3 mg/dL over 48 h or 1.5 times creatinine over 7 days), and worsening of albuminuria.

Results: We included 93,598 adults with diabetes undergoing 891,536 routine HbA1c tests (median 8 tests per person) during a median follow-up of 5.2 years. Compared with persons showing low HbA1c variability (HVS 0–20%), any increase in variability was associated with a higher risk of adverse kidney outcomes. For example, for patients with a baseline HbA1c variability of 81–100%, the adjusted HR was 1.47 (95% CI, 1.38-1.56) for CKD progression, 1.27 [1.19-1.36] for AKI, and 1.28 [1.21-1.36] for worsening of albuminuria.

Results were robust across subgroups (diabetes subtypes, baseline eGFR or albuminuria categories) and in sensitivity analyses including time-weighted average HbA1c or alternative metrics of variability.

Conclusion: A higher long-term visit-to-visit HbA1c variability is robustly associated with the risks of CKD progression, AKI and worsening of albuminuria.
Figure 2: Associations between 3-year baseline HbA1c variability score with kidney-related outcomes. Abbreviations: AKI, acute kidney injury; CKD, chronic kidney disease.
COMPLEMENT GENES PROFILE OF PATIENTS WITH SEVERE HYPERTENSION AND RENAL THROMBOTIC MICROANGIOPATHY

Mariam Akaeva1, Larisa Bobrova1, Natalia Kolozovskaya2, Olga Vorobyeva3, Ekaterina Stolyarevich4 and Peter Shatalov5

1Sechenov University, Moscow, Russia, 2Peoples’ Friendship University of Russia, Moscow, Russia, 3National Center for Clinical Morphological Diagnostics, Saint-Petersburg, Russia, 4City Clinical Hospital №52, Moscow, Russia and 5Pirogov Russian National Research Medical University, Moscow, Russia

Background and Aims: Hereditary or acquired complement system dysregulation found to be driving cause of endothelial damage in atypical haemolytic uremic syndrome (aHUS) – ultrarare life-threatening disease, that always manifests with renal thrombotic microangiopathy (TMA), resulting in poor outcome in absence of appropriate treatment. Nevertheless, several studies show high incidence of rare genetic variants of complement system in other TMA’s, including hypertension-induced TMA. Here we report results of complement genes screening in patients (pts) with histologically identified renal TMA and severe hypertension in Russia, at first diagnosed as hypertension-induced TMA.

Method: A total of 28 Caucasian pts diagnosed with renal TMA (confirmed by kidney biopsy in all cases) and severe hypertension enrolled in the study. The main characteristic of the clinical picture was the absence of microangiopathic hemolysis and thrombocytopenia in prevailing of the pts, thus most of the primary and secondary causes of TMA clinically excluded. Examination of DNA samples was performed in all pts using next generation sequencing (NGS) technology. For statistical analysis continuous variables were presented as Mean (=Standart deviation) or Median (interquartile range) as appropriate.

Results: Baseline demographic and clinical characteristics of group are listed as Mean (±Standart deviation) or Median (interquartile range) as appropriate.

Conclusion: A quarter of pts with TMA and severe hypertension may have genetic defects in the complement system. These results confirmed that complement-mediated HUS may be misdiagnosed as hypertension-induced TMA. Lack of convincing hematological signs of TMA is common in this group, making aHUS diagnosis more sophisticated.
Background and Aims: Tubular epithelial cells under certain microenvironmental conditions, such as injury, driving inflammation, proliferation, fibrosis and inducing death of renal of its function in kidney injury is required. TWEAK is involved in tissue diet, gut microbiota, and kidney disease. However, a detailed characterization (SCFAs) produced by the microbial fermentation of indigestible fibers. It Butyrate is a well-known short-chain fatty acid

Method: A dose-response curve evaluated cell viability in murine tubular cells (MCT) at different butyrate concentrations using MTT assay. For this, cells were pre-treated with butyrate 0.5, 1 or 5 mM for one hour. After that, they were treated either with TWEAK (tumor necrosis factor-like weak inducer of apoptosis), a member of the TNF superfamily or TTI (TWEAK 100 ng/mL, /Gamma1-activated receptor

Results: When MCT cells were pre-treated with butyrate and then injured either with TWEAK or TTI (TWEAK, TNF-α, IFN-γ), the expression of klotho, a nephroprotector and anti-aging gene, and peroxisome proliferator-activated receptor F coactivator-1α (PGC-1α), a transcription factor that promotes mitochondrial biogenesis, were preserved, as opposed to decreased by cytokines only. Moreover, cells pre-treated with butyrate had decreased expression of inflammatory markers such as MCP1 as compared to increased expression upon cytokine stimulation. In the kidney-on-a-chip, cell viability was reduced after exposure to TWEAK compared to the cells treated only with butyrate, while cells treated with butyrate and TWEAK had lower toxicity as assessed by LDH release. Furthermore, results for Klotho, PGC-1α and the inflammation markers MCP1 and IL-6 were aligned with those in MCT cells.

Conclusion: In summary, in-vitro, butyrate prevents injury caused by TWEAK, preserves protective factors such as the anti-aging factor Klotho and the master regulator of mitochondrial biogenesis PGC-1α and decreases inflammation. Furthermore, these results were validated in a kidney-on-a-chip microphysiological system. Characterization of the mechanism behind the protection of butyrate for kidney injury is ongoing.

Figure 1: Single-cell atlas of mouse AKI to CKD.

and 28). These data indicated that multi-identity cluster was rapidly adopting a pro-inflammatory phenotype early after AKI, which present a profibrotic phenotype in late chronic stages. We retrieved two distinct trajectories of macrophage populations, tissue-resident and monocyte-recruited. Starting at monocyte, multi-identity cluster progressed along lineage 1 towards pro-inflammatory cluster, suggesting that the monocyte-derived infiltrating multi-identity macrophages significantly contributed to the formation of the pro-inflammatory M1 cells. On the other hand, proliferative and immature cluster branched off along lineage 2 towards an endpoint of pro-repair cells, indicating that tissue-resident macrophages contribute to repair of kidney by local proliferation. Furthermore, ligand-receptor analysis identified enhanced interaction between diverse macrophage clusters and neighboring cells in the failed repaired stages after AKI, supporting that intercellular communication drives kidney fibrosis. Importantly, we identified that the Igf1-Igf1r interaction was highly specific in multi-identity macrophage and fibroblast intercellular communication.

Conclusion: Our study demonstrated the spatiotemporal dynamics of macrophage heterogeneity and the transitionary functions of multi-identity macrophages in the process of AKI to CKD transition.

ADMINISTRATION OF ASTRAGALUS MEMBRANACEUS IMPROVES RENAL CONDITIONS AND SERUM CARNOSINE LEVELS IN AN ACUTE KIDNEY INJURY MODEL

Kagemasa Kajiwara¹, Makoto Arai² and Tatsuya Nogami²

¹Tokai University, School of Medicine, Molecular Life Sciences, Isehara, Japan and ²Tokai University, School of Medicine, Department of Kampo Medicine, Isehara, Japan

Background and Aims: Astragalus membranaceus (AM) exhibits various pharmacological effects against many diseases, including chronic kidney disease (CKD) (see http://nccih.nih.gov/health/astragalus). Acute kidney injury (AKI) is a sudden episode of kidney failure. AKI occurs frequently but is believed to heal completely and is likely an important factor causing CKD pathogenesis or progression. Previously, we demonstrated the lethal dose in old mice is 20 mg/kg cis-diamminedichloroplatinum (CDDP), and the dosage that will cause AKI in young mice is 14 mg/kg of CDDP. Low doses of CDDP caused AKI in old mice. However, the same dosage in young mice would manifest AKI that was subsequently completely reversible. On administration of AM, old mice (50 mg/kg) showed significantly improved AKI pathology, suggesting the therapeutic effect of AM is age-dependent with regard to AKI pathogenicity. Here, we further examined the possible effect of AM in preventing AKI and delaying CKD progression.

Method: Female C57BL/6 mice were separated into three groups based on age: young, 10 weeks; middle-aged, 35 weeks; and old, 52 weeks. The mice received oral administration of either AM powder mixed with sterilized 0.5% methylcellulose 400 (w/v) (AM group) or 0.5% methylcellulose 400 alone in the control group (CG). Four hours after most recent dose (twice a day at 20 mg/kg AM), 0.5 mg/ml CDDP (reduced dose: 14 mg/kg or 0.9% NaCl for the CG) was injected intraperitoneally. We measured blood serum urea nitrogen (BUN) and creatinine (CRE) levels, which are biomarkers of AKI. Additionally, we assessed histochemical changes in kidney sections stained with anti-CD3 and anti-CD68 antibodies after the mice were sacrificed on day x. Thereafter, serum carnosine levels in the samples collected 4 hours after AM administration (n = 6 per group) were determined using a carnosine ELISA kit (Novus, NBP2-75013). Data were analyzed statistically with PRISM software. Significance was considered P = 0.05.

Results: The 14 mg/kg CDDP dose in old mice significantly increased BUN and CRE levels and caused histological damage in renal tubule epithelial cells and glomeruli. However, these pathological changes were not observed in young and middle-aged mice receiving the same CDDP dose. Histochemical analysis of the old mice showed a significant increase in the number of CD3- and CD68-positive cells following AKI induction (Fig. 1). However, the increase of these inflammatory markers was clearly ameliorated by the AM pretreatment in the experimental group. Serum carnosine levels were markedly increased in young and middle-aged mice following AM administration (Fig. 2). Moreover, the serum carnosine concentration in old mice was upregulated at levels corresponding to those in young mice with AM administration. However, serum carnosine levels showed no additional increase after AM administration in old mice and remained stable. Our findings suggest that normal renal conditions show a simple upregulation of serum carnosine level after AM administration. Furthermore, AM administration improves renal conditions in old mice with high levels of CD3 positive cells in particular (Fig. 1, arrow). Figure 2 shows the increased and then subsequent stabilizing of the serum carnosine levels (Fig. 2, arrow).

Conclusion: AM administration can upregulate serum carnosine in younger mice and shows at least some effectiveness in older mice, where serum carnosine is downregulated but concentrated. Serum carnosine might not be necessary for reducing the pathogenesis of AKI in younger mice, but it becomes important to prevent AKI in old mice. This indicates the effect of AM is probably age-dependent because AKI sequelae manifested spontaneously in all mice but were specifically ameliorated when administered to old mice as opposed to younger mice who recovered completely irrespective of AM administration.

Figure 1: AM decreased infiltration of CD-3 and CD-68 positive cells during reduced dose of cisplatin-induced AKI in old mice.
Background and Aims: Acute kidney injury (AKI) is a life-threatening condition. The absence of oxygen during the acute ischemic phase would disturb energy metabolism and cause kidney tubular epithelial cell damage. Fatty Acid Oxidation (FAO) is the main source of energy production of renal proximal tubular epithelial cells. Timely promoting FAO, increasing supplies of energy, and promoting cell proliferation are essential to improve kidney injury, but there is no clinically recognized effective treatment for this. Cyclin D1 (CCND1), a member of the cell cycle family, plays a vital role in cell proliferation. Our previous study found that CCND1 improved AKI accompanied with increased fatty acid oxidation. Therefore, we investigated the role and molecular basis for CCND1 involvement in fatty acid oxidation of AKI.

Method: CCND1 was evaluated in AKI in human kidney proximal tubular epithelial cells (HK-2 cells) and male C57BL/6J mice (wild type). The protective role of CCND1 in AKI was investigated in a mouse model of ischemia-reperfusion AKI treated by ultrasound-microbubble-mediated kidney-specifically transferring CCND1-expressing plasmids in male C57BL/6J mice (wild type). Eight-week-old male C57BL/6J mice (wild type) were subjected to bilateral renal artery occlusion for 30 min followed by 24 h of reperfusion. We evaluated FAO, proliferation, and autophagy in vitro and in vivo. In addition, we evaluated the concentrations of blood urea nitrogen and creatinine, evaluated kidney ultrastructure and so on.

Results: In vivo studies had shown that activation of CCND1 can prevent AKI-induced lipid accumulation, kidney tubule injury and kidney function declined after ischemia-reperfusion injury. Compared to test control, the treatment significantly (p < 0.05) lowered the concentrations of blood urea nitrogen and creatinine. Kidney specific overexpression of CCND1 promoted FAO, promoted proliferation and reduced apoptosis. Mechanistically, CCND1 activated the AMPK pathway, which increased the expression of phosphorylation AMP activated protein kinase (p-AMPK) and upregulated FAO. On the contrary, inhibiting the expression of CCND1 exacerbated impairment of FAO and disturbed energy metabolism.

Conclusion: Thus, CCND1 improved FAO and reduced lipid accumulation via active AMPK pathway in kidney proximal tubular epithelial cells (PTECs). Hence, reconstruction of the expression of CCND1 may be a novel therapeutic strategy for treating AKI.
SINGLE-CELL SPATIAL TRANSCRIPTOMICS OF THE KIDNEY IN HEALTH AND DISEASE DEFINES INJURY-SPECIFIC DOMAINS AND IDENTIFIES NOVEL CELL-CELL INTERACTIONS

Louisa Gerhardt1,2, Michal Polonsky3, Shiwei Zheng4, Jina Yun3, Kari Koppiot2, Guocheng Yuan4, Andrew P. McMahon2 and Long Cai3

1Mannheim University Hospital, Mannheim, Germany; 2Keck School of Medicine of USC, Los Angeles, United States of America; 3California Institute of Technology, Pasadena, United States of America and 4Icahn School of Medicine at Mount Sinai, New York, United States of America

Background and Aims: Single-cell sequencing has revealed an unexpected diversity of cell types throughout the body. However, the loss of spatial context in many single-cell sequencing techniques hampers our understanding of cell-cell interactions, which are central to almost all (patho-)physiological processes, particularly in highly complex organs such as the kidney. In this study, we aim to profile the spatial organization of, and cell-cell interactions within, the healthy and diseased mouse kidney with single-cell resolution. We focus on changes induced by acute kidney injury (AKI), since AKI is highly prevalent and can progress to chronic kidney disease (CKD), with no targeted treatment strategy to prevent this AKI-to-CKD transition existing to date.

Method: To model ischemic AKI in the mouse, we performed bilateral ischemia-reperfusion injury on C57BL/6J mice. Kidneys were collected in the transition phase from AKI to CKD at 4 weeks after AKI (n = 3). Kidneys from non-surgery mice were used as controls (n = 3). To characterize the spatial complexity of the kidney with single-cell resolution we used seqFISH+, a sequential fluorescence in situ hybridization approach that allows the multiplexing of thousands of genes by sequential hybridization and confocal imaging, thus enabling RNA-quantification at the single-transcript level.

Results: Quantifying and clustering 1300 genes in 230,422 cells identified all major cell types of the kidney and revealed changes in the kidneys’ cellular composition at 4 weeks post AKI. While the cortical vasculature and cells of the proximal tubule segment 3 were reduced, the abundance of injured proximal tubule cells (identified by Haver1 and Vcam1 expression), immune cells and fibroblasts increased. Clustering the identified cell types on their neighbors within a 30um radius revealed distinct spatial domains comprising different combinations of cell types. Certain domains were consistently present across samples and corresponded to the known regional organization of the kidney, thus providing an internal validation. Other domains developed de novo after AKI, illustrating the structural changes induced by AKI. One of these injury-specific domains was comprised of injured proximal tubule cells, macrophages and fibroblasts, while another mainly comprised macrophages, dendritic cells and T cells. Ligand-receptor analysis within domains revealed novel cell-cell interactions, for example highlighting a Crlf1-expressing fibroblast population in close proximity to injured proximal tubule cells, which express the interleukin-6 cytokine Clcf1, a usually co-secreted binding partner of Crlf1. Zooming in on one injury-specific domain, we found that the fraction of fibroblasts and macrophages in the vicinity of injured proximal tubule cells increases with the degree of injury-related gene expression in these cells, suggesting a causal role of injured proximal tubule cells in defining a “pathogenic niche” associated with kidney disease progression.

Conclusion: This study provides a spatial characterization of the kidney with unprecedented resolution, highlights AKI-induced structural changes in the kidney, defines injury-specific spatial domains and reveals cell-cell-interactions relevant to disease progression from AKI to CKD.
ANGIOTENSIN II TYPE 1A RECEPTOR IN KIDNEY PERICYTES MEDIATES TERTIARY LYMPHOID TISSUE FORMATION AFTER ACUTE KIDNEY INJURY

Yu-Hsiang Chou, Yu-Han Shao, Yung-Ming Chen and Shuei-Liong Lin
National Taiwan University Hospital, Renal division, Department of Internal Medicine, Taipei City, Taiwan, R.O.C.

Background and Aims: Tertiary lymphoid tissues (TLTs) have been demonstrated as a major cause of sustained inflammation after acute kidney injury (AKI), indicating a possible contribution of ensuing chronic kidney disease (CKD). And heterogeneous fibroblasts play the crucial role of induction of TLT by secretion of chemokines. Angiotensin II receptors also express on fibroblasts including pericytes. Our study aimed to investigate whether the blockade of angiotensin II receptor could attenuate TLT formation and ensuing CKD after AKI.

Method: Ischemia-reperfusion injury (IRI) was used as AKI model. In vivo, systemic angiotensin II receptor blockade was performed by administration of an angiotensin II receptor antagonists called losartan after the recovery of AKI. Cell-specific angiotensin II receptor blockade was performed using Gli1-CreERT2;AT1Rfl/fl mice to knockout angiotensin II type 1a receptor in pericytes. We also investigated the effect of angiotensin II receptor blockade using 3T3 fibroblasts cell line.

Results: During the 8-month follow-up period after IRI, the activity of intra-renal renin-angiotensin system (RAS) elevated without treatment of losartan. We also displayed that multiple TLTs developed in ensuing CKD after IRI both in a CD-1 and C57BL/6 mice model, which were confirmed by staining of CD3 and B220 representing T and B lymphocytes, respectively. Notably, losartan could not only reduce the size and number of TLT, but also downregulate proinflammatory cytokines such as CXCL13, CCL21 and CCL19 which trigger the initiation of TLT. In vitro, using 3T3 fibroblasts cell line and primary pericytes isolated from kidney after IRI, angiotensin II administration could induce the development of fibroblasts with distinct phenotypes and stimulate production of aforementioned proinflammatory cytokines, particularly CCL19. Additionally, we discovered that angiotensin II-stimulated fibroblasts induced migration of lymphocytes via CCL19 production. Using Gli1-CreERT2;AT1Rfl/fl mice, we found that TLT formation decreased after IRI compared to control groups.

Conclusion: Losartan can reduce ensuing CKD and TLT formation. Distinctive pericytes inhibition by losartan is the plausible mechanism of amelioration of TLT formation. As a result, losartan might be the promising therapeutic agent to prevent AKI-CKD continuum.

KINETICS OF THE DE NOVO NAD/NADH PATHWAY FROM AKI TO CKD

Justine Serre1, Alexandre Bras1, Franck Merlier2, Chloé Samson3, Sandrine Placide4, Liliane Louedec5, Karsten Haupt6, Pierre Gallichon1,4 and Juliette Hadchouel1

1 INSERM, UMRS1155, PARIS, France, 2 UTC Compiègne, Compiègne, France, 3 APHP, La Pitié Salpêtrière, Transplantation rénale, PARIS, France and 4 Sorbonne université, Néphrologie, paris, France

Background and Aims: Mitochondrial dysfunction and energy metabolism deficiency are part of the acute kidney injury (AKI) pathophysiology. In particular, recent studies highlighted the role of nicotinamide adenine dinucleotide (NAD) production in the pathogenesis of AKI. NAD is an electron carrier for mitochondria and a cofactor for cytoplasmic redox reactions. Its production is decreased during AKI following a decreased of the expression of PGClα (Peroxisome proliferator activated receptor gamma co-activator-1-α). PGClα inactivation worsened its overexpression prevented renal injury in a mouse model of renal ischemia. It was also shown that the consequences of PGClα decreased expression included the alteration of the de novo NAD synthesis pathway. This was due to a reduction in the expression of the Quinolinate Phosphoribosyltransferase (QPRT), which led to an accumulation of quinolinate. Consequently, the quinolinate/tryptophane (uQ/T) ratio increased in the urine. The modulation of this de novo has been studied mainly in the acute phase immediately following the injury. However its evolution with degree of severity and during the transition from AKI to CKD has not been described yet. In order to answer these questions, we designed the following studies: (1) A “severity” study in which we provoked ischemic AKI of increasing intensity in mice and quantified kidney PGClα and QPRT mRNA expression. (2) An “AKI to CKD” study in which we followed kidney PGClα and QPRT mRNA expression and uQ/T.

Method: Renal ischemia-reperfusion was performed in C57Bl6/J male mice using the new vascular occluder we recently developed (RIRI clamp), after nephrectomy of the contralateral kidney. For the ‘severity’ study, a 5–30 minutes ischemia was performed. Renal function (measurement of plasma creatinine and urea) and structure (Periodic Acid Schiff staining) were assessed 24h after ischemia. For the ‘AKI to CKD’ study, renal ischemia was performed during 10 minutes. Mice were sacrificed 1, 2, 3, 6 and 28 days after ischemia. For both studies, PGClα and QPRT mRNA expression was quantified by qPCR in the kidneys. Urinary Q/T was determined by mass spectrometry.

Results: PGClα and QPRT mRNA expression is inversely corrected to the AKI severity

We induced AKI in mice by unilateral ischemia reperfusion injury of increasing time to induce several degrees of AKI severity. The measurement of plasma urea and creatinine concentration confirmed that the severity increased with

Figure 1: Losartan attenuated TLT formation after AKI. (A) Representative images showed PAS staining of the kidneys of each group at day 240 after AKI or Nx. Scale bar, 50 μm. thecdurationofischemia.PGC1α andQPRTmRNAexpressiondecreasedprogressivelywithischemiaseverityuntilreachingplateauat15minutesofischemiaforPGC1α(Fig.1A),likeplasmacreatinineandurea,whereasQPRT(Fig.1B)decreasedislinearuntil30minofischemia.PGC1αmRNAdecreaseisalsoinverselycorrelatedtokidneydysfunction(p < 0.001)(Fig.1C).

**PGC1α and QPRT expression recovery after AKI**

A 10-minute ischemia led to the development of Chronic Kidney Disease (CKD), as evidenced by an incomplete recuperation of the kidney function at 28 days. QPRT and PGC1α mRNA expression showed a progressive but incomplete recuperation during the transition from AKI to CKD compared to sham mice (Fig. 1D, E). uQ/T increases after ischemia and is restored during transition from AKI to CKD (Fig. 1F).

**Conclusion:** In addition to confirming the decrease of PGC1α and QPRT mRNA expression during AKI, we show that it is correlated to the severity of the ischemic AKI. Furthermore, we describe the recovery during renal repair and transition to CKD.

**#6078 MODULATION OF TRYPTOPHAN METABOLISM IN SEPSIS-INDUCED ACUTE KIDNEY INJURY (AKI): A NEW THERAPEUTIC APPROACH TO PREVENT NEUROCOGNITIVE IMPAIRMENT**

Maria Teresa Cimmarusti1, Alessandra Stasi1, Rossana Franzin1, Carmela Cosola1, Emanuela Lavarra1, Marco Fiorentino1, Monica Campioni1, Francesco Staffieri2, Alberto Crovace2, Luca LaCittignola1, Fabio Sallustio1, Paola Pontrelli1, Antonio Crovace2 and Loreto Gesualdo1

1Nephrology, Dialysis and Transplantation Unit, Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J), Bari, Italy and 2Veterinary Surgery Unit, Department of Precision and Regenerative Medicine and Ionian Area (DiMePRe-J), Bari, Italy

**Background and Aims:** Partial recovery following AKI could lead to long-term consequences that predispose to chronic dysfunction and may also accelerate progression of neurocognitive impairment. In this scenario, a tight crosstalk between kidney and brain named “kidney-brain axis” seems to play a pivotal role leading to detrimental outcome for AKI patients. Notably, many studies suggest a high relationship between kidney damage and brain dysfunction (cognitive impairment, taste and olfactory dysfunction, peripheral nerve dysfunction) even after the resolution of AKI. Furthermore, patients who suffered AKI may afterward show a disturbance of arousal, also called “brain fog”. Although major advances have been made in our understanding of the pathophysiology of AKI and brain dysfunction, there are no available preventive and therapeutic strategies in this field. Recent findings have revealed remarkable link existing between dyslipidemia/low High-density lipoprotein (HDL) levels and Kynurenine pathway (KP) alterations that lead to the production of neuroactive metabolites such as kynurenine (KYN) and quinolinic acid (QA) in AKI setting.

**Method:** Sepsis-induced AKI (SI-AKI) was induced in a porcine model by intravenous infusion of a saline solution containing 300 μg/kg of LPS. After LPS injection, 12 animals were treated with different doses of recombinant HDL (rHDL) (20–40 mg/kg) (rHDL group), while 6 animals did not receive treatment (LPS group). Animals were sacrificed after 24h from the start of experimental procedure.

**Results:** Endotoxemic pigs developed oliguric AKI with increased tubular and glomerular damage and interstitial inflammatory infiltrate. We found that rHDL treatment significantly decreased the inflammatory process and tubular damage, preventing AKI, especially in the rHDL 40 mg/kg group. Then, we evaluated the Indolamine-2,3-dioxygenase 1 (IDO1) enzyme activation, which is the first and rate-limiting step of KP, upregulated during inflammation in both sera and brain tissue, and has been linked to cognitive dysfunction. In our model, LPS induced an increased activation of the IDO-1 gene expression at brain level in endotoxemic animals, meanwhile it appears to be reduced in both treated arms (p < 0.005). Furthermore, sera from the rHDL group showed a significant reduction in IDO1 activity (KYN/Tryptophan ratio) (p < 0.05) and QA levels (p < 0.005) compared with the LPS group. Moreover, a significant decrease of both systemic and brain IL-6 levels was observed after rHDL treatments.

**Conclusion:** Our preliminary data indicated that HDL-enhancing therapies may decrease the inflammatory response, the retention of waste products and neuroactive compounds, improving renal and cognitive function in SI-AKI.
Background and Aims: The "weekend effect" is the finding of worse outcomes in hospital admissions occurring over weekends. The reasons for this are still unclear but shorter staffing has been suggested to contribute. Little is known about the impact of the "weekend effect" on renal outcomes. We aim to analyze the impact of the weekend effect on patients admitted with acute kidney injury (AKI). We evaluated one-year renal outcome and mortality in patients admitted for AKI over weekends and weekdays.

Method: We conducted a retrospective analysis of all adult patients admitted in a tertiary medical center in Portugal over a period of 6 months with a diagnosis of AKI. Variables were retrieved using clinical and laboratory data. AKI was defined and severity was accessed according to Kidney Disease Improving Global Outcomes classification. Patients were categorized according to weekdays or weekend admission. Outcomes were in-hospital mortality, hemodialysis (HD) requirement and one-year mortality. Statistical significance was defined as a P-value <0.05.

Results: We included 163 patients with mean age of 69.8±16.2 years and 52.7% were male. The majority of patients were admitted on weekdays (74.2%, n = 121). Also, the majority had AKI stage 3 (65.6%, n = 107). Forty eight patients (29.4%) required HD during hospitalization and in-hospital mortality was 24.5%. There were no significant differences in HD requirement (31.4% vs 23.8%, p = 0.434), mortality (25.6% vs 21.4%, p = 0.680) nor HD requirement at discharge (25.6% vs 26.2%, p = 0.681) between weekday or weekend admissions. Of the 123 patients discharged, during the one-year follow-up 30.1% (n = 37) died and 7.3% (n = 9) required HD. There were no differences between weekdays or weekend admissions concerning mortality (32.2% vs 24.2%, p = 0.507) and HD requirement (7.8% vs 6.1%, p = 0.746).

Conclusion: In this cohort of patients with AKI there was no "weekend effect", which reflects the adequacy of care independently of the day of admission. The retrospective design with a limited number of patients may have influenced the results. Further studies focusing on renal outcomes are required to better understand the occurrence of the weekend effect and its long-term impact.

Background and Aims: Diabetic kidney disease (DKD) is a leading cause of end-stage kidney disease (ESKD), however therapies targeting causal pathways have been limited by disease heterogeneity. Integrating electronic health record (EHR) data and genomics may uncover hidden subphenotypes in DKD. In this study, we use deep learning to identify a novel genetic variant of ARHGEF18 associated with significantly higher risk of DKD and ESKD (Figure 1A). We further employed quantitative microscopy techniques and biochemical assays to elucidate the mechanistic role of ARHGEF18 and its variant in podocytes.

Method: DKD patients from the Mount Sinai BioMe Biobank were used in this study. Unsupervised clustering and accounting for population structure in a deep learning framework identified two clusters: Cluster M (mild) and S (severe). We then performed a genome wide association study (GWAS) of patients within each cluster compared with healthy controls. For mechanistic studies of the novel variant, cytoplasmic, focal adhesion, cytoskeletal morphometrics as well as live-cell motility, Rho GTPase activity, and protein degradation experiments were performed using confocal and total internal reflection fluorescence (TIRF) microscopy as well as cell-free biochemical assays using immortalized human podocytes expressing ARHGEF18 wild-type (WT) and mutant transcripts.

Results: We employed autoencoders and unsupervised clustering of EHR data on 1,372 DKD patients to establish two clusters with differential prevalence of ESKD. There was a greater prevalence of proteinuria in Cluster S compared to Cluster M (Figure 1B). Further exome sequencing study in these patients identified a novel variant in ARHGEF18, a Rho guanine exchange factor highly enriched in podocytes (Figure 1A). Nephroseq database showed an increased ARHGEF18 expression in chronic kidney disease (CKD) kidney biopsy samples compared to healthy controls (Figure 1C). Overexpression of ARHGEF18 mutant transcripts in human immortalized podocytes led to impairments in cell adhesion, focal adhesion architecture, and cell motility. Live TIRF microscopy experiments showed preferential subcellular localization of GEF18 mutant to the periphery of migrating podocytes whereas GEF18 WT localized at the perinuclear/cytoplasmic region (Figure 2A, B). GEF18 mutant cells also displayed an increased RhoA activation (Figure 2C). Upon inhibition of protein synthesis using cycloheximide (CHX), we observed a significantly slower degradation of GEF18 mutant protein over a 12h period indicating increased protein stability (Figure 2D). GEF18 mutant also showed resistance to ubiquitin mediated degradation leading to pathologically increased protein levels.

Conclusions: We report a novel gain of function variant of ARHGEF18 that drives podocyte dysfunction through impaired protein localization and degradation. Targeting this pathway could help regulate RhoA activation and cytoskeletal rearrangements preventing podocyte effacement in DKD.

RENAL ORGANOID FROM URINE-DERIVED HUMAN ADULT RENAL PROGENITOR CELLS CAN SPONTANEOUSLY GENERATE LONG RENAL TUBULES
Fabio Sallustio¹, Francesca Giannuzzi², Angela Picerno², Francesca Montenegro², Silvia Maiullari², Antonella Cicirielli², Alessandra Stasi¹, Giovanni Pertosa¹ and Loreto Gesualdo¹
¹University of Bari Aldo Moro, Department of Precision and Regenerative Medicine and Ionian Area, Bari, Italy and ²University of Bari Aldo Moro, Department of Interdisciplinary Medicine, Bari, Italy

**Background and Aims:** Organoids are self-organizing 3D aggregations of cells that represent the structure and function of organs. Kidney organoids have the potential to advance the field of nephrology by providing a tool for the study of human kidney development and disease, by providing a tool for in vitro drug screening, and ultimately, for regenerative therapy. They can be derived from embryonic stem cells or induced pluripotent stem cells. We aimed to explore for the first time, the potentiality of human adult renal progenitor cells (ARPCs), isolated from urine of healthy subjects and patients, to generate spheroids and organoids for regenerative purpose.

**Method:** ARPCs were isolated from urine by immunolabeling. Optical microscopy, immunofluorescence experiments and cytotoxicometric analysis were used to characterize spheroids and organoids. CD133, NANOG, SSAG, OCT 3-4 and GATA-3, SOX2 stemness marker antibodies were used to study spheroids and CD13, Lotus tetragonolobus lectin, ZO-1, uromodulin, and aminopeptidase antibodies were used to investigate renal tubular markers. PKH26 was used to study cell migration from organoids to tubules. Real-time PCR was used to generate gene expression data of aquaporin profile in renal tubules. Chick embryo chorioallantoic membrane (CAM) assays were used as in vivo model for angiogenesis.

**Results:** We isolated ARPCs from urine of healthy subjects or CKD patients. Usually, organoids were generated using complex induction protocols with several chemical factors. However, for the first time we generated renal spheroids and organoids under 3D culture conditions without any stimulation, such as chemokines or growth factors, starting from ARPCs isolated from subject urine. We showed that the spheroids express high levels of stem cell markers as CD133 and NANOG, functional and constitutional marker of ARPCs, and high levels of stem cell markers that normally are low or not at all expressed in ARPCs and are typical of embryonic stem cells: GATA-3, SSEA4, and Sox2. Moreover, the spheroids were able to induce angiogenesis when implanted in chick embryo chorioallantoic membrane. The urine-derived CD133+ organoids can spontaneously generate long renal tubules in 6–12 days, as showed by PKH26 tagging. The renal tubules were positive for the proximal tubule cell markers CD13 (aminopeptidase N), Lotus tetragonalobus lectin and ZO-1. Moreover, renal tubules expressed the aminopeptidase A (CD249) that is normally present in proximal tubules and glomeruli of the kidneys and that catalyzed the conversion of the Angiotensin II in Angiotensin III which is important in the local regulation of blood pressure. Also uromodulin was expressed by tubules. It is normally present in epithelial cells of the thick ascending limb of Henle’s loop, and after proteolytical cleavage, is secreted into urine. In addition, the renal tubules express several genes typical of renal tubules as AQP1 channel protein that facilitates the flow of water molecules into the cells of the proximal tubule and descending limb of the loop of Henle; yGlut enzyme used for the transport of amino acids across cell membranes; Na/H exchanger 1 (SLC9A1), transporter involved in the regulation of pH homeostasis, cell migration and cell volume; Na/Gluc-1 co-transporter SGLUT1, which promotes the passage of glucose across the membrane in renal tubular cells. In some cases, tubule structures were similar to that found in nephrons, including proximal convoluted tubule, Loop of Henle, Distal Convolutetubule and collecting duct, as shown by optical microscopy.

**Conclusion:** For the first time we demonstrated that kidney organoids can be generated starting by urine-derived human adult renal progenitor cells from patients and for the first time we showed that these organoids can generate, spontaneously, without specific stimulation, long portions of renal tubules. These results open new perspectives in the field of the regenerative medicine.
as ARPCs can be isolated from urine of patients and used to generate spheroids for the study of human kidney development and disease, for in vitro drug screening, and ultimately, for regenerative therapy.

CARNITINE ACETYLTRANSFERASE (CRAT) MODULATES MESOTHELIAL CELL RESPONSE TO FIBROTIC STRESS
Valentina Masola1, Luciano D’apolito2,3, Angelo D’alessandro1, Mario Bonomini1, Giovanni Battista Capasso2,3, Francesco Trepiccione2,3, Maurizio Onisto1, Lorenzo DI Liberato1, Tommaso Prosdocimi4 and Arduino Arduini6

Background and Aims: It has been shown that long-term exposure to the high glucose load of peritoneal dialysis (PD) fluids can induce peritoneal fibrosis causing loss of peritoneal ultrafiltration capacity. TGF-beta is a master regulator factor in the onset of peritoneal fibrosis and recent findings suggest that production of it is dependent on a hyper-glycolytic state caused by glucose-based PD solutions. Currently, a different class of bio-compatible PD solutions are under development; they are based on two synergistic strategies: reducing the amount of glucose, and using osmotic-metabolic agents that may provide metabolic benefits able to mitigate local and systemic glucose over-exposure [1, 2]. One such is L-carnitine [1]. The aim of the present study is to explore the role of L-carnitine and carnitine acetyltransferase (CrAT, a key enzyme in L-carnitine metabolism) on the modulation of TGF-beta pro-fibrotic effects.

Method: CrAT proved overexpressed in the human mesothelial cell line Met5A. Plasmid-coding CrAT ORF (Origene RG21296) was transfected by Lipofectamine 3000 and subsequently cells underwent antibiotic selection. Single clones were isolated, and CrAT expression was measured at the gene and protein level by real-time PCR and WB respectively. Metabolomic analyses were performed on WT and CrAT overexpressing mesothelial cells. WT and CrAT-overexpressing mesothelial cells were also treated with and without TGF-beta in the presence of physiological and supra-physiological L-carnitine concentrations (50 μM and 2 mM, respectively). The expression of fibrosis and inflammatory markers was analyzed.

Results: Gene and protein expression analyses confirmed CrAT overexpression in several clones and the two with the highest expression rate were used in subsequent analyses. WT and CrAT-overexpressing mesothelial cells displayed a different metabolic profile, as gleaned by unsupervised hierarchical clustering analysis of the top 50 significant metabolites employing ANOVA and partial least square-discriminant analysis (Figure 1). Most interestingly, they showed a different behavior in response to TGF-beta (Figure 2). In detail: treatment with TGF-beta significantly increased the expression of fibrotic markers alpha-smooth muscle actin (alpha-SMA) and vimentin (VIM) as well as that of pro-inflammatory markers interleukine-6 (IL-6) and interleukine-1β (IL-1β) at a physiological L-carnitine concentration (50 μM). Treatment with supra-physiological L-carnitine levels (2 mM) significantly reduced the up-regulation of the markers analyzed. Similarly, TGF-b was unable to modulate the expression of alpha-SMA, VIM, IL-6 and IL-1β in CrAT-overexpressing cells.

Conclusion: Studying CrAT-overexpressing mesothelial cells may prove to be a useful tool in elucidating how L-carnitine metabolism manages to keep in check the development of fibrosis and inflammation during PD. The use of L-carnitine as an osmo-metabolic agent in PD solutions could significantly slow down the progression of fibrosis in PD therapy.

ROLE OF ENDOTHELIAL CELLS IN VASCULAR CALCIFICATION
Luisa Artioli, Paola Ciceri and Mario Gennaro Cozzolino
University of Milan, Health of Sciences, Milan, Italy

Background and Aims: Vascular calcification (VC) represents a common pathological feature of cardiovascular disease and VC caused by hyperphosphatemia is one of the hallmarks of chronic kidney disease (CKD). Therefore, elucidating the pathogenesis of VC may have significant clinical benefits for CKD patients. Vascular smooth muscle cells challenged with high-phosphate (Pi) actively participate to VC by trans-differentiating into simill-osteoblastic cells that acquire the capability to deposit hydroxyapatite crystals in the extracellular matrix of tunica media in arteries. The role of endothelial cells (ECs) in high-Pi calcification has been poorly investigated until now. Nonetheless, following particular stimuli ECs can lose their endothelial characteristics and acquire several different phenotypes transdifferentiating with a process known as endothelial-to-mesenchymal transition (EndMT). Given the central role of VC for CKD patients wellbeing we decided to investigate whether ECs may have a role in VC process.

Method: We set up an \textit{in vitro} calcification model with human aortic ECs (HAECs) challenged with 2, 2.5, 3, 3.5 mM high-Pi for 7 days. Calcium deposition, cell viability and cell trans-differentiation were evaluated.

Results: In our model we observed deposition of calcium phosphate crystals induced by high-Pi that resulted significant from 3 up to 3.5 mM Pi (Ctr 0.43 ± 0.01; 3 mM Pi 6.72 ± 1.15; 3.5 mM Pi 17.31 ± 1.88; micromol Ca$^{++}$/mg protein; $P < .01$; Fig 1A-B). We found that calcification is mediated by Pi-influx, as demonstrated by the inhibition of calcium deposition by Phosphonomiform acid (PFA), an inhibitor of Na/Pi cotransporter Pit-1 (3.5 mM Pi 15.52 ± 1.97; 1 mM PFA 0.6 ± 0.05; micromol Ca$^{++}$/mg protein; $P < .0001$; Fig 1A, C). In addition, in our model high-Pi did not show any significant toxic effect at every concentration tested compared to control cells. In Pi-treated ECs we observed a clear change in cell-morphology from cobblestone to spindle shaped, a recognized sign of EndMT. Moreover, we observed a change in extracellular matrix composition more similar to osteoblastic matrix. In facts, ECs treated with Pi were Alcian Blue positive, a staining that binds glycosaminoglycans contained in bone matrix, with blue granules of calcium-phosphate in the cytoplasm of treated cells.

Starting from day 5 up to day 7 the transition was confirmed by an up-regulation of SNAIL and N-cadherin mRNA expressions, one of the master genes and one the markers of EndMT process, respectively. A modification of endothelial phenotype was also supported by a progressive decrease in protein expression of Von Willebrand factor and VE-Cadherin observed at day 9 of calcification ($-53.7\%$ and $-32.6\%$ respectively).

Moreover, from day 5 till day 7 we found some osteoblastic differentiation signs such as a progressive increase of RUNX2 and BMP2 mRNA expression and an increase of protective MGP mRNA levels.

Conclusion: Our data demonstrate that HAECs are able to calcify. High-Pi induces trans-differentiation in simill-osteoblastic cells and a progressive loss of endothelial characteristics through the EndMT process. More studies are needed to better elucidate the role for ECs in CKD VC process.

Figure 1: (A) Representative images HAECs challenged with 2, 2.5, 3 and 3.5 mM Pi and 1 mM PFA, stained with Alizarin Red. (B–C) Calcium deposition measured by de-staining and normalized by protein content expressed as #x03BC;mol Ca$^{++}$/protein.
Transcriptional coactivator with PDZ-binding motif

Background and Aims: Podocytes, highly-specialized renal epithelial cells, display the outer aspect of the glomerular filtration barrier. Changes of their complex 3D morphology with interdigitating foot processes are the leading cause for 80% of chronic kidney disease (CKD) cases. During injury development podocytes release increased amounts of extracellular vesicles like exosomes with disease-specific small RNA cargo composition. Exosomes are referred to as important means of cell-cell communication and display an interesting tool for understanding intercellular communication in CKD pathogenesis. It is not clear if exosomes could serve as delivery system for specific small RNAs to podocytes as potential therapeutic approach. To address this, we investigated if isolated exosomes, directly transfected with fluorescently labeled small RNAs, are suitable for exosomal cargo trafficking and for functional delivery of small RNAs in cultured podocytes.

Method: We isolated exosomes from cultured, murine podocytes and transfected them directly with Cy3-labeled siRNAs and miRNAs using ExoFect siRNA/miRNA transfection kit. The transfected exosomes were characterized by transmission electron microscopy and Western blot. The fluorescently labeled exosomes were incubated with cultured, murine podocytes and exosome cargo uptake was observed time- and localization dependently by confocal laser-scanning microscopy. Isolated exosomes were also transfected with filamin A (FlnA)-siRNAs and pre-miR-21 and were co-incubated with cultured, murine podocytes. Transfection- and knockdown efficiency were confirmed by RT-qPCR, Western blot and immunofluorescence microscopy, respectively.

Results: The isolated exosomes displayed a typical shape and size of 20 nm revealed by transmission electron microscopy. This was also consistent after transfection. They also exhibited exosomal marker proteins CD9 and TSG101 before and after transfection. We could show that cultured, murine podocytes take up fluorescently labeled exosomal RNAs. We could observe an increasing amount of fluorescently labeled RNA intracellularly compared to a decreasing amount of fluorescently labeled RNAs in the periphery over 1 week of treatment indicating a time-dependent exosome uptake by podocytes. Transfection of exosomes with FlnA-siRNAs led to a decrease of FlnA-expression in podocytes co-cultured with transfected exosomes as revealed by immunofluorescence microscopy and Western blot. Podocytes incubated with pre-miR-21-transfected exosomes exhibited a 338-fold upregulation of miR-21 in RT-qPCR.

Conclusion: Here we show that direct transfection of exosomes with fluorescently labeled small RNAs is a useful tool for exosome cargo trafficking in podocytes. Additionally, we proved that small RNAs transfected into exosomes can be functionally used for RNAi in cultured podocytes. This might be a novel strategy for regulating protein and miRNA expression in cultured podocytes.

A NOVEL STRATEGY TO TARGET V2R IN RENAL CARCINOMA

Laura Zucaro1,2, Yoko Suzumoto2, Luciano D’apolito2, Giuseppe De Rosa1, Giovambattista Capasso1 and Francesco Troppicciol1,4

1University of Campania Luigi Vanvitelli, Department of Mental, Physical Health and Preventive Medicine, Naples (IT), Italy, 2Biogem Scarl, Institute of Genetic Research, Ariano Irpino (IT), Italy, 3University of Naples Federico II, Department of Pharmacy, Naples (IT), Italy and 4University of Campania Luigi Vanvitelli, Department of Translational Medical Sciences, Naples (IT), Italy

Background and Aims: The vasopressin V2 receptor (V2R) is a G-protein Coupled Receptor (GPCR) selectively expressed in the kidney. V2R is located at basolateral membrane of principal cells of the distal nephron and thick ascending limb cells and in response to circulating levels of vasopressin (AVP), promotes sodium and water reabsorption. Ectopic expression of V2R plays a role in clear cell renal carcinoma (ccRCC). A recent study shows that tolvaptan, a V2R-antagonist, inhibits cancer growth in an experimental model of ccRCC. However, polyuria remains a serious side effect, limiting the repositioning of this drug in clinical practise. Recent evidences demonstrate that ccRCC have an up regulation of the transferrin receptor 1 (TfR1). Based on this, we developed Transferrin-conjugated liposomes (TF-LPs) encapsulating tolvaptan to allow a site-specific delivery to the tumor site, in the attempt to reduce drug side effects. We performed in vitro studies to evaluate the effect of TF-LPs on cell proliferation and the immunoblotting of cyclin A2, an essential regulator of the cell cycle that participates in the regulation of S phase as well as mitotic entry.

Method: Liposome formulation and characterization. Liposomes composed of DSPC/DSPPEPEG2000/DSPPEPEG-MAL were mixed with tolvaptan and prepared by hydration of a thin lipid film, followed by extrusion. Transferrin was conjugated to liposomes at room temperature, overnight. The resulting liposomes were then purified by ultra-centrifuge (80000 rpm, 40 min, 4°C). Liposomes were characterized in terms of colloidal dimensions, polydispersity index and surface charge by dynamic light scattering (DLS) and Zeta analyzer Nano Z, Malvern, UK. Liposome encapsulation efficiency of Tolvaptan was measured by spectrophotometry (Epoth, Biotek) at the wavelength of 266 nm. In vitro studies. Caki-1 cells were cultured until the exponentially growing phase. Cells were then incubated with TF-LPs with or without tolvaptan in growth medium with 0.2%FBS for 24h. Cell viability was assessed by measuring the mitochondrial activity by the 3(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay quantified by spectrophotometry at 570nm. Cell lysate were immunoblotted and Cyclin A2 primary antibody tested as a marker of cell proliferation.

Results: The liposomes we have generated have an average diameter of about 100 nm, a low polydispersity index (<0.2) and a 50% encapsulation efficiency. MTT assay showed that, compared with control, cells treated with TF-LPs encapsulating tolvaptan have a reduction in cell proliferation. Interestingly, this reduction starts at lower concentrations and timescales than in a previous study performed with free drug. To further confirm the previous result, we also performed immunoblotting of cyclin A2 which is usually linked to cell proliferation and as such is often found expressed at a high level in human cancers. The expression level of this protein is significantly reduced when cells are treated with TF-LPs+TOLV while it remains the same in the treatment with TOLV.

Conclusion: In this study we developed and tested TF-LPs encapsulating tolvaptan with cytotoxic activity on tumor cells. The preliminary results of this study will be confirmed by subsequent in vivo studies to demonstrate the advantages of this system: site-specific delivery to the tumor site and reduction of drug side effects.
**Results:** In this in silico electrophysiological model, the resting membrane potential is maintained at $-75$ mV, as this value is cited by various experimental studies. The ionic concentrations and biophysical parameters for all ion channels are varied in the physiological ranges. Under the voltage clamp protocol, the voltage steps are increased from a holding potential of $-80$ mV to $-10$ mV with a $10$ mV step voltage. In Figure 1, the red and blue solid lines represent recorded outward KA current from the isolated USM cell under both control and applied Tamsulosin dose conditions. Figure 1 reveals that the KA current is elevated after the application of the Tamsulosin drug regarding all step voltages. As a result, the total outward current is elevated and the USM action potential duration is shortened. It is also observed that the steady-state activation curve of the KA channel is shifted to more negative after applying Tamsulosin. The USM cell is electrically less excitable with the Tamsulosin.

**Conclusion:** This first in-silico study reveals the KA ionic current, which plays a major role in coordinating ureteral contractions, is altered due to Tamsulosin. It implies that the pharmacological maneuver of Tamsulosin is substantially beneficial to treat dysfunctional peristalsis by reducing the symptoms and installation complexities from the ureteral stents procedure.

NOVEL OPTIMISED PROTOCOL FOR ISOLATION OF PTEC AND SYSTEMATIC CHARACTERISATION FROM HUMAN KIDNEY BIOPSY

Tadej Petreski¹, Luka Varda², Lidija Gradišnik³, Uros Mave₃,₄, Robert Ekart²,₅, Radovan Hojš¹,₅ and Sebastjan Bevc¹,₄,₅

¹University Medical Centre Maribor, Department of Nephrology, Maribor, Slovenia, ²University Medical Centre Maribor, Department of Diaysis, Maribor, Slovenia, ³Faculty of Medicine, University of Maribor, Institute for Biomedical Sciences, Maribor, Slovenia, ⁴Faculty of Medicine, University of Maribor, Department of Pharmacology, Maribor, Slovenia and ⁵Faculty of Medicine, University of Maribor, Department of Internal Medicine, Maribor, Slovenia

Background and Aims: Human kidneys have a role in water homeostasis, acid-base control, reabsorption of compounds, and secretion of xenobiotics and endogenous metabolites, exposing them to substances that could cause harm. This results in an alarming number of acute kidney injuries (AKI) worldwide, estimated at 13%. Furthermore, one-quarter of hospitalised cases are due to drug-induced AKI [1]. Current methods for nephrotoxicity assays are based on animal testing and/or the use of simple human cell lines. Meta-analyses show that we can correctly predict human drug responses in only 10–50% [2]. Our work aimed to develop a novel and optimised protocol for isolating proximal tubular epithelial cells (PTEC) from human kidney biopsy to aid future research regarding AKI and nephrotoxicity studies.

Method: Isolation and cultivation of primary human adult PTEC obtained with biopsy during the regular diagnostic procedure was performed. We used a protocol consisting of micro-dissection of a tissue sample to get ∼1 mm³ fragments, enzymatic dissociation with 0.2% collagenase type 1, and use of selective culture media (Advanced DMEM/F12 with added insulin, transferrin, and selenite (all three together termed ITS), epidermal growth factor (EGF), and hydrocortisone). Light microscopy was used for morphologic characterisation. Some cells were cultured on Transwell inserts, and the transepithelial electric resistance (TEER) was measured in mature cells that formed a confluent culture. For phenotypic characterisation, several markers characteristic of PTEC were chosen [3], and immunocytochemical staining was performed using a fluorescent microscope to evaluate the PTEC phenotype.

Results: Following the described protocol resulted in isolating cells that formed first colonies after 24 h. Using light microscopy, the cells exhibited a cobblestone appearance, reached confluence after eight days, and showed dome (hemicysts) formation after 13 days. The isolated cells were marked positive using immunocytochemistry for sodium-glucose cotransporter 2 (SGLT2), multidrug-resistant protein 4 (MRP4), organic anionic transporter 1 and 3 (OAT1 and OAT3), organic cationic transporter 2 (OCT2), p-glycoprotein (p-gp), multidrug and toxin extrusion protein 1 (MATE1), and N-cadherin.

Conclusion: In this study, we developed a protocol for isolating and cultivating primary human PTEC from biopsy samples. To the best of our knowledge, we have performed the most extensive systematic characterisation following the isolation of PTEC from kidney biopsy reported to date.

POLY(ADP-RIbose) POLYMERASE 1 AFFECTS THE VASOPRESSIN-MEDIATED AQP2 EXPRESSION VIA AN INTERACTION WITH BETA-CATENIN

Hyo-Ju Jung1, Eui-Jung Park1, Hyun Jun Jung2 and Tae-Hwan Kwon1

1Kyungpook National University, School of Medicine, Biochemistry & Cell Biology, Daegu, Korea and 2Johns Hopkins University, School of Medicine, Division of Nephrology, Department of Medicine, United States of America

Background and Aims: Poly(ADP-ribose)ylation (PARylation), which is mediated by poly(ADP-ribose) polymerases (PARPs), catalyzes the transfer of ADP-ribose from NAD+ molecules to acceptor proteins, regulates diverse cellular processes. Since PARP1 gene-deficient mice revealed an increase in urine volume, we aimed to examine the role of PARP1, the most abundant type of protein in the PARPs family, in the vasopressin-mediated AQP2 regulation.

Method: 1) Immunoblotting for PARP1 in mpkCCDc14 cells; 2) Pulldown assay of biotin-conjugated NAD+ and immunoprecipitation (IP) assay using poly(ADP-ribose) (PAR) antibody; 3) qRT-PCR and immunoblotting for AQP2; and 4) Bioinformatics for elucidating PARP1-interacting proteins in kidney collecting duct (CD) cells.

Results: Immunoblots showed that dDAVP treatment (10−9 M, 2 h, 6 h, 24 h, and 48 h) induced the cleavage of PARP1 (both 89 kDa and 25 kDa) in mpkCCDc14 cells. dDAVP treatment (10−9 M, 24 h) also increased the abundance of total PARylated proteins in biotin-NAD+ pulldown and IP assay of PAR in mpkCCDc14 cells. On the other hand, siRNA-mediated PARP1 knockdown significantly attenuated the dDAVP-induced mRNA and protein abundance, suggesting a role of PARP1 in AQP2 regulation. PARP1 cleavage induced by dDAVP was not changed under PARP1 knockdown, indicating that PARP1 cleavage is unlikely to be involved in AQP2 regulation. In contrast to PARP1 knockdown, PARP1 inhibitor (PI34) did not reduce the dDAVP-induced AQP2 abundance, despite the significant decrease in the PARylation. The results suggest that dDAVP-regulated AQP2 expression is associated with PARP1 protein per se, but not with PARP1-mediated PARylation. Bioinformatics study revealed that 408 proteins interact with PARP1 in the kidney CD cells. Among them, 49 proteins were mapped on the vasopressin V2 receptor (V2R) signaling pathway. In particular, β-catenin, which is phosphorylated (S552) by dDAVP, was identified as the PARP1-interacting protein mapped on the V2R signaling. Immunoblotting demonstrated that siRNA-mediated knockdown of PARP1 was associated with decreased dDAVP-induced phosphorylation of β-catenin at S552 in mpkCCDc14 cells.

Conclusion: PARP1 is likely to play a role in vasopressin-mediated AQP2 regulation via the protein interaction with β-catenin rather than PARylation of proteins and/or PARP1 cleavage in the kidney CD cells.

Figure 1: A co-expression Venn-diagram showing differentially expressed genes (DEG) count in renal sinus fat (RS) compared with omental (OAT) and subcutaneous adipose tissue (SAT) (RS vs OAT n = 26, RS vs SAT n = 22).

A DISTINCT TRANSCRIPTOME SIGNATURE IN HUMAN RENAL SINUS ADIPOSE TISSUE – A POTENTIAL IMPORTANCE FOR RENAL DYSFUNCTION?

Maria J. Pereira1, Alicia Otero1, Amir Sedigh1, Jan W. Eriksson1 and Maria Eriksson Svensson1

1Department of Medical Sciences, Clinical Diabetology and Metabolism, Uppsala University, Uppsala, Sweden and 2Department of Medical Sciences, Transplantation Surgery, Uppsala University, Uppsala, Sweden and 3Department of Medical Sciences, Renal Medicine, Uppsala University, Uppsala, Sweden

Background and Aims: Previous studies have suggested that the anatomical location and function of adipose tissue (AT) is of relevance for normal as well as impaired renal function. Renal sinus AT (RSAT) is a perivascular fat compartment located around the renal arteries. The aim of this study was to perform a transcriptomic characterization of RS in comparison with omental (OAT) and subcutaneous (SAT) AT in healthy individuals.

Method: 30 kidney donors (15 men (50%), age 50 ± 11 years, BMI 25.8 ± 2.9 kg/m², eGFR 83 ± 9 mL/min/1.73 m², HOMA-IR 2.5 ± 1.1) were included in the study. RS, OAT and SAT biopsies were performed during laparoscopic unilateral nephrectomy. RNA-sequencing analyses and untargeted transcriptomics were performed. Analysis of differentially expressed genes (DEG) was employed to discover quantitative changes in expression levels between two adipose depots (RSAT) vs OAT and SAT, respectively. Gene Ontology (GO) term enrichment was used to summarize the function of genes that were differentially expressed.

Results: Paired samples of renal sinus fat (RSAT) to be compared with omental (OAT) or subcutaneous adipose tissue (SAT) were available in 26 and 22 subjects, respectively. Out of 12210 genes characterised in these AT depots, 463 genes (3.7%) were uniquely expressed in RS when compared to both OAT and SAT (co-expression Venn-diagram in figure 1). In addition, DEG analyses showed that 1639 genes had higher, whereas 384 had lower, expression in RS than in OAT. For RSAT versus SAT the corresponding numbers were 3789 and 2534, respectively. Among the gene that were differentially regulated, the following pathways were most significantly enhanced in RSAT compared to OAT or SAT (figure 2): chemotaxis and cell migration (e.g. cell and leukocyte chemotaxis and leukocyte migration), and immune response (e.g. T-cell activation, immune response-activating signal transduction, adaptive immune response). Conversely, ATP synthesis (e.g. oxidative phosphorylation, cellular respiration, mitochondrial complex) and extracellular matrix pathways were significantly attenuated in RS compared to SAT and OAT, respectively (not shown). A targeted analysis of specific gene markers that have previously been reported to be associated with chronic kidney disease (CKD) showed that AT expression of pro-inflammatory factors such as visfatin, IL-6, IL-11, IL-1α and IL-18 were higher in RSAT vs SAT or OAT (not shown). In addition, the expression of some genes, differently regulated in RSAT, and known to associated with progression of CKD, e.g. Fc Gamma Receptor Ila (FCGRIIa), NF-kappa-B inhibitor beta (NFKBIB), Nuclear Factor, Erythroid 2 (NFE2) and Oncostatin M (OSM), were positively correlated with BMI (data not shown).

Conclusion: This study in healthy kidney donors indicates that the transcriptome signature of renal sinus AT seems to be distinct from subcutaneous and omental AT. Gene ontology analyses pointed towards an inflammatory environment and lower mitochondrial function in the renal sinus compared to other adipose tissue depots. These findings are likely to define depot-specific AT functions that may be of importance for renal function and disease.

Figure 2: Gene Ontology (GO) term enrichment of the differential expressed genes (DEG) that were most significantly upregulated in renal sinus fat (RS) versus omental (OAT) and subcutaneous adipose tissue (SAT) (RS vs OAT n = 26, RS vs SAT n = 22).
MOLECULAR AND FUNCTIONAL CHARACTERIZATION OF THE PERITONEAL MESOTHELIAL AND ENDOTHELIAL CELL BARRIER

Background and Aims: Solute transport across cellular levels is mediated by paracellular and transcellular pores, channels and carriers. Knowledge on their cell specific expression, regulation and function in peritoneal dialysis (PD) is limited.

Method: Polarized primary (HPMC) and immortalized human peritoneal mesothelial (MeT-5A), microvascular (HCMEC) and umbilical vein endothelial (HUVEC) cells underwent RNA sequencing and gene enrichment analysis. Key findings were confirmed by western blotting (WB), confocal and single molecule localization microscopy (SMLM). Arteriolar transcriptome and proteome datasets of non-CKD, CKD5 and PD children (n = 6/group) underwent targeted transport pathways analysis. Key transporter proteins were quantified in parietal peritoneum (n = 20–30/group) and related to peritoneal transport rates available in 23 children. Barrier function was studied in vitro (transepithelial electrical resistance, TER, and molecular weight dependent flux), ex vivo and in vivo.

Results: Junction, transmembrane and transcytotic transporter expression was highly cell type specific on RNA and protein level. Sealing Claudin (CLDN5) was only expressed in mesothelial cells, sealing CLDN5 in endothelial cells. TER which reflects functional junction status, was 50% lower in HCMEC compared to HUVEC and the two mesothelial cell lines; 4- and 10-kDa dextran permeability was higher in HCMEC. At nanoscale, SMLM yielded highest distance of junction molecules in HCMEC and different spatial organisation, reflecting the low TER. In sheep peritoneum, removal of the mesothelium abolished tissue TER. In mice, short-term LPS exposure to modify mesothelial permeability resulted in faster transperitoneal 4- and 70-kDa dextran transport, suggesting a specific barrier function of the mesothelium. In human parietal peritoneum, total endothelial surface area per section was age dependently 1.5- to 2-fold higher than the respective mesothelial surface area, and further increased with double-chamber PD fluid, due to major hypervascularisation. Tight junction proteins CLDN-1 to -5, and -15, ZO-1, occludin and tricellulin, and transcellular transporter ENaC, PIT1, and SGLT1 were detected in mesothelial and arteriolar endothelial cells. In CKD mesothelial CLDN-1 and arteriolar CLDN-2 and -3 were more abundant than in non-CKD controls, and PD patients had highest mesothelial and arteriolar CLDN-1 and mesothelial CLDN-2, lower mesothelial and arteriolar claudin-3 and lower arteriolar ENaC. D/P creatinine and D/D0 glucose correlated with arteriolar CLDN-2 and with mesothelial CLDN-4 and -15, which are pore forming junctions, and for creatinine with mesothelial PIT-1, a sodium/phosphate co-transporter.

Conclusion: We provide the first in-depth analysis of peritoneal determinants of solute transport. The molecular expression pattern of the mesothelial and endothelial cell barrier and transporter proteins differs substantially. Disruption of the mesothelial layer increases peritoneal solute absorption rate. In the human peritoneum, peritoneal transporter status is modified by CKD and PD, and pore forming junction proteins are associated with dialytic solute transport function. These represent a promising target for therapeutic intervention.

REDUCTION OF SUBACUTE LEAD INDUCED PARATHORMONE LEVELS FOLLOWING ANTIOXIDANTS OR VITAMIN D/CALCIUM ADMINISTRATION IN RATS

Minerva Martinez-Alfaro 1, Yolanda Alcaraz 1, Alejandro Antaño 2, Aldo Santoyo 2, Juvencio Robles 2 and Silvia Gutiérrez 2

1Universidad de Guanajuato, Pharmacy, Guanajuato, Mexico and 2UMSS-Unidad medica de alta especialidad No. 25 Centro Medico Nacional Noreste, Monterrey, Mexico

Background and Aims: Lead (Pb) is a toxic heavy metal; exposure is associated with many diseases. Accordingly, the World Health Organization considers Pb one of 10 chemicals of major public health concern. Experimental evidence suggests that Pb exposure induces both structural and functional kidney alterations. Epidemiological studies on lead exposed workers, show alteration on calcium metabolism (reduction in serum calcium, phosphorous and vitamin D and increase level of PTH) that increases with exposure length. Two of the suggested molecular mechanism of lead toxicity are: protein binding sites competition with endogenous cations such as calcium or zinc and the production of free radicals. The aim of this work is to analyze the effect of lead exposure, the therapeutic administration of antioxidants (melatonin or silymarin) or VitD +Ca and its potentially beneficial effect on calcium metabolism.

Method: Male Wistar rats (150–180 g body weight) of 6 weeks of age were housed in groups of three in standard cages with free access to water and food (Rodent Lab Standar Diet), under a 12/12 hour light/dark cycle, C, control: untreated rats not exposed to Pb or treatment; Pb, exposed to Pb for 1 month and assessed immediately; Pb 1NT, exposed to Pb for 1 month followed by 1 month without any treatment; Pb 1TM, exposed to Pb for 1 month followed by 1 month of melatonin treatment; Pb 1TS, exposed to Pb for 1 month followed by 1 month of silymarin treatment; Pb 1TVDca, exposed to Pb for 1 month followed by 1 month of VitDca treatment. M, melatonin (10 mg/kg/body weight/day dose), S, silymarin (200 mg/kg/body weight/day dose) or total amount of VitD (232 IU/Kg/day) and Calcium 299 mg/Kg/day received from diet and therapeutic regimen were equal to 1.8 fold the daily requirement of VitD 800 IU/Kg/day and Calcium 1000 mg/Kg/day. Chemicals: Lead acetate trihydrate, Pb(CH3CO2)2.3H2O purity 99.99% from Sigma 215902, Melatonin Sigma M5250 98% TLC, VitaminD3 ampoules (100 000IU/mL), vitamin D oral ampoules (100 000IU/2 mL) from TRB Lab. Rat parathyroid PT Elisa Kit CUSBIO, 25-hydroxy Vitamin D3 ELISA Kit (Colorimetric) Kit NOVUS

Results: Blood Lead Levels There were statistical differences between the control group and all other groups P<0.0001. The group exposed to Pb for 1 month without any subsequent treatment (Pb 1NT) show differences in BLL with rats exposed to Pb and subsequently treated with antioxidant or VitD therapy and with the group immediately assessed after lead exposure. BLL were all in µg/dL C 2.3, Pb 11, PbNT14.15, PbTM 10.28, PbTS 10.23 and Pb VDca 10.18 Vitamin D Blood Levels Interestingly the highest mean vitamin D blood level was found in rats exposed to Pb for 1 month followed by 1 month of VitDca therapy (Pb 1TVDca) and the lowest mean value was found in rats exposed to Pb for 1 month and assessed immediately (Pb). Pb Blood Levels Pb blood levels were increased in rats exposed to Pb without any other treatment, whether assessed immediately after exposure or after one month. All therapies reduced blood Pb under control levels. Conversely a negative moderate correlation was found between blood levels of PTH vs. VitD r = −0.533 and r² = 0.2843 P (two tailed) = 0.002.

Conclusion: All therapies using the antioxidants (melatonin or silymarin) or VitD+Ca supplementation reduced the lead induced increase in parathorome levels in rats.

In mechanistic studies, ISx upregulated mRNA levels of hairy and enhancer of markers were recovered by AHR antagonist and knockdown (KD) of antagonist CH223191, while downregulated gene expressions of osteogenic The ISx-induced mineralization defects of BMSCs were counteracted by AHR μM significantly downregulated mineralization of BMSCs, particularly in the early stage of osteogenesis. ISx-induced AHR upregulated Hes1, which inhibited expressions of not only Runx2, but also BMP2, which has not been published before. A study of the underline signal transduction pathways relevant to the AHR genomic control system may provide potential therapy for low bone formation in early CKD.

**Conclusion:** ISx under clinically relevant concentrations attenuated mineralization of BMSCs, particularly in the early stage of osteogenesis. ISx-induced AHR upregulated Hes1, which inhibited expressions of not only Runx2, but also BMP2, which has not been published before. A study of the underline signal transduction pathways relevant to the AHR genomic control system may provide potential therapy for low bone formation in early CKD.

**Method:** Mineralization of D1 cells (mouse BMSCs) was evaluated by alizarin red S staining (ARS). The mRNA expressions and protein levels of osteogenic markers including Runx2, BMP2, ALP, and osteocalcin were determined by quantitative real-time polymerase chain reaction (RT-PCR) and western blotting. AHR translocation into the nucleus was evaluated by an immunofluorescence confocal microscope. Reporter gene assays were adopted to study the transcriptional regulation of Runx2 and BMP2. Results: ISx at concentrations <50 μM significantly downregulated mineralization of BMSCs with the most influence in the early stage of osteogenesis. ISx decreased the mRNA expressions and protein levels of osteogenic markers Runx2, BMP2, ALP, and osteocalcin. ISx of 50 μM induced AHR translocation into the nucleus and upregulated AHR target genes CYP1a1 and CYP1b1. The ISx-induced mineralization defects of BMSCs were counteracted by AHR antagonist CH223191, while downregulated gene expressions of osteogenic markers were recovered by AHR antagonist and knockdown (KD) of AHR. In mechanistic studies, ISx upregulated mRNA levels of hairy and enhancer of split (HES1), which is a primary target of NOTCH signaling. Although there were no significant differences in expressions of Notch1~4, the upregulated Hes1 was attenuated by the antagonist and KD of AHR, which indicated that Hes1 was directly regulated by AHR. We identified putative binding sites of transcription repressor Hes1 in the promoter area of BMP2 and Runx2. Following experimental treatment of ISx, expression levels of BMP2 and Runx2 monitored by reporter assays were downregulated, which indicated that Hes1 plays as a transcription repressor to downregulated BMP2 and Runx2.

**Conclusion:** ISx under clinically relevant concentrations attenuated mineralization of BMSCs, particularly in the early stage of osteogenesis. ISx-induced AHR upregulated Hes1, which inhibited expressions of not only Runx2, but also BMP2, which has not been published before. A study of the underline signal transduction pathways relevant to the AHR genomic control system may provide potential therapy for low bone formation in early CKD.

dehydrated, with no other noticeable findings. Blood lab tests showed a serum creatinine \( (\text{Cr}) \) of 2.86 mg/dL (baseline 1.10 mg/dL, estimated glomerular filtration rate of 72 mL/min/1.73 m\(^2\)), a corrected serum total calcium (sCa) of 16.0 mg/dL and a normal serum phosphate of 4.0 mg/dL. The patient was admitted in the oncology ward with the collaboration of the nephrology department and was started on fluid therapy with 3000–4000cc NaCl 0.9%/day for a target urinary output of 75–200 mL/h. Hypercalcaemia work-up showed low PTH of 8.8 pg/dL (reference range: 12–69 pg/dL). Measurement of PTHrP and 1,25(OH)\(_2\)D were requested but took longer. After 3 days, despite the improvement of both sCr 2.23 mg/dL and sCa 13.6 mg/dL, zolodreric acid was started. Results revealed an increased 1,25(OH)\(_2\)D of 309 pg/dL (reference range: 10.9–79.3 pg/dL) and negative PTHrP. At the 6th day, a clear improvement of analytical (sCr 1.60 mg/dL; sCa 11.9 mg/dL) and clinical status, so the patient was discharged. The diagnosis was GIST 1,25(OH)\(_2\)D overproduction causing malignant hypercalcaemia and prednisolone on 20mg id was started. In June 2022, the patient had tumour progression, presenting lethargic, disoriented, and dehydrated; blood lab results showed AKI (sCr 197 mg/dL) and worsening hypercalcaemia (SCa 14.7 mg/dL). He was admitted for fluid therapy and bisphosphonates but, even though there was a recovery of the hypercalcaemia and renal function, the patient’s clinical status got worse and he had a fatal outcome in the following days.

Conclusion: Malignant hypercalcaemia caused by GIST 1,25(OH)\(_2\)D overproduction is a rare condition. The work-up of an oncological patient with ureteral obstruction is a rare condition. The work-up of an oncological patient with ureteral obstruction.

### LYMPHOCYTE SENESCENCE: A CROSS-SECTIONAL STUDY COMPARING SYSTEMIC LUPUS ERYTHEMATOSUS AND END STAGE RENAL DISEASE

Eleni Moyisdou\(^1\), Georgios Lioullos\(^1\), Michalis Christodoulou\(^1\), Aliki Xochelli\(^2\), Vasiliki Nikolaidou\(^2\), Zoi Mitsoglou\(^1\), Stamatia Stai\(^1\), Asimina Fylaktou\(^2\), Aikaterini Papagianni\(^1\) and Maria Stangou\(^1\)

\(^1\) Aristotle University of Thessaloniki, Greece, Department of Nephrology, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece and \(^2\) Hippokration Hospital of Thessaloniki, Department of Immunology, National Periphery Hospital, Thessaloniki, Greece.

Background and Aims: Immunosenescence, as a consequence of ageing or chronic inflammation, encompasses a spectrum of lymphocyte characteristics, including the presence or absence of certain lymphocyte surface molecules. Aim of the present study was to evaluate the immunosenescent effect of two different forms of chronic inflammation, Systemic Lupus Erythematosus (SLE), a chronic autoimmune disease and end stage renal disease (ESRD), a chronic inflammatory disorder.

Method: Certain lymphocyte surface molecules, including CD31, CD45RA, CCR7, CD28, CD27, for T, and IgD, CD27 for B lymphocytes, were analyzed by flow cytometry, and distinct naïve, active and senescent lymphocyte subtypes were determined, in SLE and ESRD patients. Results were compared to healthy controls (HC) of similar age, sex and nationality.

Results: Lymphopenia was significant in both SLE and ESRD patients, compared to HC, affecting B cells 75.1(14.4–52.0)% of HC, 97(32–341) and 214(84–576) cells/\(\mu\)L, respectively, \(P < 0.0001\), and CD4+ cells 651.2(71.1–1478.2), 713(234–1509) and 986(344–1591) cells/\(\mu\)L, respectively, \(P < 0.0001\). The allocation of B cell subpopulations was remarkably different between SLE and ESRD patients, with the SLE showing a clear shift to senescent (IgD--CD27-) 11.75(2.3–74.2)% vs. 8.1 (1.7–35), and ESRD patients, to naive subpopulations, compared to HC: 69.9(1.1–92)% vs. 62 (4.3–86.9)%), \(P = 0.019\). Instead, senescent subtypes of CD4+ lymphocytes were reduced in SLE, compared to ESRD and HC, 3.2 (0.1–42.2)% 6.0 (0.4–56.4)% and 3.5 (0.3–19.5)% for CD4+CD28null cells and 1.2 (0.1–23.9)% 2.5 (0–51.9)% and 1.9 (0–17.9)% for CD4+CD28-CD57+ cells. CD8+ lymphocyte subtypes presented a complete redistribution, in favor of CD8+CD45RA-CCR7+ (central memory), CD8+CD45RA+CCR7+ (naïve), and 53.1(1.8–92.4)%, 52.2(0.1–91.5)% and 23.4(0.1–92)% respectively, and lowering the terminally differentiated populations (CD57+CD28null) 7.8 (0.2–54.4)% and 12.8(0–71.6), respectively. CD8+CD28null cells were significantly reduced in SLE, compared to ESRD and HC, 31.9(1.1–87.2)%, 44.4(14–89.7)% vs. 34.5(6.4–72.3)%, respectively, \(P = 0.04\).

Conclusion: Senescent phenotype of B lymphocytes predominated in SLE patients, while ESRD patients showed a completely different profile, with increased senescence involving mainly CD8+ lymphocytes.

### EFFECTS OF COMMON OSMOLYTES ON THE EXPRESSION OF FOXP3 SPLICE VARIANTS IN HUMAN PBMCs

Zhidan Luo\(^1\), Qais Saleh\(^2\) and Martin Tepel\(^2\)

\(^1\) Chongqing General Hospital, Department of Geriatric, Chongqing, P.R. China and \(^2\) University of Southern Denmark, Institute of Molecular Medicine, Cardiovascular and Renal Research, Odense, Denmark.

Background and Aims: Regulatory T cells modulate autoimmune and allogenic responses in glomerulonephritis and transplantation. The two most abundant fork-head box P3 (FOXP3) splice variants, full-length FOXP3 (FOXP3-FL) and FOXP3 lacking exon 2 (FOXP3-Δ2), confer suppressive ability to regulatory T cells. Some studies showed a weaker suppressive ability of FOXP3-Δ2. Renal organic osmolites, urea and Trimethylamine N-oxide (TMAO), play critical roles in the hyperosmotic renal environment with high concentrations of Na+ and glucose. However, the effects of these osmolites on FOXP3 splice variants in peripheral blood mononuclear cells (PBMCs) remain unclear. The aim of this study was to evaluate the effects of common osmolites on the expression of FOXP3 splice variants in human PBMCs.

Method: PBMCs were isolated from the blood of healthy donors using ficoll density gradients and cultured in RPMI-1640 with or without additional osmolites at 37°C. A part of PBMCs were activated with 25ng/ml Phorbol-12-myristate-13-acetate (PMA) and 1ug/ml ionomycin (PMA-IONO), FOXP3-FL and FOXP3-Δ2 mRNA were detected by qPCR after 4hrs’ incubation, using specific primers. The relative expression value was calculated by the formula of \((1+E^\beta Ct)/(1+E^\beta Ct))\) Ct (target gene). Values are given as the mean±S.E.M. Statistical significance was determined by One-Way ANOVA with Post Hoc Test, using Graphpad Prism 9. A P-value <0.05 was considered significant.

Results: The cell viabilities after 4 hours’ incubation were all above 90%. PMA-IONO significantly increased the relative expression of both FOXP3-Δ 2 (from 0.001051 to 0.001609, \(P = 0.0289\), \(n = 5\)) and FOXP3-FL (from 0.001024 to 0.001684, \(P = 0.0101\), \(n = 5\)) (Figure 1). However, increased concentrations of urea (from 5mM to 50mM) had no effect on either of the two FOXP3 splice variants (\(P > 0.05\), \(n = 5\), Figure 1). TMAO of 4mM significantly reduced FOXP3-FL in the PMA-IONO-activated PBMCs from 0.001605 to 0.0007208 (\(P = 0.0051\), Figure 2). However, TMAO didn’t affect FOXP3-FL expression in non-activated PBMCs and had little effect on FOXP3-Δ2 expression either (\(P > 0.05\), \(n = 4\)). On the other hand, compared with control group, the high concentration of glucose (25mM) significantly increased the expression of FOXP3-Δ 2 from 0.002815 to 0.003461 (\(P = 0.0375\), \(n = 3\)) in non-activated PBMCs (Figure 2). The high concentration of NaCl (147mM) had no significant effect on either of the FOXP3 splice variants (\(P > 0.05\), \(n = 3\), Figure 2). Furthermore, the equal osmolality of mannitol didn’t affect the mRNA expressions of FOXP3 splice variants, either (\(P > 0.05\), \(n = 3\), Figure 2). But compared with glucose group (0.003461), the expression of FOXP3-Δ 2 was significantly lower in mannitol group (0.002785) (\(P = 0.0479\), \(n = 3\), Figure 2). It suggested that the effect of high glucose in non-activated PBMCs was independent of the osmolality change.

Conclusion: In isolated human PBMCs, PMA-IONO increases both FOXP3-Δ 2 and FOXP3-FL expressions. PMA-IONO-induced FOXP3-FL increase can be inhibited by TMAO. Urea and NaCl had little effect on FOXP3 splice expressions. High concentration of glucose increases FOXP3-Δ 2 mRNA in non-activated PBMCs, which was independent of the osmolality change.

Abstracts i193
Figure 1: Expressions of FOXP3-Δ 2 (Exon 2 deleted) mRNA (A) and FOXP3-FL (full length) mRNA (B) in human peripheral blood mononuclear cells (PBMCs) without (Control) or with the presence of PMA, ionomycin (IONO) and different concentrations of urea in RPMI-1640 at 37°C for 4 hours. Values are given as the mean±S.E.M. N=5. Statistical significance was determined by One-Way ANOVA with LSD Post Hoc Test. A P-value < .05 was shown.

Figure 2: Expressions of FOXP3-Δ 2 (Exon 2 deleted) mRNA (A) and FOXP3-FL (full length) mRNA (B) in non-activated human PBMCs without (Control, the concentration of glucose and NaCl is 11mM and 140mM respectively) or with addition of glucose (25mM in total), NaCl (147mM in total) or mannitol (14mM). Values are given as the mean±S.E.M. N=3. Statistical significance was determined by One-Way ANOVA with LSD Post Hoc Test. A P-value < .05 was shown.

CENTRAL DIABETES INSIPIDUS ASSOCIATED WITH ACUTE MYELOID LEUKEMIA
Neeharik Mareedu¹ and Asadullah Jat²
¹UPMC Western Maryland Nephrology, Nephrology, Cumberland, United States of America and ²UPMC Western Maryland, Internal Medicine, Cumberland, United States of America

Background and Aims: Central Diabetes Insipidus (CDI) is a rare condition in which there is decreased release of antidiuretic hormone (ADH) from the posterior lobe of the pituitary gland resulting in polyuria. CDI is most commonly idiopathic with other known causes being primary or secondary tumors, cranial nervous system (CNS) infiltrative diseases, head trauma or neurosurgical procedures. Acute Myeloid Leukemia (AML) is rarely associated with CDI. We report a case of elderly male patient with recently diagnosed AML who developed polyuria due to CDI.

Method: Review of medical literature and hospital patient case workup based on reviewed medical literature.

Results: A 78-year-old male patient diagnosed with acute myeloid leukemia was started on treatment with Decitabine and Venetoclax 4–6 weeks prior to his hospitalization with chief complaints of back pain and oropharyngeal mucositis. The patient was also noted to have significant polyuria with hypernatremia during his hospitalization. His urine output ranged around 6–7 liters per day and his serum sodium levels were noted to be elevated to 162 mmol/L. 24-hour urine osmolality was calculated at around 1700 milliosmoles/day. Though patient’s initial labs were suggestive of osmotic diuresis as a cause of his polyuria from ongoing hyperosmolar IV fluids input and significant increased oral dietary osmolar input, his polyuria persisted despite decreased total daily osmolar input. Further investigation with desmopressin suppression testing was notable for doubling of his urine osmolality with 10 mcg intranasal desmopressin administration with urine osmolality reaching to a peak of 447 mOsm/kg, indicating CDI as a reason for patient’s ongoing polyuria. Patient’s urine output as well as hypernatremia improved with initiating the patient on daily Desmopressin. MRI head with and without contrast ruled out any intracranial masses or infiltrative CNS diseases.

Conclusion: The pathogenic mechanism for association between CDI and AML is not completely clear, but it is thought to be secondary to infiltration of the central nervous system with leukemic cells, especially Sella Turcica, though this may not be evident on CNS imaging studies in all the cases, like in our patient. Polyuria can present in patients with AML either before or after the diagnosis of AML and sometimes it might be the only presentation in patients with AML which would lead to further workup and diagnosis of AML.
Early identification of CDI in these patients lead to prompt management and avoidance of any significant electrolyte imbalances which could be sometimes attributed to patient's chemotherapeutic agents rather than to the patient's disease process itself.

**FUROSEMIDE DECREASES KYNURENIC ACID SYNTHESIS IN RAT KIDNEY IN VITRO**

Izabela Zakrocka and Wojciech Żałuska

Lublin, Department of Nephrology, Lublin, Poland

**Background and Aims:** Loop diuretics are highly potent agents, particularly beneficial in patients with impaired kidney function or heart failure exacerbation. Furosemide, due to fast onset and short time of action, remains the most commonly used drug from this class of diuretics. Inhibition of sodium-potassium-chloride cotransporter (NKCC2) in the thick ascending limb of Henle's loop is the main mechanism of furosemide's action. Other effects of furosemide, like modulation of potassium channels activity or activation of prostaglandin synthesis, were previously described. It was postulated that furosemide may exacerbate kidney injury in a dose dependent manner. Kynurenine acid (KYNA) is a tryptophan derivative synthesized from L-kynurenine (L-KYN) by kynurenine aminotransferases (KATs). KAT I and KAT II are the main KAT isoenzymes. Non-selective antagonism towards ionotropic glutamatergic receptors, as well as activation of aryl hydrocarbon receptors and the α7 nicotinic acetylcholine receptors are known mechanisms of KYNA's action. KYNA was shown to regulate water and electrolyte balance through natriuretic effect. By some researchers KYNA, together with other tryptophan metabolites, is classified as uremic toxin. We aimed to analyze the influence of furosemide, widely used loop diuretic, on KYNA's synthesis and the activity of both KATs in rat kidney in vitro.

**Method:** The influence of furosemide on KYNA's production with KAT I and KAT II activity was tested in rat kidney homogenates in vitro after 2 hours incubation in the presence of KYNA precursor L-KYN and furosemide. Diuretic was examined at increasing concentrations: 1 μM, 10 μM, 50 μM, 100 μM, 500 μM and 1 mM. Enzymatic KYNA's production was measured by high performance liquid chromatography (HPLC) with fluorometric detector. All applicable international, national and institutional guidelines for the care and use of animals were followed.

**Results:** Furosemide at 500 μM and 1 mM lowered KYNA formation in kidney homogenates in vitro to 80% (p < 0.05) and 70% (p < 0.05) of control value, respectively. At 1 mM concentration furosemide inhibited kidney KAT I activity in vitro to 38% (p < 0.01) of control value. Similarly, furosemide at 500 μM and 1 mM concentration decreased kidney KAT II activity in vitro to 53% (p < 0.01) and 18% (p < 0.001) of control value, respectively.

**Conclusion:** Our study presents a novel mechanism of action of furosemide. Inhibition of KYNA synthesis in the kidney by furosemide may have influence on kidney function.

**ANALYSIS OF MACROPHAGE POPULATIONS IN THE KIDNEY WITH RENAL TUBULAR CELL-SPECIFIC SENESCENCE INDUCTION**

Ross Campbell1, Marie-Helena Docherty1,2, David Baird1,2, David Ferenbach1,2 and Katie Mylonas1

1 University of Edinburgh, Centre for Inflammation Research, QMRI, Edinburgh, United Kingdom and 2 Royal Infirmary of Edinburgh, Renal Medicine, Edinburgh, United Kingdom

**Background and Aims:** Ageing is a risk factor for multiple diseases, including kidney disease. To improve quality of life, pharmaceutical treatments are given to ageing patients, often with side-effects and cross-reactions. Research is needed into the effects and mechanisms of ageing in order to identify new druggable targets to improve quality of life. Cells can become senescent with age and are seen at sites of tissue injury. Senescent cells (SCs) undergo irreversible cell-cycle arrest, but remain metabolically active, producing a range of signalling molecules called the senescence associated secretory phenotype (SASP, made up of pro-inflammatory/fibrotic elements). Senescent cells within the kidney post-acute kidney injury (AKI) may be involved in ongoing damage, leading in some cases to chronic kidney disease (CKD), possibly due to interactions with macrophages. We hypothesise that the recruitment of monocytes/macrophages by senescent cells is due to the signalling components present in their SASP.

**Method:** Pax8 is renal tubule marker. We use Pax8-creERT2;mdm2 fl/fl mice to study kidney-specific senescence induction in absence of age/injury. Upon administration of tamoxifen, the mdm2 alleles are floxed out by cre recombinase, allowing p53 to stabilise and activate the p21CIP1 cell-cycle inhibitor, inducing senescence in Pax8+ kidney-specific cells. The use of an endogenous tdTomato reporter allows visualisation of cells undergoing successful recombination upon the administration of tamoxifen (TAM).

**Results:** As expected, cell-cycle inhibitor/SC marker, Cdkn1a was upregulated by qPCR in TAM-treated young murine whole kidneys 10-fold compared to controls (p = 0.0173) (Figure 1). Ccl2 (monocyte chemoattractant) was up-regulated 20-fold in young (p = 0.0405) TAM-treated TG mice vs controls (Figure 1). In agreement with an increase of Ccl2 transcripts, there was a significant increase of renal macrophages as quantified by flow cytometry of kidney digests (p = 0.0141) in TAM treated young TG mice. Immunofluorescence staining of transgenic mice revealed an increase of Iba1 positive macrophages, correlated with staining of tdTomato tubules, suggesting that increase in macrophage numbers was in response to senescence induction (Figure 2). Iba1-p21 co-stains show a increases in p21 positive cells in TAM-treated transgenic mice, evidently a result of construct activation and appear in proximity to the macrophages (Figure 2).

**Conclusion:** Apparent increases in macrophages due to the presence of senescent cells may indicate one of the mechanisms by which AKI progresses to CKD, particularly if inflammatory macrophage phenotypes are present and persist. Macrophage and monocyte populations fluctuate with age and the use of this model allows analysis of macrophage recruitment/polarisation due to senescent cell burden in the absence of age/injury and possible confounding factors, in young mice.

---

**Figure 1:**
Figure 1: Indicators of senescence and incipient SASP. (A) Transcripts for cell cycle inhibitor p21\textsuperscript{CIP1} (Cdkn1a) are significantly increased in the Pax8-creERT2;mdm2 \textsuperscript{fl/fl} transgenic mice treated with tamoxifen (TAM) compared to vehicle (VEH) treated wild type (WT) mice. (B) Transcripts for the potent macrophage/monocyte chemoattractant Ccl2 are significantly upregulated compared to vehicle treated young WT mice.

Figure 2: Recruitment of macrophages, and increase of p21 positive cells in response to construct activation. In response to tamoxifen (TAM) treatment, Pax8-creERT2;mdm2 \textsuperscript{fl/fl} transgenic (TG) mice show an increase of Iba1 positive cells (macrophages – red), localised around tdTomato positive (green) tubules, not observed in wild-type (WT) mice. Senescent marker p21\textsuperscript{kip1} was also seen at higher levels in TAM treated TG mice compared to age-matched TAM treated WT mice.

VALUE OF EXOME SEQUENCING “FIRST” FOR AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE

Marine Dancer1, Ilias Bensouna2, Thomas Robert3 and Laurent Mesnard4
1 Eurofins Biomnis, Genetics, Lyon, France, 2 Tenon Hospital, Paris, France and 3 Hospitals Academics De Marseille, Marseille, France

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common Mendelian kidney diseases, that can progress to end-stage kidney failure. Pathological variants in PKD1 or PKD2 genes are found in about 78% and 15% respectively. Additional variants in genes such as GANAB, DNaJB11, and ALG8/5 have been identified in ADPKD. The sequencing of PKD1 by short read sequencing technics with exome capture such as Exome sequencing (ES) has been describe as technically challenging given 6 pseudogenes with more than 98% homology in PKD1 exonic regions 1 to 33. Moreover, the presence of repeated motifs and GC-rich in PKD1/2 add difficulties. We study the relevance of exome sequencing (ES) “first-hand” during autosomal dominant polycystic kidney disease.

Method: ES was performed in 684 unrelated adult patients with kidney disease from the department of Nephrology of Sorbonne University, Paris, France. Genomic DNA was extracted and exonic coding regions (37 megabases) were enriched with the Twist Human Core Exome kit, and paired-end sequenced on NextSeq500 (Illumina) machine. Sequences were analyzed with in-house and the SeqOne v1.3, 2019 pipelines according to GATK4 best practices. If necessary, co-segregation of pathological variants was studied by Sanger sequencing in relatives.

Results: Of the 684 patients, 143 had renal cysts. Pathogenic or probably pathogenic variations in the PKD1, PKD2, and DNaJB11 genes have been identified in 26 patients, all with cystic disease; with respectively 17 variants in PKD1, 6 variants in PKD2 and 3 variants in DNaJB11. In this cohort, 18.2% of the 17 pathogenic variants are reported in PKD1, and 14 (82%) are included in exons 1 to 33. All variants were eventually confirmed by Sanger sequencing without false positive. Moreover, in 5 of the 26 patients diagnosed (19%), meaningful additional genetic data have been found, falling either in CFTR, DHCNR7, HFE, F8, or ACTA2 gene.

Conclusion: ES highlights PKD1 and PKD2 pathogenic variants detection without false positive. This strategy allowed us to provide appropriate genetic counseling (CFTR, DHCNR7), as management of yet unexpected additional genetic diseases that can affect ADPKD (F8, HFE, and ACTA2) phenotype. Given these preliminary data, ES appears effective for PKD1/PKD2 variant detection, providing additional information for ADPKD management in 20% of cases.

HYPOXIA INDUCES COMPLEMENT ACTIVATION ON HUMAN KIDNEY EPITHELIAL CELLS
Saltanat Moldakhmetova¹, Simi Ali² and Neil Sheerin²,³,⁴

¹Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne, United Kingdom, ²Newcastle University, Translational and Clinical Research Institute, Faculty of Medical Sciences, Newcastle upon Tyne (England), United Kingdom, ³National Renal Complement Therapeutics Centre, Newcastle upon Tyne, United Kingdom and ⁴Newcastle-upon-Tyne NHS Foundation Trust, Newcastle upon Tyne, United Kingdom

Background and Aims: Ischemia-reperfusion injury is an inevitable event associated with kidney transplantation (Tx) and has a major impact on short- and long-term graft survival. Proximal tubular epithelial cells are both a source of complement during Tx and a target of complement activation. The normal kidney has a capacity to protect itself from complement activation through cellular expression of complement regulatory proteins. In this study we investigated whether hypoxia and reoxygenation increase C3 deposition and alter complement regulatory protein expression (CD46, CD59 and CD55).

Method: In vitro, HKC-8 renal proximal tubular epithelial cells were subjected to 24h of hypoxia (1% O₂) and then reoxygenated for 4h (O₂ = 21%) in the presence of 40% normal human serum. qRT-PCR was used to estimate the level of VEGF-A (as a positive control), C3, CD46, CD59 and CD55 expression. Similar analysis was performed in untreated, normoxic cells. Immunofluorescence staining was used to determine C3 deposition on the cell surface and intensity quantified by ImageJ. Experiments were repeated three times.

Results: qRT-PCR analysis of HKC-8 cells in hypoxia revealed significant increases in the expression of VEGF-A after 24h (p = 0.0113). C3 expression...
following hypoxia and reoxygenation increased insignificantly. Increased expression of CD59 with the presence of serum was observed in epithelial cells (p = 0.026). However, no significant change was seen in the expression of CD55 and CD46. Reoxygenation in human serum led to significantly greater deposition of C3 on hypoxic cells compared with normoxic HKC-8 cells (Figure 1, 2).

**Conclusion:** Our preliminary data suggests that hypoxia and reoxygenation significantly increases C3 deposition on the proximal tubular cell surface. CD59, as one of the regulators of complement activation is upregulated at mRNA level after hypoxia followed by 4h reperfusion in the presence of serum. These data demonstrate that hypoxia and reoxygenation activate complement system with upregulation of CD59 as a cell defence. However, expression of CD46 and CD55 do not change. Further study is needed to identify the impact of hypoxia on complement regulation in primary epithelial cells and kidney tissues.

### A3 - GENETIC DISEASES (INCLUDING CYSTIC DISEASES)

### #3023

**KARYOMEGALIC INTERSTITIAL NEPHRITIS SECONDARY TO FAN1 VARIANTS: CHARACTERIZATIONS AND OUTCOMES. RESULTS OF THE FAN1 STUDY GROUP**

Clince Michelle1, Elhussein Elhassan1, Anthony Bleyer2, Susan Mcanallen1,3, Kendrah Kidd4 and Peter Conlon4

1 Beaumont Hospital, Department of Nephrology and Transplantation, Dublin, Ireland, 2Wake Forest University School of Medicine, Rare Inherited Kidney Disease Team, Winston-Salem, United States of America and 3Royal College of Physicians of Ireland, Aspire Fellowship Programme, Dublin, Ireland

**Background and Aims:** Karyomegalic Interstitial Nephritis (KIN) is a rare monogenic disorder caused by biallelic variants in Fanconi Anaemia-associated Nuclease 1 (FAN1), a gene involved in DNA repair. Less than 50 cases have been reported in the literature. Affected individuals suffer from kidney and pulmonary disease and increased susceptibility to cancer. In this international study, we report comprehensive clinical and genetic data on 32 individuals with FAN1-defined KIN.

**Method:** We performed a comprehensive literature review and an online survey to compile updated data of new and published cases via the FAN1 Study Group. Data collected included genotype, age at diagnosis, initial cause of presentation, kidney progression, transplantation status, and occurrence of cancer and pulmonary disease.

**Results:** Clinical and genetic data were obtained on 32 individuals, 20 previously unpublished. A total of 27 disease-causing variants in FAN1 were identified, predominantly protein-truncating alleles (see table 1). The median age of initial presentation was 39 years (range 1–69), and 26 (81%) were males. Kidney biopsy was performed in 15 individuals, where characteristic tubular karyomegaly was observed in all biopsies. Extrarenal manifestations were observed in 13/32 (40%) individuals and included liver dysfunction (9%), respiratory disease (22%) and malignancy (9%). At last assessment, 15 (46%) individuals progressed to end-stage kidney disease at an average age of 37.2 years (range 27 to 48 years). Eight (25%) individuals received a kidney transplant at a mean age of 45.1 years (range 34 to 62 years). 25% of individuals with a FAN1 variants developed a malignancy post-transplant. Overall mortality in this group was 12.5% (n = 4). 37.5% (n = 3) of transplant recipients died. One patient died from lung cancer 2.5 years post-transplant, another died from pulmonary aspergillosis 10 years post-transplant and a third died 10 years post-transplant due to interstitial lung disease. Post infectious respiratory failure was the cause of death for the remaining non-transplanted patient.

**Conclusion:** FAN1 variants result in a high burden of kidney failure and extrarenal comorbidities in this young population group. Incidence of malignancy was almost double that which has been reported in the general transplant population. This result may suggest that careful consideration and counselling should be provided to patients with FAN1 prior to transplantation given their potential for increased risk of malignancy and respiratory failure. In this study, international collaboration has provided new clinical and genetic data for 20 cases of FAN1 not previously published adding to our understanding of the natural history of a very rare disease. Please contact michelleclince@gmail.com if you have a case that you could contribute to our survey.

### Table 1: Clinical, biological, and genetic characterization of 32 individuals with FAN1 variants.

Method: PEG-CZNPs were synthesized using a non-hydrolytic sol-gel reaction method. HK-2 cells were transfected with α-galactosidase A (α-GLA) siRNA for permanent cellular model of FD. For in vivo study 4-week-old male B6.129-Gla<sup>min10ld</sup> mice were treated for 48 weeks with 10mg/kg of PEG-CZNPs twice per week via intraperitoneal injection. PCR, immunoblotting, immunofluorescence assay, electron microscopy analysis, ICP-MS, biochemical and histological analysis were done.

Results: TFEB translocated to the nucleus by treatment with PEG-CZNPs. Autophagy flux was evaluated with chloroquine. Autophagy flux was enhanced by PEG-CZNPs treatment. To show whether TFEB plays the important role in autophagy flux, we transfected HK-2 cells with siTFEB. Autophagy flux significantly decreased after knockdown of TFEB with PEG-CZNPs treatment. We next assessed upper signaling pathway of TFEB by PEG-CZNPs. TFEB dephosphorylation was independent of both mTOR and ERK but GSK3β signaling pathway showed massive impact on TFEB dephosphorylation by PEG-CZNPs. PEG-CZNPs decrease intracellular globothriaosacercyamide (Gb3) accumulation and decreased the levels of Collagen type IV, αSMA and MMP9 expression in cellular model of FD. Gb3 levels were significantly reduced in the kidney tissues and the levels of Fibronectin, Collagen type 4 and αSMA was decreased by PEG-CZNPs in animal model of FD.

Conclusion: These results suggest PEG-CZNPs promote autophagy flux through GSK3β -TFEB signaling pathways, showed the beneficial effect on renal fibrosis in cellular and animal models of FD. It thus provided a new insight of the potential therapeutics on FD.

FOCAL SEGMENTAL GLOMERULOSCLEROSIS DUE TO A3243G POINT MUTATION IN THE MTDNA CODING FOR TRNALEU(UUR)

Michele Marchini¹, Valentina Blanco², Michela Ardini¹, Laura Panaro¹, Sonila Mocka¹, Matteo Trezzi¹, Nadia Chiappini¹, Francesca Lauria¹ and Davide Rolla¹

¹Ospedale Sant’Andrea, U.O.C. Nefrologia e Dialisi, La Spezia, Italy and
²Piacenza, Nefrologia e Dialisi, Piacenza, Italy

Background and Aims: Mitochondrial Diseases represent a heterogeneous set of maternally inherited diseases that arise by mutations either of the mitochondrial DNA (mtDNA) or in genes of nuclear DNA (nDNA) linked to the cell mitochondrial cross-talk. Many mutations in mtDNA that code for different genes are linked to a wide spectrum of kidney manifestations ranging from focal segmental glomerulosclerosis (FSGS), tubule-interstitial disease (TIN), nephrotic syndrome (NS), and proximal or distal tubulopathy. Renal manifestations of mtDNA disorders are poorly recognized in clinical practice and often misdiagnosed for other conditions like FSGS, Alport Syndrome, steroid-resistant nephrotic syndrome. The guanine for adenine point mutation (A–G) at position 3243 in the mtDNA has emerged as the most common mutation found in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis, (FSGS) is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness. Focal Segmental Glomerulosclerosis is the prevalent histologic finding in patients with FSGS often accompanied by diabetes mellitus and deafness.

Method: A 34-year-old man presented for evaluation with recently diagnosed Type II diabetes mellitus and serum creatinine of 3.9 mg/dL with nephrotic range proteinuria (3.2 gr/die). His family history included Type II diabetes mellitus, chronic kidney disease, coronary artery disease, and hypertension. The patient medical history included hypertension, dyslipidemia, and sensorineural hearing loss which had initially developed during adolescence. Serum creatinine was reportedly elevated years before this presentation, and urinalysis showed mild proteinuria with no microhematuria, white cells, or casts.

Results: On evaluation his blood pressure was 150/90 mmHg, presented mild peripheral leg edema. Laboratory results showed serum creatinine 3.4 mg/dl (eGFR 23 ml/min), HbA1c of 7.2%, albumin 2.8 gr/dL. Urinalysis showed protein (3+), glucose (+1) and no hematuria. Urinary protein-creatinine ratio was 3 mg/g. Serum C3 and C4, immunoglobulins, liver enzymes were normal; autoimmunity tested negative (ANCA, Anti-PLA2r, Anti nuclear antibodies). A kidney biopsy was performed. Light microscopy revealed glomeruli with segmental obliteration of glomerular capillaries by collagenous sclerosis (Fig. 1). Both the Jones methenamine silver stain and Masson’s trichrome stain (Fig. 1B, C) showed segmental collagen deposition and sclerosis of glomerular capillaries. Tubular atrophy and fibrosis were also present. Immunofluorescence microscopy was negative. A diagnosis of not otherwise specified focal segmental glomerulosclerosis (NOS FSGS) was made. Interestingly electron microscopy showed mitochondrial abnormalities in the tubular cells. In particular, the cytoplasm of a tubular cell appears to be whiffed by mitochondria of enlarged size and altered shape (Fig. 2). Mitochondria appeared dysmorphic with extensive reduction of mitochondrial cristae (Fig. 2 arrows). The patient was screened for mtDNA mutations and guanine for adenine substitution (A–G) at position 3243 was detected. The patient received a diagnosis of chronic kidney disease with histological features of FSGS due to an A3243G point mutation in the mtDNA with associated diabetes mellitus and sensorineural deafness.

Conclusion: This case underscores the role of electron microscopy in identifying mitochondrial related nephropathies. Even more important is to evaluate mtDNA mutations in cases with familial FSGS, sensorineural hearing loss, cardiomyopathy and diabetes.
INTRAFAMILIAL HETEROGENEITY AND IMPACT OF FAMILY SCREENING IN PRIMARY HYPEROXALURIA TYPE 1

Lisa Deesker, Hazal Karacoban, Ella Metry and Jaap Groothoff

Emma children’s hospital, Amsterdam UMC, Department of pediatric nephrology, Amsterdam, Netherlands

Background and Aims: Primary hyperoxaluria is a rare genetic disease, caused by an autosomal recessive mutation of the AGXT gene. Clinical variability in outcome is reported within families with primary hyperoxaluria type 1 (PH1) with identical genotypes, leading to the question which differences in the disease course between affected family members can be attributed to environmental factors and which to early diagnosis or therapy. The limited research on this subject results into prognostic challenges and leads to difficult decision-making concerning the timing of transplantation and therapy. Therefore, the objective of this study was to determine whether and to what extent intra-familial heterogeneity is present, based on a clear definition of intra-familial heterogeneity in PH1 and to analyse the impact of therapeutic intervention and early diagnosis via family screening on the prognosis of siblings.

Method: A retrospective registry study was performed using data from the OxalEurope registry. All families with PH1 were identified and analyzed. A six-point PH1 scoring system was developed to calculate the heterogeneity score within a family, based on the clinical outcome of siblings (Table 1). A score ≥2 was considered as significant intra-familial heterogeneity. Assessment of the impact of family screening was conducted by stratification of the patients based on family screening and symptoms. The Fisher-Freeman-Halton exact test, Mann-Whitney U test, Kruskal Wallis test and Kaplan Meier analysis were used for statistical testing.

Results: A total of 88 families were included in this study, including a total of 193 patients with PH1. The median (IQR) follow-up time was 7.8 (1.9–17) years. Family screening was conducted in most families (77%), although not all. Intra-familial heterogeneity was found in 38 (43%) families. A (partly) B6-responsive mutation did not lead to a significant difference in intra-familial heterogeneity score. In more than half of the families (54%), affected siblings had a better outcome than the index case and in 67% of families one or more cases of kidney failure occurred. Asymptomatic siblings had a significant better clinical outcome compared to symptomatic siblings and index cases based on clinical outcome score (p < 0.001). Kaplan-Meier analyses (Figure 1) revealed that index cases reached kidney failure at an earlier age and earlier in follow-up compared to siblings (Log-rank; p < 0.0001).

Conclusion: Intra-familial heterogeneity is found in nearly half of families with PH1. These findings confirm that intra-familial heterogeneity is present in PH1, in line with previous reports. Asymptomatic siblings found by family screening had a significant better outcome based on clinical outcome score and kidney survival, substantiating the benefit of family screening. Although the exact cause of heterogeneity in PH1 could not be identified, family screening is essential and strongly recommended since it may improve kidney survival in siblings.

Figure 1: Kaplan-Meier analysis of death-censored kidney survival by age, stratified by index case, sibling asymptomatic at time of diagnosis and sibling symptomatic at time of diagnosis. Log-rank test analysis showed a significant difference (p < 0.0001) between the groups.

Table 1: 6-point PH1 clinical outcome scoring system for calculating intra-familial heterogeneity.

MT-TL1 M.3243A>G MITOCHONDRIAL DNA VARIANT DETECTED FROM WHOLE EXOME SEQUENCING CAN EXPLAIN CASES OF ADULT UNKNOWN NEPHROPATHIES
Ilia Bensouma1, Marine Dancer2, Anne-Sophie Lebre3, Laure Raymond2, Alice Doreille1, Florence Lauteri-Badin1 and Laurent Mesnard1
1APHP, Sorbonne University, Tenon Hospital, SINRA Nephrology Department, Paris, France; 2Biominis, Genetics, Lyon, France and 3APHP, Sorbonne University, Pitié-Salpêtrière Hospital, Genetics, Paris, France

Background and Aims: In a population-based study, mainly constituted of unknown nephropathies (cohort Sorbonne University, Paris, France N = 1197 patients), beyond reporting the diagnostic yield of nuclear genes, we also investigated the incidence of the mtDNA pathogenic variant MT-TL1 m.3243A>G. This variant was systematically searched from whole exome sequencing (WES) data. In retrospect, we described the renal phenotype and studied the heteroplasmy level of the mtDNA variation in urine or kidney tissues compared to its blood fraction. The prevalence of m.3243A>G has been estimated ranging from 0.08% to up to 0.25%.

Method: From September 2018, to February 2023, WES has been prospectively performed, as a first exploration of adult nephropathies of unknown origin or when a genetic renal disease was clinically suggested. As off-target result, we retrieved m.3243A>G variation in blood DNA and then determined the mtDNA heteroplasmy level respective from urine sample or kidney tissue when available with an orthogonal method.

Results: We report a molecular diagnosis in 294 over 1197 adult patients sequenced (diagnostic yield: 24%, Age 43 y/o in average). Among these 294 patients with molecular diagnoses, 48 were distinct monogenic disorders, out of which 47% accounted for 52% of the genetic diagnoses. MT-TL1 m.3243A>G pathogenic variant was detected in 1.7% of the patients (20 patients over 1197 patients). An orthogonal method confirmed the presence of m.3243A>G variant in 10 patients supporting the possibility to diagnose from blood DNA analysed by WES. In all cases, the presence of m.3243A>G had major clinical implications for the patients and their families: living related donor aborted for two patients, a molecular diagnosis in three patients with unknown nephropathies and in three patients with histological diagnosis of focal segmental glomerulosclerosis. Other mitochondrial diseases appeared less likely involved in our adult cohort (only one patient with COQ2 pathogenic variants).

Conclusion: This population-based study reinforces the place of WES as first-tier exploration for adult patients with chronic kidney disease in whom phenotypes are often poor and/or atypical. The mitochondrial genome analysis with the same assay allowed the detection of yet unsuspected MT-TL1 m.3243A>G variant in 1.7% of patients suggesting enrichment compared to current prevalence observed in other population. Our data suggest that the entity "mitochondrial nephropathy" can represent a significant part of adult unknown nephropathies.

TOlvaptan dose adjustment in ADPKD based on urinary osmolality: similar efficacy and low dropout rate
Francisco Roca Oporto1, Cristina Andrade Gómez2, Gema Montilla Cosano1, Alicia Luna Aguilara2 and José Luis Roche Castilla1
1Hospital Universitario Virgen del Rocio, Nefrología, Sevilla, Spain and 2Hospital Puntal de Europa, Nefrología, Algeciras, Spain

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited renal disease. Tolvaptan is the only treatment that has been shown to slow disease progression. The current recommendation is to reach the maximum tolerated dose while controlling side effects such as hepatotoxicity. There are data suggesting a marked decrease in tolerability at high doses of the drug. We explored the possibility of an individualized tolvaptan dose adjustment, based on urinary osmolality (Uosm), as an indirect indicator of treatment efficacy.

Method: A single-center prospective cohort study of tolvaptan in patients with ADPKD and rapid progression, with dose adjustment according to Uosm, with dose increase if Uosm > 200 mOsm/kg. Glomerular filtration rate (GFR) estimated by CKD-EPI, Uosm, adverse effects and dropouts were analyzed.

Results: 40 patients: 35 patients with more than 2 years treatment, mean follow-up 30±6 months. Mean age 45±7 years, 82% hypertensive and 47% male.

Evolution: mean annual fall in GFR during the previous 3 years without treatment -7.24 ± 1.5 ml/min/year. Baseline GFR 51.05±12.5 ml/min and baseline Uosm 391±87 mOsm/kg. Average annual drop in GFR over 3 years with treatment -3.18±1.3 ml/min/year. Average Uosm achieved during treatment 171±47 mOsm/kg. Maximum tolvaptan dose reached 60 mg (90%) and 90 mg (10%). The adverse events recorded highlight that there were no cases of hepatotoxicity (0%). The most frequent alterations were hyperuricemia (18%) and hypernatremia (11%), but in all cases asymptomatic. Polyuria was recorded in all our patients (100%), with a median diuresis 6000 ml/day (7000-5500), but the dropout rate due to aquaretic effects was minimal, only 2 patients (5%).

Conclusion: In our series of patients, treatment with tolvaptan at a dose adapted to Uosm, seems to show a similar efficacy to the reference studies in the annual fall of GFR, with a low rate of adverse events and very low dropout rate.
ADPKD is the most common form of inherited renal disease worldwide. ADPKD care has advanced over the past decade by the identification of several clinical/genetic risk factors of progression and approval of first disease-modifying drug. Further clinical outcomes research is needed to improve patient-centered clinical care; in addition new disease-modifying therapies are in pipeline, requiring a growing need for patient enrolment in clinical trials. To advance these goals, the Italian Society of Nephrology, therapies are in pipeline, requiring a growing need for patient enrolment in clinical trials. To advance these goals, the Italian Society of Nephrology, supported by the Italian PKD Foundation (AIRP) established in 2020 the creation of a National web-based ADPKD Registry. Here we present the design of this Registry and the preliminary results.

Method: Adult patients with clinical or genotypically confirmed diagnosis of ADPKD have been enrolled in the Registry, hosted by a secure online platform including both a clinical and genetic database. Databases have modular design collecting clinical features, including demographic data, type of diagnosis, e-GFR at onset and at time of first and last nephrological referral, age at onset of hypertension (HTN) and major urological complications (UC), Total Kidney Volume (hTKV) and Mayo Imaging Classification of ADPKD, age at ESRD, use of aspecific renal-protective and disease-modifying drugs, additional risk factors for CKD progression (smoke, diabetes, NSAID), extra-renal manifestations. Genetic data collected include type of PKD1/2 variant using linear-mixed modelling.

**Results:** By January 2023, the Registry had recruited 985 ADPKD patients across 21 Italian Nephrology Unit; 513 (52.1%) were females; 967 (98.2%) Caucasians. Familiar history of ADPKD was reported in 738 patients (79%). All CKD stages were represented and 105 (14.1%) patients reached ESRD (median age 57.4 ± 11.5). hTKV was available for 353 (35.9%) patients, with a median value of 1100 ± 996 ml/m³; a Mayo class of 1C or higher was found in 221 (70.4%). PROPKD score was evaluated in 162 patients, and in 50% of them it was associated with low risk of progression. A total of 191 (21.6%) were receiving Tolvaptan. Demographic and clinical characteristics are summarized in Table 1.

Genetic testing was performed in 288 patients; 111 (38.5%) had PKD1 truncating (T) variants; 66 (23.3%) PKD1 non truncating variants; 69 (24.2%) PKD2 variants. In 41 patients (14.2%) no pathogenic variants were detected. In our cohort deterioration of renal function over time, estimated using eGFR slope was significantly associated with Mayo Imaging classes, high-medium (p = 0.014). Conclusion: The Italian ADPKD National Registry is an important research tool collecting clinical and genetic information. Our preliminary data confirm that in the Italian population genotype, early onset HTN or UC, Mayo Imaging classification and PROPKD score are able to predict deterioration of GFR in ADPKD. The future empowerment of the Registry will provide a comprehensive description of clinical features and genetic variants related to ADPKD in a large cohort of Italian patients, enabling us to better understand genotype-phenotype correlation. Furthermore, the Registry could be an opportunity to identify patients suitable for future clinical trials or observational studies concerning specific aspects of the disease.
INVESTIGATION OF NOTCH PATHWAY ACTIVATION AND ITS RELATION TO GREMLIN IN AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE

Lucia Tejedor1,2, Laura Núñez González3, Laura Marquez-Exposito1, Adrian Cordido3, Vanessa Marchant1,2, Pamela Estefania Basaneta1,2, Raul Rodrigues Diez4, Antonio Tejera1, Sandra Rayego-Mateos1, Ana Belen Sanz1, Alberto Ortiz1, Miguel Angel Garcia Gonzalez3 and Marta Ruiz-Ortega1,2

1IIS-Fundación Jiménez Díaz, Madrid, Spain, 2Facultad de Medicina UAM, Madrid, Spain, 3Institut de Investigación Sanitaria de Santiago, Santiago de Compostela, Spain and 4Fundación para la Investigación y la Innovación Biosanitaria de Asturias, Oviedo, Spain

Background and Aims: Activation of the NOTCH signalling pathway has been described in several progressive kidney diseases. Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a genetic disease caused by PKD1 or PKD2 mutations, which codify for the Polycystin-1 and Polycystin-2 proteins, respectively. ADPKD prevalence is among 1:800 and 1:1000 of live births and is characterized by fluid-filled renal cysts. During this process the production of chemokines, cytokines and growth factors by epithelial cells, interstitial fibroblasts and inflammatory cells, such as macrophages, increases, leading to end-stage renal disease (ESRD). GREMLIN has been proposed as an important mediator of chronic kidney disease in preclinical studies. In addition, urinary levels of GREMLIN may be a biomarker in any renal disease. However, there are no studies on GREMLIN in polycystic kidney disease.

Method: We have done the studies in an orthologous murine model of polycystic kidney disease (Pkd1cond/cond;Tam-Cre+/−) where we investigated the role of GREMLIN and its related mechanisms (its receptor VEGFR2 and the Notch signalling pathway) in different stages of renal cystic progression. The polycystic phenotype was induced in lactating mice by administering tamoxifen to the mother on postnatal days 10 and 11, causing a deletion in

Figure 1: (A) Correlation between eGFR slope and early onset of hypertension (HTN); (B) Correlation between eGFR slope and genotype (T = truncating, NT = non truncating); (C) Correlation between eGFR slope and Mayo Imaging Class; (D) Correlation between eGFR slope and PROPKD score.
usually in mid-adulthood. ADTKD has a progressive decline in kidney function, reaching end-stage renal disease (ESRD) as a common end-stage phenotype. Subforms, exclusively caused by a characteristic frameshift mutation, leading to MUC1-framedeleted (MUC1-fs) protein levels. MUC1-fs protein revealed a significantly shorter half-life than wildtype mucin 1, possibly due to its different cellular distribution.

**Conclusion:** Our data confirm and extend previously published information on intracellular MUC1-fs localization and regulation (Dvela-Levitt et al., Cell 2019). The protein kinetics of MUC1-fs appear quite dynamic in terms of synthesis and decay, which should argue for it being a suitable pharmacological target. Both, BRD4780 and RNA interference potently downregulate MUC1-fs. Interestingly, in primary and immortalized patient derived cells MUC1-fs localization is not confined to the early secretory pathway. Should the effect of BRD4780 be restricted to TME-derived COP vesicles, this can suggest a possible reduced effectiveness. Therefore, RNA interference may be more efficient, since it reduces MUC1-fs at an earlier stage and is not dependent on intracellular processing.

### #4297

**AN ALTERNATIVE METHOD FOR SCREENING FABRY DISEASE IN WOMEN - PARTIAL RESULTS OF A BRAZILIAN STUDY**

1 Universidade Estadual Paulista (UNESP), Postgraduate program, Botucatu, Brazil, 2 DLE, Brazil, 3 UFRN, Brazil, 4 Instituto de Medicina Integral Fernando Figueira - IMIP, Brazil, 5 UFBAM, Brazil, 6 Santa Casa de Maringá, Brazil, 7 Metta Saúde Clínica do Rim, Brazil, 8 Serviço de Terapia Renal de Ourinhos, Brazil, 9 USP, Brazil, 10 Fundação Ipy-Rim, Brazil, 11 Santa Casa da Misericórdia de Itabuna, Brazil, 12 Grupo Instituto do Rim do Paran, Brazil, 13 Universidade Federal de Goiás, Brazil, 14 Clirenal, Brazil, 15 Centro de Nefrologia de Nova Friburgo, Brazil and 16 Universidade Federal do Paraná, Brazil

**Background and Aims:** Fabry disease (FD) is a rare X-linked lysosomal storage disease that can affect multiple organs, including the kidneys. The main objective of this study was to evaluate the effectiveness of a combination of α-GAL enzyme activity and plasma levels of lysosomal α-GAL enzyme activity.

**Conclusion:** Preliminary results suggest that the combination of α-GAL enzyme activity and lysosomal α-GAL enzyme activity may be a good alternative for screening FD in women with chronic kidney disease (CKD).

**CHARACTERIZATION AND REGULATION OF THE PATHOGENIC MUCIN1 FRAMESHIFT PROTEIN IN PATIENT DERIVED CELLS CAUSED BY ADTKD-MUC1**

Karl Knauß1, Karen Schneider1, Sonja Rehrl1, Florian Wopperer1, Mario Schiffer1, Maike Büttner-Herold2, Kerstin Amann2, Ursula Schloetzer-Schrehardt3 and Michael Wiesener4

1 University Hospital Erlangen, Department of Nephrology & Hypertension, Erlangen, Germany, 2 University Hospital Erlangen, Division of Nephrology, Erlangen, Germany and 3 University Hospital Erlangen, Department of Ophthalmology, Erlangen, Germany

**Background and Aims:** Autosomal Dominant Tubulointerstitial Kidney Diseases (ADTKD) are caused by mutations in one of at least five genes (UMOD, MUC1, HNF1B, REN and SEG61A1) and are characterized by progressive decline in kidney function, reaching end-stage renal disease (ESRD) usually in mid-adulthood. ADTKD-MUC1 is one of the most frequent subforms, exclusively caused by a characteristic frameshift mutation, leading to the de novo protein MUC1-fs. MUC1-fs is believed to play the distinct pathogenic role in terms of a toxic proteinopathy, accumulating in the early secretory pathway. The substance BRD4780 was reported to re-route MUC1-fs towards lysosomal degradation (Dvela-Levitt et al., Cell 2019), with interventional trials being in preparation. Therefore, we aimed to gain more insights into MUC1-fs temporal and spacial regulative characteristics, comparing pharmacological intervention vs. RNA interference in patient derived tubular cells.

**Methods:** Cells culture (HCK-8 cells and patient derived human urinary Primary Tubular Cells, huPTC); siRNA knockdown; Transient transfection; Immunofluorescence; immunogold electron microscopy (EM); Immunoblotting (IB); Lentiviral SV40/Large-T antigen immortalization of huPTC; Generation of a novel polyclonal MUC1-fs antibody with an independent antigen downstream of the VNTR.

**Results:** To analyze MUC1-fs protein in more detail, we generated iTCs (immortalized tubular cells) from huPTC of patients with ADTKD-MUC1. Clonal selection of cells was performed to gain immortalized clones with MUC1-fs expression. MUC1-fs mainly localizes to the secretory pathway. Co-localization was only partially observed with TMED9, which localizes to COP vesicles, being involved in protein trafficking within the early secretory pathway. TMED9 negative components of this pathway also showed MUC1-fs staining, such as the Golgi apparatus and Early Endosomes. Immunogold EM of huPTC reveals MUC1-fs expression within the ER (and secretory) vesicles. Ultrastructural analyses of biopsies by EM from ADTKD-MUC1 patients did not show specific protein accumulation, as previously described in ADTKD-MUC1 and pharmacological application of BRD4780 was performed in huPTC and iTCs, with detailed description of MUC1-fs regulation kinetics. Both approaches led to strongly reduced MUC1-fs protein levels. MUC1-fs protein revealed a significantly shorter half-life than wildtype mucin 1, possibly due to its different cellular distribution.

**Conclusion:** Our data confirm and extend previously published information on intracellular MUC1-fs localization and regulation (Dvela-Levitt et al., Cell 2019). The protein kinetics of MUC1-fs appear quite dynamic in terms of synthesis and decay, which should argue for it being a suitable pharmacological target. Both, BRD4780 and RNA interference potently downregulate MUC1-fs. Interestingly, in primary and immortalized patient derived cells MUC1-fs localization is not confined to the early secretory pathway. Should the effect of BRD4780 be restricted to TME-derived COP vesicles, this can suggest a possible reduced effectiveness. Therefore, RNA interference may be more efficient, since it reduces MUC1-fs at an earlier stage and is not dependent on intracellular processing.

---

Figure 1: Pkd1 gene. Studies were performed considering different sacrifice points: at 18, 30 and 45 days. Furthermore, in urine and renal tissue from ADPKD patients, we studied the expression of GREMLIM.

**Results:** We have been able to see how in Pkd1-/- mutant mice, greml-1 renal expression (that encoding GREMLIN protein), was increased from 18 days, with a significant increase at 30 days. This increase was associated with progressive cysts expansion and detritum in renal function measured by BUN. These results were confirmed at the protein level by western blot. Immunohistochemistry revealed positive GREMLIN staining since pre-cystic tubulopelithelial cells, which remained elevated in the tubules at later times. Positive GREMLIN expression was observed in biopsy samples of cysts from ADPKD patients as well as GREMLIN protein presence in urine samples. In the polycystic model, GREMLIN induction was correlated with VEGFR2 activation in the same tubular segments. Cyst formation was associated with activation of the NOTCH pathway, characterized by NOTCH1 and NOTCH3 activation.

**Conclusion:** Thus, we can suggest that GREMLIN expression may be an important mediator of renal damage progression in ADPKD and this protein would act through the Notch pathway.

Recogni6on of Renal Tubular Dysgenesis in Ado5lescent Ckd by Biallelic Agt Variants Required Broad Genetic Analysis

Florian Woppe6r1, Eric Olinger2, Karl Knaup1, Antje Wiesenecker3, Katharina Broerek, Mario Schieffer, Karl Hilgern, Francesca Pasu6o, John Sayner5 and Michael Wiesenecker4

1Department of Nephrop7y and Hypertension, University Hospital Erlangen, Friedrich-Alexander-Universit6t Erlangen-N6rnberg, Erlangen, Germany; 2Translational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom; 3Institute of Human Genetics, University Hospital Erlangen, Friedrich-Alexander-Universit6t Erlangen-N6rnberg, Erlangen, Germany and 4Institute of Physiology, University of Regensburg, Regensburg, Germany.

Background and Aims: Autosomal recessive renal tubular dysgenesis (ARRTD) is a rare inherited disorder of renal (tubular) development, clinically characterized by fetal oligo-/anuria leading to oligohydramnion and Potter sequence, resulting in high mortality within the prenatal and neonatal period. Variants in genes encoding components of the renin-angiotensin system (RAS) are causative for this disorder. Herein, we report 2 European families with biallelic variants within AGT and aim to provide novel insights into disease understanding.

Method: The study was approved by our institutional ethics committee (approval number: 251_18 B). Clinical, histological and pedigree analyses were performed. Exome sequencing of a preselected gene panel (nephrop7y, 560 genes associated with renal disease) was analysed on the HiSeq System 2500 (Illumina) after enrichment by TWIST human core technology (TWIST Bioscience). Immunohistochemistry staining (IHC) and in-situ hybridization (ISH) for expression of renin were performed on kidney biopsy. In addition, renin expression was determined in primary tubular cells of the index patient by qPCR. Allele frequencies of heterozygous and biallelic predicted deleterious variants were determined by analysis of the Genomics England 100,000 Genomes Project.

Results: The first family was identified after transition from pediatric to adult nephrop7y at the University Hospital Erlangen. Initially, the male index patient of consanguineous Turkish descent presented with oligohydramnion in the prenatal period. Directly after birth (32nd gestational week) he suffered from profound hypotension, pulmonary hypoplasia and pulmonary stenosis, as well as third degree acute kidney injury leading to ICU treatment, but no need of hemodialysis. He survived the perinatal period. It is not reported if these individuals reached adulthood.

Conclusion: We hereby demonstrate two extremely rare cases, affected by biallelic variants within AGT, that survived the perinatal period and eventually led to chronic kidney disease. Since the phenotypes may be variable, a contemporary approach by broad genetic analysis is the only option to decode the genetic background in individuals with a suspected genetic disorder. Upregulation of renin in tubular cells by inactivation of AGT in the germline may drive tubulointerstitial fibrosis, which is a theoretical concern regarding ongoing targeted pharmacological approaches against AGT for arterial hypertension.

Monoallelic Ift140-related Polycystic Kidney Disease in an Italian AdPkd Cohort

Chiara Dordoni1, Letizia Zeni2, Cinzia Mazza3, Gianfranco Savoldi4, Laura Econimo5, Roberta Cortinovis4, Federico Alberici4, Francesco Scolari2 and Claudia Izzi1,2

1ASST Spedali Civili of Brescia, Medical Genetics Clinic, Department of Obstetrics and Gynecology, Brescia, Italy; 2University of Brescia and ASST Spedali Civili of Brescia, Division of Nephrop7y and Dialysis, Department of Medical and Surgical Specialties, Radiological Sciences, and Public Health, Brescia, Italy; 3ASST Spedali Civili of Brescia, Medical Genetics Laboratory, Italy and 4ASST Spedali Civili of Brescia, Medical Genetics Laboratory, Italy.

Background and Aims: Autosomal-dominant polycystic kidney disease (ADPKD) is the most common inherited renal disorder characterized by progressive bilateral renal cysts development and extrarenal phenotype, i.e. liver and/or pancreatic cysts, intracranial aneurism, hernias, mitral valve prolapse and diverticulosis. More than 90% of patients harbour heterozygous pathogenic variant in PKD1 or PKD2 genes, rarely in other cystogenes (e.g. GANAB, DNAJB11, ALG8, ALG9). Recently, NGS genetic testing protocol for ADPKD has been updated with IFT140 gene, thus the ADPKD gene panel included: ALG8, ALG9, ANKS6, DNAJB11, GANAB, IFT140, LRP5, PARN, PKD1, PKD2, PRKCSH, SEC61A1, SEC63. The new protocol has been offered to patients evaluated since January 2022 and to all genetically unresolved patients evaluated in 2021. All patients performed also multiple ligation probe amplification (MLPA) analysis of PKD1 and PKD2.

Results: In 2021 and 2022 ADPKD genes testing has been performed in 129 patients. Pathogenic variants in PKD1 or PKD2 genes were detected in 110/129 patients (85%); among the negative cases (19/129, 15%), 3 patients (P1, P2, P3) resulted heterozygous carrier of LoF variants in IFT140 gene: p.Arg307*, p.Lys1275Argfs*23 and p.Arg834* respectively. Overall 2.3% of ADPKD patients harboured IFT140 pathogenic variant; considering unresolved cases only, the prevalence was 15.7% (3/19). Segregation analysis identified the LoF variant in 3 daughters of P1 and in a son of P2. The 3 probands were diagnosed with renal disease in adulthood from fourth to sixth decade. In P1 eGFR (CKD-EPI formula) slowly declined from 104 ml/min/1.73 at onset (43 year-old) to 74.6 ml/min/1.73 at age 55. In P2 eGFR at first evaluation was 38 ml/min/1.73 (68 year-old); at last follow-up 32.9 ml/min/1.73 (73 year-old). In P3 eGFR declined from 51.7 ml/min/1.73 (55 year-old) to 42 ml/min/1.73 at age 67. Renal imaging in P1 at and P2 disclosed increased total kidney volume (TKV 1042 and 5520 cc respectively), large cysts and absence of cystic liver disease. P3 had slightly increased kidneys (TKV 447 cc) with large renal cysts and few liver cysts. Hypertension was present in 4 patients, all with adult-onset (46-60 years). Two patients had an early diagnosis of kidney stones (age 24 and 18). No macroscopic hematuria or cyst infections were reported. In accordance with ADPKD-like disease form, P1 presented inguinal hernia. Imaging data are summarized in Figure 1.

Conclusion: In this Italian cohort, heterozygous LoF variants in IFT140 gene is confirmed to be the third most common genetic cause of ADPKD spectrum disease, the prevalence being 2.3%. The major features are late onset hypertension, increased kidney volume due to large cysts and slow progressive renal failure. IFT140 gene must be included in diagnostic protocol of ADPKD patients to better define renal prognosis, therapy and familial screening.
#CLINICAL UTILITY OF GENETIC TESTING IN A KIDNEY TRANSPLANT CLINIC

Cristina Castro Alonso1, Aina Quilis2, Eva Gavela2, Julia Kanter2, Emma Calatayud Aristoy3, Ana Rodriguez Muñoz4, Amaya Hernandez Espinilla5, Alejandro Valero Antón2, Jonay Pantoja2 and María Asuncion Sancho Calabuig2

1Doctor Peset University Hospital, Nephrology, Valencia, Spain, 2Doctor Peset University Hospital, Nephrology, Valencia, Spain and 3Doctor Peset University Hospital, Clinical Analysis, Valencia, Spain

Background and Aims: Inherited kidney disease (IKD) is one of the leading causes of end-stage of kidney disease. Genetic diagnosis plays an important role in the counseling and management of kidney transplant patients or those on the waiting list, as it makes it possible to identify the cause of CKD, help in the selection of living donors, carry out genetic counseling and find out the prognosis around the graft survival and the risk of recurrence of the primary disease. The objective of the following study is to analyze the prevalence of IKD in our kidney transplant population and those on the waiting list, the phenotypic characteristics, genetic findings, and the diagnostic reclassification performed after the genetic study.

Method: This retrospective study has included all genetic test (by next-generation sequencing (NGS) until 529 genes associated with kidney disease) performance between January 2018 and January 2023 in kidney transplant patients or on the waiting list for kidney transplant at Doctor Peset Hospital, using a multidisciplinary team approach. The patients were considered for genomic evaluation if they met one of the inclusion criteria: CKD of unknown etiology, family history of CKD, glomerular disease or chronic tubulo-interstitial disease with no recognized cause, suspicion of aHUS, CKD and other extrarenal syndromic signs or with renal malformations or nephrocalcinosis. Demographic data, family burden and screening, CKD phenotype, urinary anormalities, hypertension, diabetes, results of genetic test, were analyzed.

Results: We performed genetic testing in 76 patients (43.4% women; 88% Caucasian). Median age at time of kidney failure was 37 years (range: 17–77), 62% of patients had a positive family history of CKD and 29% presented extrarenal manifestations. The majority were male patients (56.6%) and Caucasian patients (88.2%). Most patients presented with an original clinical diagnosis glomerular disease 52.6% (FSGS lesion on biopsy (8/27) and non-diagnostic histology (10/27)), followed by ciliopathy (13%), aHUS (10.5%), and chronic kidney disease of unknown cause (6.6%), tubulointerstitial nephritis (6.6%), and with congenital anomalies (6.6%). In 46 patients had a genetic diagnosis defined as finding a pathogenic or likely pathogenic gene variant that explained the patient’s kidney disease. With majority being COL4 variants (26.3%), followed by autosomal dominant polycystic kidney disease (ADPKD) (10.5%), podocytopathy and autosomal dominant tubulointerstitial kidney diseases. There were confirmed within a clinical diagnostic in 28% (above all ADPKD) and resulted in reclassification of the clinical diagnosis in 33% (above all COL4-related nephropathy) and there are more frequently a negative result if clinical diagnosis was unknown etiology, congenital anomalies or aHUS until 60%. With this data, 78% of the patients could have avoided a biopsy and 50% an immunosuppressive treatment with the diagnosis by genetic test. A genetic cause was identified by family screening in 16 families comprising 19 patients. A genetic diagnosis were more likely to have a family history of kidney disease (47.4% versus 14.5%, P < 0.001). There was otherwise no statistically significant difference in any other clinical characteristic (age at onset of kidney disease, age at kidney failure, race, hypertension, diabetes, hematuria, renal cyst or stone).

Conclusion: Our study demonstrates the clinical utility of genetic study in kidney transplants with unknown etiology or glomerulonephritis or chronic tubule-interstitial disease with no recognized cause or with positive family history of kidney disease, getting a genetic diagnosis until 60%, with a reclassification of the clinical diagnosis in a one-third. A genetic diagnosis is necessary to evaluate to kidney transplant recipients, to identify the etiology of CKD, to perform a genetic counseling and to improve patient management and prognosis.
EARLY IDENTIFICATION OF PODOCYTOPATHIES AND COLLAGENOPATHIES REDUCE UNNECESSARY MEDICATION FOR PATIENTS AND ECONOMIC BURDEN ON HEALTHCARE SYSTEM

Luigi Cirillo1,2, Becherucci Francesca1,2, Tommaso Mazzieri1, Jacopo Lomi1, Eleonora Superchi1, Valentina Raglanti1, Gianmarco Lugli2, Samuela Landini1, Viviana Palazzo1, Benedetta Mazzinghi2 and Paola Romagnani1,2

1University of Florence, Experimental and Clinical Biomedical Sciences “Mario Serio”, Firenze, Italy, 2University Hospital Meyer IRCCS, Nephrology, Firenze, Italy and 3University Hospital Meyer IRCCS, Genetics, Firenze, Italy

Background and Aims: Despite the efforts to improve guidelines on genetic testing of podocytopathies and collagenopathies, data on the economic burden of these diseases on healthcare systems is lacking, and economic studies have been identified as an unmet need. The lack of awareness about the genetic etiology can often lead to unnecessary procedures and treatments. We recently showed that many non-genomic examinations could be avoided using a “genetic-fist” approach. The aim of this study was 1) to quantify the healthcare resource utilization, including medications, and financial burden on the Healthcare System for the diagnosis of patients affected by collagenopathies and podocytopathies from real-life data 2) to evaluate the possible savings considering an early genetic testing.

Method: A collaborative network of regional nephrology centers was recently established by our group. Patients referred to our tertiary hospital for genetic testing from June 2014 to December 2022 were retrospectively enrolled in the study. All patients received a diagnosis of podocytopathy or collagenopathy; the length of follow-up was considered from the onset of symptoms to the genetic testing. Direct costs (medication use, in-hospital visits, invasive procedures, blood sampling, imaging studies, hospital admissions, and genetic tests) were collected from clinical records. Costs were calculated based on the Regional Health Reimbursement System, including supplies, staff, results reporting and overheads and expressed in euros. The costs were compared with those of “genomic first” approach (a basic panel of examinations according to genetic etiology can often lead to unnecessary procedures and treatments. The resulting hyperoxaluria can cause nephrocalcinosis, urolithiasis and renal failure. Conservative treatment options such as hydration, citrate and pyridoxine aim to slow the progression of the disease with a liver transplant currently being the only curative treatment. Since November 2020 Lumasiran is approved for use in patients with PH 1. Lumasiran reduces the hepatic oxalate production by RNA interference and may hence reduce hyperoxaluria. To date there is limited real world data available on the effectiveness of the treatment with Lumasiran.

Method: This observational study looked at the outcome of Lumasiran treatment in 10 patients under the age of 18 years with genetically confirmed PH 1. The primary end point was percentage reduction in plasma oxalate in the two patients on haemodialysis and percentage reduction of urinary oxalate excretion in the patients with preserved renal function. Secondary end points were change in nephrocalcinosis, urolithiasis and renal function. The follow up time was 6 months in one patient and 12 months in the other nine patients.

Results: Four of the patients were girls and the median age at the start of treatment was 5.25 years (range 0.3-17.9 years). One of the two patients on haemodialysis showed a decrease in plasma oxalate which allowed for a reduction of dialysis frequency from 5x/week to 3x/week whilst the other patient’s dialysis had to be intensified due to worsening systemic oxalosis. In the patients with preserved renal function the median reduction of urinary oxalate was 71% (range 10–91%) after 6 months and 78% (range 61–86%) after 12 months. Two patients reached values in the age specific normal range (Matos et al.). Lumasiran was discontinued after 4 months in one patient and after 8 months in another one due to treatment failure. An improvement in nephrocalcinosis was seen in three patients and two patients showed a subjective reduction in urolithiasis. Renal function improved slightly in one patient and remained stable in the others. Injection site reactions were the only observed side effects.

Conclusion: Our data highlights the heterogeneity of the disease and treatment response to Lumasiran. Despite promising data regarding the benefits of Lumasiran 2 of 10 patients did not benefit from Lumasiran injections. Hence, it is imperative to regularly re-evaluate hyperoxaluria during treatment with Lumasiran. Ideally the data should be entered into a registry for PH 1 patients to monitor the effectiveness and side effects of this novel drug not only in the short- but also the long term.

EARLY IDENTIFICATION OF PODOCYTOPATHIES AND COLLAGENOPATHIES REDUCE UNNECESSARY MEDICATION FOR PATIENTS AND ECONOMIC BURDEN ON HEALTHCARE SYSTEM

Luigi Cirillo1, Becherucci Francesca1, Tommaso Mazzieri1, Jacopo Lomi1, Eleonora Superchi1, Valentina Raglanti1, Gianmarco Lugli2, Samuela Landini1, Viviana Palazzo1, Benedetta Mazzinghi2 and Paola Romagnani1,2

1University of Florence, Experimental and Clinical Biomedical Sciences “Mario Serio”, Firenze, Italy, 2University Hospital Meyer IRCCS, Nephrology, Firenze, Italy and 3University Hospital Meyer IRCCS, Genetics, Firenze, Italy

Background and Aims: Despite the efforts to improve guidelines on genetic testing of podocytopathies and collagenopathies, data on the economic burden of these diseases on healthcare systems is lacking, and economic studies have been identified as an unmet need. The lack of awareness about the genetic etiology can often lead to unnecessary procedures and treatments. We recently showed that many non-genomic examinations could be avoided using a “genetic-fist” approach. The aim of this study was 1) to quantify the healthcare resource utilization, including medications, and financial burden on the Healthcare System for the diagnosis of patients affected by collagenopathies and podocytopathies from real-life data 2) to evaluate the possible savings considering an early genetic testing. The study enrolled 43 patients (23 female), 22 with a diagnosis of podocytopathy and 21 with collagenopathy. Four patients were followed-up by more than one nephrology department from different hospitals. The median length of follow-up was 3.5 years (range 1–33 years). 20 patients were treated with steroids, with 9 receiving more than one course, while others were treated with cyclosporine, tacrolimus, MMF, rituximab, cyclophosphamide, or abatacept. 11 patients received renal replacement therapy during the follow-up, and 2 underwent a renal transplant (one patient underwent two transplants). Each patient underwent a mean of 13 blood drawings and urinalysis (mean 4 times/year/patient), with 39 patients undergoing at least one imaging study, most commonly a renal ultrasound. 26 patients underwent a renal biopsy (5 needed more than one biopsy). On average, each patient needed 7 in-hospital visits (2 visits/year/patient). Each patient underwent one genetic test, mainly exome sequencing, with 4 patients undergoing Sanger and 11 undergoing a gene panel. The economic costs related to medication during the follow-up were 98,252 euros (mean 698 euros/patient/year). In-hospital visits cost 4,125 euros, while hospital admissions for biopsy cost in total 68,138 euros. Blood exams and urinalysis cost 68,926 and 2,560 euros, respectively (mean 532 and 31 euros/patient/year). Imaging studies cost 9,023 euros (mean 83.5 euros/patient/year), and genetic testing cost 146,000 euros (1,540 euros/patient/year) for exome sequencing, 21,398 euros for gene panels, and 2,216 euros for Sanger sequencing. In total, we recorded expenses of 3,897 (mean 83.5 euros/patient/year), and genetic testing cost 146,000 euros (1,540 euros/patient/year) for exome sequencing, 21,398 euros for gene panels, and 2,216 euros for Sanger sequencing. In total, we recorded expenses of 3,897 euros per patient per year of follow-up before the diagnosis. This was almost the amount of a basic panel of exams coupled with exome sequencing (3,878 euros); however, after the first year, the early genome sequencing approach is cost-saving since other medications and non-genomic examinations can be avoided.

Conclusion: This study highlights the substantial amount of unnecessary treatments and examinations the patients are exposed to in unsuspected genetic diseases with consequent economic impact on the Healthcare System. Early identification of these diseases can reduce this burden. These data are important for policy makers in resource allocation.

Figure 1: Number and proportion of patients with/without cystic phenotype stratified by age and eGFR.

An expanded phenotypic spectrum of AS has been described, including recent reports of multiple kidney cysts in affected patients. The aim of the study was to evaluate the prevalence and characteristics of renal cysts in a cohort of adult patients with AS.

Method: This retrospective study included subjects with AS followed at the Outpatient Nephrogenetic Clinic of Spedali Civili di Brescia (Italy) from 2002 to 2022 and with at least one available renal imaging study (Ultrasonography/CT scan). Genetic testing was performed by using a next generation sequencing multi-gene panel for kidney disease. Cystic phenotype was defined as the presence of ≥3 cysts in each kidney. The prevalence of renal cystic phenotype was compared between patients (pts) with AS and a group of age- and eGFR-matched pts with sporadic IgA nephropathy (IgA-N). Demographic and clinical features were compared between pts with or without cystic phenotype. Logistic regression was performed to test whether sex, age, type of variant and eGFR (CKD-EPI formula) were independently associated with the cystic phenotype.

Results: A total of 96 AS pts were studied. The pattern of inheritance was AD in the majority of the cohort (56%), XL in 25%, AR in 2% and unknown in the remaining 17%. The cystic phenotype was observed in 36 pts (38%). When compared to a matched IgA-N cohort (n = 79), the cystic phenotype was significantly more common in AS (42% in AS; 19% in IgA-N; p = 0.002). The majority of AS pts with cystic phenotype showed normal/reduced sized kidneys and multiple cortical and/or parapelvic renal cysts. Increased total kidney volume, in keeping with primary cystic kidney disease, was observed in three patients; however, pathogenic variants in known cysto-genes were excluded. At the time of renal imaging, AS pts with cystic phenotype were older and had a more marked reduction in kidney function than their non-cystic counterparts (Table 1). When stratifying patients based on age or eGFR, the prevalence of the cystic phenotype gradually increased in parallel with older age and declining eGFR (Figure 1). Independent predictors of the cystic phenotype were age (HR 1.96 [95% CI 1.31-2.94] per 10 years; p = 0.001) and eGFR (HR 0.75 [95% CI 0.64-0.89] per 10 ml/min/1.73m²; p = 0.001). Serial longitudinal ultrasounds were available for 15 cystic pts, among whom the cystic phenotype was first observed from 40 years of age onwards, at an overall median age of 59 (IQR 46–65).

Conclusion: Our data show that multiple bilateral kidney cysts, with no increase in kidney size, are frequently found in AS patients. The cystic phenotype is associated with older age and eGFR decline, suggesting that it can reflect the severity and/or duration of CKD. However, the higher frequency of cystic phenotype in AS than IgAN, the role of the collagen IV α3 to α5 chains in the basement membranes in the glomerulus and distal tubule, and the occurrence of kidney cysts in a canine model of ADAS, support a possible pathogenetic link between type IV collagen mutations and cystogenesis in AS. Finding kidney cysts should not discourage from considering the diagnosis of AS, particularly in adult patients and in the presence of familial CKD. Future prospective studies will be needed to shed light on the prognostic implications of the cystic phenotype and possible genotype-phenotype associations.
CLINICAL DIVERSITY OF STEROID-RESISTANT NEPHROTIC SYNDROME CAUSED BY TRPC6 MUTATIONS
Quynh Tran1, Linh Tran1, Hiroko Ueda1, Hitoshi Nakazato2, Keisuke Sugimoto3, Shojo Kagami1,4,5, Motoshi Hattori4, Kandai Nozu2 and Hiroyasu Tsukaguchi1

Background and Aims: Steroid-resistant nephrotic syndrome (SRNS) is a clinically and genetically heterogeneous disorder caused by either genetic or immunological factors or their combination. Approximately 30–40% of patients with SRNS make a fast progression to ESRD. SRNS represents the second leading cause of end-stage renal disease in individuals under the age of 25 years worldwide. More than 60 podocyte-related gene mutations have thus far been reported in monogenic SRNS. Recent studies indicate that almost 30% of patients with childhood-onset SRNS have monogenic causative variants in one of the 27 SRNS genes. Among these, a mutation in Transient Receptor Potential Canonical 6 (TRPC6) gene, encoding non-selective cation channel, accounts for 6% of familial SRNS and approximately 2% of sporadic cases. We recently detected eight patients with TRPC6 mutations in our SRNS cohort (n = 39, 21%) and found inter- and intra-familial heterogeneity of clinical phenotypes in terms of disease onset and progression.

Method: A total of 39 Japanese SRNS patients were studied according to the protocol approved by the institutional review board of each affiliation. Subjects who manifested SRNS at age one to 14-year-old with biopsy-proven FSGS were enrolled. A total of 39 SRNS patients, whose average onset of proteinuria at median age 4 (range 0.9 to 17 yr) and ESRD at median age 7 (49% of total n = 19, range 3.0 to 16.0 yr) were studied. Family history was found in 44% (n = 17), including 13 autosomal recessive, 3 dominant, and one X-linked transmission. Sixteen percent (n = 10) of the patients who underwent renal transplantation win no recurrence. Sequence analysis revealed the pathogenic variants in 62% (n = 24) of all cases. Library for whole-exome sequencing or targeted panel sequencing were prepared from genomic DNA by use of SureSelect Human All Exon V5 (Agilent) or a HaloPlex target enrichment system kit (Agilent Technologies), or Ampli-Seq (Thermo). Prepared samples were run on a HiSeq 2000, or MiSeq (illumina), or Ion PGM (thermo). The sequence reads with 101-bp paired-end reads and 7-bp index reads were mapped to the human reference sequence (hg19, GRCh38.p7). After filtering the superfluous begin variants, only variants that fulfill the “pathogenic” criteria of ACMG and/or ClinVar, Varsome were selected.

Results: Sequence analysis revealed the pathogenic variants in 62% (n = 24) of all cases. TRPC6 mutations were the most frequent cause of SRNS (n = 8), which was followed by NUP107 (n = 5), PLCE1 (n = 3), COL4A3 (n = 2), COL4A5 (n = 1), and others were identified in only single case. The eight TRPC6 mutations clustered into the two distinctive cytoplasmic domains; N-terminal ANK (Y173D, R175W, R175G) and C-terminal coiled-coil domain (p.E875V, p.R867X, p.R866Del, p.S893N, p.R895C). The p.R895C is deposited as the pathogenic in ClinVar and may be a gain-of-function. The remaining 7 variants are of unknown functions: six have not yet been deposited in ClinVar, whereas one is VUS. Four patients were de novo occurrence, three followed the dominant transmission, and one arose from gonadal mosaicism. Two index patients exhibited SRNS in early childhood (< age 3), four manifested it in childhood (age 3–12), while the remaining two developed it in adolescence (age >12). In familial cases, for example, affected ones harboring R175W or p.E875V showed a remarkable discordant age onset and disease severity.

Conclusion: TRPC6 channelopathy was found to be the most frequent cause in our SRNS cohort, of which age onset ranges from age 0.9 to 17 year. Heterogeneity of disease severity may reflect that channel activity is regulated by the mode of action (gain- or loss-of-function), the combination of channel subunit assembly, and interaction with other modifying factors. Mutations in these TRPCs are associated with relatively common kidney diseases as well as other pathologies. Further expression studies will improve our mechanistic understanding of TRP channel pathology and may help the development of novel therapeutic targets.

#5496 EVALUATION OF THE PREDICTIVE ABILITY AND CONCORDANCE OF PROGNOSTIC SCORES FOR RAPID PROGRESSION IN ADPKD: A MULTICENTER COHORT

Orsola-Malpighi University Hospital, Bologna, Italy, 8Charité Universitätsmedizin, Department of Nephrology, Berlin, Germany and 9Nephrology, Dialysis and Transplantation Unit, IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is a common cause of end-stage kidney disease (ESKD). It is characterized by the progressive development of bilateral renal cysts, resulting in enlargement of the kidney volume, hypertension (HBP), and ESKD. Recently, a position statement of the ERK-NET was published to assess indications for Tolvaptan according to 3 algorithmic criteria: total kidney volume (HTKV) and Mayo Clinic Imaging Class (MCIC), rate of decline in eGFR, and the Predicting Renal Outcome in Polycystic Kidney Disease (PROPKD) score, combining clinical and genetic variables. In this scenario, these scores (MCIC and PROPKD) are alternatively used to define rapid progressor patients. In this retrospective multicentric cohort, the primary outcome was to evaluate and improve the concordance of sensitivity and specificity of MCIC and PROPKD predictive abilities for rapid disease progression.

Method: Data from adult ADPKD patients were obtained from 3 different renal centers (Bologna, Dublin, Berlin/Leipzig). We defined rapid disease progression as individuals with eGFR slope ≥ 3 mL/min/1.73m2/yearly over 4 years (Clinical Score), or MCIC classes 1C-D-E (Image Score), or high-risk PROPKD score (7 to 9 points). Descriptive statistics were used to summarize clinical parameters. The concordance between MCIC and PROPKD was assessed using kappa statistics. In individuals with PKD1 missense variants, the REVEL score was obtained and treated as a continuous variable; score greater than 0.65 were considered ‘pathogenic’ and regarded as PKD1-truncating variants for PROPKD score calculation.

Results: We evaluated 298 ADPKD patients, demographic and clinical data are summarized in Table 1. After 4 yr of follow-up, MCIC (p = 0.041), HBP (p = 0.031), and urolological events (p < 0.001) result were statistically significant on multivariate analysis (Table 1). Assessment of rapid disease progression using PROPKD and MCIC scores yielded Kappa Cohen of 0.149; 47.9% (n = 143) were concordant, 49.32% (n = 148) patients identified as rapid progressor (RP) for MCIC were non-RP for PROPKD, while 2.3% (n = 7) of PROPKD score considered RP using PROPKD score were considered non-RP using MCIC classes. Following the reclassification of PKD1 missense variants by REVEL score, K of Cohen improved to 0.174, and PROPKD becomes predictive of fast progression also at multivariate (p = 0.010).

Conclusion: Concordance between scores results low (K of Cohen 0.149). The PROPKD is more selective compared to the Mayo. Nevertheless, PROPKD allows the identification of some rapid progressor patients excluded from using the Mayo score only. The combined use of scoring may increase the ability to identify progressive patients. REVEL score could improve the agreement.

** p-value

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is a ciliopathy which is characterized by abnormal tubular epithelial proliferation and fluid secretion. Anoctamin 1 (ANO1) is a calcium-dependent chloride channel, which has recently been shown to be involved in ADPKD progression. However, how ANO1 contributes to ADPKD is largely unexplored.

Method: 1. Based on mRNA gene chips, the expression of ANO1 abnormally increased in human ADPKD kidneys. 2. Immunohistochemical staining showed ANO1 location. 3. Real-time PCR and Western blot showed mRNAs and protein of ANO1 in ADPKD patients and animal model-PKD1RC/RC.

Figure 1: ANO1 is up-regulated in mouse and human ADPKD kidneys. (A) QT-PCR analysis of ANO1 expression in kidney tissues of PKD1RC/RC mice with different ages. (B) QT-PCR analysis of ANO1 expression in human normal control and ADPKD patients renal tissues. (C,D) WB analysis of ANO1 expression in human normal and ADPKD patients renal tissues and was further quantified. (E) Immunohistochemistry analysis of ANO1 (in brown) expression in human normal and ADPKD patients renal tissues. Scale bars, 200 μm. *p < 0.05. **p < 0.01.
Figure 2: ANO1 is localized in primary cilia. (A,B) IF staining for ANO1 and Glu-tubulin was performed on RCTE and ADPKD cells (PKD1+/− cells) and further quantitatively analyzed by confocal microscopy. Scale bars, 10 μm. (C) Super-resolution 3D structured illumination microscopy analysis of ANO1 in RCTE cells.

Figure 3: Knockdown of ANO1 increases the cilium length and the expression of polycystin 2 (PC2). IF: nonsense control (NC) siRNA or siRNA against ANO1 was transfected in human PKD1+/− cells. IF for PC2 and AC-tubulin was performed on RCTE and PKD1+/− cells and further analyzed by confocal microscopy. Cilia length and intensity of PC2 were quantified. The knockdown efficiency of siRNA was determined by RT-PCR. Scale bars, 5 μm.

Figure 4: Knock-down of ANO1 inhibits renal cyst formation in 3D culture models. (A,B) 3D culture model of cyst formation was established using IMCD3 cells which were treated with two different ANO1 inhibitors (Tinh16-A01 or Tannic acid). After 2 weeks of culture, the Surface area of cysts (SA) was measured. Scale bars, 300 μm. (C,D) 3D culture model of cyst formation was established using MDCK cells which were transfected with siRNA against ANO1. Knock down efficiency was measured by RT-PCR before MDCK cells were planted into the collagen gel. After 2 weeks of culture, the diameter of cysts was measured. Scale bars, 100 μm.

Abstracts i213
formation in 3D culture models. Moreover, inhibition of ANO1 abolished the activation of STAT3 and ERK pathways in PKD cells.

**Conclusion:** Our data indicate ANO1 may aggravate ADPKD by regulating the cilia length and PC2 expression. Moreover, ANO1 could support cyst growth by activating STAT3 and ERK pathways. Thus ANO1 is a negative regulator for both cilia formation and cilia trafficking of polycystins and provide mechanistic insights regarding the therapeutic potential of ANO1 pathway in ADPKD treatment.

#4440

**PREVALENCE OF GENES INVOLVED IN HEREDITARY KIDNEY DISEASE AS A TOOL FOR THE DEVELOPMENT OF A GENE PANEL**

Cristina Andrades Gómez, Gema Montilla Cosano, Miguel Ángel Pérez Valdivia, José Luis Rocha Castilla, Francisco Javier Toro Prieto and Manuel Lopez-Mendoza

Hospital Universitario Virgen del Rocío, Nephrologist, Seville, Spain

**Background and Aims:** Genetic study is the fundamental tool for the diagnosis of Hereditary Kidney Diseases (HKD). The proliferation of its use has led to an increase in diagnostic complexity due to phenotypic overlap and genotypic heterogeneity. The aim of this study is to evaluate the prevalence of genes in our series of adult patients with suspected monogenic kidney disease in order to develop the basis for the elaboration of a gene panel that will make its usefulness in our routine clinical practice profitable.

**Method:** A retrospective descriptive observational study was performed with the collection of all genetic studies that were positive in the period between October 2014 and December 2020 in our center. With a description of the causative genes involved, as well as the clinical data of the proband patients who turned out to be carriers of these variants. Descriptive results of continuous variables are expressed as mean and standard deviation (SD) or median and interquartile range (IQR) according to their distribution. For categorical data, frequency and percentage are reported.

**Results:** The results of a total of 77 genetic studies on probands were collected, of whom 51% were women with a mean age at diagnosis of 46 years (SD ± 13.4) and 64.9% had a family history of kidney disease. Renal function measured by mean estimated glomerular filtration rate (eGFR) using the CKD-EPI (CKD Epidemiology Collaboration) was 90.1 ml/min/1.73 m² (SD ± 29.64) with a mean proteinuria quantified in 24-hour urine of 627.9 mg (SD ±43.7) and 7.7% were on renal replacement therapy. (Table 1) 40.25% of probands were carriers of a mutation for Alport syndrome, in this group the most frequent gene was COL4A3 in 50% of cases. The second most frequent entity was autosomal dominant polycystic kidney disease (ADPKD) with 37% of the studies and among these the great majority were carriers of a variant in the PKD1 gene with 96.5%. The remaining diagnostic entities in order of frequency were Fabry disease, autosomal dominant tubulointerstitial nephropathy (ADTKD), congenital anomalies of the kidney and urinary tract (CAKUT), nephrotic syndrome, hereditary angiopathy with nephropathy, aneurysm and cramps syndrome (HANAC) and tuberous sclerosis (Figure 1).

**Conclusion:** Alport syndrome was the most frequently identified entity in patients with suspected monogenic renal disease in whom the genetic study was performed. Based on the results of our series, a proposal has been made for the genes to be included in a panel for hereditary renal diseases in our center. The development of these panels increases the efficiency and increases the cost-effectiveness of genetic studies in the diagnosis of these patients.

THE GENOTYPE DISTRIBUTION IN A SINGLE-CENTRE COHORT OF PATIENTS WITH POLYCYSTIC KIDNEY DISEASE

Isabella Pisani, Enrico Tinti, Giuseppe Giovanniello, Francesca Guglielmi, Isabella Tommasoni, Lucio Manenti and Enrico Fiaccadori

1Nephrology Unit, Parma University Hospital, and Department of Medicine and Surgery, Parma University Medical School, Parma, Italy and 2SC Nefrologiae Dialisi. ASL5 Liguria, La Spezia, Italy

Background and Aims: Polycystic kidney disease (PKD) is one of the most common causes of chronic kidney disease (CKD) and could lead to the end-stage kidney disease (ESKD) both in adulthood and in childhood. In the last few years many genes were discovered to be associated with PKD beyond the classical genes PKD1 and PKD2, that account for the majority of patients with ADPKD (Autosomal Dominant Polycystic Kidney Disease), and PKHD1 and DZIP1 that are responsible of ARPKD (Autosomal Recessive Polycystic Kidney Disease). The new genes are associated with different type of extra-renal involvement and with variable chance to develop CKD or ESKD. Thus, it is important for clinicians to define what mutation is involved in each patient to improve care in a context of precision medicine. We here describe a cohort of 65 consecutive patients followed at our PKD outpatient clinic who underwent genetic analysis.

Method: We conducted a retrospective study of patients followed at our PKD outpatient clinic who underwent a genetic test for clinical reasons. We recorded why test was performed, with which modality and what was the result. If the analysis was positive we analyzed if only one or more genes were found mutated and if they belong to new genes described as being involved in PKD or if they are usually described in association with different diseases. Then, we collected demographic and clinical information (age, sex, renal function/presence of absence of ESKD) and the radiological description of kidneys in order to distinguish between typical and atypical PKDs.

Results: Among the 65 patients of our cohort 28 (43%) were males and 37 (57%) were females, the mean age was 56±18.6 years old; 20% had ESKD. They underwent genetic analysis for different reasons: 31 because of atypical PKD forms, 6 to define a suspected de novo mutation, 14 as a familiar screening and 14 for a better prognosis definition or when they approached the kidney transplant. The genetic analysis was conducted in two main ways: sequencing of PKD1 and PKD2 genes according to modern standards or exome sequencing. The first type of analysis was used for typical ADPKD forms whereas the second type was used when patients displayed an atypical presentation for both cysts distribution and kidney diameter (usually not enlarged kidneys with multiple bilateral cysts) and in two patients in which PKD1 and PKD2 sequencing was negative despite the PKD phenotype. We found that 25% of patients were negative, and the others are almost equally distributed between typical gene mutations and mutations in other genes (40% and 35% respectively) (Figure 1A). Of those with typical mutation, 81% was PKD1 positive and 19% PKD2 positive, a distribution that reflects that of literature (Figure 1B). Of those with other genes positivity: 52% had a DNAJB11 mutation, 17% a mutations in other PKD genes (ALG8, LRP5, PKHD1, COL4A1, IFT140), 32% had a mutation in genes usually associated with CAKUT (congenital anomalies of kidney and urinary tract) or with syndromic or extra-renal diseases (Figure 1C). 18 patients presented with multiple mutations, usually 2, in one case three and in another 4. Of them, the 22% had a double PKD1 mutation, while the others showed mutations in different genes associated with syndromic or extra-renal diseases (Figure 1D).

Conclusion: Our cohort revealed a wide variety of genetic mutations and also an almost equal distribution between typical genes and atypical/other genes. This could be the result of the small number of patients involved and of the monocentric design of the study (we have a cluster of patients with DNAJB11 belonging to the same small geographical area), but also of the larger inclusion of patients presenting with atypical PKDs. Unfortunately a 25% of patients remained genetically unresolved despite the use of exome sequencing.

Figure 1: A: The distribution of patients between negative and positive genetic analysis with distinction between typical and atypical/other genes; B: PKD1 and PKD2 division of typical mutated patients; C: the division among patients with atypical/other genes mutations; D: the distribution of double mutations.

ULTRASOUND AND 3D IMAGING CHARACTERISATION OF A RAT MODEL OF POLYCYSTIC KIDNEY DISEASE

Michael Christensen, Trine Porsgaard, Johanne Perens, Frederikke Emilie Sembach, Henrik Bjirk Hansen and Maria Ougaard

Gubra aps, Denmark

Background and Aims: Polycystic kidney disease (PKD) is a congenital fibrocystic disorder where cysts are primarily forming within the kidneys causing enlargement, loss of kidney function and resulting in chronic kidney disease for which there is no curative treatment. Consequently, PKD is classified as a medical condition with high unmet therapeutic need. Animal models with improved clinical translatability can optimally inform about potential clinical efficacy of novel drug candidates for PKD. The polycystic kidney (PKC) rat is an established genetic model of PKD with natural history and renal histologic abnormalities that resemble the human disease. Gubra has established a PKC rat breeding program to enable fast turnaround time of preclinical drug discovery studies for PKD. In this study, we have characterised disease progression in the PKC rat to aid in designing future pharmacological intervention studies.

Method: Male PKC (PKC/CrlCr-Pkhdl/pck/Crl) and control (CRL:CD(SD)) rats (Charles River) were randomised into groups based on body weight at the age of 10 weeks. At the age of 17 and 25 weeks, rats underwent ultrasound assessment of kidney volume, urine collection for quantification of albuminuria, and plasma sampling for analysis of urea and creatinine levels. At termination, whole kidneys were harvested and total kidney volume, cyst number and cyst volume were analysed using quantitative 3D light sheet imaging.

Results: Compared to age-matched control rats, PKC rats displayed marked albuminuria which was significantly increased at week 25 of age. Whereas plasma urea was progressively increased at both time points, plasma creatinine increased at week 25. Ultrasound measurements revealed that total kidney volume progressive increased compared to control rats. 3D Light sheet imaging enabled whole-kidney counting of cysts and quantification of cyst volume as well as the total kidney volume that closely correlated to kidney ultrasound results.

Conclusion: The PKC rats displays histological hallmarks of PKD, characterized by age-dependent progressive increases in biomarkers of kidney injury, kidney hypertrophy and cyst formation. In vivo ultrasound and ex vivo quantitative whole-kidney 3D light sheet imaging is highly instrumental for detailed assessment of progressive disease in the PKC rat. The renal histopathological markers may serve as key histological endpoints for assessment of therapeutic effects of preclinical drug candidates in this translational rat model of PKD.

MIRNA PROFILING OF URINARY EXTRACELLULAR VESICLES (EVS) IN TBMN AND CFHR5 NEPHROPATHY FOR THE IDENTIFICATION OF NOVEL DISEASE BIOMARKERS

Stavroula Louka1, Andrea Kakouri2, Gregory Papageorgiou1 and Constantinos Deltas1,3

1University of Cyprus, Molecular Medicine Research Center, biobank.cy, Center of Excellence in Biobanking and Biomedical Research, Nicosia, Cyprus and 2University of Cyprus, School of Medicine, Nicosia, Cyprus

Background and Aims: Thin basement membrane nephropathy (TBMN) and complement factor-H related protein 5 (CFHR5) nephropathy are two of the most common renal monogenic diseases with high phenotypic heterogeneity that is only partly accounted for by locus and allelic factors. Intra-familial variability in the age of ESKD onset for some patients particularly exemplifies that is only partly accounted for by locus and allelic factors. Intra-familial variability in the age of ESKD onset for some patients particularly exemplifies that is only partly accounted for by locus and allelic factors. Intra-familial variability in the age of ESKD onset for some patients particularly exemplifies.

Method: MiRNA profiling of human urinary EVs was carried out by small RNA-sequencing in an initial discovery cohort of 54 patients with TBMN and 44 patients with CFHR5 nephropathy, each classified further into three subgroups based on disease severity (Grey-zone: eGFR >60 ml/min/1.73m² and age <50 y/o; Mild: eGFR >60 ml/min/1.73m² and age <50 y/o; Severe: eGFR <60 ml/min/1.73m² independently of age). Differential expression of miRNAs from urine-derived EVs was compared with 30 age and sex matched healthy controls, whilst bioinformatic analysis was performed to delineate their associated mechanisms.

Results: Kidney-enriched candidate miRNA families were identified in urine-derived EVs for both TBMN and CFHR5 patients and further verified by RT-qPCR in the respective validation cohorts. Distinct miRNAs with significantly differentiated expression levels, compared to that of healthy control cohort, showed significant correlations with some of the evaluated clinical characteristics both for TBMN and CFHR5 patients suggesting a possible diagnostic and prognostic value on long follow-up. Finally, inverse correlations of miRNA expression with their predicted targeted genes identified dysregulated pathways and transcriptional networks for further investigation.

Conclusion: Collectively, distinct profiles of miRNAs from urine-derived EVs were identified in TBMN and CFHR5 nephropathy suggesting that a subset of differentially expressed miRNAs could serve as novel non-invasive biomarkers of disease progression and/or targets for the development of novel therapeutic approaches.

ARE KIDNEY CYSTS MORE COMMON IN PEOPLE WITH COLA3/COLA4 PATHOGENIC VARIANTS?

Melissa Pilco Teran1, Monica Furlano1,2, Marc Pybus2, Victor Martinez Jiménez3, Asunción Rius Peris4, Maria Vanessa Perez Gomez5, Gerson Berna Redondo1, Leonor Fayos De Arizón1, Elisabet Aris1 and Roser Torra1

1Fundación Puigvert, Nephrology, Barcelona, Spain, 2Fundación Puigvert, Genetic Laboratory, Barcelona, Spain, 3Hospital Universitario Virgen de Arrixaca, Nephrology, Murcia, Spain, 4Hospital General de Castellón, Nephrology, Castellón de la Plana, Spain and 5Fundación Jiménez Diaz, Nephrology, Madrid, Spain

Background and Aims: Individuals with pathogenic heterozygous variants in the COLA3/COLA4 genes are usually asymptomatic or present only with microhaematuria, although some may develop proteinuria and chronic kidney disease (CKD). Simple renal cysts are common in healthy individuals, with an increasing incidence with age and CKD grade. A possible association between pathogenic variants of collagen type IV and renal cysts has been described. This study investigates the presence of renal cysts in a large cohort of individuals with heterozygous pathogenic variants in COLA3/COLA4.

Method: We evaluated the presence of kidney cysts, kidney size and lithiasis by ultrasound in 162 individuals with pathogenic variants in COLA3/COLA4 without kidney replacement therapy. The correlation between kidney cysts and age, proteinuria, eGFR, causing gene and type of variant, was analysed. Genetic testing had been performed in index cases by next generation sequencing (NGS) of a kidney-disease gene panel containing more than 400 genes including COLA3, COLA4 and COLA5 genes.

Results: 153 patients with a heterozygous disease-causing variant in COLA3 or COLA4 and 9 patients with digenic/complex inheritance were included. The mean age at renal ultrasound was 46.19 years (SD 14.93) and the mean eGFR was 75 ml/min/1.73 m² (SD 35 ml/min/1.73 m²). Renal cysts were present in 50% of patients (81/162) and were bilateral in 30.25%. The mean age of patients with renal cysts was 53.26 years vs. 39.12 years for those without, and the mean eGFR was 60ml/min/1.73 m² vs. 89ml/min/1.73 m² for patients with and without renal cysts. Only 2.5% (4/162) of patients had renal lithiasis. The mean kidney size was 104.05 mm (SD 13.86 mm) for the right kidney and 104.98 mm (SD 13.94 mm) for the left kidney. Cystic nephromegaly was observed in 3.7% (6/162). No correlation was found between renal cysts and gender (p = 0.632). Age and CKD stage had a positive correlation with the development of renal cysts (p = <0.001) (Tables 1 and 2). Proteinuria was more common in individuals with renal cysts 61% vs 39% (p = 0.012), but was related to age and CKD stage. The presence of a kidney cyst did not correlate with the mutated gene or the type of variant.

Conclusion: Individuals with COLA3/COLA4 pathogenic variants develop kidney cysts at a higher rate than age-matched healthy individuals, and their presence is also related to ageing, as in the general population. Gender is not relevant for the development of renal cysts, in contrast to the general population cohorts. Proteinuria and CKD grade correlate with the development of renal cysts but nephromegaly is rare. Renal cysts in heterozygous carriers of COLA3 or COLA4 pathogenic variants are common but have no clinical consequences.

**BONE SPECIFIC ALKALINE PHOSPHATASE AS A POTENTIAL BIOMARKER OF AUTOSOMAL DOMINANT POLycystic KIDNEY DISEASE PROGRESSION**

Magdalena Jankowska1, Abdul Rashid Tony Qureshi2, Mathias Lobberg Haarhaus2, Alicja Debska-Slizien1, Peter Stenvinkel1, Pieter Evenepoel1 and Bengt Lindholm2

1Medical University of Gda´nsk, Department of Nephrology, Transplantology and Internal Medicine, Gda´nsk, Poland, 2Karolinska Institutet Clince, Division of Renal Medicine and Baxter Novum, Department of Clinical Science, Intervention and Technology, Sweden and 3University Hospitals, Department of Nephrology and Renal Transplantation, Leuven, Belgium

**Background and Aims:** Autosomal dominant polycystic kidney disease (ADPKD) is a systemic disease, resulting in a dysfunction of the primary cilium, a sensory organelle ubiquitously present in human cells. Ciliopathies are characterized by disorders of seemingly unrelated organs and functions, which depend on integrity of the primary cilium, among them the skeleton and the kidneys. A distinct bone phenotype has been reported in ADPKD patients in several cohort studies. Findings, however, were heterogeneous. Present study aimed to measure bone turnover biomarkers in patients with ADPKD across disease severity measured by eGFR and height-adjusted total kidney volume (HtTKV).

**Method:** In this cross-sectional study, we included 80 ADPKD patients with different chronic kidney disease (CKD) stages (G1 and G2 (n = 39), and G3 and G4 (n = 41)) with median age 44.0 (33.5–50.5) years, 62.5% men, and BMI 25.1 (23.3–28.7) kg/m². HtTKV was measured with magnetic resonance imaging. We measured biochemical parameters of mineral metabolism, including bone specific alkaline phosphatase (BALP) and total ALP, calcium (Ca), parathyroid hormone (PTH), and 25(OH) vitamin D (25(OH)D) and bone strength index (BSi) with microindentation, using an OsteoProbe® (Active Life Scientific, USA). Microindentation is minimally invasive technique assessing bone quality. The cortical bone at the mid-shaft of the tibia is penetrated with the indenters to measure bone resistance.

**Results:** Bone biomarkers expressed as median and interquartile range were as follow: Ca 9.6 (9.3–9.9) mg/dL, BALP 9.0 (7.0–12.5) ug/L, ALP 59.0 (46.0–72.0) U/L, PTH 43.5 (26.6–72.0) pg/mL, and 25(OH)D 25.8 (16.6–33.5) ng/mL. Median BSI was 79.1 (73.5–82.1) in men and 68.5 (62.1–78.6) in women (lower than the average score in healthy caucasians). Among analyzed bone markers only BALP significantly associated with severity of ADPKD. BALP - but not eGFR - associated with HtTKV and was different across HtTKV tertiles. BALP was also higher in the highest BSI group, but BSI did not associate with HtTKV (Figure 1).

**Conclusion:** In patients with ADPKD and different stages of CKD, BALP associates with bone strength and kidney volume, suggesting that it may be a sensitive marker of systemic ADPKD manifestations. Further studies should elucidate whether BALP may be a more sensitive marker for ADPKD progression than GFR.

**REAL-LIFE USE OF TOLVAPTAN IN ADPKD: A RETROSPECTIVE ANALYSIS OF A LARGE CANADIAN COHORT**

Luca Calvaruso1,2, Kevin Yan1, Pedram Akbari1, Fatemeh Nasri1, Shirley X. Deng1, Saima Khowaja1, Ning He1, Amirreza Haghigi1, Korosh Khalili2 and York Pei1

1Division of Nephrology, University Health Network and University of Toronto, Toronto, Canada, Toronto, Canada, 2U.O.C. Nefrologia, Fondazione Policlinico Universitario A. Gemelli, IRCCS, Roma, Italy and 3Department of Medical Imaging, University Health Network and University of Toronto, Toronto, Ontario, Canada

**Background and Aims:** Tolvaptan is the first disease-modifier therapy proven to slow eGFR decline in high-risk patients with ADPKD. However, barriers to its use in real-life settings have not been examined.

**Method:** Single-center, retrospective study of 523 current or new patients with ADPKD followed at the Center for Innovative Management of PKD in Toronto, Ontario between January 1, 2016 to December 30, 2018. All patients had clinical assessment and total kidney volume measurements; those deemed to be at high risk based on their Mayo Clinic Imaging Class (MCIC) 1C, 1D, or 1E, were offered tolvaptan with their preference (yes or no) and reasons for their choices recorded.

**Results:** Overall, 315/523 (60.2%) patients had MCIC 1C-1E; however, only 96 (30%) of them were treated with tolvaptan at the last follow-up. Among these high-risk patients, those treated with tolvaptan were more likely to have a higher eGFR (61 ±27 vs. 82 ±26 ml/min/1.73 m²), CKD stages 1–2 (41% vs. 79%), and MCIC 1D-1E (69% vs. 37%). The most common reasons provided for not taking tolvaptan were lifestyle preference related to the aquaretic effect (51%), older age ≥60 (12%), and pregnancy or family planning (6%).

**Conclusion:** In this real-world experience, at least 60% of patients with ADPKD considered to be at high risk for progression to ESKD by imaging were not treated with tolvaptan; most of them had earlier stages of CKD with well-preserved eGFR. The most common reason for their refusal to consider tolvaptan is a concern for tolerability of the aquaretic side-effect; strategies to mitigate this side-effect may help to reduce the barrier to tolvaptan therapy.
Figure 1: Reasons for not using tolvaptan among ADPKD patients with Mayo Clinic Imaging Classification 1C, 1D, 1E (n = 219) from the cohort followed primarily or co-managed with their primary nephrologists by the Center for Innovative Management of Polycystic Kidney Disease.

THERAPY WITH BUROSUMAB IN ADULT PATIENTS WITH X-LINKED HYPOPHOSPHATEMIA: A YEAR OF FOLLOW-UP

Silverio Rotondi, Lida Tartaglione, Adolfo Perrotta, Nadia Carroccia, Marzia Pasquali and Sandro Mazzaferr

Sapienza University of Rome, Roma, Italy

Background and Aims: X-linked hypophosphatemic rickets (XLH) is a genetic disorder secondary to the mutation of the PHEX gene that results in increased circulating levels of FGF23. Increased FGF23 causes hypophosphatemia secondary to renal phosphate loss. Clinically, the disease is characterized by reduced growth, bone alterations, weakness, chronic pain and reduced mobility. From a biochemical point of view, patients have hypophosphatemia, increased values of alkaline phosphatase, increased fraction excretion of phosphate (FEP). Recently, therapy with Burosumab, a monoclonal antibody against FGF23, has been introduced. Burosumab by reducing the receptor availability of circulating FGF23 reduces its activity. This leads to a normalization of serum phosphate and in paediatric patients an improvement of the clinical phenotype. In adult patients, the effectiveness of therapy in improving the clinical outcome and quality of life is being investigated. The purpose of the study was to evaluate the efficacy in improving the biochemical, bone and clinical picture of adult patients with XLH in therapy with Burosumab for one year.

Method: We enrolled patients with XLH naive for Burosumab therapy. In all we evaluated the biochemical aspects (phosphatemia, alkaline phosphatase, FEP), bone Radiographic Global Impression of Change score and clinical improvements (six-minute walk test, UP and go timed test, WOMAC Index) pre therapy and after a year of therapy. Burosumab was administered monthly at a dose of 1 mg/Kg.

Results: We enrolled 5 patients (45 ± 10 year old, weight 60 ± 10 Kg, Burosumab dose 60 ±10 mg) with genetic diagnosis of XLH. The comparison between pre therapy and post-one-year therapy showed in all patients: increase in average phosphatemia (pre 1.9±0.5 mg/dl vs post 3.4±0.6 mg/dl p = 0.003),
reduction in FEP (pre 50 ±15% vs 20 ±10% p = 0.004), reduction of UP and go test (pre 20 ± 5 sec vs post 11 ± 3 sec p = 0.005) increase of the distance in the six minutes’ walk test (pre 150 ± 30 meters vs post 250 ± 50 meters p = 0.01), improvement of the WOMAC test (pre 15± 3 vs post ± 2; p = 0.008) and reduction of the Radiographic Global Impression of Change score (pre -2 ±0.5 and post 2± 0.4; p = 0.001). The serum value of alkaline phosphatase was high and it did not change with the Burosumab therapy (pre 200± 50 U/L vs post 220± 60 U/L; p. n. s. n. v. 33–98 U/L). No patients had significant complications during the first year of treatment.

Conclusion: The therapy with Burosumab was well tolerated by patients. It resulted in a marked improvement in the biochemical picture associated with a better quality of life identified by increased strength (improved walk test and UP and go timed test) reduction of pain (best WOMAC test) and bone damage score. In conclusion, Burosumab may be a good and safe therapy option for adults’ patients with XLH.

COEXISTENCE OF 2 (DE NOVO) MUTATIONS IN 2 DIVERSE GENES (PKD1, LRPS) IN A PATIENT WITH RENAL AND LIVER POLYCYSTIC DISEASE
George Tsirpanlis1, Danai Palaiologou1, Leandro Lazaros2, Michaela Louka2, Eirini Evangelou1, Dimitra Gkalitsiou1 and Emmanouil Kanavakis2
1General Hospital of Athens “G. Gennimatas”, Athina, Greece and 2Genesia Genoma Lab (GenLab.gr), Chalandri, Greece
Introduction: In Autosomal Dominant Polycystic Kidney Disease (ADPKD) the genotype is variable. The most common extrarenal manifestation of the disease is the presence of hepatic cysts. Parallel cysts appearance in two different organs is possibly related to the genetic injury. We present in this report the case of a patient without family history of ADPKD and 2 different mutations related to cyst formation.

Case report: A 53 year old woman came to our outpatient ADPKD clinic with known multiple hepatic and renal cysts, diagnosed 11 years ago. She had no family history of ADPKD, both her parents aged 89 years old, had no renal or liver cysts on recent ultrasound scans. The patient had a background of recurrent UTIs, nephrolithiasis and hypertension diagnosed at 40 years old. Currently she was found to have e-GFR 49ml/min and liver function tests within normal range. Genetic testing and Magnetic Resonance Imaging (MRI) for estimating Total Kidney Volume (TKV) and hepatic imaging were conducted. In the genetic testing with a second generation sequencing, two heterozygous mutations in two different genes were depicted. The first was found in PKD1 gene: c.1396G>A (p.Val466Thr) and causes the replacement of the amino acid alanine by threonine at position 1196 of the produced protein (Low density lipoprotein Receptor-related Protein-5). It is also referred as a variant of uncertain clinical significance, and exhibits autosomal dominant inheritance also. The MRI shows a particularly high cystic load in the liver (innumerable cysts) and multiple renal cysts in the two large kidneys, in a quite atypical form (not innumerable but many large cysts). The TKV was 1842 ml (1071 ml/m) and classified her in the class 1C (or possibly 2C because of the atypical form) according to the Mayo Clinic imaging classification system for ADPKD. The estimated prediction of the End-Stage Chronic Kidney Disease (ESCKD) (as long as the disease is not atypical) was according to the Mayo Clinic formula, 11 years.

Discussion: In a recent publication, pathological nucleotide variants of the LRPS gene were associated with hepatic cystogenesis. Coexistence of PKD1 and LRPS mutations was also identified in 2 families with polycystic kidney and liver disease. The underlying pathogenetic mechanism appears to be related to the connection between Polycystin-1 (the product of PKD1 involved in the pathogenesis of ADPKD) and the Wnt signaling pathway (affected by LRPS gene mutations and linked to hepatic cystogenesis). The coexistence of the two mutations possibly means synergistic action. Unique facts and important phenotypic characteristics in this particular patient, is the de novo simultaneous appearance of the two mutations (the parents were not genetically tested but do not have cysts in very old age), the particularly large cystic liver load (which is also observed in typical ADPKD, especially in women), the atypical renal cyst imaging and the moderate to severe renal disease (expected ESCKD at 64 years, which is more than expected in a PKD1 mutation only, but less than in a solitary PKD2 mutation). In conclusion, genetic complexity appears to go hand in hand with phenotype diversity in ADPKD and polycystic liver disease.

RAPID COMPLEMENT INHIBITION WITH THE C5 INHIBITOR CROVALIMAB: A TIMING ANALYSIS USING ANIMAL MODEL AND COMPOSER TRIAL DATA
Cristian Brocchieri1, Leigh Beveridge2, Muriel Buri3, Niels Janssen4, Patty Leon5, Yoshihori Tsuboi6 and Simon Buatös6
1F. Hoffmann-La Roche Ltd., Basel, Switzerland, 2Genentech, Inc., South San Francisco, United States of America and 3Chugai Pharmaceutical Co., Ltd., Chuo City, Japan
Background and Aims: Atypical haemolytic uraemic syndrome (aHUS) is a life-threatening disease, characterised by acute kidney injury, thrombocytopenia, and microangiopathic haemolytic anaemia due to complement dysregulation. Currently approved treatments for aHUS include the anti-complement C5 monoclonal antibodies eculizumab and ravulizumab. Although currently approved therapeutic options are effective at both inhibiting complement-mediated thrombotic microangiopathy (TMA) and improving renal function, the regular intravenous (IV) infusion dosing regimens impose a significant treatment burden, particularly in paediatric patients (pts) with aHUS, who may need dialysis in the future due to chronic kidney injury and would benefit from preservation of vascular access. Crovalimab is a novel monoclonal antibody developed against complement C5, engineered to allow for small volume subcutaneous (SC) self-injection once a week, in a weight-based dosing regimen [1]. In the adaptive Phase II/I COMPOSER trial (NCT03157365) evaluating crovalimab in pts with paroxysmal nocturnal haemoglobinuria (PNH), that, like aHUS, is a complement disorder characterised by uncontrolled complement activation, crovalimab has shown maintained disease control and was well tolerated after a median exposure of 3 years. Further, a Phase III study evaluating crovalimab in previously untreated pts met its primary efficacy endpoints [2]. The efficacy and safety of crovalimab are currently being evaluated in adult and paediatric pts with aHUS, either treatment-naïve or switching from another complement inhibitor, in the ongoing Phase III single-arm COMMUTE-a and COMMUTE-p trials [3]. Due to the rapidly progressing nature of aHUS, pts experiencing a TMA require rapid suppression of complement activation upon diagnosis to shut down the complement cascade and avoid further kidney deterioration and organ damage. Here, data from in vivo models and the COMPOSER trial were used to determine the time to complete complement inhibition after first crovalimab IV dose.

Method: Crovalimab’s ability to suppress C5 function and complement activity rapidly was initially studied in in vivo models of cycnomolus monkeys. This study assessed the pharmacokinetics and pharmacodynamics of crovalimab in these monkeys after a single IV or SC dose. As part of this study, four animals per group were evaluated with single 4 mg/kg IV and 20 mg/kg IV doses. Crovalimab was also evaluated in the four-part, Phase II/I COMPOSER trial. Part 2 (n = 10) and Part 4A (n = 8) enrolled pts with PNH who were naïve to complement inhibition. Pts in Part 2 received crovalimab 375 mg IV on Day 1, 500 mg IV on Day 8, 1000 mg IV on Day 22 and 170 mg SC weekly from Day 36 for 20 weeks. Pts in Part 4A received an optimised crovalimab dosing regimen of 1000 mg IV on Day 1, 340 mg SC on Days 2, 8, 15, and 22 and 680 mg SC Q4W from Day 29 onwards for 20 weeks. Crovalimab concentration, free C5 and complement activity were measured using validated assays in cynomolgus monkeys and in pts with PNH.

Results: Compared with baseline values in cycnomolus monkeys, a single crovalimab IV dose of 4 mg/kg reduced mean free C5 concentration by 99.6% and terminal complement activity by 81.4%, within 5 minutes after administration. In treatment-naïve pts from COMPOSER Parts 2 and 4, mean free C5 concentration dropped to below 1 µg/mL, indicating a high level of target engagement within 1–6 hours from the first IV dose (Figure 1). Correspondingly, inhibition of terminal complement activity was reached within 1 hour, with values near or below the limit of quantification (10 U/mL; Figure 2). Complete complement blockade was generally maintained long-term, up to Week 20, in both Parts 2 and 4, regardless of dose.

Conclusion: Crovalimab induced a complete, rapid, and sustained blockade of terminal complement activity in both non-human primates and pts with PNH, within hours from first dose. The dosing schedule of crovalimab included an initial IV loading dose, allowing for a rapid onset of action, followed by a convenient long-term SC maintenance regimen.

WHEN WHOLE EXOME SEQUENCING IS NOT GOOD ENOUGH: BACK TO THE ROOTS OR FORWARD TO THE FUTURE
Arif Ekici1, Karl Knaup1, Karen Schneider1, Florian Wopperer1, Antje Wiesener1, Anne Dieterle2, Mario Schiffer2, Andre Reis1, Francesca Pasutto1 and Michael Wiesener2
1Institute of Human Genetics, University Hospital Erlangen, Erlangen, Germany, 2Dept. Nephrology and Hypertension, Erlangen, Germany and 3Dept. Nephrology and Hypertension, University Hospital Erlangen, Erlangen, Germany

Background and Aims: Over the last few years, massively parallel sequencing (MPS) has been established in genetic diagnostics, where large virtual panels of candidate genes can be screened on a whole exome basis. This has enabled large analyses for most medical indications, including renal genetic diseases. The 25 year old, index female patient was referred for disease clarification. Both non-related parents suffered from end-stage renal disease, with kidney failure in mid adulthood and familiar cystic disease in both the maternal and paternal lines. An external genetic analysis applying MPS on a restricted panel of genes retrieved no conclusive result, apart from two variants in the UMOD gene, classified as class 3 and 4 following ACMG criteria.

Method: Whole exome sequencing (WES), linkage analysis, haplotype reconstruction, whole genome sequencing (WGS), long-range PCR (LR-PCR).

Results: The detailed pedigree of the family displayed an autosomal dominant disease with several family members reaching end-stage kidney disease on both the maternal and paternal sides. The maternal family is characterized by polycystic disease of the kidney and most profoundly the liver, with two female members already liver transplanted and one on the waiting list. The paternal family shows more unspecific chronic kidney disease (CKD) with multiple cysts in the kidney, but not in the liver. Two male members reported gout attacks, before the knowledge of CKD. We consented 12 family members for research studies and collected blood for DNA. Contemporary MPS of a virtual

**GENETIC TESTING FOR MOLECULAR DIAGNOSIS OF NEPHROLITHIASIS AND NEPHROCALCINOSIS IN ADULT PATIENTS: A SINGLE-CENTER COHORT**

Elena Emanuela Rusu1,2, Adrián Catalin Lungu1,3, Gabriel-Robert Pandele1, Alexandru Iordache4, Raluca Bobeica2, Lucia PKD1

**Conclusion:** ADPKD is one of the most frequent genetic diseases of the human genome, with PKD1 being involved in > 80% of cases. With the apparent ease of modern technology, increasingly ADPKD families are presented for genetic consultation, also to non-specialized centers. It is tempting to use MPS considering the number of candidate genes and the size of PKD1 (46 exons). However, a negative result should be supported either by LR-PCR or WGS, taking the profound difficulties with the 6 pseudogenes of PKD1 into consideration. It is hard to explain why the positive correlation of liver disease in this family with the PKD1 c.2180T>C variant implies a genotype-phenotype correlation, or whether other (genetic) modifiers may play for a liver phenotype. The renal prognosis of the index case is feared to be worse among both diseases, even with the pathogenes being different with a ciliopathy (ADPKD) and a toxic proteinopathy (ADTKD-UMOD), respectively. Since both affected genes are situated on the respective chromosomes 16, the patient bears a 100% risk of receiving children with an adult onset kidney disease, where pre-implantation technology will not solve this specific problem.

**#6086 NEUTRAL LIPID STORAGE DISEASE WITH RENAL INVOLVEMENT: A CASE REPORT**

Olivieri Antonella1, Rosamaria Roperto2, Federica Allegrotta2, Sarah Ecoorte3, Fiamentta Ravaglia3, Francesca Massaro1 and Campolo Gesualdo2

1Università degli Studi di Firenze, Scienze Biomediche, Sperimentali e Cliniche “Mario Serio”, Florence, Italy, 2Ospedale Santo Stefano, Nefrologia e dialisi, Prato, Italy and 3Ospedale Santo Stefano, Neurologia, Italy

**Background and Aims:** Neutral lipid storage diseases (NLSD) are rare conditions caused by an inborn error of neutral lipid metabolism that results in a deficit in the degradation of cytoplasmic triglycerides and a consequent abnormal storage of the neutral lipids. Their accumulation in cytoplasmatic lipid droplets in most tissues of the body results in a very heterogeneous phenotype: myopathic syndrome, intellectual deficit, cataract, nephrocalcinosis, cardiomyopathy, hepatomegaly are the main clinical manifestations. Less frequent conditions are diabetes, chronic pancreatitis and renal involvement.

**Method:** A 27-year-old woman visited our hospital on November 2022 because of progressive onset of edema, dyspepsia, nausea and loss of appetite. The medical history showed that 4 years before she was diagnosed with diabetes mellitus and she has been suffering from severe muscle weakness (she was helping herself with the wheelchair) for two years. In 2017 a proctological evaluation showed an anal hypotonia from likely neuropathy. Blood chemistry tests revealed a metabolic acidosis, a decreased renal function, anaemia and nephrotic range proteinuria at the urinalysis. A bilateral pleural effusion was described at the chest radiograph and a circumferential pericardial effusion at a first echocardiogram. The ultrasound of the abdomen described a small size of the right kidney (90 mm) and an angiomyolipoma on the left kidney. Neurological examination showed a mild intellectual disability, facies with dysmorphic appearance and hypotonia of proximal and distal muscular masses of the upper limbs. Lower limbs showed a more pronounced strength deficit on the left and a hypotonia to proximal muscle masses. Electromyography showed a condition of severe sensitivity polyneuropathy: signs of chronic denervation and morphological alterations of the motor unit especially in the proximal districts of the lower limbs. Ophthalmological examination showed an advanced cataract. Cardiological evaluation through heart echo scans showed a dilated heart disease with ventricular function and dilation of the pulmonary artery. A quadriceps muscle biopsy finally revealed myogenic features consistent with neutral lipid storage disease. Fabry test came back negative. Despite several drug treatments, the patient continued to be asthenic, inapprarent

**Abstracts**
and the oxygen therapy could not be removed because frequent episodes of desaturation. The deterioration of the patient's clinical conditions required the onset of dialysis immediately. Unfortunately, despite adequate information on the risks of possible refusal, the patient denied consent for central venous catheter placement and hence the beginning of renal replacement therapy. Sadly, the patient was lost to follow up and it was not possible to carry out other diagnostic investigations.

**Results:** Our patient developed an end-stage renal disease in the framework of a remarkable BM disease decrease before cytotoxic lipid droplets are ubiquitous organelles, we can assume that in this case, kidney involvement is due to a pathogenetic mechanism similar to that of other storage diseases such as Fabry disease (Table 1).

**Conclusion:** Here we describe a 27-year-old NLSD female patient showing late onset myopathy and difficulties in mobilization in association with severe cardiac and ocular involvement, mild intellectual disability, diabetes mellitus, type 2 and end stage renal disease. Our data expand the clinical manifestations of NLSD, providing further evidence for clinical NLSD heterogeneity and mainly, further evidence for storage diseases with renal involvement.

**ASSOCIATION BETWEEN PLASMA LYSO-Gb3 LEVELS AND BONE MINERAL DENSITY IN PATIENTS WITH FABRY DISEASE**

Yuma Nose, Hideki Fujii, Shunsuke Goto, Keiji Kono, Hayaki Okamoto, Kentaro Watanabe and Shinichi Nishi

Kobe University Graduate School of Medicine, Division of Nephrology and Kidney Center, Kobe, Japan

**Background and Aims:** Fabry disease is a rare X-linked genetic disorder that contributes to various clinical manifestations including cardiac hypertrophy, renal dysfunction, cerebrovascular disease, angiokeratoma, and anhidrosis. Several previous reports showed that male patients with Fabry disease had decreased bone mineral density (BMD). However, the association of BMD with clinical characteristics and biomarkers of organ damage in patients with Fabry disease has not been sufficiently studied. Therefore, we aimed to investigate their associations in patients with Fabry disease.

**Method:** Patients with Fabry disease who attended our hospital from January 2008 to June 2021 were included in this study. Patients without enough clinical and laboratory data were excluded from this study. The remaining fifteen patients were assessed in this study. We examined clinical characteristics, biomarkers including blood globotriaosylsphingosine (lyso-Gb3) levels, and BMD, and compared them between male and female patients. We measured the lumbar spine and femoral BMD by dual-energy bone X-ray absorptiometry and calculated the Z-score. Furthermore, we also examined ΔBMD, defined as the two-year change in the Z-score, for ten patients who underwent BMD measurement before and after starting ERT. Because two patients already had received ERT, two did not undergo BMD measurement, and one took an anti-osteoporotic agent, they were excluded from the analysis.

**Results:** Both lumbar spine BMD and femoral BMD decreased in male patients, while they were preserved in female patients (lumbar spine Z-score: -1.9 ± 2.0 versus 0.8 ± 0.8, p < 0.05; femoral Z-score: -1.0 ± 1.4 versus 0.6 ± 0.6, p < 0.05) among all the study patients. Lumbar spine and femoral BMD showed a significantly negative correlation with blood lyso-Gb3 levels. Moreover, blood lyso-Gb3 levels were significantly correlated with the lumbar spine BMD (r = -0.92; p < 0.01) and femoral BMD (r = -0.91; p < 0.01) in male patients. On the other hand, there was no significant correlation of blood lyso-Gb3 levels with the lumbar spine BMD (r = 0.66, p = 0.18) and femoral BMD (r = 0.41, p = 0.99) in female patients. After starting ERT, blood lyso-Gb3 levels were significantly reduced in both male and female patients. The lumbar spine ΔBMD in male patients improved whereas that in female patients remained unchanged despite no changes in kidney function and serum calcium and phosphates levels.

**Conclusion:** Our findings suggested that lumbar spine BMD and femoral BMD decreased in male patients with Fabry disease possibly due to the deposition of lyso-Gb3 in bone tissue and ERT could improve BMD in these patients.

**#2845**

**TOLVAPTAN TREATMENT FOR THREE YEARS SIGNIFICANTLY IMPROVED RENAL PROGNOSIS IN AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE (ADPKD) PATIENTS**

Vasiliki Gikas1, Michaela Louka1, Eirini Evangelou1, Yiyraki Vasileiou1, Dimitra Gkalitsiou1, Konstantina Kanellopoulou1, Angelos Drakopoulos1, Eirini Tigka1, Mihail Tsagkatakis2 and George Tsirpanlis3

1 General Hospital of Athens “G. Gennimatas”, Athens, Greece and 2 Bioiatriki, Department of Magnetic Resonance, Greece

**Background and Aims:** Vasopressin receptor antagonist, tolvaptan, is the first specific treatment approved for ADPKD. Long-term real clinical results with this drug are not yet available. We present the results regarding renal function, cyst-kidney volume and renal prognosis in patients with rapidly progressive disease after three years of tolvaptan treatment.

**Method:** Forty-one ADPKD patients who remained in tolvaptan treatment, without adverse reactions for 3 years, were included in the study. Total kidney volume (TKV) was measured using Magnetic Resonance Imaging (MRI), before and after three years of treatment. The Mayo Clinic Imaging Category (MCIC) and the prediction of End Stage Renal Disease (ESRD) based on the Mayo Clinic formula (Irazabal MV et al, JASN, 2015) were also calculated for all patients, before and 3 years post treatment. Using the same formula the expected estimated-glomerular filtration rate (e-GFR) at 3 years without treatment was calculated and compared to the e-GFR found after three years of treatment. The expected TKV increment at 3 years was calculated (5.3% increment per year) and was compared to the TKV measured in the second MRI. Finally, the expected renal prognosis at the time of treatment initiation (i.e. minus 3 years at the end of the study) was compared to the prognosis calculated based on real patients’ data found after 3 years of treatment. The dose of tolvaptan was adjusted according to the urine osmolarity (< 200 mOsm/Kg). In the third year of treatment, 15, 13 and 13 patients were treated with 90/30, 60/30, and 45/15 mg/day of tolvaptan respectively. Paired t-test and Wilcoxon signed-rank test were used for statistical analysis.

**Results:** Forty-one patients (18 females, 23 males), mean (SD) age 42.5 (8.6) years old were treated with tolvaptan for 3 years. According to MCIC, 41% of the patients were classified as 1C, 44% as 1D, and 15% as 1E. Pre-treatment mean (SD) e-GFR was 61.8 (24.6) ml/min while 15% of the patients were on stage 1 of Chronic Kidney Disease, 42% on stage 2, 12% on stage 3a, 24% on stage 3b, and 7% on stage 4 (>25 ml/min). The expected mean (SD) TKV at 3 years without treatment was 2717 (1839) ml, while the measured TKV found
after 3 years of treatment was 2773.3 (2086.9) ml (p = 0.44). The expected e-GFR at 3 years without treatment was calculated at 31.1 (25.2) ml/min while the measured e-GFR after 3 years of treatment was 57.3 (30.2) ml/min (p = 0.001). Finally, while the expected mean (SD) ESRD prediction at the time of treatment initiation was 10 (6.9) years, the calculated ESRD prediction after 3 years of tolvaptan treatment was 12 (8) years (p < 0.001).

Conclusion: Tolvaptan treatment for three years slowed down the clinical course of ADPKD in terms of renal function decline and ESRD prediction, but had no impact on total kidney volume.

Background and Aims: We report the baseline and genetic characteristics of the nationwide genetic cohort for Korean hereditary cystic kidney disease prior to detailed molecular analysis.

Method: We performed a 3-year prospective, multicenter cohort study at 9 hospitals from May 2019 to May 2022. Patients with more than 3 renal cysts were enrolled and classified into 3 categories: typical and atypical autosomal dominant polycystic kidney disease (ADPKD), and pediatric PKD. Clinical and genetic characteristics were compared among categories. Genetic analysis was performed by using gene panel comprised of 89 ciliopathy-related genes.

Results: A total of 798 patients were enrolled. Mean age was 42.7 ± 17.3 years, and 47.8% were male. Patients were categorized into typical ADPKD (560, 70.2%), atypical ADPKD (165, 20.7%), and pediatric PKD (73, 9.1%). Typical ADPKD group of 62 subjects with ADPKD (mean age -54.3years old, men:women 34:28, with 1A and 1B Mayo ADPKD risk classes) and a group of 37 healthy subjects, similar as sex, mean age, ADPKD diagnosis was based on familial history, clinical exam and CT or MRI scan. We excluded from the study subjects that presented cysts in other organs except the kidney, with hypertension treatment for less than 6 months; metabolic disorders (carbamoyl phosphate synthase 1 and N-acetyl glutamate synthase deficiencies, lack of ornithine transcarbamilase, hyperargininemia, phenylketonuria). Laboratory tests: serum level of arginine, enzymatic activity of arginase 2 (ARG-2) and nitric oxide synthesis (Asymmetric Dimethylarginine -ADMA, Symmetric Dimethylarginine -SDMA). ADMA and SDMA were overexpressed in ADPKD group compared with control group.

Conclusion: The measured e-GFR after 3 years of treatment was 2773.3 (2086.9) ml (p < 0.001). Pathogenic variants were found in 40% of patients (122/306). Having higher discovery rate (62.3%) compared to atypical ADPKD (57.3%) and control group (33.9%).

L-ARGININE-NITRIC OXIDE MOLECULAR PATHWAY IN AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE
Corina-Daniela Ene1,2, Ilina Nicolae3, Mircea Penescu1,2 and Cristina Capusa1,2
1Carol Davila Clinical Hospital of Nephrology, Nephrology, Bucharest, Romania, 2Carol Davila University of Medicine and Pharmacy, Nephrology, Bucharest, Romania and 3Victor Babes Clinical Hospital of Infectious Diseases, Research, Romania

Background and Aims: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is an inherited, complex disease, cystogenesis and phenotypic changes in this disorder being not yet fully understood. Recently, arginine, important for renal cells metabolism, was proved to play an important role in ADPKD physiopathology [1]. The inability of cells to recycle or synthesize intracellular arginine through the urea cycle is defined as arginine auxotrophy. Arginine auxotrophy in ADPKD induces cell hyperproliferation, and cysts formation [2]. We aimed to explore L-Arginine (Arg) - Nitric Oxide (NO) molecular pathway in ADPKD, a multisystemic, arginine auxotrophy disease.

Method: We developed a prospective, case control study, in Carol Davila Clinical Hospital of Nephrology, Bucharest, Romania. The study included a group of 62 subjects with ADPKD (mean age -54.3years old, men:women 34:28, with 1A and 1B Mayo ADPKD risk classes) and a group of 37 healthy subjects, similar as sex, mean age, ADPKD diagnosis was based on familial history, clinical exam and CT or MRI scan. We excluded from the study subjects that presented cysts in other organs except the kidney, with hypertension treatment for less than 6 months; metabolic disorders (carbamoyl phosphate synthase 1 and N-acetyl glutamate synthase deficiencies, lack of ornithine transcarbamilase, hyperargininemia, phenylketonuria). Laboratory tests: serum level of arginine, enzymatic activity of arginase 2 (ARG-2) and nitric oxide synthesis (Asymmetric Dimethylarginine -ADMA, Symmetric Dimethylarginine -SDMA).

Results: In ADPKD patients, the serum levels of arginine and of the stable metabolites of nitric oxide had statistically significant lower levels compared with control group (Table 1). The levels of the principal enzymes that metabolizes arginine – arginase 2 and nitric oxide inducible synthase, respectively the endogenous inhibitors of nitric oxide synthesis were statistically significant higher in ADPKD group when compared with control group (Table 1). The AR2/Arg, NOS2/Arg, Nitrite/Arg, Nitrate/Arg, ADMA/Arg and SDMA/Arg ratios were statistically significant overexpressed in ADPKD group when compared with control group.

Conclusion: ADPKD is a metabolic kidney disease, auxotrophic for arginine. The metabolic ADPKD phenotype of renal cells with low risk of progression (1A and 1B Mayo) is defined by the alteration of L-Arginine-NO molecular pathway, the significant reduction of systemic arginine, moderately increased enzymatic activities of ARG2 and NOS2, the reduction of the synthesis and bioactivity of NO. Exploring arginine reprogramming and related molecular L-Arg-NO pathways disturbances could offer more information about ADPKD physiopathology.

REFERENCES
Background and Aims: In approximately 10% of adults with chronic kidney disease, a hereditary cause can be identified. Important representatives are Alport syndrome and inherited podocytopathies, which often show the histological picture of focal segmental glomerulosclerosis (FSGS). FSGS is a histological finding of various etiologies (primary, hereditary, secondary). Especially in suspected glomerular kidney disease, kidney biopsy can provide a clue to the underlying inherited kidney disease. Biopsies were further investigated by proteomics via liquid-chromatography-mass spectrometry (LC-MS) to potentially elucidate the underlying protein defect.

Method: The cohort for this retrospective study consisted of 23 individuals with a genetically confirmed inherited nephropathy and a previously performed kidney biopsy. A systematic pathological secondary review of the 23 biopsies was carried out (genetic diagnosis unknown at secondary review). The findings of the biopsies were compared with the molecular genetic results. 9 proband and 9 control biopsies were additionally evaluated through LC-MS. Laser capture microdissection was used to extract glomeruli from the tissue samples, which were then further analyzed on alterations in protein expression secondary to the respective disease-causing variants.

Results: In the cohort, disease-causing variants were identified in the following genes: COL4A3 (n = 3), COL4A5 (n = 4), WT1 (n = 3), UMOD (n = 3), and each n = 1 for the genes INF2, DAAM2, MUC1, COQ8B, NPHS4, TRIM8, CD2AP, NPHS2, CLCN5, and PAK2. The biopsies showed predominantly segmental glomerulosclerosis and parenchymal scarring, as well as podocyte damage. Four individuals with the histological diagnosis of Alport syndrome were genetically confirmed as having X-chromosomal (n = 2; including one female carrier) and autosomal-recessive (n = 2) Alport syndrome. Proteomics showed heterogeneous results. Proband samples carried variants in COL4A3 (n = 3), COL4A5 (n = 3), ADCK4, NPHS4, and WT1 (the last three each n = 1). COL4A3 was detected in 6/9 of control samples and in 0/9 of proband samples; COL4A5 was detected in 5/9 of control samples and in 0/9 of proband samples. ADCK4, NPHS4, and WT1 could not be detected in this analysis, neither in control, nor in proband samples.

Conclusion: In this study, molecular genetic diagnostics allowed a more precise disease assignment and thus provided information on therapy, prognosis, recurrence in the transplant, possible extrarenal phenotypes, and inheritance. Histological findings can indicate an inherited disease and help to trigger genetic testing (e.g., Alport syndrome). However, genetic diagnostics can also classify cases for which there are no typical morphological criteria described or if severe scarring impairs morphological diagnosis. Numerous cases of a respective monogenic disease would have to be analyzed in order to establish common histopathological criteria, if present. This is a challenge due to the rapid discovery of new disease-associated genes and the rarity of the respective diseases. LC-MS-based proteomics from kidney biopsy samples showed to be of limited value in further characterizing changes associated with specific variants. Unlike the genome, which is consistent due to the stability of DNA, the proteome is influenced by various effects: Different stages of fibrosis depending on the time of biopsy and other factors like coexistent disease lead to varying protein intensities even in two separate samples that present identical genetic variants. The detected protein intensity patterns could not be sufficiently correlated with the genetic findings. Despite the detection of certain proteins of interest like type IV collagens, their intensity variation due to advanced tissue damage did not allow reliable conclusions on the underlying cause. Alternatively, molecular methods such as MALDI imaging could further visualize these changes.
Figure 1: Genotype-phenotype relationship in FRG patients. (A) Twenty-four-hour urinary glucose excretion (24hUG) is inversely related to RTG (\(\log(24hUG) = -0.1881 \times \text{RTG} + 2.252, R^2 = 0.7650\)). (B) In our cohort, patients with two SLC5A2 variants had lower RTG than those with only one (Mean RTG 3.9±2.1mmol/L vs 6.2±2.0mmol/L, \(p = 0.057\)). (C) Literature review showed that 24hUG corrected by body surface area of patients carrying a single SLC5A2 variant were significantly lower than those carrying two variants (7.20±9.28g/1.73m\(^2\) vs. 52.39±45.22g/1.73m\(^2\), \(p<0.0001\)). (D) Patients from the literature were divided according to the type of variant they carried: mis+in-frame (missense variants and in-frame indels), truncating (nonsense variants and frameshift variants), and splicing variants. Patients with homozygous splicing variants had significantly less 24hUG (35.8±27.10g/1.73m\(^2\)) than those with homozygous truncated (81.6±39.88g/1.73m\(^2\)) or mis+in-frame variants (82.3±40.34g/1.73m\(^2\), \(p<0.05\)). Homo = homozygous, hetero = heterozygous. (E) Patients carrying missense variants were divided according to the conservation of the involved amino acid. Patients with homozygous variants at conservative residues had more 24hUG (104.7±31.70g/1.73m\(^2\)) than those with variants involving non-conservative residues (46.3±22.38g/1.73m\(^2\), \(p = 0.0031\)). (F) Daily urinary glucose excretion (24hUG) mapped on the SLC5A2 gene structure. Each node represents one variant, and the node's height corresponds to an average of 24hUG of FRG patients carrying this variant. Nodes on the top: homozygotes; nodes on the bottom: heterozygotes. The color of the nodes represents variant types (black: missense variants; pink: in-frame indels; green: frameshift indels; blue: nonsense variants; cyan: splicing variants). Circles: 24hUG normalized by body surface area (g/1.73m\(^2\)/d); squares: 24hUG in g/d.

CLINICAL AND GENETIC CHARACTERISTICS OF CHILDREN WITH BARTTER SYNDROME: A SINGLE CENTER LONG-TERM EXPERIENCE
Varvara Askiti, Argyroula Zampetoglou, Maria Mila and Andromachi Mitsioni
Children's Hospital "P&A Kyriakou", Pediatric Nephrology, Athens, Greece

Background and Aims: Bartter syndrome is an autosomal recessive renal tubular disorder. Clinical diagnosis can be challenging due to rarity and phenotypic overlap. Little information is available on a long term follow-up in Bartter syndrome. Our aim was to describe clinical -genetic correlations as well as our experience from the long term follow up of these patients.

Method: Clinical and genetic characteristics of patients with Bartter syndrome at diagnosis and long term follow up are reported in 19 children. Genetic testing (whole exome sequencing, WES) was done in 14/19 patients. The study period was 17 years (January 1, 2006 to December 31, 2022).

Results: 16 Caucasian and 3 of gipsy origin (13 boys, 68%) were included. The median age at diagnosis was 0.52 yrs. Median follow up time was 9.8yrs (IQR 6.86-13.8). WES revealed 6 mutations in KCNJ1 genes, 5 in SLC12A1 and 3 in CLCNKB genes. 4 new mutations were identified (3 in KCNJ1 genes and 1 in SLC12A1). 18/19 children were born pre-term (including 2/3 patients with CLCNKB). Nephrocalcinosis was present in 18/19 patients (included the 3 patients with CLCNKB mutations). 4/6 patients with KCNJ1 mutations presented initially with hyperkalemia. Medical treatment in the last follow up included supplementation with potassium in 18, non-steroidal anti-inflammatory agents in 15 and gastroprotective drugs in 13, ramipril in 2. 2/19 received recombinant growth hormone. At last follow up body weight and height were within normal ranges in 16/19 (84%) patients. Hyperparathyroidism (median time of PTH 151.5 pg/ml) have 6/11
(56%) of patients with Bartter I (KCNJ1 mutation) and Bartter II (SLC12A1 mutation) and only 1/3 with Bartter III (CLCNKB mutation). 2/19 patients have proteinuria. Chronic kidney disease (CKD) occurred in 7/19 (37%) suggesting that the long term prognosis can be unfavorable (4 CKD stage II, 3 CKD stage III). Of note 2 patients with CKD had impaired renal function since diagnosis while the remaining 5 progressed gradually during followup. Conclusion: WES is useful in dealing with the phenotypic heterogeneity of Bartter syndrome. Our results emphasize the need for early diagnosis, regular followup and appropriate treatment in order to maintain normal renal function and achieve normal final height and weight.

A NOVEL CT-BASED RADIOMICS APPROACH FOR KIDNEY FUNCTION EVALUATION IN ADPKD
Luca Calvaruso1, Pierluigi Fulignati1, Luigi Larosa2, Huong Elena Tran1, Claudio Votta2, Viola D’ambrosio1, Giulia Condello1, Pietro Manuel Ferraro1, Luca Boldrini2 and Giuseppe Grandaliano1

1Nephrology, Dialysis and Transplantation Unit, Fondazione Policlinico Universitario A. Gemelli IRCCS, Università Cattolica del Sacro Cuore, Roma, Italy and 2Department of Diagnostic Imaging, Oncological Radiotherapy, and Hematology – Fondazione Policlinico Universitario “A. Gemelli” IRCCS, Rome, Italy

Background and Aims: Clinical management of autosomal dominant polycystic kidney disease (ADPKD) might take advantage of the use of new tools to predict risk of progression towards end stage kidney disease (ESKD). The aim of this study is to develop and validate a model based on radiomic features to predict kidney function among patients with ADPKD obtained from CT scans performed for the determination of total kidney volume (TKV).

Method: We retrospectively selected a cohort of 58 patients with ADPKD who underwent CT scan from February 2020 to March 2021, including 30 patients with eGFR ≥ 60 mL/min/1.73 m² and 28 with eGFR < 60 mL/min/1.73 m² at baseline. An expert radiologist generated a region of interest (ROI) segmentation for cystic kidney compounds, obtaining 58 ROIs from which we extracted 217 radiomic features using a dedicated software. We built three different logistic regression models to predict kidney function based on different predictors: height-adjusted TKV (ht-TKV), a selected radiomic feature (F_cm_merged.clust.tend), and both. Area under the curve (AUC) of the receiver operating characteristic (ROC) and accuracy were employed to evaluate models’ performance in discriminating between the two eGFR groups. Internal 3-fold cross-validation (CV) was performed.

Results: The ht-TKV, radiomic and combined models presented respectively an AUC (95% confidence interval) of 0.79 (0.67, 0.91), 0.83 (0.72, 0.93), 0.84 (0.74, 0.94), confirmed by the CV. Mean (standard deviation) values of the accuracy over CV iterations were 0.67 (0.10), 0.77 (0.09), 0.77 (0.09) for the three models. A model combining ht-TKV with a radiomic feature based on CT images from polycystic kidneys resulted effective in the prediction of baseline kidney function in our cohort. Furthermore, a logistic regression model based on a different radiomic feature (F_cm.2.5Dmerged.info.corr.2) selected among a subcohort of 29 ADPKD patients with a clinical follow-up, predicted rapid progression with an AUC of 0.81, a sensitivity of 100% and a specificity of 53%.

Figure 1: ROC curves from Ht-TKV, radiomic and combined models.
Conclusion: This is among the first studies which aimed to investigate, in a clinical setting, radiomics potential ability in discriminating eGFR at baseline and to explore as well whether a reliable radiomic feature could be taken into account in predicting faster rapid kidney function impairment over time. Further studies should implement a model extension to predict kidney function slope in order to confirm the role of radiomics in ADPKD management.

DEVELOPMENT OF AN EXPERT MODEL FOR THE DIAGNOSIS OF INHERITED KIDNEY DISEASES

Leonor Fayos de Arzión1, 2, Elizabeth Romelia Viera Ramírez1, 2, Rafael Leon1, Melissa Pilco Teran2, 3, Monica Furlano4, Montserrat Valverdu1, Lluís Guirado3, 5, Alexandre Perera4 and Roser Torra1, 2

1 Fundació Puigvert, Inherited Kidney Diseases, Nephrology Department, Barcelona, Spain, 2 Institut d’Investigació Biomèdica Sant Pau (IIB-SANT PAU), Barcelona, Spain, 3 BarcelonaTech University and Biomedical Engineering Research Centre (CREB), Barcelona, Spain, 4 BarcelonaTech University and Biomedical Engineering Research Centre (CREB), Barcelona, Spain and 5 Fundació Puigvert, Nephrology Department, Spain

Background and Aims: Inherited kidney diseases (IKDs) account for 10–20% of cases of Chronic Kidney Disease (CKD). Mutations in over 400 genes are known as drivers of more than 150 monogenic kidney disorders. Clinical diagnosis is often challenging as these disorders are characterized by numerous clinical features often shared by many diseases as well as very variable expression. Over the years, rare-disease databases such as OMIM and Orphanet have compiled information to facilitate diagnosis of rare diseases. Based on these, The Human Phenotype Ontology (HPO) developed a standardized directory for phenotypes with phenotype-disease associations. New phenotype-driven gene-priorization tools such as Phenomizer have been developed in the recent years using these resources, however structural inaccuracies prevent a proper uptake of these tools. To date, no specific renal disease databases have contributed significantly to improving the clinical diagnosis of rare diseases. However, these tools are nonspecific and imprecise when focusing on a specific field such as IKDs. Curation of current annotations by experts in the field will greatly improve the accuracy of these tools and facilitate clinical diagnosis of IKDs.

Conclusion: Current phenotype-based gene prioritization tools and rare disease databases have contributed significantly to improving the clinical diagnosis of rare diseases. However, these tools are nonspecific and imprecise when focusing on a specific field such as IKDs. Curation of current annotations by experts in the field will greatly improve the accuracy of these tools and facilitate clinical diagnosis of IKDs.

CLINICAL EXOME SEQUENCING AS A TOOL FOR GENETIC DIAGNOSIS OF ALPORT SYNDROME AND THIN BASEMENT MEMBRANE DISEASE

Giulia Margherita Brach del Prever1, 2, Valeria Bracciamà1, 2, Chiara Vizzuso1, 2, Elisa Longhiatano1, 2, Licia Peruzzi3, Roberta Fenoglio4, 5, Domenico Santoro5, 6, Dario Roccatello5, 6, Antonio Amoroso1, 2, Tiziana Vaisitti1, 2 and Silvia Deaglio1, 2

Background and Aims: Alport syndrome (AS) is an inherited nephropathy caused by pathogenic variants in COL4A3 (autosomal dominant -AD- and autosomal recessive -AR- inheritance), COL4A4 (AR) and COL4A5 (X-linked dominant –XLD). It is characterized by glomerular nephropathy with
hematuria progressing to end-stage renal disease, frequently associated with sensorineural deafness and ocular anomalies. In thin basement membrane disease (TBMD) most patients are asymptomatic and are incidentally noted to have microhematuria, mild proteinuria, and occasionally gross hematuria, with normal renal function. This condition is caused by pathogenic variants in COL4A3 and COL4A4 (AD). We have systematically applied genetic testing to pediatric and adult patients with clinical features suggestive of AS (Table 1).

Method: Clinical exome sequencing (CES) was performed on a cohort of 95 patients referred to our center from 2019 to 2022. Analyses were performed on an in-silico designed panel including 523 renal genes. Whenever possible, identified variants were segregated by Sanger sequencing.

Results: We identified causative (C4/C5) variants in 43 (45.3%) patients. Among them, genetic diagnosis of AS was obtained in 25 patients (58.1%): one (4.0%) with biallelic variants in COL4A4, 13 (52.0%) with COL4A5 variants (6 females and 7 males), 5 (20.0%) with COL4A3 variants (4 heterozygous and 1 homozygous) and 6 (24.0%) cases with coexisting variants in one or more other collagen genes. In 16 (37.2%) patients, we found causative monoallelic variants compatible with TBMD: 12 (75.0%) patients with variants in COL4A4 and 4 (25.0%) in COL4A3. Lastly, in 2 cases, we found variants in COL4A1 (#120130) and MYH9 (#160775), both genes associated with other renal diseases with a clinical presentation partially overlapping with AS. In additional 16 cases (16.8%), we identified C3 variants in collagen genes. In the remaining patients, genetic testing was negative (14 patients, 14.7%) or inconclusive (22, 23.2%). Of note, we identified 6 families with digenic AS. In 4 of them - 3 with COL4A5/COL4A4 variants and one with COL4A3/COL4A4 variants – the coexistence of two variants was associated to earlier renal failure, compared to family members bearing a single variant. In contrast, in the remaining 2 families (33.3%), members with COL4A5/COL4A3 missense variants had a milder phenotype compared to male family members with the single variant COL4A5 variant. In families with digenic AS, at least one variant involved the substitution of a glycine with another amino acid in the triple helix domain, frameshift indel variants in the triple helix domain or inframe indel in the collagen IV domain non-collagenous. To better understand the impact of multiple variants on collagen structure, computational studies are currently ongoing.

Conclusion: CES is a powerful tool to clearly define the diagnosis when AS or TBMD are suspected, as witnessed by a detection rate of 43.2%. Genetic diagnosis allows to identify the causative gene offering the possibility of extending diagnosis to other family members, also in the prenatal setting. In addition, it offers the possibility to identify multiple variants in collagen genes associated with digenic AS, as well as to find variants in other genes implicated in kidney disease. Notably, the presence of digenic variants is not necessarily predictive of a worse disease outcome. For all these reasons, molecular diagnosis can be useful to improve clinical management, to calculate recurrence risk and to better define the prognosis of the patient.

FAMILIAL LECITHIN: CHOLESTEROL ACYLTRANSFERASE (LCAT) DEFICIENCY AS A CAUSE OF CHRONIC KIDNEY DISEASE – A CASE REPORT
Motaz Obeidat1, Marya Obeidat2 and Mohammad Al-Shboul2

1Jordan University of Science and Technology, Faculty of Medicine, Irbid, Jordan and 2Jordan University of Science and Technology, Faculty of Applied Medical Sciences, Irbid, Jordan

Background and Aims: Genetic causes of chronic kidney disease are becoming more recognized. Familial lecithin: cholesterol acyltransferase (LCAT) deficiency (FLD) is a rare genetic disorder caused by loss of function mutations in LCAT gene. Patients present with abnormal lipid profile characterized with markedly reduced HDL-C, corneal opacification, anemia, and renal disease, which eventually progresses to kidney failure. Several studies reported genetic variants in LCAT gene that are associated with FLD, and others in certain apolipoprotein genes that act as risk factors for the disease. Incomplete form of FLD, caused by certain mutation, leads to fish-eye disease characterized by progressive corneal opacification. FLD was described in studies from Europe, Latin and North America, Australia and Japan. In Jordan, genetic and clinical studies in FLD patients are absent.

Method: We present a 36-year-old female who presented with nephrotic-range proteinuria, high serum creatinine, hypertension and corneal opacity. Further examination showed a severely reduced HDL level, an increased triglycerides level, anemia and mild thrombocytopenia. Patient’s laboratory values at presentation are shown in Table 1. Her blood film showed normocytic and normochromic red blood cells, anisopoikilocytosis and target cells. Light and electron microscopy examination of the kidney biopsy revealed intramembranous, subendothelial and mesangial lipid deposition and vacuolization. In addition, the patient was found to have a family history of corneal opacity and chronic kidney disease. Therefore, FLD was suspected. Whole exome sequencing was employed to identify FLD variants.

Results: The patient was found to be homozygous at 154+5delG in LCAT gene, heterozygous at 388T>C in apolipoprotein E gene (APOE) and homozygous at 1114G>C in WW domain-containing oxidoreductase gene (WWOX). The patient’s chronic kidney disease was managed supportively with low salt diet, moderate protein intake, statins, angiotensin receptor blockers and blood pressure control. After one year of follow up, her serum creatinine is 220 μmol/l and estimated proteinuria is 1.2 gm/24 hrs.

Conclusion: FLD should be suspected in patients who present with kidney disease associated with significantly low HDL cholesterol and corneal opacity. Family members should also be screened for kidney disease and genetic mutation in LCAT gene. To date, treatment is mainly supportive and enzyme replacement therapy is not yet widely available.

Abstracts

Background and Aims: Alport Syndrome (AS; ORPHA63) is one of the most frequent hereditary kidney diseases (HKD). Its autosomal dominant form due to COL4A3-4 heterozygous mutations is being increasingly diagnosed thanks to the generalization of genetic studies. Since there is no curative treatment for the disease, management is based on drugs that slow its progression, mainly RAAS inhibitors. The SGLT2 inhibitor Dapagliflozin has demonstrated to slow chronic kidney disease (CKD) progression by decreasing proteinuria, however very few ADAS patients were included in its clinical trial. Our aim is to analyze whether dapagliflozin is associated with a decrease in proteinuria in ADAS patients.

Method: In this prospective observational study, we analyzed 12 ADAS patients that started dapagliflozin due to proteinuria in spite of maximum tolerated RAAS inhibitor treatment and eGFR > 25 ml/min/1.73 m². We analyzed diabetes and hypertension presence (and its control), weight changes, possible adverse effects and laboratory variables before and after treatment initiation (Cr, eGFR, K, uricacid, albuminuria, proteinuria). Results: During a mean follow-up period of 7±4 months, we observed 12 patients, 5 (41.7%) male, 61±10 years old. 2 (33.3%) had type 4 diabetes, 2 (16.7%) had impaired fasting glucose (IFG), 11 had hypertension diagnosis, 1 patient had obesity (BMI 36) and other 7 were overweight (mean BMI 28±2). 9 patients had the higher dose of an RAASi, the other three couldn’t achieve it because of hypotension events. 3 patients also took an antagonist of mineralocorticoid. Only one had another diuretic prescription (furosemide 2022), in our pediatric tertiary center. Data regarding demographic variables, whether dapagliflozin is associated with a decrease in proteinuria in ADAS patients.

Conclusion: Slower progression drugs are the main treatment of ADAS nowadays. Dapagliflozin has demonstrated its beneficial effects in other proteinuric CKD, but it hasn’t been well studied in ADAS. In our sample, it seems to achieve a proteinuria improvement without significant adverse effects and known bearable eGFR fall. Large studies must be considered to determine its beneficial use in a long-term basis.
Background and Aims: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common genetic cause leading to end stage renal disease (ESRD). The most striking ADPKD feature, which is the growth of renal cysts leading to nephromegaly and renal function loss, is attributed to the loss of PKD1 and PKD2 genes coding respectively for Polycystin 1 and Polycystin 2, which are proteins located on the primary cilium. ADPKD is considered a systemic disease as several extra-renal manifestations including liver cysts and hepatomegaly, valvular heart disease, aneurysms and diverticulosis can be associated to it. Because of the remarkable renal and hepatic involvement, patients affected by organomegaly may suffer from pressure-related conditions like malnutrition. Nutritional and hydration status can be assessed through Bioelectrical Impedance Analysis (BIA), used both in the healthy population and in patients affected by chronic kidney disease (CKD). It is nowadays still not clear whether the presence of renal and hepatic cysts may exert an influence on raw BIA measurements and consequently this is an important index for malnutrition in patients affected by chronic kidney disease (CKD) secondary to ADPKD or not. Together with other values derived from BIA evaluation, this could be used in the future in order to guide the therapeutic choice even in patients with a preserved renal function or a mildly reduced eGFR.

Conclusion: The results of our study are concordant with the only one present in the literature. Phase angle (PhA) has shown to be an important index of malnutrition both in healthy and ADPKD patients, we observed that it is independent of ADPKD and mostly correlated with age.

Method: We enrolled 132 adult patients (> 18 years of age), 71 being affected by ADPKD, 33 being affected by non-ADPKD related CKD and 28 healthy controls. Each patient accepted to undergo BIA analysis and anthropometric measurements (height, weight, BMI), which were performed on the same day. We then classified ADPKD patients according to their residual renal function degree and compared them to the corresponding non-ADPKD of the same grade of renal insufficiency.

RESULTS: We observed that in ADPKD patients showing organomegaly, in particular hepatomegaly, there is a positive correlation between this factor and BIA parameters including TBW%, ECW% and ICW%. On the other hand, no significant correlation with age and GFR was found. As far as PhA concerned, which is an indicator of malnutrition both in healthy and ADPKD patients, we observed that it is independent of ADPKD and mostly correlated with age. It has also been demonstrated that PhA significantly decreases in presence of organomegaly or when renal diameters are increased, even in subjects with a preserved or mildly reduced eGFR.

Conclusion: The results of our study are concordant with the only one present in the literature. Phase angle (PhA) has shown to be an important index for malnutrition in patients affected by chronic kidney disease (CKD) secondary to ADPKD or not. Together with other values derived from BIA evaluation, this could be used in the future in order to guide the therapeutic choice even in patients with a preserved renal function or a mildly reduced one.

#6841

IS NEPHRECTOMY ALWAYS USEFUL IN ADPKD? A CASE REPORT OF HEPATIC FIBROSIS WITH SPLENOMEGALY AND PANCYTOPENIA AS LATE CONSEQUENCE

Kristiana Kola, Liliana De Rosa, Martina Catania, Marta Vespa, Romina Bucki, Giancarlo Joli, Michele Paolisi, Pierpaolo Bianca, Giuseppe Vezzoli, Paolo Manunta and Maria Teresa Sciarrone Alibrandi

San Raffaele Hospital, Milano, Italy

Background and Aims: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic kidney disease. Its main feature is the progressive enlargement of both kidneys with progressive loss of kidney function. ADPKD is the 4th leading cause of dialysis in the world. The disease has systemic involvement. Liver cysts are the most common extrarenal manifestations of ADPKD and are often incidentally found. However the liver can reach considerable size but its function is always preserved. Cysts lead to structural changes of the biliary tree and determine discomfort related to mass effect when significant liver enlargement occurs. Few cases of Budd Chiari syndrome (BCS) or of hepatic fibrosis have been reported in ADPKD patients after nephrectomy. Probably the removal of the kidneys can lead to obstruction of inferior vena cava by liver cysts.

Method: We report a case of hepatic fibrosis with splenomegaly and severe pancytopenia as a tardive complication after bilateral nephrectomy.

Case report: A 47 years old man was admitted c/o Division of Nephrology of San Raffaele Hospital in August 2018 because of a high-grade fever, general malaise, nausea and abdominal pain. The patient had a previous diagnosis of ADPKD. Genetic test indicative of PKD1 truncating mutation. He was chronically attended in the outpatient clinic of the same Division. On admission in hospital his renal function was severely impaired (crea 10 mg/dl; urea 213 mg/dl). No abnormalities at the blood count. Reactive C protein was elevated (156 mg/l nv 0-6). Urine culture was found negative. Abdominal NMR showed an important volumetric increase (compared with a NMR performed in 2014) of both kidneys with diameters of about 30 cm, several cysts with hemorrhagic and infective features and numerical and dimensional increase of the hepatic cysts; spleen was reported with normal diameters. Multiple antibiotic treatments were performed unfortunately without benefit. Therefore considering the state of end stage renal disease, the persistent infection and the severe symptoms, in September 2018 the patient underwent bilateral nephrectomy and hemodialysis was started. During the following years imaging studies aimed at the preparation for transplantation were performed. In November 2020 an abdominal NMR showed for the first time splenomegaly with a bipolar diameter of 14 cm. A NMR follow up was started. In January 2021 a further increase was reported as spleen diameter reported of 14.5 cm and a volumetric increase of hepatic cysts was shown. In September 2022 spleen reached to a diameter of 17 cm. Contextually in November 2020 patient started to present pancytopenia that had progressively been worsening with many concomitant infective and bleeding episodes. All hematologic causes were excluded. Just to explain the genesis of the splenomegaly in September 2022 a fibroscan was performed and a pathological liverstiffness was found. All hepatitis markers were negative and immunologic ones as well. Splenectomy was assumed, but patient clinical conditions so far do not allow it. Transplantation is currently contraindicated.

Conclusion: These evidences underline the necessity of scrupulous evaluation of polycystic kidneys and their anatomic relationship with the liver before nephrectomy. Nephrectomy is frequently considered in the preparation for renal transplantation. In light of these possible complications, maybe removal
of kidneys should be considered carefully in ADPKD patients with large involvement of the liver by cysts.

ADTKD DUE TO MUC-1 GENE MUTATION: A MAJOR DIAGNOSTIC CHALLENGE, NOT IDENTIFIED BY EXOME SEQUENCING

Giulia Sossai1, Marco Moscato1, Ilaria Gandolfini1, Marco Delante1, Simona Mellone2, Mara Giordano1, Calogero Cirami1 and Marco Allinovi1

1Nephrology operating unit, Florence University Hospital, Medicine and Surgery, University of Florence, Florence, Italy; 2Nephrology operating unit, Parma University Hospital, Medicine and Surgery, University of Parma, Parma, Italy and 3Laboratory of Genetics, University of Eastern Piedmont, Department of Health Sciences and IRCAD, Novara, Italy

Background and Aims: Autosomal dominant tubulointerstitial renal disease (ADTKD) is a rare cause of end-stage renal disease (ESKD) in adulthood. In addition to its rarity, ADTKD is probably underdiagnosed due to the very non-specific and heterogeneous clinical-laboratory-histopathological-instrumental picture and because of the diagnostic need to use specific methods of genetic investigation in order to highlight the mutations within the VNTR sequences of the MUC1 gene, not recognized by the most common exome sequencing. Mutations in the MUC1 gene, together with those in the UMOD gene, are the main mutations implicated in the pathogenesis of ADTKD.

Table 1: Genetic, clinical and laboratory characteristics of our cohort of patients with ADTKD due to MUC1 gene mutation.

ESKD, end-stage renal disease; CKD, chronic renal failure. In brackets the number of patients presenting the specific characteristic, out of the total number of patients for which data is available.

Figure 1: Family tree of a family followed by our center for familial nephropathy with MUC1 positive genetics.

Method: We analyzed the clinical, laboratory and histopathological characteristics of four families followed by our center with suspected diagnosis of ADTKD and detection of mutation of the MUC1 gene.

Results: Our data (Table 1) revealed a marked phenotypic variability, even within members of the same family (Fig. 1), and in particular as regards the age of disease onset and the different rate of progression towards ESKD (range 16 – 88 years). From a laboratory point of view, in 10 out of 13 patients the sediment was negative, and only in 3 patients proteinuria > 1 g/24h was highlighted. In 6/13 the onset occurred at the age of less than 35 years and among these, 4 of them presented ESKD early. In the few cases in which renal biopsy was performed (4/17), representing 0.4% of all biopsies in our centre, the most frequent finding was the presence of tubular atrophy and interstitial fibrosis (3/4), with cystic ectasia of the tubular lumen at the cortical-medullary level in half of the cases. Among the 10 patients subjected to genetic analysis, only in one case the mutation was highlighted by exome sequencing.

Conclusion: The large phenotypic variability, in particular of age at achievement of ESKD, suggests that other factors (modifier or environmental genes) could also affect disease progression. Common gene sequencing methods (e.g. exome sequencing, Sanger) have proved unable, in most cases, to identify mutations within the VNTR sequences of the MUC1 gene.

AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE (ADPKD) PATIENT CHARACTERISTICS ASSOCIATED WITH BETTER RESPONSE TO TOLVAPTAN TREATMENT

Vasiliki Gikas1, Eirini Evangelou1, Dimitra Gkalitsiou1, Paraskevi Liaveri1, Michaela Louka1, Angelos Drakopoulos4, Eirini Tigka1, Kyriaki Vasileiou1, Mihail Tsagkatakis2 and George Tsirpanlis1

1General Hospital of Athens “G. Gennimatas”, Athens, Greece and 2Bioiatriki, Department of Magnetic Resonance, Greece

Background and Aims: Tolvaptan treatment is indicated in patients with rapidly progressive ADPKD. The factors associated with a favorable mediation response are not completely analyzed. We looked into the characteristics of ADPKD patients who responded better to tolvaptan treatment after three years of treatment.

Method: Forty-one (41) patients, 18 females, 23 males, with rapidly progressive ADPKD (Mayo Clinic Imaging Category, MCIC, 1C, 1D and 1E, mean (SD) age 42.5 (8.6) years and estimated-glomerular filtration rate (eGFR) > 25 ml/min) who completed three years treatment with tolvaptan, were included in the study. Total kidney volume (TKV) was measured using Magnetic Resonance Imaging at the initiation of the study and 3 years post treatment. The expected e-GFR decline at 3 years without treatment was calculated using the Mayo Clinic formula (Irazabal MV et al., JASN, 2015) and compared to the e-GFR found after three years of tolvaptan treatment (e-GFR measured after 3 years of treatment versus expected e-GFR). Based on the same formula, the End Stage Renal Disease (ESRD) prediction was calculated, before and after 3 years of treatment (i.e. we focused on the difference between the ESRD prediction calculated prior to treatment initiation and the prediction calculated with the data measured after 3 years of treatment). The above mentioned differences in e-GFR and ESRD prediction were used as response to treatment markers and correlated with a series of patient characteristics (age, sex, age at ADPKD diagnosis, presence of hypertension (HTN) and age at HTN onset, age at ESRD of the affected parent, TKV, MCIC, etc) using univariate and multivariate statistical analysis.

Results: The median (IQR) difference between e-GFR measured after three years of tolvaptan treatment and the expected without treatment was 5.3 (-1.3, 8.7) ml/min (i.e. more than the expected at 3 years without treatment). The median (IQR) prediction of ESRD had been prolonged by 1 (0, 2) years of tolvaptan treatment and the expected without treatment was 5.3 (4.0, 6.3) years.

Abstracts
In univariate analysis, the baseline e-GFR (immediately before treatment) and the age at which the affected parent had developed ESRD were both positively associated with the e-GFR improvement and ESRD prediction prolongation (p = 0.02, 0.047, 0.01, and 0.02, respectively). In multivariate analysis, e-GFR improvement was associated with the age of the patient at treatment initiation (β = -0.9, 95%CI: -1.52 - 0.29, p = 0.006), the age of the patient at hypertension diagnosis (β = 0.88, 95%CI: 0.25 - 1.52, p = 0.008) and the age at which the affected parent had developed ESRD (β = 0.57, 95%CI: 0.16 - 0.98, p = 0.008). In addition, ESRD prediction prolongation was associated with the initial e-GFR (p = 0.001), the age at which the affected parent had developed ESRD (p = 0.013) and the MCIC (β = 1.93, 95%CI 0.46 – 3.39, p = 0.013) (i.e. greater ESRD prediction prolongation for patients at MCIC 1E than at 1C).

Conclusion: Tolvaptan treatment seems to be more efficient in younger patients with rapidly progressing ADPKD, well-preserved renal function, a less severe family history, and a shorter chronicity of hypertension.

Figure 1: The proportion and number of antihypertensive and diuretic drugs used in Polish and Japanese patients with ADPKD.
Primary hyperoxaluria type 1 (PH1) is a rare genetic disease in which hepatic oxalate overproduction can lead to kidney stones, nephrocalcinosis, kidney failure, and systemic oxalosis, a condition in which calcium oxalate is deposited in various tissues, including bone [1]. Radiological signs of bone oxalosis include findings such as dense metaphyseal bands and coarse trabeculation [2]. No scale exists to grade bone oxalosis severity using X-rays.

Method: An X-ray grading scale to evaluate systemic oxalosis in specific bones was developed based on expert opinion. Scores on individual items ranged from 0−4, except for ribs and spine, which ranged from 0−2. Higher values represent more advanced oxalosis. To validate the scale, 85 X-ray images from 5 pediatric patients with PH1 who had developed bone oxalosis were collected from charts at Shaare Zedek Medical Center and de-identified [2]. Two blinded, independent raters evaluated each X-ray twice and assigned a grade to each applicable item on the scale. Inter-rater and intra-rater reliability analyses were conducted using the weighted Cohen’s kappa with asymptotic 95% confidence intervals (CIs) of the estimate and interpreted as proposed in the literature [3].

Total weighted kappa estimates were generated by pooling all observed ratings across all items. Results: Total overall inter-rater (0.83 [95% CI: 0.79, 0.87]) and intra-rater (0.95 [0.93, 0.97]) kappas demonstrate almost perfect agreement. Overall inter-rater kappa estimates were >0.8 to 1.0 (almost perfect agreement) for the left hand/wrist, left hip, left knee (femur), and left humerus; >0.6 to 0.8 (substantial agreement) for the right hip, right knee (tibia), right humerus, spine, and ribs; and >0.4 to 0.6 (moderate agreement) for the right knee (tibia) and right knee (fibula). The overall inter-rater kappa estimate for the left knee (fibula) demonstrated poor agreement (<0.08 to −0.27, 0.10)). Overall inter-rater kappa estimates for the right hand/wrist and left tibia (tibial) were considered unreliable due to lack of variability in the data, and the standard errors were not estimable. Calculable overall intra-rater kappa estimates were >0.8 to 1.0 (almost perfect agreement) for the spine and >0.6 to 0.8 (substantial agreement) for the right knee (femur) and right knee (fibula). Most other overall intra-rater kappa estimates could not be calculated because the kappas for one or both raters lacked variability. In these instances, intra-rater kappa estimates for the first and second raters demonstrated moderate to almost perfect agreement (>0.4 to 1.0; left hand/wrist, right hip, left hip, left knee [femur], right knee [tibia], left knee [tibia], right humerus, left humerus, and ribs). For the left knee (fibula), intra-rater kappa estimates for the first and second raters were −0.14 (−0.34, 0.05) and 1.00, respectively, and for the right hand/wrist, they were 1.00 and 0.00.

Conclusion: We developed a novel X-ray–based bone oxalosis grading scale for patients with PH1. Total overall weighted kappa estimates for inter-rater and intra-rater reliability demonstrated almost perfect strength of agreement. Most individual items demonstrated reliable kappa estimates. The right and left knee (fibula) were removed from the scale due to poor reliability.

* Kruskal Wallis Test

**Background and Aims:** The most prevalent hereditary kidney disease is autosomal dominant polycystic kidney disease (ADPKD). Multiple cysts developing in the kidneys are a defining feature of this systemic, progressive disease. The quality of life, psychosocial load, and discomfort associated with renal volume in people with ADPKD have not been well studied. This study aimed to examine the relationship between renal volume, psychological issues brought on by pain and the burden of the disease, and deteriorating sleep quality in ADPKD patients.

**Method:** The study included sixty patients who were being treated in the nephrology clinic at the Bursa Uludag University Faculty of Medicine Hospital. The ADPKD Pain and Discomfort Scale (ADPKD-PDS), Beck Depression Inventory Questionnaire, Beck Anxiety Scale, Pittsburgh Sleep Quality Scale (PSQI), and Insomnia Severity Index (ISI) were assessed. The computed tomography ellipsoid formula was used to determine the total kidney volume, and kidney volume adjusted for body size was obtained for each patient. The eGFR values computed using the CKD-EPI algorithm and the patients’ baseline biochemical parameters were recorded.

**Results:** The mean age at diagnosis was 31±13, and the mean total kidney volume (TKV) was 1526.3±1595.90. Eight (13.3%) individuals were determined to have mild mood disorders, whereas seven (11.7%) patients had borderline clinical depression. Four individuals (6.7%) were found to have severe anxiety. It was shown that 25% of the patients had poor sleep quality. There was no statistically significant difference in kidney volume between the depression groups or between the pain and discomfort scale sub-dimensions (Table 1).

**Conclusion:** It was shown that, in accordance with the literature, the severity of depression increased as the patients’ sleep quality declined in ADPKD patients. However, there was no significant relationship between kidney volume and the degree of anxiety, depression, pain or discomfort.

#5882

**AN EXCEPTIONAL CASE OF A PATIENT WITH TWO RARE GENETIC VARIANTS OF AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE AND ALOPT SYNDROME**

João Venda, Andrea Dos Santos Henriques, Rita Leal and Rui Alves

Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Background:** Alport syndrome and autosomal dominant polycystic kidney disease (ADPKD) belong to the most prevalent monogenic causes of chronic kidney disease (CKD) and both progress to end stage renal disease (ESRD). Alport syndrome, is caused by mutations in genes encoding collagen IV protein family. Inheritance might be X-linked, autosomal recessive, autosomal dominant or digenic and several pathogenic variants have been identified. ADPKD is mostly caused by mutations in PKD1 and PKD2 genes but recently, the GANAB gene, that encodes the glucosidase II subunit, has been identified has a cause of a milder form of ADPKD. We present a case report of a patient with CKD-4, bilateral sensorineural hearing loss and multiple renal cysts where two unrelated and distinct genetic variants of both diseases were concomitantly found.

**Case report:** A 63-year-old caucasian male with medical history of arterial hypertension, hematuria and bilateral sensorineural hearing loss since his 40 years-old, with cochlear implant surgery 13 years ago was referred to the Nephrology unit due to progressive CKD, currently stage 4. His mother had ESRD of unknown etiology, in peritoneal dialysis since the age of 78 years and he has two healthy sons (aged 16 and 20 years old). Physical examination was irremarkable. Laboratorial workout showed serum creatinine of 2.7 mg/dL, ratio albumin/creatinine of 105mg/g with 11 erythrocytes in urinary sediment. Renal ultrasound showed normal sized kidneys with more than 10 cysts in each kidney, the biggest with 44mm. Genetic testing via next generation sequencing was performed revealing heterozygous mutations in COLA43 (c.4421T>G.p.(Leu1474Pro)), reported in ClinVar, and described in literature as an autosomal dominant variant present in Alport families. A mutation in the GANAB (c.2281A>G.p.(Thr761Ala)) gene, classified as variants of unknown significance in was also detected, but this mutations is not reported in gnomAD or ClinVar. The patient was referred for genetic counseling.

**Conclusion:** We describe a rare case of possible overlap of ADPKD and Alport syndrome. The COLA43 mutation is described has having a risk ≥ 20% of developing ESRD, but the association of a mild variant of ADPKD might increase exponentially this risk.
and 1E (n = 17). Those who received tolvaptan showed a lower eGFR decline from baseline compared to predicted (eGFR 66.7 ± 32.7 vs 61.5 ± 29.1, p < 0.001), while a greater benefit was observed in Class 1E (eGFR 60.1 ± 36.5 vs 52.4 ± 29.5, p = 0.003) and in patients with eGFR > 45ml/min (eGFR 79.4 ± 28.8 vs 73 ± 25.2, p = 0.001).

Conclusion: Our initial experience from long-term administration of tolvaptan in patients with ADPKD demonstrates benefit on kidney disease progression. The widespread use of tolvaptan in a larger number of patients and their long-term follow up are necessary to draw more secure conclusions.

Results: PH1 was confirmed due to Homozygous mutation AGXT c.731T>C9 [p.(Ile244Thr)]. Oxalate on cord blood was 15 umol/L (nv <10), on amniotic fluid 55 umol/L (nv 19-71), on first urine 401 umol/mmolCr (nv <300 umol/mmolCr). Blood Oxalate at 6h of life rose to 32 umol/L, Glycolate to 107 umol/L and urinary Oxalate to 573 umol/mmolCr. Serum Creatinin was normal (0.3 mg/dl). At 6 hours of life the child was treated with Glycolate Oxidase RNAi Lumasiran at the dose 6 mg/kg subcutaneously, in combination with Pyridoxin 10 mg/kg/day. Hyperhydration (240 ml/kg/day) was maintained iv for 16 days in combination with oral water and potassium citrate (500 mg in 500 ml/day) above breast feeding. Blood Oxalate was serially assessed every 48 hrs showing a peak level of 108 umol/l (nv <10) at day 6, higher than the supersaturation level of 60 umol/L, then a gradual decline (65-56-62 umol/L at 10-20-30 days respectively). Lumasiran 6 mg/kg was repeated at 30 and 60 days according to schedule, then at 3 mg/kg every month. After the second dose of Lumasiran a steeper decline of blood Oxalate was observed (31-17 umol/L at 45-60 days respectively) reaching the upper normal limit of 12 umol/L after three doses, at 80 days. Urinary Oxalate in spite of Lumasiran early start rose until a maximum of 4173 umol/mmolCr (nv for age <300 umol/mmolCr) at 13 days and gradually declined to 765 umol/mmolCr at 80 days, after three doses. Blood and urine Glycolate initially paralleled Oxalate then increased after each Lumasiran dose. Renal ultrasound normal at birth, showed only minimal hyperchogenic spots during the first 2 months, then mild bilateral hyperchogenic papillary deposits without signs of nephrocalcinosis/stones. Renal function at 3 months of life is normal (serum Creatinine 0.2 mg/dl); child growth on the higher centiles (7 kg), with no adverse events.

Conclusion: Blood and urine Oxalate serial analysis in a severe case of PH1 treated immediately after birth show that Glycolate Oxidase inhibition has a latency of at least 15 days, even when no previous deposits are present. In these days extremely high level of urine and blood Oxalate, far higher than supersaturation level, are reached, in spite of normal renal function, hyperhydration, B6 and citrate supplementation. This case confirms that familiar severe forms of PH1 should be treated immediately after birth with Lumasiran in combination with aggressive supportive therapy to avoid irreversible nephrocalcinosis and renal failure. Prenatal treatment of these cases might be considered in future.

OXALATE METABOLISM IN PRIMARY HYPEROXALURIA TYPE 1 TREATED WITH LUMASIRAN IMMEDIATELY AFTER BIRTH: STILL NOT ENOUGH

Licia Peruzzi1, Marta Leporati2, Michele Petraruolo2, Vitor Dias Martins1, Luca Marozio3, Alessandra Coscia4, Roberta Camilla1, Francesca Mattezzi2, Silvia Deaglio5 and Bruno Gianoglio1

1Regina Margherita Children’s Hospital, Pediatric Nephrology, Turin, Italy, 2Ospedale Mauriziano, Laboratorio Calcolosi, Turin, Italy, 3University of Turin, Obstetrics and Gynecology, Turin, Italy, 4University of Turin, Neonatal Intensive Care Unit, Turin, Italy and 5Immunogenetics and Transplant biology, CDSS, Turin, Italy

Background and Aims: Severe primary hyperoxaluria type 1 (PH1) with rapid onset nephrocalcinosis and renal function loss in early infancy required so far combined liver and kidney transplant. RNA interfering drugs are the new challenge for these children. Here we present the first case of a newborn affected by PH1 treated with RNA-interfering Lumasiran 6 hours after birth.

Method: Diagnosis of PH1 (homozygous mutation AGXT c.731T>C9 [p.(Ile244Thr)]. Oxalate on cord blood was 15 umol/L (nv 19-71), on first urine 401 umol/mmolCr (nv <300 umol/mmolCr). Blood Oxalate at 6h of life rose to 32 umol/L, Glycolate to 107 umol/L and urinary Oxalate to 573 umol/mmolCr. Serum Creatinin was normal (0.3 mg/dl). At 6 hours of life the child was treated with Glycolate Oxidase RNAi Lumasiran at the dose 6 mg/kg subcutaneously, in combination with Pyridoxin 10 mg/kg/day. Hyperhydration (240 ml/kg/day) was maintained iv for 16 days in combination with oral water and potassium citrate (500 mg in 500 ml/day) above breast feeding. Blood Oxalate was serially assessed every 48 hrs showing a peak level of 108 umol/l (nv <10) at day 6, higher than the supersaturation level of 60 umol/L, then a gradual decline (65-56-62 umol/L at 10-20-30 days respectively). Lumasiran 6 mg/kg was repeated at 30 and 60 days according to schedule, then at 3 mg/kg every month. After the second dose of Lumasiran a steeper decline of blood Oxalate was observed (31-17 umol/L at 45-60 days respectively) reaching the upper normal limit of 12 umol/L after three doses, at 80 days. Urinary Oxalate in spite of Lumasiran early start rose until a maximum of 4173 umol/mmolCr (nv for age <300 umol/mmolCr) at 13 days and gradually declined to 765 umol/mmolCr at 80 days, after three doses. Blood and urine Glycolate initially paralleled Oxalate then increased after each Lumasiran dose. Renal ultrasound normal at birth, showed only minimal hyperchogenic spots during the first 2 months, then mild bilateral hyperchogenic papillary deposits without signs of nephrocalcinosis/stones. Renal function at 3 months of life is normal (serum Creatinine 0.2 mg/dl); child growth on the higher centiles (7 kg), with no adverse events.

Conclusion: Blood and urine Oxalate serial analysis in a severe case of PH1 treated immediately after birth show that Glycolate Oxidase inhibition has a latency of at least 15 days, even when no previous deposits are present. In these days extremely high level of urine and blood Oxalate, far higher than supersaturation level, are reached, in spite of normal renal function, hyperhydration, B6 and citrate supplementation. This case confirms that familiar severe forms of PH1 should be treated immediately after birth with Lumasiran in combination with aggressive supportive therapy to avoid irreversible nephrocalcinosis and renal failure. Prenatal treatment of these cases might be considered in future.

UMOD exon 11 deletion, which was excluded in two healthy relatives (III-1, III-4), establishing the primary diagnosis of ADTKD-UMOD. It is noteworthy that the only two gross UMOD deletions associated with ADTKD affected evolutionarily conserved residues in exon 4 [1]. The presence of the SLC8A1 p.(Arg6*) allele in patients IV-1 and IV-2, who had early clinical presentations, together with its absence in patient III-5, who had a significantly later clinical onset than her older brother (III-2), suggests that it exerted a pathogenic or disease modifier role in this family, in accordance with the predicted protein truncating effect. Indeed, genome-wide linkage analysis in 5 multiplex families with ADTKD identified involvement of chromosome 2p22.1-p21; SLC8A1 was the most likely gene but no pathogenic variants could be identified; copy number variants might have been missed [2]. Unfortunately, in our family study, we could not identify any subject segregating only the SLC8A1 p.(Arg6*) allele, which would have been indispensable to demonstrate its pathogenicity.

Conclusion: Herein, we report a family with hyperuricemic nephropathy where genetic testing identified a novel, likely pathogenic UMOD variant. The mechanisms underlying the pathogenicity of exon 11 deletion require further study. Additionally, the co-segregation of an ultra-rare nonsense SLC8A1 variant in some individuals was associated with earlier onset and faster progression of CKD, suggesting once again a role for SLC8A1 in the pathogenesis of ADTKD.

FABRY DISEASE: A DESCRIPTIVE STUDY OF A COHORT OF PATIENTS
Nuria Garcia Pablos¹, Remedios Garofano², Carlos Gomez² and Francisco Gonzalez³
1 Torrecárdenas Hospital, Nephrology, Almería, Spain and 2 Torrecárdenas Hospital, Cardiology, Spain

Background and Aims: Fabry disease is a rare X-linked disease, caused by deficient activity of the lysosomal enzyme α-galactosidase A. Accumulation of globotriaosylsphingosine leads to organ failure and premature death. The aim of this study is to describe the population of patients with Fabry disease in our healthcare area.

Method: Descriptive observational study of patients with Fabry disease (n = 23). Demographic, clinical and treatment variables were analysed.

Results: The mean age of the patients was 47.5 years; 70% female. Symptom onset was at 18 years, being diagnosed 25 years later, similar to that described in the literature. Enzyme deficiency was observed in 61% of patients. Four types of pathogenic variants of the GLA gene were detected. The most prevalent was P205S, followed by W262X, V199G, and G80D. 48% of the patients had left ventricular hypertrophy (55% women). 48% had right bundle branch block, atrial fibrillation and sinus bradycardia. 47% (64% women) had renal involvement, defined by proteinuria. Other manifestations: hypocoagulability (17%), acropaesthesia and neuropathic pain (13%), ophthalmological (13%) and dermatological (4%). 22% were treated with ACE inhibitors/ARA II. 1 patient received isGLT2. Other complementary treatments: statins (22%), antiaggregants (13%), anticoagulants (13%), and Digoxin (1 patient). Regarding specific treatment, 43% were treated, the majority (39%) received enzyme replacement therapy with agalsidase beta (only 1 patient with agalsidase alpha), one patient received migalastat.

Conclusion: The characteristics of our patients are similar to those described in the literature. We observed a predominant general involvement in women, in contrast to other series. Cardiac involvement predominates with left ventricular hypertrophy; and renal involvement with proteinuria.

The diagnostic delay is similar to that described, emphasizing the need for early diagnosis and treatment to avoid severe complications and death.

COMPLICATIONS AND TREATMENT OF HYPERCALCIURIA IN FAMILIAL HYPERKALAEMIC HYPERTENSION (FHH)
Viola D’ambrosio¹,², Olivia Mcknight¹, Elizabeth Wan¹, Robert Speller³, Robert Moss¹, Keith Siew² and Stephen Walsh²
¹Università Cattolica del Sacro Cuore di Roma, Rome, Italy, ²University College of London, Department of Renal Medicine, London, United Kingdom and ³University College of London, Department of Medical Physics and Biomedical Engineering, London, United Kingdom

Background and Aims: Hypertension is frequently associated with hypercalciuria, nephrolithiasis and low bone mineral density. Familial Hyperkalaemic Hypertension (FHH) causes hypercalciuria, although complications of this are not reported.

Method: We examined a cohort of 9 patients with genetically confirmed FHH. Biochemical, radiological, and clinical data was obtained in patients before and after thiazide treatment. All patients gave informed consent. The study had ethics committee approval. Data were compared using paired t tests.

Results: 5 of the 9 patients were female (median age 41.7 years). The genetic diagnosis was confirmed in all patients, 5 patients had variants in KLHL3, 3 patients had variants of WNK4, and one had a variant of WNK1 (Table 1). Pre-treatment potassium was high (median 5.6 IQR 5.2-6.2 mmol/L). Pre-treatment calcium was in the normal range (2.34 IQR 2.29-2.38 mmol/L). There was significant hypercalciuria with a raised urinary calcium/creatinine ratio (0.69 IQR 0.41-1.13). However, PTH (4 IQR 3.95-4.35 pmol/L), phosphate (1.15 IQR 1.25mmol/L) and alkaline phosphatase (57 IQR 45-84 mmol/L) were all in the normal range. Thiazide treatment significantly reduced hypercalciuria (calcium/creatinine ratio 0.15 IQR 0.05-0.29 p = 0.04) as well as the serum potassium (3.9 IQR 3.5-4.4 mmol/L p = 0.0167) (Table 1). Patients also developed complications of hypercalciuria. 3 patients had kidney stones demonstrated on cross-sectional imaging (Figure 1). One of these patients (male, 30 years old) had DXA criteria for osteoporosis (T score Femoral neck -1.5, lumbar spine -2.4).

Conclusion: This is the first case series to demonstrate complications of hypercalciuria (i.e. kidney stones) in patients with FHH. We demonstrate that thiazide treatment normalises urinary calcium excretion. Thiazide treatment may have clinical utility in FHH even if hypertension or hyperkalaemia are not problematic in order to avoid the complications of hypercalciuria.

EVOLUTION OF HYponatreMIA IN PATIENTS WITH CHRONIC SIADH TREATED FOR 1 YEAR WITH ORAL UREA

Yésika Amézquita1,2, Yolanda Hernández1, Raquel Díaz1, Silvia Caldes Ruisánchez1, Gabriel Ledesma1, Verónica Ruth Mercado Valdivia1, R Echarri Carrillo1, Cristina Andreu1, Israel Thuissard1, Ángel Gallegos Villalobos1, María Covadonga Hevia Ojanguren1 and Antonio Cirugeda1

1Hospital Infanta Sofia, Nephrology, San Sebastián de los Reyes, Spain,
2Infanta Sofia University Hospital, Madrid, Spain and 3Universidad Europea de Madrid (Campus Villavicosa), statistics, Villaviciosa de Odón, Spain

Background and Aims: Hyponatremia (<135mEq/L) is the most common electrolyte disorder observed in clinical practice, associated with increased hospital admissions and mortality. One of its causes is the syndrome of inappropriate antidiuretic hormone secretion (SIADH). In chronic SIADH, urea is considered as a therapeutic possibility among other measures; however, its use is not widespread due to few studies on its efficacy.

Objects: To evaluate sodium levels in patients with chronic SIADH who received oral urea for at least 12 months.

Method: Observational, descriptive and retrospective study. Population: 13 patients with SIADH under treatment with urea for 12 months. The relationship between natremia and the rest of the clinical variables was analyzed using Chi-square, Student’s T test, and ANOVA or their corresponding non-parametric tests.

Results: Mean age: 64 years ±15. Men: 61% (n=8). Comorbidities: hypertension (50%, n=6), CKD (30.7%, n=4), diabetes (15.3%, n=2). SIADH etiology: Antiepileptics (n=4), idiopathic (n=3), intracranial pathologies (n=5) and cancer (n=1). 61% required admission for SIADH. Median of 10 ±6 months from diagnosis to start of treatment. The initial
dose was: 15 grams/day (53%, n = 7), 15 grams every 48 hours (30%, n = 4) and 15 grams every 72-96 hours (17%, n = 2). At one year, 61% of patients maintained the same dose (n = 8) and 39% of patients required an increase in the dose (n = 5) and of these 3 patients they increased to 30 grams/day. The treatment was well tolerated, only 1 patient out of 13 (7.6%) reported nausea and dysgeusia, no patient presented hypernatremia (Na >145 meq/L), hospital admissions due to SIADH, or adverse effects that led them to discontinue urea.

**Conclusion:** After a year of treatment, urea increases and maintains plasma sodium in the normal range safely in chronic SIADH. Treatment with urea is well tolerated, avoids hospitalizations, and is not associated with complications from its use.

**HYPERCHLOREMIC METABOLIC ACIDOSIS AFTER PLASMAPHERESIS IN A PATIENT WITH RENAL TRANSPLANT REJECTION: A CASE REPORT**

Sanédy Simon1,2, Marit van Sandwijk1,3 and Rik Olde Engberink1,2  

1 Amsterdam UMC location University of Amsterdam, Department of Internal Medicine, Section of Nephrology, Amsterdam, Netherlands,  
2 Amsterdam Cardiovascular Sciences, Microcirculation, Amsterdam, Netherlands and 3Dianet Dialysis Centre, Amsterdam, Netherlands

**Background and Aims:** Plasmapheresis is an effective therapeutic intervention for several renal disorders, including renal transplant rejection. However, repeated plasmapheresis can cause various side effects and complications. We present a 61-year-old male with a medical history of type 2 diabetes, hypertension, successfully treated multiple myeloma and a post-mortem kidney transplantation 7 months ago. The patient was hospitalized because of rapid deterioration of his renal function (eGFR CKD-EPI 15 ml/min/1.73m²). Renal biopsy of the transplanted kidney confirmed the diagnosis of antibody-mediated transplant rejection. Treatment with methylprednisolone, plasmapheresis with a 40 g/L albumin solution as a replacement fluid and intravenous immunoglobulins was initiated. After 4 plasmapheresis treatments, the patient developed gastrointestinal complaints and muscle weakness. Despite the patient's use of 3 grams of oral sodium bicarbonate supplements a day, laboratory tests revealed a hyperchloremic metabolic acidosis: bicarbonate 11.7 mmol/L, chloride 111 mmol/L, sodium 138 mmol/L. Metabolic acidosis due to citrate accumulation was ruled out with a normal total-to-ionized calcium ratio. After treatment with intravenous bicarbonate supplementation, the symptoms disappeared. Analysis of the albumin plasmapheresis solution showed a chloride concentration of 132 mmol/L.

**Results:** This is the first case that describes metabolic acidosis after albumin plasmapheresis in a patient with impaired renal function. The observed hyperchloremic metabolic acidosis is most likely the result of the administration of large volumes (3.5 litres per session) of a 4% albumin solution with high chloride concentrations. We hypothesize that patients with renal impairment are more prone to develop metabolic acidosis after plasmapheresis with albumin-saline replacement fluids due to their reduced renal capacity to excrete excess acid and chloride.

**Conclusion:** Special attention should be paid to the acid-base balance during plasmapheresis in patients with impaired renal function. Future research should investigate the incidence of hyperchloremic metabolic acidosis during albumin plasmapheresis in different eGFR categories.
EFFECTS OF URIC ACID-LOWERING THERAPY ON RENAL OUTCOMES IN CKD PATIENTS WITH ASYMPTOMATIC HYPERURICEMIA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Yuxin Luo, Qirong Song, Sha Fu, Honglei Wang, Xiaofei Shao, Junzhe Chen and Ying Tang

The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, China

Background and Aims: It is well known that hyperuricemia and gout play an important role in the adverse cardiovascular and renal events both in patients with and without renal disease. However, the effect of uric acid-lowering therapy (ULT) on renal outcomes of CKD patients with asymptomatic hyperuricemia remains controversial. Therefore, our study summarized reliable results draw from published randomized controlled trials (RCTs) to evaluate the effects of ULT on renal and cardiovascular outcomes in CKD patients with asymptomatic hyperuricemia.

Method: Pubmed, EMBASE, China National Knowledge Internet (CNKI) and the Cochrane Library were searched systematically for trials up to October 2021. RCTs assessing the effects of uric acid-lowering agents on renal and/or cardiovascular outcomes in CKD patients with asymptomatic hyperuricemia were included. Both the fixed-effect and the random-effect models were used.

Results: A total of 17 RCTs (one trial divided patients into two groups according to CKD stages), including CKD patients with asymptomatic hyperuricemia were included in this meta-analysis. Compared with placebo or no treatment group, ULT group showed a higher estimated glomerular filtration rate (eGFR) with a weighted mean difference (WMD) of 3.679 mL/min/1.73 m², 95% CI [-1.592, 5.766] (p = 0.001) and a lower serum creatinine (Scr) with a WMD of -46.131 umol/L, 95% CI [-65.643, -26.619] (p < 0.0001). Subgroup analysis demonstrated a significant benefit from ULT in patients with CKD stage 1-3 (p = 0.035), from Asian countries (p = 0.005) and those younger than 60 years (p = 0.002). At the same time, ULT was associated with lower incidence of events of doubling of Scr without dialysis (relative risk (RR) 0.314 [0.203, 0.485] (p < 0.0001)). However, no difference was found for all-cause mortality, incidence of AKI, progression to end-stage kidney disease (ESKD), and cardiovascular events. In addition, ULT with allopurinol was associated with lower cardiovascular events (RR 0.678 [0.473, 0.971] (p = 0.034)).

Conclusion: ULT could slow down the progression of renal impairment in CKD patients complicated with asymptomatic hyperuricemia, especially for patients under 60 years old, early CKD stage(1-3) and the Asian descent.

Figure 1: Forest plot for the effect of uric acid-lowering therapy (ULT) on the change in estimated glomerular filtration rate (eGFR).
THE ASSOCIATION BETWEEN THE LEVELS OF URIC ACID AND RENAL OUTCOMES IN EARLY CKD PATIENTS: A MULTI-CENTER REAL-WORLD DATA ANALYSIS

Yuxin Luo1, Qirong Song1, Sha Fu1, Qin Liu1, Xiaohong Chen2, Sheng Nie3, Junzhe Chen1 and Ying Tang1

1The Third Affiliated hospital of Southern Medical University, Department of Nephrology, Guangzhou, P.R. China, 2Sun Yat-sen University research center of water resources and environment, Guangzhou, P.R. China and 3National Clinical Research Center for Kidney Disease, Guangdong Provincial Institute of Nephrology, Guangdong Provincial Key Laboratory of Renal Failure Research, Division of Nephrology, Nanfang Hospital, Southern Medical University, Guangzhou, P.R. China

Background and Aims: It is well known that serum uric acid (SUA) plays an important role both in patients with and without chronic kidney disease (CKD). However, the effect of SUA on renal outcomes of CKD patients, especially with asymptomatic hyperuricemia, remains controversial. Therefore, our study explores the relationship between SUA and adverse events in early CKD (stage 1-3) patients in a real-world setting.

Method: This multi-center real-world study analyzed the data from Chinese Renal Data System (CRDS). Eligible CKD patients (eGFR) (estimated glomerular filtration rate $\geq$ 30 mL/min/1.73 m$^2$) were enrolled. The primary endpoint is the decline of renal function defined as at least 40% decrease in eGFR. The secondary endpoints include onset of composite cardiovascular events and all-cause mortality. A multivariable cox regression model was used and the associations between levels of mean SUA and all endpoints were evaluated on a continuous scale with restricted cubic spline (RCS) curves based on Cox proportional hazards models. Kaplan-Meier survival curves were used to illustrate the ability of SUA to predict the end points.

Results: 25,202 adults (mean [SD] age, 52.59 [17.90] years, 8,212 male [46.1%], 9,604 female [53.9%]) were included in this study. During a median follow-up period of 2.61 years, 3,451 (15.9%) at least 40% decreased in eGFR. After adjustment for confounders, higher uric acid concentrations were independently associated with the higher risk for the decline of renal function [Per SD increment adjusted hazard ratio [aHR]: 1.41, 95%CI 1.36-1.47]; composite cardiovascular events [Per SD increment [aHR]: 1.04, 95%CI 1.01-1.07], all-cause mortality [Per SD increment [aHR]:1.32, 95%CI 1.14-1.54]. RCS curves showed that HRs for renal function progression, all-cause mortality and composite cardiovascular events increased significantly with the increase of SUA concentration in CKD patients. Results were consistent in stratified analyses. The KM curves suggested that patients with asymptomatic hyperuricemia had a substantially worse survival rate for renal function.

Conclusion: SUA is an independent risk factor for the decline of renal function, cardiovascular events and all-cause mortality in early CKD patients (stage 1-3). Treatment of asymptomatic hyperuricemia may be a potential avenue to improve outcomes in CKD patients.
Figure 1: Association between serum uric acid (SUA) concentrations and the primary endpoint (at least 40% decline in eGFR) using a restricted cubic spline (RCS) regression model. Multivariable adjusted HRs (blue solid lines) and 95% CIs (light blue shadow).

Figure 2: Kaplan-Meier curves showing survival of the primary endpoint (at least 40% decline in eGFR) for patients grouped by the level of SUA (asymptomatic hyperuricemia defined that SUA > 7.0 mg/dl (416.4 μmol/L) in men and > 6.0 mg/dl (356.9 μmol/L) in women with no prior gout flares).

CHANGES IN ALBUMINURIA AND KIDNEY FUNCTION AFTER 8 WEEK HIGH-INTENSITY INTERVAL TRAINING PROGRAM IN 2ND AND 3RD TRIMESTER OF PHYSIOLOGICAL PREGNANCY

Wojciech Wołyniec¹, Andrzej Kochanowicz², Łukasz Radzimński², Jan Mieszkowski², Marcin Renke¹ and Anna Szumilewicz²

¹Medical University of Gdańsk, Department of Occupational Medicine, Gdańsk, Poland and ²University of Physical Education and Sport-AWFIS, Department of Physical Culture, Gdańsk, Poland

Background and Aims: Physical exercise is the best prophylaxis of many disorders and should be continued during uncomplicated pregnancy. Several studies suggested that most pregnant women had no contraindications to perform intensive exercises. In recently published studies the beneficial effect of high-intensity interval training (HIIT) on both mental health and reduction of excessive weight gain during pregnancy has been demonstrated. The knowledge regarding kidney function after exercise in pregnancy is very scarce and only few studies concerning this topic were published. The aim of this study was to estimate changes in markers of kidney function in healthy pregnant exercising women. Changes after single intensive exercise and after 8 week training program were analyzed.

Method: The group of 36 women in 2nd and 3rd trimester of pregnancy were recruited to the study. At the beginning of the study all participants had normal kidney function (serum creatinine level below 0.6 mg/dl) and albuminuria (uACR below 30 mg/g) in rest. 19 women participated in 8-week HIIT program and 17 women in 8-week educational program (EDU group). Before and after 8 week training and education programs a progressive maximal exercise test on cyclometer was performed. Several biochemical measurements were performed.

Results: Women from both groups revealed mild changes concerning kidney function in rest, typical for physiological pregnancy (e.g. low sodium, creatinine and uric acid levels). After progressive maximal exercise test some unexpected findings were found: the fractional excretion of urea and uric acid increased (FeUrea from 41.25 to 50.05%; FeUA from 7.18 to 8.04%) and serum uric acid decreased significantly (sUA from 3.35 to 3.28mg/dL). Other changes after short exercise were typical: significant increase of uACR (from 5.12 to 21.65 mg/dL), among others. The 8-week HIIT training program did not change kidney function in rest. In both groups a significant increase of eCrCl and sUA were observed. The interesting observation was that uACR increased significantly only in EDU group.

Conclusion: Changes in kidney function after short intensive exercise in pregnancy were typical for healthy subjects, but there was no negative impact on markers of renal hyperperfusion. It was probably related to increased renal blood flow occurring in healthy pregnancy. The supervised 8-week HIIT training program had no negative impact on kidney function. The possible positive impact of this training on albuminuria was suggested.

CIRCULATING SCLEROSTIN AFFECTS URINARY CALCIUM EXCRETION AMONG STONE FORMERS

Fernanda Guedes Rodrigues¹, Milene Subtil Ormanjit, Igor Pietrobon¹, Ana Cristina Matos¹, Martin de Borst² and Ita Pfefferman Heilberg³

¹Federal University of São Paulo, Nephrology, São Paulo, Brazil, ²University Medical Center Groningen, Groningen, Netherlands and ³Federal University of São Paulo, Brazil

Background and Aims: Sclerostin plays an important role in bone metabolism and adipose tissue. Experimental studies suggest that sclerostin also influences urinary calcium excretion (Uca), but this relationship has not been addressed in humans. We aimed to study the association of Uca levels with serum sclerostin, bone mineral density (BMD) and body composition among stone-formers (SF).

Method: We retrieved data from patient records, including clinical characteristics, nutritional, biochemistry and hormonal data as well as BMD and body composition determined by dual energy X-ray absorptiometry. Serum sclerostin levels were measured using ELISA kits. Determinants of Uca were studied using multivariate linear regression.

Results: A total of 107 SF (35.8 ± 9.3 years, 54% male) with eGFR of 99.8 ± 14.5 mL/min/1.73 were included. The subjects were divided by sex and clustered into tertiles according to Uca as shown in Table 1. In men the highest Uca tertile had higher body mass index (BMI) and serum sclerostin levels, were more likely to have hypertension and metabolic syndrome, had lower lean mass, a trend towards higher fat mass (p = 0.06), and no statistical differences in BMD. Women in the highest Uca tertile had higher BMI and a trend towards higher serum sclerostin levels (p = 0.06), were more likely to have hypertension and metabolic syndrome, with no differences in BMD. Sclerostin was positively correlated with fat mass (r = 0.38, p = 0.004) and inversely correlated with lean mass (r = −0.32, p = 0.01) among men, but not among women. To further adjust for the influence of weight load on BMD for both sexes, the latter was also expressed as a ratio per BMI (BMD/BMI). Although lumbar spine BMD/BMI was inversely associated with Uca (β = -0.26, p = 0.01) in univariate analysis, it lost significance in the multivariate model (Table 2). Hypertension, metabolic syndrome and serum sclerostin were independent determinants of Uca (Table 2).

Conclusion: Present findings disclosed that serum sclerostin, hypertension and metabolic syndrome were independent determinants of urinary calcium in stone formers. These data suggest that in addition to the hormones traditionally thought to alter calcium reabsorption in the kidney, sclerostin may play a significant additional role, warranting further intervention studies in order to test potential medication strategies to reduce calciuria in this population.
Table 1. Clinical, biochemistry and BMD data of SF clustered into tertiles according to urinary calcium.

UNEXPLAINED METABOLIC ACIDOSIS - A DIAGNOSTIC DILEMMA
Abhishek Kumar
Paras HMRI, Nephrology, Patna, India

Background and Aims: Metabolic Acidosis is a common condition for which nephrology consult is sought. Most often the etiology is quite obvious like renal failure, diabetic ketoacidosis, lactic acidosis etc. We describe a case of high anion gap metabolic acidosis, unresponsive to medical management requiring hemodialysis, where finding the etiology became a diagnostic challenge because of medical and social reasons prevailing in this eastern part of India.

Method: A 55 year old obese gentleman came to emergency department at 3 am with complaints of restlessness, pain abdomen and chest discomfort for last 4-6 hours. On clinical examination he had tachycardia with normal blood pressure and oxygen saturation. His sensorium was normal and systemic examination did not reveal any major abnormality. A possibility of acute cardiac event was considered but his ECG showed sinus tachycardia, echocardiography did not show any wall motion abnormality and Troponin I was less than 0.01 ng/mL. His blood gases showed an uncompensated metabolic acidosis with an anion gap of 21 (pH 7.19 / pCO2 44 / HCO3 15). The laboratory parameters showed a serum creatinine of 0.9 mg/dL, random blood sugar of 130 mg/dL. Any history of poisoning or drug overdose was denied by patient’s attendants. Pending further workup patient was admitted in intensive care unit and correction of metabolic acidosis was started with intravenous sodium bicarbonate.

Results: The metabolic acidosis initially improved with medical management but within next 6 hours patient again had severe metabolic acidosis. Meanwhile patient’s sensorium worsened and he had an episode of seizure. Patient was intubated and mechanical ventilation started. Within 30 minutes patient had status epilepticus which ultimately required intravenous thiopentone. Hemodialysis was started for correction of metabolic acidosis. Patient’s history was re-evaluated. On persistent questioning his attendants admitted that patient had consumed alcohol 4-5 hours before the symptoms started. It is important to mention here that consumption of alcohol is a punishable offence in Bihar which a state in eastern part of India. Despite alcohol being completely banned in this part of country illicit alcohol is smuggled and consumed by some. Illicit alcohol is prone to be adulterated and sub-standard. It was because of this fact that patient’s attendants suppressed the facts. Also alcohol consumption is a valid ground for rejection of medical insurance claims because of obvious reasons. After obtaining the complete history a possibility of consumption of alcohol adulterated with methyl alcohol was very likely. Serum methyl alcohol estimation was not available at our institute and patient had already received hemodialysis hence it was not done. With patient already having seizures MRI (Magnetic Resonance Imaging) of brain was done. MRI brain revealed altered hyperintense signal with cytotoxic edema in bilateral basal ganglia predominantly putamen. Subcortical white matter in bilateral cerebral hemisphere and bilateral optic nerve head showed restriction on diffusion weighted imaging. These typical features on MRI were highly suggestive of methanol toxicity. These MRI features along with the clinical scenario and history of illicit alcohol intake helped us reach the diagnosis of methanol toxicity. Patient was managed with hemodialysis sessions to remove methanol from blood until he improved clinically.

Conclusion: The etiology of the high anion gap metabolic acidosis turned out to be methanol toxicity. Typical MRI brain findings helped confirm the diagnosis. Our case highlights the importance of obtaining the correct medical history and how social and medicolegal issues sometimes become a hindrance to obtaining the same.
Conclusion: In familial nephrocalcinosis/lithiasis/hyperparathyroidism genetic counselling and screening defines individualized treatment and may prevent extra renal disease manifestations.

THE BURDEN OF SYMPTOMS AND PROCEDURES IN PATIENTS WITH RECURRENT KIDNEY STONES – A REPORT FROM A STONE CLINIC
Rok Tilšič1, and Andrej Skoboren1,2
1 University Medical Center Ljubljana, Department of Nephrology, Ljubljana, Slovenia and 2Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

Background and Aims: Kidney stones (KS) are increasing in prevalence and becoming a major public health problem. The extent of the disease has been described as the stone burden, a measurement based on the size and number of stones. However, the quality of life of these patients is not affected by these parameters per se, but rather by the frequency and intensity of symptoms and the need for surgical procedures. The current data on this subject is very limited. The aim of our study was to record the frequency of symptoms and surgical procedures in patients with recurrent KS and to evaluate possible associations with basic clinical data and common comorbidities.

Method: We report a retrospective study on 181 consecutive patients with recurrent KS who were examined at the University Medical Centre Ljubljana stone clinic for the first time during the period of 2018 – 2022. We performed a standardized questionnaire to record common KS symptoms, procedures, basic clinical data, and comorbidities. Events were defined as number of severe lumbar pain (SLP) events per year (8-10/10 on the visual analog scale – VAS) and number of surgical procedures (SP) for stone removal per year. Moderate lumbar pain (MLP) events (VAS 4-7/10) and passing of stones were quantified on a scale from 0-4. Due to the wide variety of frequencies the associations were analyzed with Chi-Square test using terciles when possible or with presence and absence of symptoms. We considered p values < 0.05 as statistically significant.

Results: Mean age was 51.1 (SD 14.5) years, with 51.8% females. Arterial hypertension (AH) was present in 29.8% of patients, diabetes mellitus in 6.6%, and a family history of KS in 30%. The median frequency of SLP and SP was 0.68 (IQR 0.01-1) events/year and 0.08 (IQR 0.0-0.33) procedures/year, respectively; while 26.7% and 12.8% of patients had at least one SLP event or SP per year, respectively. When comparing terciles of frequency of SLP we found an association with more common SLP events in patients with a positive family history of KS, with 40.7% with and 21.6% of patients without a family history of KS, with 40.7% with and 21.6% of patients without a family history of KS, respectively (p = 0.033). When comparing terciles of frequency of procedures we only found a trend towards more common procedures in patients with AH (p = 0.062). The frequency of MLP was as follows – 42.6% had it less than once per year, 11.6% had it once or twice per year, 11% three to five times per year, 12.9% every month, and 21.9% on a weekly basis. We found no statistically significant association between MLP and basic clinical data or comorbidities only a trend towards more frequent episodes in patients with AH (p = 0.096).

In regards to the passing of KS we found the following frequencies – 72.4% had episodes less than once per year, 14.9% once or twice per year, 5.3% three to five times per year, 3.9% every month, and 3.3% on a weekly basis. There was statistically significant difference between passing of KS and sex, with 34.5% of males and 21.3% of females passing KS at least once per year, respectively (p = 0.047). Additionally, there was a significant difference between passing of KS and family history of KS, with 40.7% with and 21.6% of patients without a history of KS passing KS at least once per year, respectively (p = 0.008).

Conclusion: Our study showed that symptoms and surgical procedures were common in patients with recurrent KS referred to our clinic. Half of the patients had severe lumbar pain at least every three years, and a quarter had severe lumbar pain and passed KS at least once per year. About a third of patients had moderate lumbar pain at least once per month. Patients with a family history of KS developed stones earlier in life and had more common severe lumbar pain and passed KS more frequently. These issues should be analyzed in greater detail, with symptom scores that would define the burden of KS in a more objective manner and help in assessing the effectiveness of KS therapies.

SEDIMENT IN CLEAR AND CLOUDY URINE: CAN INTERMITTENT CATHETERS DRAIN IT?
Sotiria Athanasiadou1, Lene Nielsen2, Christian Nielsen2, Betina Sulvdart2 and Per Bagi2
1 Coloplast A/S, Medical Affairs, Humlebæk, Denmark and 2 Coloplast A/S, Pre-clinical Department, Humlebæk, Denmark and 3 Righospitalet, Urology, Copenhagen, Denmark

Background and Aims: This study characterised the types and size of sediment in clear and cloudy urine and subsequently investigated the ability of conventional eyefull intermittent catheters and a novel Micro-hole Zone catheter to drain them.

Method: Clear urine was collected from three clinical studies where subjects drained with the conventional eyefull catheter and two prototypes of the Micro-hole Zone catheter. The studies included 60 subjects, equally distributed between male and female, healthy volunteers and intermittent catheterisation users. The sediment in the samples was analysed via automated microscopy (oCelloscope). Cloudy urine was collected from patients during their visits at the Urology Department of Righospitalet, Denmark. The samples were collected after spontaneous voiding, or via a conventional eyefull catheter and were analysed with the oCelloscope. An in vitro drainage test with the two catheters was subsequently performed.

Results: The analysis of clear urine (n = 180) showed most sediment to be smaller than 50 μm, with the largest sediment up to 200 μm (2.05 to 195.76 μm). The sediment included primarily crystals, cells, and bacteria, in line with published literature. Cloudy urine was divided into two categories, based on the presence of large particles visible to the naked eye. The samples without visible particles (n = 4) contained sediment with a mean size 12.81±0.038 μm (2.75 to 131.71 μm). The sediment identity corresponded to the sediment in clear urine, but the quantity was higher. Visible particles could not be analysed in the oCelloscope due to lack of light diffraction. These particles were soft and in various shapes and sizes. The Micro-hole Zone catheter drained sediment of larger size in clear urine compared to the conventional eyefull catheter. Both catheters drained cloudy urine efficiently but had challenges draining samples with visible particles (n = 20); the Micro-hole Zone catheter drained 12 samples, either directly or after light wiggling, while the conventional eyefull catheter drained 18 of the samples.

Conclusion: The analysis showed that the type of sediment does not differ between clear and cloudy urine without visible particles, but it is rather the abundance of sediment that induces the non-transparent appearance. The sediment was smaller than the size of the micro-holes (400 μm), therefore the novel catheter could efficiently drain urine and sediment and even larger size sediment. The latter could be explained by the design of the Micro-hole Zone, that allows urine and sediment to be drained continuously through a larger area, starting below the catheter tip, and extending to the bottom of the bladder lumen, acting on the SGLT2 proteins in the renal proximal convoluted tubules, Sodium-glucose co-transporter-2 (SGLT2) inhibitors are a class of antihyperglycemic agents that recently revolutionized the paradigm of chronic kidney disease. It exerts its effect by preventing the reabsorption of filtered glucose from the tubular lumen, acting on the SGLT2 proteins in the renal proximal convoluted tubules, and thus promoting a greater urinary glucose excretion. The authors described SEVERE HYPERCHLOREMIC METABOLIC ACIDOSIS WITH SGLT-2 INHIBITORS IN PATIENTS WITH URINARY DIVERSION

1 Hospital de Vila Franca de Xira, Internal Medicine, Vila Franca de Xira, Portugal and 2Hospital de Vila Franca de Xira, Nephrology, Vila Franca de Xira, Portugal

Background and Aims: Urinary diversion after cystectomy using autologous intestinal segments has been the gold standard treatment of benign and malignant diseases of urinary tract. The most frequent metabolic abnormalities is hyperchloremic metabolic acidosis, due to ammonium absorption alongside chloride gain and bicarbonate excretion in the bowel conduit. Sodium-glucose co-transporter-2 (SGLT2) inhibitors are a class of antihyperglycemic agents that recently revolutionized the paradigm of chronic kidney disease. It exerts its effect by preventing the reabsorption of filtered glucose from the tubular lumen, acting on the SGLT2 proteins in the renal proximal convoluted tubules, and thus promoting a greater urinary glucose excretion. The authors described

DIGITAL SPATIAL PROFILING CAN BE USED TO STUDY GLOMERULAR ENDOTHELIAL CELLS IN IGA NEPHROPATHY

Harsh Selvaskanthan¹, Charlotte Boys², Izabella Pawluczyk¹ and Jonathan Barratt¹

¹University of Leicester, Mayer IgA Nephropathy Laboratories, Department of Cardiovascular Sciences, Leicester, United Kingdom and ²Heidelberg University, Heidelberg, Germany

Background and Aims: IgA nephropathy (IgAN) is the most common primary glomerular disease worldwide; approximately 30% of cases progress to kidney failure 10-20 years from diagnosis. Five histopathological kidney lesions independently predict a poor prognosis in IgAN (MEST-C score) [1]. Published case series highlight the ‘endocapillary hypercellularity’ (E1) lesion as potentially reversible with systemic immunosuppression, improving clinical outcomes [2]. Delineating differences in the transcriptomes of glomerular endothelial cells (GEnCs) associated with and without E1 (E0) may highlight avenues for safer therapeutic strategies, given the overt risks associated with systemic immunosuppression in IgAN. GEnC transcriptomes have never been profiled in diseased kidneys before. Here we used digital spatial profiling (DSP) to achieve this.

Method: DSP was performed on a Nanostring GeoMx platform. Single 5μm sections were collected from four formalin fixed paraffin embedded (FFPE) kidney biopsies with E1 and five with E0. Following deparaffinization and antigen retrieval, the tissue was incubated with a whole transcriptome atlas probe set. GEnCs were stained for CD31 (red) and macrophages (which associate with E1[3]) with CD68 (yellow) with conjugated antibodies. Glomeruli were selected as regions of interests (ROIs), and a custom JavaScript function was used to mask over GEnCs and macrophages (segmentation), which were selected as areas of illumination (AOIs) (Fig 1). Photocleaved nucleotide barcodes were sequenced using an Illumina sequencer. Single cell enrichment was assessed using the SpatialDecon algorithm, differential gene expression was explored using a linear mixed effects model, and pathway analysis was performed using Reactome.

Results: The custom written JavaScript function allowed good segmentation on GEnCs and macrophages (Fig 1). Single cell deconvolution performed using the human kidney cell atlas as a reference showed significant enrichment of GEnCs relative to neighbouring cell types (Fig 2). Exploration of differential gene expressions using a linear mixed effects model found an up-regulation of TRIM23, IL27RA, TMEM139, P14K2B and PSMD9, after P value adjustment, among GEnCs associated with macrophages in glomerular capillary loops compared to those in the absence of macrophages (Fig 3). Pathway analysis based on differential gene expression performed using Reactome revealed that the complement cascade and regulators of the complement cascade were enhanced in GEnCs associated with macrophages (Fig 4).

Conclusion: This pilot study found DSP on the GeoMx to be effective at enriching GEnC transcript signals from neighbouring cell types in FFPE tissue. This preliminary data also shows that GEnCs associated with macrophages may display a more inflammatory phenotype, which may be related to up-regulation in complement activity and may account for the progressive phenotype associated with E1 in IgAN. With several trials investigating complement system targeting therapeutics in IgAN, validation of these findings might highlight a cohort of patients with IgAN most likely to benefit from treatment.

REFERENCES

**Background and Aims:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by immune-complex deposits and inflammatory cell infiltrations in multiple organs, and approximately half of lupus patients have nephritis. Lymphangiogenesis is the proliferation of pre-existing lymphatic vessels (LVs), which regulate tissue fluid homeostasis and immune cell trafficking, responding to the tissue environment. In this study, we evaluated the therapeutic effect of SAR131672, a selective VEGFR3 inhibitor, on the murine lupus nephritis model by regulating inflammation and lymphangiogenesis.

**Method:** First, we reviewed medical records for the biopsy-proven lupus nephritis and performed an immunohistochemistry study for D2-40. For
animal experiments, seven to eight-week-old male BALB/c mice were used. The back area’s skin was shaved and treated topically three times per week, with 100 μg of resiquimod in 100 μl of acetone for eight weeks and concomitantly treatment of VEGFR3 inhibitor, SAR 131672 by oral gavage. We evaluated renal histology and immunofluorescent study for inflammatory cells and lymphatic vessels. We also evaluated inflammatory cytokines and chemokines, lymphangiogenic factors by qRT-PCR.

Results: In a human study, we found that the higher lupus activity index, the more D2-40(+) lymphatic vessels are expressed in the tubulointerstitial areas. In an animal study, eight weeks of topical treatment of resiquimod to BALb/c mice induces lupus-like symptoms such as weight loss, splenomegaly, and glomerular immune complexes deposits such as IgG, IgM, and C3 in immunofluorescent staining. Histologically, glomerular mesangial cell proliferation and increased inflammatory cells in tubulointerstitial areas were noted in the H&E stain. Inhibition of VEGFR3 by oral SAR131672 treatment decreases glomerular and tubulointerstitial inflammation and decreases LYVE-1(+) lymphatic vessels. The pro-inflammatory cytokines and chemokines such as ICAM-1, VCAM-1, MCP-1, CCL19, CCL21, CCR7, CXCL13, and BAFF mRNA levels were increased compared with the vehicle-treated group. Treatment SAR131672 decreases pro-inflammatory cytokines and chemokine.

Conclusions: Inhibition of VEGFR3 by SAR131672 decreases the resiquimod-induced lupus nephritis model by regulating inflammation and lymphangiogenesis.

Conclusion: Analysis of patient-specific podocytes is possible ex vivo via direct derivation from patient-derived fibroblasts by episomal reprogramming, into hiPSC-derived podocytes, with the potential to study alterations of disease-specific mutations regarding phenotypical and functional behavior in a personalized manner. The use of hiPSCs bypasses the limitation of restricted podocyte cell number and has the advantage of maintaining the patients’ genetic background at podocyte cell level. This enables future large-scale experiments regarding intercell-cell communication and interaction in glomerular and interstitial三维 structural co-cultures or via treatment with therapeutic substances or stress factors.

#5158 AUTOSOMAL DOMINANT TUBULAR KIDNEY DISEASE: FROM PHENOTYPE TO GENOTYPE

Sofía Jorge1, Telma Pais1, Joana Gameiro1, Iolanda Godinho1, Estela Nogueira4, Cristina Outerelo4, Márcia Rodrigues4 and José António Lopes2

1Centro Hospitalar Universitário Lisboa Norte, Nephrology and Renal Transplantation, Lisbon, Portugal and 2Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal

Background and Aims: Autosomal dominant tubulointerstitial kidney disease (ADTKD) represent a recently described group of kidney diseases, characterized by chronic interstitial nephritis (CIN), in most cases hereditary, with an autosomal dominant inheritance pattern, subclassified according to its genetic cause, when identified. Mutations in UMOD, MUC1, REN and PKD1 genes have been implicated in their pathogenesis. Recent molecular diagnostic technologies, such as Next-Generation Sequencing (NGS), and particularly the use of restriction and Snapshot method for the detection of a cytokine insertion on the coding variable-number tandem repeat (VNTR) sequence in the MUC1 gene encoding mucin 1, have allowed the nephrologists to diagnose renal diseases of previously unknown cause, with a real prevalence probably underestimated. We present the cohort of patients identified with ADTKD in the Nephrogenetics’ clinic from the Nephrology department of our hospital from 2015 to 2022.

Method: Patients with chronic kidney disease (CKD) of unknown etiology and renal phenotype suggesting CIN (bland urinary analysis, hyperuricemia and/or anemia unrelated to the degree of CKD, hypo/hypercalcaemia, acidemia, urinary protein concentration defects, absent hypertension, renal cysts), especially with a family history of similar CKD, were referred for the Nephrogenetics’ clinic and ADTKD was investigated. In these cases, we performed a genetic study of ADTKD by the following steps: 1) UMOD, REN, HNF1B mutations studied through NGS; 2) if negative, search for the insertion of a single cytokine of the repeat unit comprising the extremely long (~1.5-5 kb), GC-rich (>80%) coding variable-number tandem repeat (VNTR) sequence in the MUC1 gene encoding mucin 1 (see Kirby et al Nat Genet. 2013). It is used a restriction and Snapshot method. 3) if negative, search for HNF1B Large deletion, detected by MLPA (kit P241-D2, MRC-Holland). Pre-genetic counselling was performed by the nephrologist, and post-genetic counselling was performed by the nephrologist and geneticist, namely to proceed with family screening of potentially affected family members when a pathogenic mutation was identified or when segregation studies were necessary.

Results: 31 families were studied and a confirmed genetic diagnosis was obtained in 11 (35%), allowing the identification of 30 patients with ADTKD; the mutations identified were in MUC1 in 4 families (13 patients), UMOD in 4 families (11 patients), HNF1B (2 families, 5 patients) and REN: 1 patient with a phenotype compatible with ADTKD but with a genotype compatible with renal tubular dysgenesis (two mutations in REN gene from each of the parents). One patient with HNF1B deletion also presented with a heterozygous variant of unknown significance in PKD1 gene, and a pathogenic variant of SLC2A3, heterozygous. Three families are still under study: 2 families are being studied with segregation studies to evaluate the pathogenicity of mutations in UMOD (1 family) and HNF1B (1 family), and 1 family with a phenotype of ADTKD (3 young patients with positive family history) with negative results for mutations in ADTKD genes is in study, with a negative result in WES. The study will be pursued in a specialized laboratory to better study MUC1, but at this moment we classify this family as ADTKD-NOS. If positive results are obtained for these 3 families, the percentage of families identified using this protocol will increase to 43.3% of the families studied through this model.

Conclusion: In our cohort, a genetic diagnosis was established in 35% of the families studied. MUC1 and UMOD are the most prevalent genes implicated in ADTKD at our center, similarly to what has been reported in other cohorts of ADTKD. Given the rarity of these diseases and the fact that they require specific molecular techniques for accurate diagnosis, we believe that Nephrogenetics’ clinics with dedicated nephrologists and geneticists in close cooperation are critical for an accurate diagnosis.
Background and Aims: Hyponatremia is the most common electrolyte disturbance in clinical care. Even mild presentations are associated with poor prognosis and increased mortality, in spite of which there is a trend to minimize the importance of small variations in natremia, that have historically been dismissed as not having negative consequences despite growing evidence against it. In this regard, it has not been studied to date whether an intermittent but recurrent hyponatremia is relevant. There are clinical scenarios where this condition could occur and be overlooked, such as cirrhosis or heart failure.

Method: Different rat models have been used to study the effects of different hypotonic situations on the electrolyte balance and central nervous system: intermittent recurrent hyponatremia (intraperitoneal (i.p.) daily dose of desmopressin acetate (ddAVP) and a water dose equivalent to 2.5% of the animal's body weight in hypodipsic diet fed animals), acute on intermittent recurrent hyponatremia (i.p. water overload equivalent to 10% of the animal's body weight water overload in chow fed animals). Apparent diffusion coefficient (ADC) evaluated at 7 and 14 days after the immunization. Results: In the intermittent recurrent hyponatremia model, mild and transient hyponatremia was induced (baseline Na\textsubscript{p} 136.50 ±1.73 mM/L vs 4h post-medication 129.44 ±2.00mM/L, p < 0.001), which was recovered 24h after treatment (141.25±0.96mM/L, NS compared to baseline). However, this situation was repeated over a 7 day period. This translated into a lower ADC value in the whole brain (WB) compared to chow fed animals (25.07±1.71 vs 26.71±2.40*10^{-3}mm\textsuperscript{2}/s, p = 0.05) after this 7 day period, suggesting an increase in total brain water in this situation. There was also an increase in ADC of GM and WM (1.16mEq/L, p = 0.01) and MBP 45.20 ± 8.32 vs 28.76±7.03au, p <0.01), although no significant changes in GFAP expression in the GM (p > 0.05) after this 7 day period, suggesting an increase in total brain water in this situation. There was also an increase in GFAP expression in the gray matter (GM) compared to chow fed animals (33.22±5.25 vs 25.07±2.31au, p = 0.031), although no significant changes in MBP expression were seen. Acute on intermittent recurrent hyponatremia induced hypertonic hyponatremia (116.00±1.16mM/L, p <0.001 compared to baseline). In this situation, a progressive decrease in ADC values in the WB was seen, and it was less pronounced compared to chow fed animals (slope -0.11±0.02 vs -0.26±0.006, p = 0.014). When GM and white matter (WM) were analysed separately, they both showed a progressive increase in ADC values, more evident in the WM (slope WM 0.19±0.04, p < 0.05; slope WM 0.05±0.02, p < 0.05). The water overload increased GFAP and MBP's expression in the GM (GFAP 23.17±6.37 vs 16.83±5.17au, p = 0.001; MBP 45.20±8.32 vs 28.76±7.03au, p <0.001), but no changes were seen in the GM, similarly to what had been observed in the acute hyponatremia model.

Conclusion: Intermittent recurrent hyponatremia is a novel animal model that suggests there can be significant water retention after only a few hours of hyponatremia a day, provided this situation is repeated over time. Such water retention translates into greater brain water accumulation and astroglial activation in the GM. These animal's response to an additional water overload does not show big variations compared to what is observed in acute hyponatremia. This study highlights the importance of slight fluctuations in natremia, which, if maintained over time, can translate underlying water retention with consequences at the central nervous system level.
Myeloproliferative neoplasms (MPN) are chronic disease.

**Background and Aims:** Minimal change disease (MCD) is a podocytopathy more commonly seen in children, but it also accounts for 10%–25% of adult NS. Patients with MCD manifest with abundant albuminuria, which is related to the damage of the glomerular filtration barrier. Podocytes are major components of the glomerular filtration barrier and play a crucial role in maintaining the integrity of the glomerular filtration barrier. Alterations in podocyte actin critically affect podocyte function. Tubulin polymerization-promoting family member 3 (TPPP3) is a regulator of microtubule dynamic that has microtubule bundling activity. However, the mechanism of TPPP3 involved in podocyte apoptosis is remains unknown.

**Method:** Single-cell RNA sequencing comprehensively characterized the expression of TPPP3 in human glomeruli. We cultured human immortalized podocyte cells (HPC) in vitro, and constructed the HPC injury model. Immunofluorescence, western blot were used to determine the expression of TPPP3, α-tubulin, acetylated tubulin, phospho-YAP1, Podocyte apoptosis was determined by Annexin V APC Apoptosis Detection Kit.

**Results:** TPPP3 was specifically expressed in human glomerular podocytes, and its expression level was significantly decreased in the cases of MCD and ADR induced podocyte injury (P < 0.05). Knockdown of TPPP3 led to decreasing expression of acetylated tubulin in podocytes (P < 0.05). Phospho-YAP1 was also observed in the TPPP3 knockdown HPCs (P < 0.05). Apoptosis was increased in the TPPP3 knockdown HPCs, suggesting TPPP3 may be related to the podocytes injury and apoptosis.

**Conclusion:** TPPP3 is involved with the apoptosis of podocytes by regulates nuclear recruitment of YAP which was promoted by microtubule acetylation.

---

**SPECTRUM OF GLOMERULAR AND VASCULAR KIDNEY PATHOLOGY ASSOCIATED WITH MYELOPROLIFERATIVE NEOPLASMS**

Thibaut D’izarny-Gargas, Pierre Isnard, Idris Boudhabhay, David Buob, Anissa Moktefi, Alexandre Hertig, Emmanuel Esteve, Marion Rabant, Alexandre Karras and Jean-Paul Duong Van Huyen

1 Necker Hospital, Pathology, Paris, France, 2Necker Hospital, Nephrology, Paris, France, 3Henri-Mondor University Hospital, Pathology, Créteil, France, 4Hospital Foch, Nephrology, Suresnes, France, 5Tenon Hospital, Nephrology, Paris, France and 6European Hospital Georges Pompidou, Nephrology, Paris, France

**Background and Aims:** Myeloproliferative neoplasms (MPN) are chronic blood disorders defined by an overproduction of clonal, differentiated hematopoietic cells. A high prevalence of chronic kidney disease (CKD) is described in patients with MPN. The glomerular histological pattern of MPN-related kidney disease, MPN-related glomerulopathy (MPN-RG), may not account for the entirety of CKD risk in this population, as it appears to be rare and has mostly been reported in patients with myelofibrosis. The inflammatory and prothrombotic state of clonal blood cells has been linked to a systemic vasculopathy in MPN patients, characterized by thromboses and microvascular disease. Thus, we put forward the hypothesis that intrarenal vessel injury may occur during MPN, and that vascular necrolysis may be a common histological pattern in MPN patients presenting with kidney disease.

**Method:** We conducted an exhaustive, retrospective, multicenter study of MPN kidney biopsies in four kidney pathology units. All adult patients with a history of MPN who underwent a kidney biopsy were included. We performed a systematic histological review of glomerular and vascular compartments. MPN-RG was defined as mesangial expansion and negative glomerular immunofluorescence studies, with at least one of the following: mesangial hypercellularity, or features of chronic glomerular thrombotic microangiopathy. Hematopoietic cells were detected using anti-glycophorin C, anti-myeloperoxidase, and anti-factor VIII immunohistochemistry (IHC).

**Results:** We included 47 MPN patients who underwent a kidney biopsy, including 16 patients with chronic myeloid leukemia, 14 with polycythemia vera, 10 with essential thrombocythemia and 7 with primary myelofibrosis. 14 cases (29.8%) met our definition of MPN-RG. MPN-RG was strongly associated with myelofibrosis (primary or secondary, P = 0.021) and poorer ESRD-free survival (P = 0.007). Positive IHC for circulating cells in the glomerular capillaries was not associated with glomerular injury but was positively correlated with blood leukocyte count (P = 0.004). Thirty-three patients (75.0%) had moderate-to-severe arteriosclerosis; 39 patients (84.8%) had moderate-to-severe arteriolar hyalinosis. Multivariable models including 188 control kidney biopsies revealed an association between MPN and chronic kidney vascular damage, which was independent of established risk factors such as age, diabetes mellitus and hypertension (Table 1 and Table 2).

**Conclusion:** We demonstrate the strong association between MPN-RG and myelofibrosis and confirm its poor renal prognosis. We argue that the finding of glomerular intracapillary hematopoietic cells should not be considered in the diagnosis of MPN-RG. Most notably, our results show that MPN represent a novel, independent risk factor for vascular nephrosclerosis, and establish a new link between MPN and CKD. These findings raise new hypotheses regarding the pathophysiology of vascular nephrosclerosis in the general population.

CLINICOPATHOLOGIC CHARACTERISTICS IN RENAL THROMBOTIC MICROANGIOPATHY
Daan van Doorn 1, Sjoerd Timmermans 1, Myrurgia Abdul Hamid 2 and Pieter Van Paassen 1

1 Maastricht University Medical Center, Nephrology and Clinical- and Experimental Immunology, Maastricht, Netherlands and 2 Maastricht University Medical Center, Pathology, Maastricht, Netherlands

Background and Aims: Thrombotic microangiopathy (TMA) is a life-threatening condition that can be caused on the background of various mechanisms, converging to a severe endotheliopathy that often affects the kidneys. Morphologic features of TMA on kidney biopsy have not been systematically studied. We studied the diagnostic and prognostic role of a kidney biopsy in patients with TMA, either linked to a coexisting condition (i.e., secondary TMA) or not (i.e., complement-mediated [C-]TMA).

Method: Patients with TMA on kidney biopsy and an enzymatic activity of ADAMTS13 > 10% were recruited from the Limburg Renal Registry. C-TMA was defined as massive ex vivo C5b9 formation on the endothelium and/or rare variants in complement genes [1]; secondary TMA was defined as the presence of a coexisting condition and normal complement regulation. Kidney tissue sections were studied for activity and chronicity; also, C3d staining was performed.

Results: C-TMA and secondary TMA was diagnosed in 35 and 39 patients, respectively. The diagnosis TMA was based on a kidney biopsy in 52 (70%) out of 74 patients as systemic hemolysis, that is, microangiopathic hemolytic anemia (MAHA) and thrombocytopenia, was lacking. Morphologic activity, such as, glomerular thrombosis and mesangiolysis, was not associated with MAHA (p = 0.116) and/or thrombocytopenia (p = 0.380). Morphologic activity, however, was associated with C-TMA, as was lower age and higher serum creatinine. C3d staining did not differentiate C-TMA from secondary TMA. A Mayo Clinic Chronicity Score (MCCS) of ≥ 4 was associated with an increased partial- (p = 0.023) and complete renal remission rate (p = 0.030), and decreased end-stage kidney disease (p = 0.050).

Conclusions: Only a small proportion of patients with TMA on kidney biopsy initially present with systemic hemolysis, suggesting an essential role of histologic examination to prevent underdiagnosing. Glomerular thrombosis and mesangiolysis were associated with C-TMA, however there is no role for staining of C3d in differentiating C-TMA from secondary TMA. An increased MCCS indicates worse renal outcome in patients with TMA.

SEX-, AGING AND DIABETES-RELATED ALTERATIONS IN GLOMERULAR DIMENSIONS AND PODOCYTE DENSITIES USING DEEP-LEARNING QUANTIFICATION

Martin Klaus, Manga Motrapu, Stefanie Steiger and Hans Joachim Anders
University Hospital, LMU Munich, Division of Nephrology, Department of Medicine IV, Munich, Germany

Background and Aims: Kidney function, as well as its morphology, changes markedly with age and disorders such as diabetes. This process is associated with structural and functional alterations in cortical and juxtamedullary glomeruli. Currently, data on differences in cortical and juxtamedullary glomeruli associated with sex, age, genetic factors, and diabetes are limited. In this study, we investigated the abundance and morphometry of podocytes and glomeruli in mice of different ages and sex', and suffering from diabetes or not using a deep-learning based analysis of immuno-stained kidney sections.

Methods: Male and female non-diabetic C57BL/6J mice and diabetes type II (db/db) mice were sacrificed at different time points: 4, 10, 20, 30, 34, 40 weeks and 6, 24 weeks, respectively. Subsequently, kidneys were extracted, embedded in paraffin, cut into sections, stained, and imaged for histological analysis. We used immunohistochemistry staining with Wilms Tumor 1 (WT1) antibody to specifically stain podocyte nuclei. Both manual and deep-learning based image segmentation were performed to analyze abundance and morphometry of podocytes and glomeruli. In total, 4134 glomerular structures were detected, and morphometry of glomeruli and podocytes was extracted and analyzed by an automated algorithm.

Results: Our study aimed to investigate aging- and diabetes-related differences in cortical and juxtamedullary glomeruli with respect to podocyte abundance and loss. Using a customized deep learning algorithm, podocyte nuclei could be quantified with comparable quality as a time-tedious manual analysis, which takes approximately 1 minute per glomerulus. Extracted morphometric features showed that juxtamedullary glomeruli had a larger cross-sectional area than cortical glomeruli (Figure 1a). For both cortical and juxtamedullary glomeruli the cross-sectional area slightly increased on average with aging (Figure 1b). As expected, podocyte endowment in cortical glomeruli was lower than in juxtamedullary glomeruli with podocyte density being higher (Figure 2a, 2b). Over life-time the number of podocytes and podocyte density per glomerulus slightly decreased both in cortical and juxtamedullary glomeruli (Figure 2b, 3b). Interestingly, female cortical glomeruli were on average smaller and had a higher podocyte density compared to males (Figure 1c, 3c). However, podocyte numbers did not differ between male and female (Figure 2c). Finally, we found that 24 weeks old db/db mice presented with glomerular hypertrophy in contrast to non-diabetic C57BL/6J mice of the same age (Figure 1d). Db/db mice lost podocytes from 6 weeks to 24 weeks of age with a decreased podocyte density. Surprisingly, podocyte loss occurred to a lower extent in non-diabetic mice (Figure 2d, 3d).

Conclusion: During aging and early diabetic disease both podocyte loss and glomerular hypertrophy occur. Similar changes occurred in juxtamedullary and cortical glomeruli in both sex'. Hyperfiltration might explain the pronounced extent in glomerular area in diabetic mice and should represent an increase in filtration surface to handle diabetes-related hyperfiltration. Less podocyte loss in diabetic mice at 24 weeks age compared to C57BL/6J mice might relate to the different mouse model and still moderate podocyte stress during the early stage of diabetic kidney disease.
ROLE OF INTEGRIN, FIBRONECTIN, AND uPAR IN PODOCYTE-GLomerular Basement Membrane Interaction Under Fluid Shear Stress

Jae Seok Kim1, Ji-Hee Kim2, Junyoung Kim3, Minseob Eom4, Jae Won Yang1, Byoung Geun Han1, Seong Ok Choi1 and Seung-Kuy Cha2

1Yonsei University Wonju College of Medicine, Internal Medicine, Wonju, Rep. of South Korea, 2Yonsei University Wonju College of Medicine, Physiology, Wonju, Rep. of South Korea, 3College of Software and Digital Healthcare Convergence, Yonsei University, Biomedical Engineering, Wonju, Rep. of South Korea and 4Yonsei University Wonju College of Medicine, Pathology, Wonju, Rep. of South Korea

Background and Aims: Podocyte-glomerular basement membrane (GBM) interaction is the main component to maintain glomerular filtration barrier. Interestingly, the podocyte-GBM interaction is not static, but dynamic according to various podocyte conditions. Thus, we hypothesized that the podocyte-GBM interaction would be changed under stress conditions such as fluid shear stress (FSS). Here, we aim to explore the change of specific integrin (Itg αVβ3), fibronectin, and uPAR in the podocyte-GBM interaction under fluid shear stress (FSS).

Method: We used conditionally immortalized human podocyte cells which were differentiated only under specific (non-permissive) temperature (37°C). We exposed the podocytes to 200 rpm of FSS and applied various dish coating agents. We observed cell morphology and documented the protein and mRNA expressions of Itg β3, fibronectin, and uPAR under FSS.

Results: Podocyte morphology became more elongated with actin rearrangement under FSS. Protein expression of Itg β3 did not change under FSS, while activated Itg β3 increased from early phase (30 min after exposure to FSS) (Figure 1). Fibronectin (Figure 2) and uPAR (Figure 3) gradually increased under FSS. mRNA expressions of Itg β3, fibronectin, and uPAR did not change under FSS. Cell viability increased in collagen-1 coated dish compared to non-coated under FSS.

Conclusion: This study demonstrates that Itg αVβ3 is activated, fibronectin and uPAR increase under FSS. In addition, it is shown that extracellular matrix contributes to podocyte stability. The results suggest that Itg αVβ3, fibronectin and uPAR may have specific roles to maintain podocyte’s stability through the modulation of the podocyte-GBM interaction.

Figure 1: Activated Itg β3 increased from early phase (30 min after exposure to FSS).

Figure 2: Fibronectin gradually increased under FSS except for collagen-4 coated group.

Figure 3: uPAR gradually increased under FSS.

HEPARANASE OVEREXPRESSION MODIFIES PODOCYTE MOTILITY
Aviya Lensky*, Hanan Abu-Tayeh Suleiman*, 1, 2, Israel Vladovsky 1, Neta Ian* and Suheir Assady1, 2

1 Technion-Israel Institute of Technology, The Ruth & Bruce Rappaport Faculty of Medicine, Haifa, Israel, 2 Rambam Health Care Campus, The Clinical Research Institute at Rambam, Haifa, Israel and 3 Rambam Health Care Campus, Department of Nephrology and Hypertension, Haifa, Israel

Background and Aims: Heparanase is an endo-ß-ß-glucuronidase that degrades heparan sulfate side chains, which are essential components of extra-cellular matrices and cell surfaces, including in the kidney filtration apparatus, the glomerulus. Upregulation of heparanase in glomerular diseases (GDs) was demonstrated in experimental models of GDs and in humans. Using transgenic mice overexpressing the human heparanase gene, we recently showed that heparanase reduced proteinuria and preserved the glomerular filtration barrier (GFB) after Adriamycin-induced injury. Furthermore, heparanase improved survival of key GFB cells, the podocytes and enhanced their autophagic flux both in vitro and in vivo. Here, we aimed to study the potential role of heparanase on podocyte locomotion and adhesion.

Methods: We utilized immortalized human podocyte cell line AB8/13 (a kind gift of Prof. Moin Saleem, Bristol, UK) as an experimental platform. Cells were infected with pLenti6/VS-DEST carrying the heparanase gene construct (H) or control empty vector (V) and were allowed to differentiate for 14 days. To induce injury, differentiated podocytes were treated with Adriamycin (0.5 ßg/mL), mimicking Adriamycin nephropathy, an established experimental model for progressive proteinuric GDs. For readouts, we used scratch assay, RT-qPCR, Western blot (WB) and immunofluorescence (IF) analyses.

Results: The in vitro scratch assay showed that differentiated (H) podocytes migrated at a slower rate compared with control (V) podocytes, both at baseline and after a 12-hour treatment with Adriamycin. Hence, we hypothesized that heparanase may alter podocyte adhesion properties. Indeed, IF staining of differentiated (H) podocytes exhibited an increase in focal contacts containing vinculin compared with control (V) cells treated with Adriamycin. Of note, we observed no differences in vinculin abundance by WB, suggesting that heparanase mediates the active form of vinculin. Moreover, among the integrins, we noticed temporal upregulation of ITGB1 transcription, as early as two hours after Adriamycin treatment, in (H) compared with control (V) podocytes (P = 0.032).

Conclusions: Collectively, our results suggest that in response to Adriamycin injury, constitutive heparanase overexpression could stabilize podocyte focal adhesions and control motility. Although further research is needed, improving the anchoring of podocytes over the basement membrane may provide an additional cellular mechanism by which heparanase conferred protection against Adriamycin toxicity.

GLOMERULAR DISEASES ASSOCIATED WITH SARS-COV2 INFECTION AND VACCINATION: A MULTICENTRIC REGIONAL RETROSPECTIVE STUDY

Flavia Capaccio, Michele Rossini, Paolo Protopapa, Vincenzo DI Leo, Marica Gilberti and Loreto Gesualdo

Nefrologia - Policlinico di Bari, Bari, Italy

Background and Aims: The SARS-CoV2 caused a pandemic disease, leading to millions of cases and fatalities worldwide. Kidney involvement is frequent and glomerular diseases (GD) have been reported in association with infection. Podocytropathies, endothelial injury with thrombotic microangiopathy are the most common histological findings in literature. From January 2021 anti SARS-CoV2 vaccination became available. Several GD has also been associated with vaccination. IgA nephropathy (IgAN) and minimal change disease (MCD) are the most common GD reported in patients who received vaccination. Our aim was to assess the histological findings in patients who presented kidney involvement after SARS-CoV2 infection and/or vaccination and to compare the frequencies of GD in these patients to those in non-Covid19 population.

Method: We conducted a retrospective study of kidney pathology in patients undergoing native kidney biopsy within 90 days of SARS-CoV2 infection and/or vaccination, between February 2020 and August 2022 in Apulia Region of Italy. We considered separately patients without history of urinary abnormalities and/or kidney dysfunction prior to infection and/or vaccination in order to detect GD which were more likely to be related to infection and/or vaccination than to pre-existent pathologies. We used a database of kidney biopsies performed in a period of 5 years (from January 2015 to February 2020) prior to the Covid19 pandemic as a control comparison cohort to examine glomerular diseases frequencies.

Results: Among the 808 biopsies: 36 (4.4%) were carried out within 90 days of SARS-CoV2 infection (Group 1) and 142 (17.6%) within 90 days of vaccination (Group2). Among them, we identified 12 patients with renal symptoms raised after COVID19 infection (Group 3) and 26 patients after vaccination (Group 4). In the Group 1 the main histological diagnosed founded were: podocytropathies (25.1%), IgAN (16.7%) and ANCA-vasculitis (13.9%). In Group 2, the most common histological diagnosis were IgAN (18.3%), podocytropathies (17%) and membranous nephropathy (MN) (10.6%). In the Group 3 we found a predominance of podocytropathies (33.3%) followed by ANCA-vasculitis and IgAN (three patients each, 25%). In the Group 4, the most frequent GD were podocytropathies (36.6%) followed by ANCA-vasculitis (19.2%) and IgAN (15.4%). Between the 1380 kidney biopsies from the 5 years pre-Covid19 period, the most frequent histological diagnosis were IgAN (18.3%), podocytropathies (18%) and MN (10.9%). Comparing Group 1 and Group 2 data with the 5 years pre-Covid19 database we found a significant increased prevalence only of ANCA vasculitis in group 1 (13.9% of patients after Covid19 infection vs 5.6% of pre-covid database (p-value: 0.03)). Comparing data from patients who had developed renal signs after Covid19 infection (group 3) and/or vaccination (group 4) with those in the 5 years database a significant higher prevalence of ANCA-related crescentic glomerulonephritis was found in both group. The 25% of patients of the Group 3 and the 19.2% of the Group 4 had a histological diagnosis of vasculitis, while these were found only in the 5.7% of patients from the pre-Covid19 database (p-value: 0.004 for Group 3 and 0.003 for Group 4). Furthermore podocytropathies in group 4 were significantly higher than pre-covid19 (36.6%vs18.3%, p = 0.02).

Conclusion: We found a higher prevalence of ANCA vasculitis and podocytropathies in patients with symptoms developed after SARS CoV2 infection/vaccination compared to diagnosis prevalence in a pre-Covid19 reference database.

SERUM AND URINARY SOLUBLE PD-1, PD-L1 AND PD-L2 AS BIOMARKERS FOR CHECKPOINT INHIBITOR RELATED ACUTE INTERSTITIAL NEPHRITIS
Francisco Gomez-Preciado¹, Laura Martinez Valenzuela¹, Paula Anton Pampols¹, Marina Gomez-Tena², Montserrat Goma², Ana Melissa Rau Lertora¹, Belén Rubio Rodriguez¹, Ernest Nadal¹, Maria Jove³, Xavier Fulladosa Oliveras¹, Josep Cruzado¹, Joan Torras Ambros¹ and Juliana Draibe³

¹Bellvitge University Hospital, Nephrology, L’Hospitalet de Llobregat, Spain, ²Bellvitge University Hospital, Pathology, L’Hospitalet de Llobregat, Spain and ³Catalan Institute of Oncology, L’Hospitalet de Llobregat, Spain

Background and Aims: Acute interstitial nephritis (AIN) related to Immune Checkpoint Inhibitors (ICI) is a frequently described adverse effect, although the mechanisms are not fully understood. The gold standard for the diagnosis is kidney biopsy. Although it is invasive, it is necessary as AIN can be confused with other causes of acute kidney injury (AKI) in oncologic patients. The diagnosis of AIN has therapeutic consequences such as the need to withdraw the drug if confirmed, possibly diminishing patients’ life expectancy. Few biomarkers have been proposed for non-invasive diagnosis or the follow-up of these patients, which could be useful when the biopsy is contraindicated or not available. Our aim was to study the Immune Checkpoint pathway during the event, as well as analyse potential biomarkers directly related to the pathway.

Method: We performed an observational study. We recruited patients with incident diagnosis of AIN related to ICI in our institution from 2018 to 2022. We obtained serum and urine at the time of diagnosis after signing informed consent. We recruited n = 18 patients with the diagnosis of AIN related to ICI. For comparison, we recruited patients with non ICI-related AIN (n = 18), patients with active ANCA-vasculitis (n = 35), patients with acute tubular necrosis (ATN) (n = 22), and controls (n = 36) (patients with diagnosis of malignancy without AKI (n = 22), and healthy controls (n = 14)). We determined soluble PD-1 (sPD-1), sPD-L1 and sPD-L2 in serum and urine using a multiplex bead-based Luminex assay. Besides, we performed PD-L1 immunohistochemistry and PD-L2 immunofluorescence staining of kidney biopsies from patients with ICI-related AIN (n = 14) and compared to patients with non ICI-related AIN (n = 10).

Results: Serum sPD-1 was higher in patients with AIN compared to controls (p = 0.0004) and patients with ATN (p = 0.021). There were no differences between controls and ATN (p = 0.76). Urinary sPD-1 was lower in subjects with AKI compared to controls (control vs AIN (p = 0.019), control vs active vasculitis (p<0.0001) and control vs ATN (p = 0.0304)). Patients with ATN exhibited the lowest urinary sPD-1 levels, and there were statistically significant differences when compared to AIN (p = 0.0304). Focusing on oncologic patients, urinary sPD-1 concentration < 129.3 pg/ml had a 71.43% sensitivity and 94.12% specificity to differentiate ATN from AIN, with a likelihood ratio of 12.14. Serum and urinary sPD-L1 and sPD-L2 did not show statistically significant differences between AIN and ATN. In kidney biopsies, patients with ICI related AIN showed higher density of PD-L1 positive tubules than patients with non-ICI related AIN (p = 0.037). Proportion of patients having more than 2.64/mm² PD-L2 positive tubules was higher among patients with ICI related AIN compared to non ICI-related AIN (p = 0.034). There was a positive correlation (p = 0.009, r = 0.72) between urinary sPD-1 and the density of PD-L1 positive tubules (tubules/mm²). As for PD-L2, serum PD-L2 was higher in patients with positive tubular PD-L2 expression (p = 0.009).

Conclusion: Serum sPD-1 increases in AIN, contrary to patients with ATN and controls. Urinary sPD-1 decreases in patients with AKI. This decrease is more intense in the case of patients with ATN, thus being useful in the differentiation between ATN and AIN, especially in patients with neoplasms. Patients with ICI-related AIN exhibit higher positivity for PD-L1 and PD-L2 staining compared to other causes of AIN. Altogether, our findings suggest a role for these soluble molecules in the ICI-related AIN pathophysiology.

Figure 1: (a) ROC curve of urinary sPD-1. Concentrations less than 129.3 pg/ml differentiates ATN from AIN with 71.43% sensitivity and 94.12% specificity, likelihood ratio of 12.14. (b) Immunohistochemistry PD-L1 staining of a kidney biopsy section showing a PD-L1 positive tubule.
MASS-SPECTROMETRY ANALYSIS OF CONGOPHILIC URINE AND ITS DETERGENT RESISTANT FRACTION IN PATIENTS WITH AMYLOID AND NON-AMYLOID NEPHROPATHIES

Maria Khrabrova1,2, Sergey Fedotov3,4, Anastasia Anpilova1,2, Vladimir Dobronravov5 and Aleksandr Rubel1,5

1Pavlov University, Research Institute of Nephrology, St. Petersburg, Russia, 2St. Petersburg State University, Laboratory of Amyloid Biology, St. Petersburg, Russia, 3Russian Academy of Sciences, Pavlov Institute of Physiology, St. Petersburg, Russia, 4National Academy of Sciences of the Republic of Armenia, I.A. Orbeli Institute of Physiology, Yerevan, Armenia and 5St. Petersburg State University, Department of Genetics and Biotechnology, St. Petersburg, Russia

Background and Aims: Being a well-known intrinsic property of amyloid, congophilia was recently demonstrated in urine of patients with proteinuria of different etiology including renal amyloidosis (RA) and non-amyloid nephropathies (NANP) [1]. Urine proteins (UPs) responsible for congophilia in RA and NANP are supposed to have another property of amyloid such as resistance to ionic detergents and present in urine as detergent-resistant aggregates (DRA). In the pilot study we performed mass-spectrometry (MS) analysis of congophilic urine samples and its detergent-resistant fraction in patients with RA and NANP to investigate UPs and their specificity to the particular kidney disease.

Method: We collected first morning void urine samples from patients with RA (n = 4) and NANP (n = 4). Urine congophilia was assessed by Congo red Dot test as described previously [1]. To analyze bulk urine (BU) proteins, 30 µl of supernatant was precipitated with 80% acetone and boiled in 2% sodium dodecyl sulfate (SDS) for 30 minutes. Then 5 µg of UPs was separated in 10% polyacrylamide gel electrophoresis (PAGE) followed by Coomassie blue staining. The further centrifugation of 0.5-3 ml of urine at 300,000x g for 16h following by the treatment of precipitate with 3% sarcosyl in phosphate-buffered saline (PBS) for 10 min with subsequent washing of resistant aggregates in PBS were applied to obtain DRA. After boiling in SDS 8 µl of the sample was separated in 10% PAGE. UPs concentration in the DRA was estimated by densitometry regarding to 2 µg of bovine serum albumin. Then 6 µg of UPs was digested with trypsin, followed by purification on silicate (CDS Empore™ C18 Extraction Disks). Prepared samples of BU and DRA were analyzed by electrospray ionization tandem MS. We used MsFragger software to obtain lists of UPs for each sample. Most representative UPs in the sample were selected by the unique spectral count (USC). We considered the protein as having diagnosis-specific potential (DSP) if it was present in every sample of the particular disease group, i.e. AA, AL, NANP in BU or DRA, and was absent in any sample of another disease group.

Results: The patients had following characteristics: age 51±13 years, 3 male/5 female, eGFR = 45 (19; 95) ml/min/1.73 m²; 24h proteinuria = 6.3 (4.5; 7.9) g. In PAGE analysis, BU proteins appeared to be similar in all 8 samples with 2 major bends in 70 kDa and 50 kDa regions, corresponding to albumin and immunoglobulin (lg) heavy chains, respectively (Fig. 1A). The amount of protein in DRA was small and comprised 1.02 (0.71; 1.61) % of the total protein in the sample (4.7 (2.3; 5.1) g/l). Compared with BU PAGE analysis of DRA proteins revealed other bends with trace albumin bend, predominance of 45 kDa region bend and more apparent 30 kDa bend (lg light chains) in the majority of patients (Fig. 1B). Results of MS analysis are shown on the Figure 2. There were more DSP revealed in DRA vs BU: 14 vs 5, 46 vs 2 and 4 vs 2 UPs in samples of AL, AA and NANP, respectively. When compare by a particular disease group, there were no DSP found either in BU or DRA in RA samples. One protein (aminopeptidase N) and 3 proteins (isofrom 3 of unconventional myosin-LC, protein S100-A8, elongation factor 1-α 1) were detected as DSP in BU and DRA in AL, respectively. Alpha-1-acid glycoprotein 1 was only DSP for AA in DRA as well as serum paronoxase 1 for NANP in BU.

Conclusion: Although DRA represented a small portion of UPs, its composition significantly differed from BU and could contain more specific disease markers that makes urine detergent-resistant fraction promising for the future research. Understanding the role of DRA proteins in the pathogenesis of amyloid and non-amyloid renal disease and their diagnostic utility requires further studies.

THE EFFECT OF TRPC5 AND PALLADIN EXPRESSION ON TREATMENT RESPONSE AND RECURRENT OUTCOME IN FOCAL SEGMENTAL GLOMERULOSCLEROSIS

Zeynep Üral1, Betül Öğüt2, İpek Göñül2 and Galip Guz1

1Gazi University Faculty of Medicine, Nephrology, Ankara, Turkey and 2Gazi University Faculty of Medicine, Pathology, Ankara, Turkey

Background and Aims: Focal segmental glomerulosclerosis (FSGS) is a disease that is among the primary glomerulopathies and often progresses to chronic renal failure. Despite advances in immunosuppressive therapy for the treatment of glomerular diseases, some FSGS patients are resistant to single or combination immunosuppressive regimens containing: glucocorticoids, cyclophosphamide, calcineurin inhibitors, mycophenolate mofetil (MMF), and/or rituximab. FSGS-related nephrotic syndrome, the degree of proteinuria and response to steroid therapy are the most important factors associated with long-term prognosis, independent of histological findings. Failure to respond to immunosuppressive therapy, including corticosteroids, has been evaluated as one of the most important markers of the risk of developing renal failure. Unfortunately, there is no reliable marker that can predict steroid response. One of the earliest manifestations of podocyte damage is cytoskeletal remodeling, known as deletion of foot ridges. It was recently shown that transient receptor potential channel 5 (TRPC5) plays an important role in initiating this process. However, the role of TRPC5 in disease progression is unknown. It is thought that calcium influx caused by sustained TRPC5 activation in the chronic disease setting may lead to calcium toxicity and podocyte death. It is known that the actin regulatory protein palladin, which is highly expressed here, is also highly related to podocyte function and podocyteopathies, and plays an important role in the stability of the actin cytoskeleton. The aim of our study was to define the frequency of TRPC5 and palladin renal expressions in podocytes in focal segmental glomerulosclerosis (FSGS) and its relationship with prognosis and treatment response.

Method: A total of 182 patients were enrolled for baseline clinical and histopathological features and 103 patients with a clinical follow-up for more than 2 years were evaluated for outcomes. Immunohistochemical staining was performed with TRPC5 and palladin antibodies on kidney biopsies and glomerular staining was evaluated.
Results: Baseline characteristics, and health parameters were similar between TRPC5+/TRPC5− and palladin+/palladin− groups. TRPC5 expression was observed in 69% of the patient biopsies and palladin expression in 73%. We found that TRPC5 and palladin expression was a significant predictor of FSGS severity and poor treatment response (both p<0.05). In addition, TRPC5 expression was significantly associated with the development of end-stage renal disease and ongoing proteinuria.

Conclusion: The development of proven treatments that delay the progression of FSGS is critical to patient survival. The development of new treatments is possible only by knowing the underlying pathophysiological mechanism of the disease. Podocyte loss is a critical step in the development of irreversible glomerulosclerosis, which causes chronic kidney disease. Therefore, blocking TRPC5 channel and palladin may be an effective treatment strategy, especially in treatment-resistant FSGS patients with positive staining on biopsy. Our study is the first in the literature to show these two antigens in kidney tissue for MCTO patients.

Figure 1: FSGS patients treatment response rates according to TRPC5 and Palladin expressions in kidney biopsy.

#3939 EFFECTIVENESS OF IMATINIB FOR MCTO NEPHROPATHY
Toshiaki Usui1, Naoki Morito1, Shun Ishibashi1, Natalia Gogoleva2, Maho Kanai2, Yuri Inoue1, Sayaka Fuseya1, Akihiro Kuno2, Seiya Mizuno3, Michito Hamada1, Satoru Takahashi1 and Kunihiro Yamagata1
1University of Tsukuba, Department of Nephrology, Tsukuba, Japan, 2University of Tsukuba, Anatomy and Embryology, Tsukuba, Japan and 3University of Tsukuba, Transborder Medical Research Center, Tsukuba, Japan

Background and Aims: MAFB is a podocyte-specific transcription factor. Point mutations in the MAFB transactivation domain in humans result in multicentric carpometacarpal-tarsal osteolysis (MCTO). MCTO patients show focal segmental glomerulosclerosis (FSGS) due to podocyte damage, known as MCTO nephropathy. Effective treatment for MCTO has not been found. Imatinib is a tyrosine kinase inhibitor (TKI), which inhibits PI3K-Akt pathway, and is in long-term use for the treatment of chronic myeloid leukemia.

Method: In order to develop a new treatment for MCTO, we generated disease model mice using the CRISPR-Cas9 system. These animals have the same genetic mutation as human MCTO patients. Albuminuria was evaluated at 4 weeks of age, and renal histological analysis was performed at 26 weeks of age. In addition, RNA-seq for isolated glomeruli of 10-week-old MCTO mice and wild-type animal was performed for genetic and pathway analysis.

Results: MCTO mice exhibited growth retardation, and presented albuminuria from 4 weeks of age. Foot process effacement and FSGS-like renal histological changes were shown. Nephropathy symptoms were similar to that of human MCTO patients. Interestingly, the upregulated genes in RNA-seq analysis were a group of receptor genes associated with PI3K-Akt signaling, including lpar1 and csfr1. Transcerebral administration of imatinib, a PI3K-Akt pathway inhibitor, treatment for 5 consecutive weeks decreased albuminuria and ameliorated histological renal damage. RNA-seq of isolated glomeruli of MCTO mice after imatinib treatment showed decreased expression of genes associated with TGFβ-related signaling pathways compared to the non-treated group. Recently, enhanced PI3K-Akt signaling in podocytes has been linked to several renal diseases associated with podocyte injury. In addition, lpar1 inhibition in glomeruli is known to suppress TGFβ. Imatinib suppressed PI3K-Akt signaling, which is enhanced in podocytes of MCTO mice. This may have shown a podocyte-protective effect by suppressing fibrosis-related genes such as TGFβ. Imatinib is classified as a TKI, but frequency of podocyte toxicity is lower than other TKIs.

Conclusion: The podocyte injury mechanism of MCTO nephropathy is associated with enhanced PI3K-Akt signaling in podocytes. Imatinib inhibits this pathway and suppresses TGFβ. Imatinib may become a therapeutic agent for MCTO nephropathy.

#5466 CSF-1R SYSTEM ACTIVATES PARIELT EPITHELIAL CELLS LEADING TO FOCAL SEGMENTAL GLOMERULOSCLEROSIS (FSGS)
Ana Amaya Garrido1, Nuria Doladé1, Cristian Varela1, Anna Manonelles2, Sandra Rayego-Mateos3, Marta Ruiz-Ortega1, Sergi Codina2, Josep Cruzo2 and Anna Sola1
1Institut d’Investigació Biomèdica de Bellvitge (IDIBELL), Department of Nephrology and Experimental Transplantation, L’Hospitalet de Llobregat (Barcelona), Spain, 2Hospital Universitari Bellvitge, Nephrology, L’Hospitalet de Llobregat, Spain and 3IIS-Fundación Jiménez Díaz, Cellular and Molecular Biology in Renal and Vascular pathology, Madrid, Spain

Background and Aims: Focal segmental glomerulosclerosis (FSGS) is the most common glomerular cause leading to end-stage kidney disease. Actual treatment of primary FSGS by immunosuppressive agents presents inconsistent results. Thus, new innovative strategies different from those used to date by taking into consideration podocyte renewal and maintenance or even strategies complementary to immunosuppression are needed. In FSGS, parietal epithelial cells (PECs) switch to an activated phenotype (aPECs) in response to podocyte damage promoting glomerulosclerosis. Colony-stimulating factor (CSF-1) is a hematopoietic growth factor that acts via its specific receptor, the tyrosine kinase receptor CSF-1R. CSF-1 has been detected in sera and renal biopsies from patients with different renal complications, including FSGS, attributing their role and presence to macrophage but not to glomerular cells. The potential cellular and molecular mechanisms involved are also unknown. In this work, we evaluated the implication of CSF-1/CSF-1R axis in the pathogenesis of FSGS and its potential as new pharmacological target point by using specific CSF-1R inhibitors. Specifically, we focused on the modulation of PECs activation by de novo production of CD44 and the preservation of podocyte loss.

Method: We evaluated the role of the CSF-1/CSF-1R axis as a driver of glomerular damage in FSGS in adriamycin-induced nephropathy (ADR) in mice, the main experimental model to study human FSGS. To this end, we treated or not ADR-animals with CSF-1R specific inhibitors, GW2580 or Ki20227 (n = 5-7 group). We determined the expression and localization of CSF-1R in the glomerulus in tissue by triple immunofluorescence (WT-1, SSChCs and CSF-1R) and their relevance in glomerulosclerosis (PAS and pro-fibrotic genes). The determination of de novo CD44 formation and its correlation with ERK1/2 pathway by immunohistochemistry (IH). We detected podocyte in the glomerulus by WT-1 IH and the localization of aPESCs in the glomerular tuft by Claudin-1 and SSChCs markers. Finally, we used
isolated human kidney progenitor cells with and without CSF-1 treatment (n = 6/group) to identify potential key interactors of CSF-1 by RNAseq. We validated genes of interest in the FSGS experimental model. 

Results: We observed a constitutively expression of CSF-1R in the glomerulus of control mice that significantly increased in ADR-treated mice, specifically in podocytes (WT1) and pECs (SSeCks), confirmed with mRNA expression. ADR-treated mice showed important events of sclerotic glomerulus and profibrotic genes as collagen that was significantly reversed by the treatment with CSF-1R inhibitors (p < 0.001). Results reflected a CSF-1R inhibitor-dependent renal function recovery with the use of the inhibitors with a reduction of proteinuria and an increase of glomerular filtration rate (p < 0.001). We found a positive CD44 staining both in Bowman’s capsule and inner the tuff of ADR-treated mice, accompanied by an increase of ERK1/2 activation. CSF-1R inhibitors significantly reduced the percentage of glomeruli with de novo CD44 production. Remarkably, podocyte depletion was also preserved with very similar levels to non-treated animals (p < 0.001). For RNAseq results, 227 differentially expressed genes (considering a criterion of a probability of differential expression >0.9 and a [M] > 1) were subjected to enrichment analysis. The top significant gene ontology terms were mainly involved with interferon-induced genes. Genes involved in this pathway were validated in the FSGS model, showing an increase in mice treated with ADR compared to controls and alleviated with CSF-1R inhibitors (p < 0.001). 

Conclusion: In this study we propose a novel therapeutic strategy for FSGS-associated pathology based on the inhibition of CSF1-R activity having an impact on reducing aPECs, glomerulosclerosis, proteinuria, improving renal function and preserving the podocyte-progenitor phenotype, thus, in podocyte preservation against damage.

ANALYSIS OF KIDNEY BIOPSIES AND URINE SEDIMENT USING SCANNING ELECTRON MICROSCOPY (SEM) AND ATOMIC FORCE MICROSCOPY (AFM)

Giuseppe Gigliotti1, Michelangelo Nigro1, Andrea Gigliotti1, Gianmarco Borriello2, Antonio Massa1, Antonio Mancini1, Scognamiglio Mariarosa1, Ernesto Reverchon1 and Davide Viggiano2

1HEboli, Nephrology and Dialysis, Eboli, Italy, 2University of Campania, Nephrology Unit, Translational Medical Sciences, Naples, Italy and 3University of Salerno, Department of Industrial Engineering, Fisciano, Italy

Background and Aims: The classification of renal diseases is dependent on the evaluation of kidney biopsies using light microscopy techniques. Ultrastructural details (e.g. podocyte foot processes, amyloid fibrils, Fabri’s intracellular inclusions) need transmission electron microscopy (TEM) which has high costs, requires specialized personnel and is time consuming. Therefore, alternative techniques are highly desirable. Here we report our experience with scanning electron microscopy (SEM) and atomic force microscopy (AFM).

Method: Paraffin-embedded kidney sections (3 μm thick) were examined after dewaxing and Jones-methenamine methane staining for type IV collagen fibers. Dried urine sediments were prepared using standard methods for urine cytological analysis. Analysis was then performed using atomic force microscopy (nGauge system) on dried specimens and with Scanning Electron Microscopy (Zeiss) after gold-sputtering of the surface. Reference images were obtained by standard microscopy.

Results: The combination of SEM and thin paraffin sections allows the observation of ultrastructural details in kidney biopsies with a very simple and fast preparation. AFM is even faster than SEM, as it does not require any preparation of the surface of the sample. An important advantage of SEM is the possibility to view the sample at low magnification, which makes it easier to identify the location of the glomeruli. It is thus possible to switch from small magnifications (100x) to very extreme magnifications (100000x). Notably, the interpretation of the images requires knowledge of the artifacts induced by paraffin inclusion. Specifically, structures and cells containing lipids (for example foamy cells) appear empty. Chromatin is also condensed in the nuclei around the periphery of the nucleus and in spike structures whith large empty areas. The recognition of nuclei in SEM and AFM is important for the subsequent interpretation of the images. Podocyte pedicles fusion can be identified relatively easily in SEM and in AFM. Both techniques add relevant ultrastructural details of urine sediment cells, from epithelial cells to isolated tubular cells. Also, casts show many ultrastructural features which are not evident in classical optical microscopy. It is also possible to measure the thickness of the basement membrane with great precision both in SEM and with AFM. The major limitation of this approach is the limited experience of pathologists with these methods and the absence of an atlas of normal and pathological kidney.

Conclusion: Considering the affordable costs of SEM and AFM instruments and the simple preparation of samples for their analysis, these should be considered a valid alternative to TEM. SEM and AFM are alternative methods, simple and relatively cheap and very fast to obtain ultrastructural details of renal biopsies. We thank ANED and AST for the great support given to research.
AUTOMATIC SEGMENTATION OF GLOMERULAR SUBSTRUCTURES BY DEEP LEARNING
Amélie Dendooven1, Aristotelis Styanidis1, Louis Raes2, Amaryllis Van Craenenbroeck3, Matthias Maeyens4, Konstantinos Kotras5 and Maarten De Vos6
1UZ Ghent, Pathology, Ghent, Belgium, 2KULeuven, ESAT, Belgium, 3UZ Leuven, Nephrology, Belgium, 4KULeuven, ESAT, Belgium, 5KULeuven, ESAT, Leuven, Belgium and 6KULeuven, ESAT and Department of development and regeneration, Belgium

Background and Aims: Electron microscopy (EM) complements light microscopy (LM) evaluation of the kidney biopsy. Foot process effacement, as assessed by EM, helps in diagnosing podocytopathies. However, human interpretation of EM images is time-intensive and often subjective. In this pilot, we investigate how deep learning techniques can help in adequate segmentation of the glomerular basement membranes (GBM) and podocytes in EM images. The ultimate goal would be to design an automatic tool for reliable and fast assessment of foot process effacement.

Method: Podocytes and glomerular basement membranes (GBM) of 10 patients, 5 with podocyte disease and 5 without glomerular changes (where biopsy showed tubulointerstitial pathology on LM) were annotated with a combination of manual annotation and thresholding for providing ground truth. After data preprocessing including splitting, flipping, rotating and tiling, a modified U-net architecture was applied ("baseline model"). This baseline model was compared to a combination of U-net and a self-supervised contrastive learning approach with pretraining on 100 additional images (SimCLR framework, "fine-tuned model"). Segmentation performance was measured by IoU score.

Results: Segmentation of the glomerular basement membrane was best achieved by the baseline model and resulted in an IoU score of 0.711±0.089 compared to a IoU score of 0.675±0.093 in the fine-tuned model. Segmentation of the podocytes was most successful in the fine-tuned model, with a IoU score of 0.609±0.118 compared to a IoU score of 0.591±0.118 in the baseline model.

Conclusion: This study pioneers in segmenting glomerular substructures on EM images by means of a modified U-net architecture. The next step is training and validation in larger datasets. Data annotation remains a challenge. Inclusion of more images is expected to greatly improve the performance of the model.

Guideline 1500-3600 characters

Figure 1: Example of image and corresponding masks where the finetuned model performs better than the baseline model (higher podocyte IoU scores, similar GBM IoU score).
SLC34A2 EXACERBATES TUBULAR INTERSTITIAL FIBROSIS VIA INDUCTION OF APOPTOSIS AND CELL CYCLE ARREST IN S PHASE

Liang-Shuan Hu1, Sheng-Cheng Chang2, Chia-Hui Tsai3, Chun-Ching Wu1, Phuong Thao Hoang Nguyen2, Wei-Che Chang1, Wei-Ya Chang2, Ya-Chien Yang3 and Tzu-Ming Jao1

1National Taiwan University College of Medicine, International Joint Degree Master’s Program in Agro-Biomedical Science in Food and Health, Taipei, Taiwan, Rep. of China, 2Kaohsiung Veterans General Hospital, Department of Medical Education and Research, Kaohsiung, Taiwan, Rep. of China and 3National Taiwan University College of Medicine, Department of Clinical Laboratory Sciences and Medical Biotechnology, Taipei, Taiwan, Rep. of China

Background and Aims: Chronic kidney disease (CKD) is an urgent public health issue in the world. However, effective treatments for intervention of CKD remain undefined. Phosphate (Pi) is an essential element for synthesis of DNA, RNA, ATP, phospholipid membranes, and for regulation of phosphor- ylation/dephosphorylation, cellular signaling and metabolic pathways. Solute carrier family 34 (SLC34) is responsible for Pi absorption in the small intestine. The role of SLC34 in progression of CKD is still unknown.

Method: A membrane protein, solute carrier family 34 member 2 (SLC34A2), was discovered by using big data mining from the National Center for Biotechnology Information (NCBI). SLC34A2 was overexpressed in human proximal tubular cells, HK-2, by Lipofectamine 3000. RNA sequencing was carried out to uncover SLC34A2-mediated signaling pathways by using Illumina platform. Apoptosis was evaluated by Annexin V-PI staining and TUNEL assay in cells and mouse kidneys, respectively. Cell cycle was measured by flow cytometry. Unilateral ureteral obstruction (UUO) and bilateral renal ischemia-reperfusion injury (bIRI) were employed to generate CKD mouse models.

Results: By using big data mining from the NCBI, we identified a membrane protein, SLC34A2, was upregulated in various types of nephropathies including diabetic nephropathy, focal segmental glomerulosclerosis, minimal change disease, ANCA-associated vasculitis. Overexpression of SLC34A2 suppressed viability of HK-2 cells. RNA sequencing revealed that apoptosis and cell cycle are high scored pathways modulated by SLC34A2. The results were further verified in HK-2 cells. Ectopic SLC34A2 promoted apoptosis via downregulation of BCL-2. Moreover, SLC34A2 induced cell cycle arrest in S phase via downregulation of CDK2. CKD mouse models of UUO and bIRI were carried out to confirm in vitro findings. In mice kidneys, the expression of Slc34a2 in UUO and bIRI groups was superior to that in sham groups. Enriched Bax and TUNEL-positive cells were observed in the fibrotic kidneys of mice. Moreover, increased expression of p21 and downregulated Cyclin A2 in the fibrotic kidneys further confirmed that Slc34a2 induced cell cycle arrest in S phase.

Conclusion: Slc34a2 induced apoptosis and halted cell cycle in S phase, resulting in subsequent tubulointerstitial fibrosis in mice. Our results suggest that targeting SLC34A2 might be a promising strategy for intervention of CKD.

SINGLE-CELL RNA SEQUENCING REVEALS THE MOLECULAR CHARACTERISTIC OF IGA-MCD

Junli Wan, Liping Peng, Qilin Chen, Huimin Jiang, Xiaojian Feng and Qiu Li

P.R. China

Background and Aims: IgA nephropathy (IgAN) is the most common primary glomerular disease in children and adolescents worldwide, and is one of the major causes of end-stage renal disease in China. Minimal change disease (MCD) is the most common pathological type of nephrotic syndrome in children. In some rare cases, the renal pathology of these patient has IgA deposits in the mesangial regions and diffuse fusion of podocyte foot process, which is called IgA-MCD. Previous studies have analyzed the characteristics of IgA-MCD from the aspects of clinical manifestations, pathological features, therapeutic response and prognosis, but the molecular mechanism of its occurrence and development has not been clarified. For the first time, single-cell transcriptome sequencing technology was used to compare IgA-MCD, IgAN and MCD, in order to describe the unique molecular characteristics of IgA-MCD and elucidate the molecular mechanism related to clinical manifestations. It lays the foundation for formulating more appropriate treatment plan and improving prognosis.

Method: Renal fine-needle puncture tissues were collected from 3 children with IgAN, 4 children with MCD, and 1 child with IgA-MCD in Children's Hospital of Chongqing Medical University, and adjacent normal tissues were collected from 1 child with renal tumor as control group. Children in the three disease groups had clinical manifestations of nephrotic syndrome, and nephrotic-level proteinuria at the time of sampling. High-throughput, unbiased single-cell transcriptome sequencing was performed on the above renal tissue samples, and the sequencing results were systematically compared and analyzed.

Results: By analyzing single-cell sequencing data, we systematically described single-cell transcriptome cell maps of renal tissues form children with nephrotic-level albuminuria with different pathologic types (IgAN, MCD, IgA-MCD). Twelve cell types, such as mesenchymal cells and podocytes, were defined by classical marker genes. By comparing the constituent ratio of renal cells and PC analysis of cell subsets in the control group and the three disease groups, it was found that IgA-MCD was closer to MCD. By comparing the differential genes of the three disease groups with those of the control group, we found that the number of differential genes in IgAN's podocytes was significantly higher than that in the other two groups. Compared with the control group, HMGCS2 was significantly up-regulated in IgA-MCD, and cellular energy metabolism was enhanced. Through pairwise comparison among the three disease groups, it was found that there was no significant difference in genes in podocytes between IgA-MCD and MCD. Compared with IgAN, CXCL12 gene expression in IgA-MCD is significantly up-regulated, and CXCL12 can recruit immune cells and lead to cell damage.

Conclusion: The overall transcription profile of IgA-MCD is more similar to that of MCD. CXCL12 was specifically highly expressed in the podocytes of IgA-MCD, which may be used as a marker molecule for functional changes of IgA-MCD podocyte. IgA-MCD mesenchymal cells were significantly different from those in the other two disease groups. The significant up-regulation of CD81 may be a molecular signal that leads to the activation, proliferation, and secretion of more extracellular matrix of IgAN-MCD glomerular mesenchymal cells. We analyzed the associations and differences among IgAN, MCD and IgA-MCD at the single-cell transcriptome level, which provided a new perspective and insight for the follow-up study of the pathogenesis of the diseases.
We designed a pilot study in paraffin-embedded kidney tissue (FFPE) from LN patients to evaluate differences between gene expression at diagnosis (kidney biopsy diagnosis) and 2 years after achieve a complete renal response (protocol kidney biopsy). We evaluated if transcriptome analysis results could be verified through immunofluorescence staining (IF) in kidney biopsies (diagnosis biopsy vs protocol biopsy).

Method: We included diagnosis and protocol biopsies from 16 LN patients with class III and/or IV. All patients received prednisone (0.5 mg/kg) plus mycophenolic acid. Complete renal remission was defined as normal renal function, uPCR < 300 mg/gr and inactive urine sediment. RNA-Seq (RNA-Seq) was performed in FFPE, Human MSigDB Collections were used for gene enrichment analysis and Gene sets derived from the Biological Process (RNA-Seq) was performed in FFPE, Human MSigDB Collections were used for gene enrichment analysis and Gene sets derived from the Biological Process

Results: 16 LN patients were included, Class III (43.8%), Class IV (43.8%) and Mixed Class (12.5%). 100% patients were women and Caucasian with mean age 40.9±7.1 years. RNA-Seq showed 2 overexpressed groups of genes (GO) in diagnosis biopsies, expression of this GO was not detected in protocol biopsies: GO-Complement_activation (NES 2.26, p = 4.2E-0.5): Properdin, Ficolin, C3, Factor B, C3AR1, C4 y CDC59.

GO-Humoral_Immune_Response_Mediated_Circulating_Immunoglobulin (NES 2.10, p = 7.6E-0.6): IgG1, IgG2, IgA, chemokine receptors 2 y 7 and receptor 13 TNF.

Results were verified using IF staining in kidney biopsies, in protocol biopsies were observed a significant reduction in C1q and C3 complement proteins staining: C1q (78% vs 22.2%, p = 0.006), C3 (73.3% vs 27.8%, p = 0.005); results in immunoglobulins staining also agree with transcriptome analysis results, so that we observed significant reduction in IgA and IgG: IgG (69% vs 36.4%, p = 0.009) and IgA (83.3% vs 16.7%, p = 0.02) while IgM staining not showed differences between diagnosis biopsy and protocol biopsy (43.8% vs 45.5%).

Conclusion: Transcriptome analysis in kidney tissue from LN patients, identified complement proteins and humoral mediators overexpressed at LN diagnosis and infraexpressed at complete renal remission; the results could help nephrologist to investigate the role of these protein as LN biomarkers.

Background and Aims: Machine learning (ML) holds great promise for improving diagnostics, prognostication and theranostics in nephropathology. So far, applications have not gone much further than segmentation of tissue compartments on whole slide images (WSIs) of paraffin sections. As a proof-of-concept study, we describe the development of a diagnostic classifier for glomerulopathies based on expert-annotated or automatically segmented glomerular transactions from periodic-acid Schiff (PAS) paraffin sections only.

Method: A total of n = 350 biopsies from 5 institutions with 12 classes of glomerulonephritis IgA nephropathy (IgAN), membranous nephaso-phy (Membranous), anti-glomerular basement membrane antibody GN (ABMGN), infection-associated GN (IAGN), ANCA-associated GN (ANCA- GN), idiopathic membranoproliferative GN (MPGN), SLE GN class IV (SLE-GN-IV), cryoglobulinemic GN (CryoGN), C3 GN (C3-GN), dense deposit disease (DDD), fibrillar GN (FibrillarGN) and proliferative GN with monoclonal immunoglobulin deposits (PGNMID) were included in the study with their respective PAS sections. Glomerular transactions were expert-annotated by a nephropathologist and automatically segmented with...
our own transformer-based segmentation model trained on 100 biopsies with thrombotic microangiopathies and a range of vascular, vasculitic and glomerular diseases closely resembling/mimicking thrombotic microangiopathies. For classification, we divided the cohort into 5 folds for internal cross-validation, performed sample size augmentation with various methods (including shifts in resolution/scale, AutoAugment and others) and trained our proprietary self-attention-based MILx architecture on an EfficientNet backbone with selection of glomerular crop batches by soft Markov chain Monte Carlo sampling in a semi-supervised fashion, with diagnostic class labels for each biopsy. We compared the performance of our proprietary architecture on both expert-annotated and automatically segmented glomerular crops with a recently published benchmark architecture (CLAM) for multiple-instance learning in histopathology.

**Results:** Automatic glomerular segmentation performance was excellent with mean AUC and sensitivity (mean average recall) over all classes at 0.904, with near perfect mean average specificity (0.994), as expected best for Membranous, worst for ABMGN. Classification performance of MILx with expert-annotated glomerular crops as inputs had a mean balanced accuracy of 0.84, with AUC metrics in descending order of 0.97 for Membranous, 0.89 for ABMGN, 0.88 for IgAN, 0.86 for Fibrillar, 0.83 for MPGN, 0.80 for ANCA-GN, 0.79 for DDD, 0.78 for PGN MID, 0.75 for IAGN, 0.73 for SLE-GN-IV and CryoGN. Performance with MILx was similar for automatically segmented glomerular crops as inputs. On this dataset, MILx outperformed CLAM with both entire WSIs as well as expert-annotated glomerular crops as inputs (mean balanced accuracy of 0.72) by a significant margin.

**Conclusion:** This proof-of-concept study indicates that nephropathology-specific architectures like our MILx can be trained for complex tasks on relatively small biopsy cohorts. We should be able to deliver an end-to-end-pipeline for this diagnostic and other tasks based on training sets with case-labels provided by trusted institutions with only minimal expert labeling or annotation required.

**AUTOGRAPHY REGULATES TUBULAR CELL SENESCENCE IN DIABETIC KIDNEY DISEASE**

Ying Zhang, Xiao Liang Zhang and Yu Zhao

School of Medicine, Southeast University, Department of Nephrology, Zhong Da Hospital, Nanjing, P.R. China

**Background and Aims:** Cellular senescence commonly occurs in innate renal cells of diabetic kidney disease (DKD) and autophagy may be implicated. However, the characteristics of senescent cells in different pathological stages of DKD, and the driving force behind the cell senescence remain primarily unknown. This study aimed to examine kidney cellular senescence and its relationship to renal function in DKD and the effect of autophagy on high-glucose-induced cellular senescence.

**Method:** According to the DKD pathologic type, 46 patients diagnosed with renal biopsy were categorized into I IIa IIb III IV classes. The other four normal kidney specimens taken from patients with renal trauma were as the control group. Pathological changes in kidney tissues were detected by PAS staining, and the expressions of autophagy-related protein LC3 and senescence marker p21 were demonstrated by immunohistochemical staining. DKD rats were established by intraperitoneal injection with streptozotocin (STZ). HK-2 cells were cultured with 35mM glucose with or without autophagy inhibitor (3-methyladenine, 3-MA) and lysosomal inhibitor (chloroquine CQ). Immunohistochemistry and Western Blot were used to detect the expression of the senescence markers p53 and p21, as well as the autophagy-related proteins LC3 and p62. The electron microscopy technique was used to observe the number of autophagosomes in the DKD rats and each group of HK-2 cells.

**Results:** (1) In renal tissues of DKD patients, p21 infiltrated the interstitium and tubules, while LC3 was primarily expressed in the tubules. Both p21 and LC3 expression increased over time as the disease progressed (P < 0.05) and were directly proportional to blood creatinine and proteinuria, respectively. Additionally, p21 and LC3 expression were positively correlated. (2) Compared with the control group, the renal tissue of DKD rats displayed higher levels of p21, p53, LC3, and p62 expression (P < 0.05), higher levels of renal tubular autophagosomes, and increased co-expression of p21 and LC3 (P < 0.05). (3) HK-2 cells treated with high glucose exhibited increased expression of p21, p53, p62 and LC3, as well as the number of autophagosomes (P < 0.05). (4) 3-MA reduced p21 and p53 expression compared to the high glucose group (P < 0.05), whereas the opposite trend was observed in the CQ treatment (P < 0.05). **Conclusion:** Renal tubular cell senescence is closely associated with DKD progression. Autophagic flow may be involved in high glucose-induced renal tubular cell senescence.

Background and Aims: The transforming growth factor-β1 (TGF-β1) is a pleiotropic cytokine, with distinct roles both in fibrosis and inflammation and acts through the Smad signalling in renal injury. We sought the expression of TGF-β1/Smads signalling in ANCA associated glomerulonephritis (AAGN) and we assessed this expression in correlation with the renal injury at diagnosis as well as the renal progression.

Method: We evaluated the immunohistochemical expression of TGF-β1, phosphorylated Smad3 (pSmad3) and Smad7 semi-quantitatively and quantitatively using computerized image analysis program in different compartments of 11 renal biopsies with AAGN and the results were statistically analysed with clinicopathological parameters. We also used healthy controls and disease controls with other types of Glomerulonephritis (GN).

Results: The expression of TGF-β1, pSmad3 and Smad7 were higher in AAGN, compared to healthy controls and other types of GN. The glomerular pSmad3 presented preferable expression at mesangial and endothelial cells and its intensity was correlated with higher chronicity index [global glomerulosclerosis (p<0.001) and interstitial fibrosis (p = 0.03)] (Figure 1). We also reported that the intensity of Smad7 was correlated with higher activity index [cellular crescents (p = 0.03), and fibroid necrosis (p<0.001)] (Figure 2). TGF-β1 expressed at peritubular capillaries around the areas of tubulitis and its expression was correlated with more severe renal injury at diagnosis [higher creatinine (p = 0.019) and proteinuria (p = 0.008)]. At last follow-up (median time 5 years) we reported a significant worst renal function with higher intensity pSmad3 (p = 0.05) and TGF-β1 (p = 0.005), while the expression of Smad7 tended to be beneficial in the maintenance of eGFR (p = 0.055).

Conclusion: The TGF-β1/Smad signalling is activated in AAGN and its expression is correlated with renal injury both at diagnosis and renal progression.

Background and Aims: Rapidly progressive glomerulonephritis/crescentic glomerulonephritis (RPGN/cGN) may compromise renal function in the short or medium term thus evolving into acute kidney injury (AKI) or chronic kidney disease. Innate and adaptive immune responses are placed at the epicentre of cGN. However, molecular pathways involved in the activation of these responses are by far less known. Sting is an innate immune DNA-sensing involved in promoting kidney injury and fibrosis with unknown participation in RPGN/cGN.

Method: We investigated whether Sting pathway activation contributes to the development and progression of RPGN/cGN in a preclinical model of nephrotic nephritis (NTN) induced by an anti-glomerular basal membrane serum. Sting expression as well as humoral and cellular innate immune responses, histological injury and functional responses in the kidney were studied in wild-type and Sting−/− mice.

Results: Sting was found expressed at higher gene and protein levels and located in tubulointerstitial and intraglomerular and periglomerular areas and tubules in kidneys from NTN wild-type mice compared to non-diseased control animals. Sting deficiency significantly decreased NTN-induced cytokine/chemokine synthesis and hence the intrarenal transit of diseased control animals. Sting deficiency significantly decreased NTN-areas and tubules in kidneys from NTN wild-type mice compared to non- and located in tubulointerstitial and periglomerular

TUNEL-positive dead cells was also significantly reduced in Sting−/− mice. Consistent with these findings, Sting absence significantly diminished NTN-increased urea and creatinine plasma levels.

Conclusion: Sting inhibition positively impacted several well-characterized cGN-associated pathogenic events thus ameliorating the outcomes of the disease. These results identified Sting antagonism as a potential therapy to help combat cGN.

Nefrologia, Brescia, Italy

Background and Aims: Renal involvement is common in light-chain (AL) amyloidosis (60%-80% cases). To date, renal biopsy is not recommended as a routine examination in patients with AL amyloidosis and renal involvement. However, renal histology can have an important prognostic role. Amyloid load, representing the quantification of amyloid deposits into the kidney, might be linked to both systemic disease severity and temporal exposure to amyloid deposition in different organs. We proposed an amyloid load scoring system in order to predict renal and overall survival in patients with AL amyloidosis.

Method: We retrospectively collected AL cases who underwent to renal biopsy from 17 Italian Institutions. The primary composite outcome includes time to death and time to end-stage kidney disease development. We applied an Amyloid load score characterized by a semiquantitative evaluation for amyloid deposition in glomeruli, interstitium, and vessels. Each lesion was scored from 1 to 3. The sum of damage (0–9) associated with amyloid deposition was calculated, indicating total numeric codes of renal pathologic damage.

Results: Between 2008 to 2022, we recruited 162 patients. Their median age at diagnosis was 66.5 (±10) years, serum creatinine was 1.95 (±1.92) mg/dl and proteinuria was 5.4 (±4.6) grams per 24hr. After a median follow-up of 4.1 (±3.6) years and a 6-month landmark analysis, the primary composite outcome was achieved by 46/122 (38%) patients. Seventy-eight patients (60%) experienced a hematologic response, classified as a complete response or very good partial response, while 49 (37.4%) patients obtained a renal response. Among them, 39 (80%) patients had an amyloid score ≤4 and only 4 had an amyloid score> 5. Higher values of Amyloid load score, as an expression of amyloid load linked to both disease severity and temporal exposure, were significantly associated with an increased risk of end-stage kidney disease (ESKD) (log rank 12.80, p = 0.005) (Figure 1A) and death (log rank 44.97, p<0.0001) (Figure 1B). Interestingly, 6/162 (3.7%) patients had a negative Congo red stain in renal biopsy (AL amyloidosis diagnosis through an abdominal fat pad aspiration plus monoclonal restriction at immunofluorescence staining or amyloid fibrils detected by electron microscopy). Moreover, 49/156 (31.4%) patients did not show a monotypic (kappa or lambda) immunofluorescence staining. Despite the widely accepted clinical definition of renal amyloidosis is “more than 0.5 g/24hr of non-Bence Jones proteinuria in presence of a positive fat pad aspiration”, 8/162 (4.9%) patients with a biopsy-proven renal AL amyloidosis showed less than 0.5 g/24hr of non-Bence Jones proteinuria. AL amyloidosis showed to overlap in 14/153 (9.2%) patients with other Monoclonal gammopathy of renal significance (MGGRS), such as LCD (4 cases), C3 nephropathy (4 cases), light-chain proximal tubulopathy (2 cases), light chain-related tubulointerstitial nephritis (2 cases), cast nephropathy (1 case), type 1 cryoglobulinemia (1 case).

Conclusion: Renal histopathological scoring of amyloid deposits is crucial to assess disease progression in patients with AL amyloidosis, and in particular a score ≥5 identifies patients at greater risk of evolution of renal damage and mortality. If these data were also confirmed in a larger independent cohort, they could support the use of renal biopsy as an essential prognostic (as well as diagnostic) tool to be included as a routine investigation in all patients with suspected AL amyloidosis.

Background and Aims: Thrombotic microangiopathies, comprising atypical hemolytic uremic syndrome (aHUS) and other diseases, can present with a broad clinical and histopathological spectrum. On our way to an evidence-base for the nephropathological work-up of TMA, we have chosen a machine-learning approach, thus eliminating suboptimal reproducibility of descriptors for individual lesions in the three decisive compartments artery, arteriole and glomerulus with human experts. Here, we present our results for an end-to-end diagnostic system.

Method: We collected 50 random biopsies with TMA s of various etiologies (including aHUS, hypertension-associated, systemic sclerosis, anti-phospholipid antibody syndrome and others) and 50 biopsies with Mimickers (diagnostic differences of TMA), including severe hypertensive nephropathy, necrotizing arteritis/arteriolitis, cryoglobulinemic vasculitis from the three participating centers Cologne, Well-Cornell Medical Center, and Turin. Whole slide images (WSIs) from all four nephropathology stainings HE, PAS, trichrome and Jones were included in this study. We developed an instance segmentation Mask-RCNN model with a Swin Transformer (t) backbone on tissue crops detected using a lightweight variant of the U-Net segmentation architecture. For the classification model we used our own MorphSet segmentation crops entered in three separate compartment channels. Batches were chosen with Monte Carlo sampling or using our own soft Markov Chain Monte Carlo (MCMC) approach. Results of the classification model are reported with 5-fold internal cross-validation.

Results: Segmentation performance measured as mIOU, mAP, mAR, mF1, mAS for artery reached 0.565, 0.739, 0.679, 0.704, 0.995, for arteriole 0.342, 0.531, 0.488, 0.490, 0.996, for glomeruli 0.818, 0.880, 0.919, 0.986, 0.993. Classification accuracy reached 90% with no false positives for TMA. Missed cases of TMA could be Salvaged by an experienced nephropathologist on the display of decisive compartment crops, which were selected using model confidence averaged across each sampling iteration.

Conclusion: We have designed and trained architectures capable of segmenting decisive compartments and diagnosing TMA s on renal biopsy sections. This will enable automatic analysis of clinicopathological datasets with TMA in large cohorts. Our ultimate goal is to use large cohorts from collaborating institutions for weakly supervised, case-level-annotated training of diagnostic, prognostic and theranostic classifiers.

CLINICOPATHOLOGIC CORRELATIONS OF URINARY PROTEOMIC AND METABOLIC ANALYSIS IN PATIENTS WITH RENAL AA AMYLOIDOSIS AND MEMBRANOUS NEPHROPATHY
Deniz Aral Ozbek1, Sila Koc2, İdil Yet3, Nazı Ezgi Kucuk4, Sevlay Kablan5, Meral Uner5, Incilay Lay6, Toluğa Yıldırım7, Seref Rahmi Yılmaz1 and Bulent Altun1
1Hacettepe University Hospital, Internal Medicine, Ankara, Turkey, 2Hacettepe University Hospital, Nephrology, Ankara, Turkey, 3Hacettepe University Graduate School of Health Sciences, Bioinformatics, Ankara, Turkey, 4Koc University College of Sciences, Molecular Biology and Genetics, Istanbul, Turkey, 5Hacettepe University Faculty of Pharmacy, Analytical Chemistry, Ankara, Turkey, 6Hacettepe University Hospital, Pathology, Ankara, Turkey and 7Hacettepe University Hospital, Biochemistry, Ankara, Turkey

Background and Aims: AA Amyloidosis is a multisystemic amyloidosis subtype that develops on the background of various chronic inflammatory etiologies. Urinary omics studies have become a promising tool for elucidating pathophysiology and prognosis of glomerular diseases. However, no urinary omics analysis has been performed focusing on renal AA amyloidosis in literature to the best of our knowledge. Our main aim in this study is to perform a comparative urine proteomic and metabolomic analysis of recently diagnosed renal AA amyloidosis and to investigate the correlation of bioinformatic results with clinical and pathological data.

Method: Urine samples of 8 recently diagnosed AA amyloidosis (AA), 8 membranous nephropathy (MN) and 6 healthy control group patients were collected before kidney biopsy procedure. Proteomic analyzes were performed with nLC-Q-TOF MS/MS and metabolomic analyzes were performed by GC/MS in all patients. Biopsy specimens were scored according to glomerulonephrosclerosis (G), tubular atrophy (TA) and interstitial fibrosis (IF) grades by two pathologists. Raw spectroscopic data was analyzed using MaxQuant and M$^3$-DIAL programs for proteomic and metabolomic studies, respectively. Statistical analysis of the differences in molecules between study groups were performed with ANOVA and HSD-Tukey tests. Principal component (PCA) and heatmap analyzes were made in R language, while gene ontology (GO), network and functional enrichment analysis of bioinformatic results were performed with PANTHER, STRING and MetaboAnalyst databases.

Results: In comparison between AA and MN groups, median eGFR values tend to be lower in the AA group (67.6 vs 112 ml/min/1.73 m² respectively, p = 0.08). Median 24-hour urine protein levels did not show statistically significant difference (9499 vs 9512 mg/day respectively, p = 0.9). Percentage of patients with moderate/severe IF/TA was higher and G score was tend to be in AA group compared to MN group (p values 0.02 and 0.07 for IF/TA and G scores, respectively). As a result of proteomic analysis, a total of 859 proteins were determined. Statistical analysis showed 51 proteins that were significantly differ in AA group compared to the control group. GO and functional enrichment analyzes showed that statistically most significant sub-domains were mainly related with cell-cell adhesion (Figure 1 & 2). In comparative analysis between AA and MN patients, uronodulin (UMOD) was lower in the AA group than in the MN group (logFC -3.37), whereas ribonuclease 1 (RNASE1) and α-1-microglobulin/bikunin precursor protein (AMBP) were higher in the AA group (logFC 3.41 and 3.07, respectively). In Spearman correlation analyzes, significant negative correlations were demonstrated between UMOD-proteinuria (r = -0.48, p = 0.03) and between AMBP-eGFR (r = -0.69, p = 0.003) variables. Metabolomic analysis showed 9 metabolites that were significantly different between AA and other study groups. Myo-inositol and urate were higher in AA group compared to MN group, while D-mannitol and N-acetylglycaramate were higher in AA group compared to the control group. Significant positive correlation independent of GFR was detected between RNASE1 and urate (r = 0.63, p = 0.01).

Conclusion: Our study is the first urinary comparative omics analysis performed on renal AA amyloidosis patients to the best of our knowledge. We demonstrated specific protein and metabolites that distinguish AA group from the control and MN groups. Enrichment and GO analyzes between AA and the control group showed a negative enrichment in cell-cell adhesion related sub-domains, suggesting a possible increased urinary shear stress resulting in downregulation of catheders in AA amyloidosis. In comparative analysis between AA and MN groups, UMOD and AMBP proteins and myo-inositol were thought to be associated with high tubulointerstitial damage, whereas RNASE1 and urate were believed to be related with systemic inflammation and endothelial damage [1].

REFERENCE
Figure 1. The analyses were performed using STRING online software with a medium confidence level (0.4), providing the significantly enriched GO terms and Reactome pathways. The vertical axis displays the significantly enriched biological functions. The horizontal axis indicates the strength of enrichment, which is the log10 (observed/expected proteins in the network that are annotated with a term). The higher the absolute value of the strength, the stronger the impact.
EFFECT OF DIET ON THE COLLECTOR DUCT BEHAVIOUR: RELEVANCE IN PRECLINICAL DRUG DEVELOPMENT

Marta Tejedor¹,²,³, Maria Angeles Gonzalez-Nicolas³, Baris Uzun¹, Luis Antonio Álvarez-Sala-Walther¹,⁴ and Alberto Lázaro¹,³

¹Complutense University of Madrid, School of Medicine, Madrid, Spain, ²Hospital Universitario Infanta Elena, Gastroenterology and Hepatology, Valdemoro, Spain, ³Instituto de Investigación Sanitaria Gregorio Marañón, Renal Physiopathology Laboratory, Department of Nephrology, Madrid, Spain and ⁴Gregorio Marañón General University Hospital, Internal Medicine, Madrid, Spain

Background and Aims: Drug induced syndrome of inadequate antidiuretic hormone secretion (SIADH) is a common problem in clinical practice. Early detection of this side effect at a preclinical level would improve safety and efficiency. We investigate the role of different diets in preclinical detection of SIADH.

Method: Animals were divided into two groups (n = 4 each), one receiving standard pellet based diet, and the other one a diluted hyposodic gelified liquid diet. After one week, both groups were administered daily intraperitoneal (i.p.) injections of desmopressin acetate (ddAVP; 0.4 μg/kg) and a volume of distilled water equivalent to 2.5% of body weight for 7 days. Animals were placed in metabolic cages for 24h at the end of each period to collect and analyse the urine, and a blood sample from the tail vein was obtained. Weight, water and food intake were measured on a daily basis.

Results: Differences in water and electrolyte balance are shown in Table 1. Pellet fed animals presented an increased water intake and produced a more concentrated urine compared to those on a hyposodic diet. When analysed in detail, urinary osmolality was mainly driven by ionic osmoles in pellet fed animals (42.25 ± 4.72 vs 266.30 ± 17.32 mOsm/kg, p<0.005). Of note, there seems to be an occult osmole, especially prominent in the pellet group (osmol gap 20.40 ± 3.18 vs 99.89 ± 9.81 mOsm/kg, p = 0.017). All of the above suggest there is a net retention of water, sodium and potassium in those animals fed with a conventional pellet diet. Daily administration of ddAVP/water induced a mild transient hyponatremia that was recovered 24h later in both groups; this situation was repeated over a 7 day period. Pellet fed animals did not modify water intake, diuresis, free water clearance or urinary osmolality after ddAVP/water treatment, suggesting that hyperosmolar diets significantly increase urinary osmolality fixating urinary water losses and impairing further urinary concentration. On the contrary, animals on a hyposodic diet did present antiaquaresis, as shown by an increase in water intake, a decrease in diuresis and free water clearance and an increase in urinary osmolality. Animals fed with hyposodic diet progressively lost weight, while pellet fed animals did not. However, this trend was reversed after 4 days of treatment with ddAVP/water, again suggesting a degree of water retention. It is remarkable that we have found signs of water retention despite the fact that the induced hyponatremia is mild and transient.

Conclusion: The antiaquaretic effect of ddAVP is overridden by the amount of urinary osmoles excreted when on a pellet diet, which seem to fixate the amount of water in the urine. Therefore, the use of hyposodic diets in preclinical drug development is essential when SIADH is likely to be expected, as its effects will be unnoticed if a standard diet is used.
Diacylglycerol (DAG) and triacylglycerol (TAG) that were significantly elevated compared to healthy controls and patients with hypercholesterolemia. We identified lccDAGs as unique lipids in pFSGS patients with a substantially different lipid profile than healthy controls and patients with familial hypercholesterolemia. We identified lccDAGs as unique lipids in patients with pFSGS, that were not present in controls. This is an interesting finding since the DAG-analogue 1-oleoyl-2-acetyl-sn-glycerol (OAG) is known to be able to induce podocyte injury in vitro [2]. In further research, we will focus on confirming whether lccDAGs are unique to pFSGS patients, whether it is suitable as a biomarker, and whether it plays a causal role in the disease process.

LIPIDOMIC ANALYSIS OF PFSGS PATIENTS’ SERUM TO IDENTIFY POTENTIAL CANDIDATES FOR THE CIRCULATING PERMEABILITY FACTOR(S) IN THE LIPID DOMAIN
Nils Rother, Ilse Rood, Siroon Bekkering, Niels Riksen, Luuk Hilbrands, Rutger Maas, Tom Nijenhuis and Raphael Duivenvoorden

Radboud University Medical Center, Nijmegen, Netherlands

Background and Aims: Patients with primary focal segmental glomerulosclerosis (pFSGS) present with nephrotic syndrome. Whereas the exact pathogenesis is largely unknown, there is strong evidence that one or more circulating permeability factors in the circulation induce podocyte injury. Podocyte injury eventually leads to foot process effacement, massive proteinuria and kidney function loss. Historically, research into the cause of pFSGS has focused primarily on identifying the circulating factor in the protein domain, but reports of successful treatment with lipid apheresis suggest that it could also be a lipid compound. Here, we set out to investigate the lipidome of pFSGS patients’ serum to identify potential candidates for the circulating permeability factor(s) in the lipid domain.

Method: For this lipidomics study, we included 5 patients with pFSGS in whom serum had been collected at the time they presented at our center with active nephrotic syndrome. We compared the serum lipidome of the pFSGS patients with age matched healthy controls (n = 5), and with age matched patients with familial hypercholesterolemia (n = 5) who, like pFSGS patients, have significantly elevated lipid values. Serum was analyzed using the Shotgun Lipidomics platform by Lipotype GmbH (Dresden, Germany), as previously described [1]. The amount of lipids was normalized to the total amount of lipids present within the sample.

Results: The lipidomic profile of patients with pFSGS was markedly different from the profile of healthy controls and patients with hypercholesterolemia. We found differences in various lipid classes in pFSGS patients, including cholesterol esters (CE), lyso-phosphatidylcholine (LPC), phosphatidylethanolamine (PE), diacylglycerol (DAG) and triacylglycerol (TAG) that were significantly changes compared to both healthy controls and FH patients. Diacylglycerols (DAG) were identified as the most significantly increased lipid species in pFSGS. By analyzing the subspecies we discovered that DAGs with carbon chains greater than 38 carbon atoms in both chains combined (long carbon chain DAGs, lccDAGs) were exclusively present in patients with pFSGS.

Conclusion: Our lipidomics data show that patients with pFSGS have a substantially different lipid profile than healthy controls and patients with familial hypercholesterolemia. We identified lccDAGs as unique lipids in patients with pFSGS, that were not present in controls. This is an interesting finding since the DAG-analogue 1-oleoyl-2-acetyl-sn-glycerol (OAG) is known to be able to induce podocyte injury in vitro [2]. In further research, we will focus on confirming whether lccDAGs are unique to pFSGS patients, whether it is suitable as a biomarker, and whether it plays a causal role in the disease process.

CLINICAL PROFILE, MICROSCOPIC FEATURES AND OUTCOMES OF PATIENTS WITH MINOR GLOMERULAR ABNORMALITIES AT NKTI: A 10-YEAR DESCRIPTIVE CROSS-SECTIONAL STUDY
Merry Ann Teus and Eric Chua
National Kidney and Transplant Institute, Adult Nephrology, Quezon City, The Philippines

Background and Aims: Minor Glomerular Abnormality (MGA) is a kidney biopsy diagnosis characterized by the presence of minor structural abnormalities which are not sufficient to be classified under the other known glomerular diseases. Although usually considered a benign renal problem, few literatures mentioned it may cause deterioration of kidney function in the long term. The objective of this study is to describe the clinical profile, microscopy findings, treatment outcome and renal survival of patients diagnosed with Minor Glomerular Abnormalities in NKTI from 2005 to 2015.

Method: This is a Retrospective, Descriptive, Cross-sectional study which included 190 patients who were diagnosed with MGA. Demographic, clinical profile, CKD classification and treatment outcomes were presented using descriptive statistics while renal survival was analysed using Fisher’s Exact Test. Based on the level of proteinuria and serum creatinine, treatment outcomes of the patients were classified as either with (1) complete response [if with reduction in proteinuria to ≤ 300 mg/day (< < 0.3 g/day) and a creatinine clearance ≥ 80 ml/min with no reduction from baseline] (2) partial response [proteinuria between 300 mg and 3 g/day OR by at least 50% from baseline level and with no deterioration in creatinine clearance], (3) relapse [patients whom (a) after a complete response to treatment (baseline proteinuria ≤ 300 mg/day), there is an increase in proteinuria to ≥ 1.0 g/day or (b) after a partial response (baseline proteinuria between 300 mg and 3 g/day), there is an increase in proteinuria to ≥ 3 g/day or increase in proteinuria by ≥ 50%, or (c) after a partial response (baseline proteinuria > 3 g/day), there is an increase in proteinuria by ≥ 50%], or (4) unsatisfactory response to treatment if complete or partial response is not met. Renal survival was assessed by classifying the renal status of the patients as either with (1) Normal or Mildly Decreased GFR [CKD 1-2] or (2) with moderately decreased kidney function to renal failure [CKD 3-5].

Results: The mean age of the MGA patients at diagnosis was 37 years old. Of the 190 subjects of this study, 53.68% were female and 73.16% has no comorbidities. Proteinuria was the most common reason for consult (66.32%), followed by hematuria (38.42%) and worsening renal function (14.21%). Most of the patients had Nephrotic Syndrome (39%) before biopsy. The top three Electron Microscopy findings were Minimal Change Disease (24.4%) Segmental Podocyte Foot Processes Effacement (True MGA) at 27.4% and Thin Basement Membrane Disease (22.6%). At one year and five years, 13.68% and 4.74% respectively have complete response to treatment while 22.10% and 13.15% respectively have either partial or unsatisfactory response to treatment. Eighty patients (86.02%) at one year and 33 patients (78.57%) at 5 years remain at CKD 1-2. When the renal survival of the True MGA and Non-MGA patients were compared using Fisher Exact Test, there was no significant difference between the two groups (p values of 0.080 at 1 year and 0.99 at 5 years).

Conclusion: Minimal Change Disease is the most common Electron Microscopy diagnosis. Majority have good renal survival, but few progressed to CKD 3-5. Survival between MGA and Non-MGA patients are similar.

**UNIQUE SIGNATURES OF EXTRACELLULAR MATRIX REMODELING IN PATIENTS WITH LUPUS NEPHRITIS, FSGS, AND MCD: A PILOT STUDY**

Nadja Sparding, Federica Genovese, Morten A. Karsdal, Ondrej Derner, Michaela Neprasova, Doubavka Frausova, Marek Kollar, Zdenka Hruskova and Vladimir Tesar

1Nordic Bioscience, Herlev, Denmark, 2First Faculty of Medicine, Charles University and General University Hospital in Prague, Department of Nephrology, CZ-121 08 Prague 2, Czech Republic and 3Institute for Clinical and Experimental Medicine, Department of Pathology, Prague, Czech Republic

**Background and Aims:** Glomerulonephritis is one of the most common causes of chronic kidney disease (CKD). Causes of glomerular diseases include lupus nephritis (LN), focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD). The hallmark of CKD is renal fibrosis characterized by an imbalanced turnover of extracellular matrix (ECM) components and CKD is associated with increased inflammation. The aim of this study was to screen a biomarker panel based on extracellular matrix remodeling biomarkers as well as fibrotic activity and inflammation biomarkers. Additionally, to identify biomarkers that are differentially expressed in glomerular diseases compared to healthy and that are differently expressed between the different etiologies. The following biomarkers were measured in serum and/or urine samples from all 154 subjects:

- Interstitial matrix remodeling biomarkers: formation of collagen type III (PRO-C3) and VI (PRO-C6), and degradation of collagen type III (C3M).
- Basement membrane remodeling biomarkers: MMP-mediated degradation of collagen type IV (C4M, C4G, TUM), laminin (LG1M) and perlecain (LG3).
- Two biomarkers of fibrotic activity; acetylated N-terminal of α-smooth muscle actin (αSMA) and transforming growth factor β (TGF-β).
- An inflammation biomarker of calprotectin (CPa9-HNE) reflecting neutrophil activity.

**Results:** Overall, all three diseases showed the same trend of change (either no change, increase or decrease compared to healthy controls) in biomarker levels. There was a significant increase of PRO-C3, PRO-C6, TUM, LG1M, αSMA, and CPa9-HNE in serum, and a significant decrease of C3M and C4M serum in patients compared to healthy controls. Four of the biomarkers were differentially expressed between the different etiologies. In serum, C4G levels were significantly higher in LN and MCD compared to FSGS, LG1M levels were significantly higher in LN compared to MCD, and CPa9-HNE levels were significantly higher in MCD compared to LN (all, P<0.05). In urine, TUM levels were significantly higher in LN compared to FSGS and MCD (P<0.05).

**Conclusion:** The data presented in this study indicate that both biomarkers of interstitial matrix and basement membrane remodeling as well as biomarkers of fibrotic activity and inflammation reflect the changes that take place during development of glomerular diseases. Some of these markers may be able to distinguish etiologies including the hardly differentiated diseases FSGS and MCD. This needs to be tested in larger studies.

**RENAL CONTRAST-ENHANCED ULTRASOUND AND GLOMERULONEPHRITIS: A GOOD MARKER OF DISEASE ACTIVITY**

Federica Urciuolo, Martina Ambrogi, Gianmarco De Luca, Fabrizio Pizzolante, Rocco Baccaro, Giuseppe Grandaliano and Stefano Costanzi

1Department of Translational Medicine and Surgery, Catholic University of Sacred Heart, Nephrology, Dialysis and Transplantation, A. Gemelli University Hospital Foundation, Italy and 2Catholic University of Sacred Heart, Gastroenterology, A. Gemelli University Hospital Foundation, Italy

**Background:** Contrast-enhanced ultrasound (CEUS) could provide a lot of information of renal blood flow. Renal blood flow is an excellent marker of inflammatory and fibrotic processes in the kidney such as glomerulonephritis. Therefore, in patients with these diseases, renal CEUS can be both a prognostic marker and an index of response to therapy. Currently in the literature there are preliminary studies showing the role of CEUS in terms of histology and outcome in the evaluation of patients with glomerulonephritis. In this pilot study we used perfusion CEUS parameters (WiR and WoR; WiAUC and WoAUC) as possible markers of renal microvascular damage. We compared the perfusion parameters with the clinical and histological findings of our patients.

**Method:** Eighteen patients with clinical and laboratory signs of glomerulonephritis were enrolled. All patients underwent ultrasound-assisted renal biopsy and B-mode ultrasound examination, color Doppler ultrasound and contrast-enhanced ultrasound. Time Intensity (TI) curves were obtained from renal CEUS. TI curves and several quantitative perfusion parameters were defined using VueBox® Quantitation Software.

**Results:** From April to October 2022, 18 patients (12 men and 6 women) with clinical and laboratory suspicion of glomerular disease were enrolled. Median age was 48.05 years, all patients underwent renal biopsy and contrast-enhanced ultrasound at basal condition. Table 1 shows patients characteristics. CKD patients were stratified into two groups according to their eGFR: group I (eGFR < 60 ml/min/1.73 m², n. = 4) and group II (eGFR ≥ 60 ml/min/1.73 m², n. = 3). Moreover, we divided patients into two groups based on the presence of nephrotic-range proteinuria (≥ 3.5 g/24h). At this time, seven patient data are suitable for analysis. The small sample size at present does not allow for statistical significance. However, in our study, the persistence of contrast agent signal during the wash-out phase was differed markedly in correlation with the degree of CKD. In particular, we observed a slower wash-in phase in the presence of vascular hyalinosis (Fig. 1).

**Conclusion:** Our experience seems to confirm that CEUS parameters can be excellent indicators both in terms of patient disease outcomes and histological data. CEUS can effectively and quantitatively demonstrate renal microvascular perfusion in patients with glomerulonephritis. Future goal is that CEUS could also be a prognostic and follow-up marker after renal biopsy in patients with glomerulonephritis.
Figure 1: Relationship between perfusion CEUS parameters and renal microvascular damage.

EFFECTS OF CONDITIONED MEDIUMS COLLECTED FROM 2D OR 3D CULTURED MSCS ON KIDNEY FUNCTIONS OF RATS WITH AUTOIMMUNE DIABETES INDUCED WITH STREPTOZOCIN
Serbay Ozkan1,2, Basak Isildar2,3, Hakan Sahin3, Halil Ibrahim Saygi2,4, Dildar Konukoglu5 and Meral Koyuturk2

1Izmir Katip Celebi University, Faculty of Medicine, Histology and Embryology, Izmir, Turkey, 2Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Histology and Embryology, Istanbul, Turkey, 3Balikesir University, Faculty of Medicine, Histology and Embryology, Balikesir, Turkey, 4Istanbul Medeniyet University, Histology and Embryology, Istanbul, Turkey and 5Istanbul University-Cerrahpasa, Cerrahpasa Faculty of Medicine, Biochemistry, Fatih, Turkey

Background and Aims: The main mechanism of therapeutic action of mesenchymal stem cells (MSCs) could be resulted from their secretome content rather than their direct differentiation into damaged cells [1, 2]. Preconditioning of MSCs with different strategies like culturing in 3 dimensional (3D) culture scaffolds could improve their therapeutic potential [1]. Based on our previous study [1] in which the concentrations of total protein and specifically VEGF and IL-4 in conditioned mediums (CMs) collected from MSCs cultured in 3D culture conditions were increased compared to one of 2D, the aim of this study is comparative analysis of effects of CMs obtained from MSCs incubated under 2D and 3D culture conditions on kidney functions of rats with autoimmune type 1 diabetes (aT1D) induced with streptozocin (STZ).

Method: Isolation and characterization of the umbilical cord MSCs and the following analysis of concentrations of total protein and paracrine factors in the 2D-CMs and 3D-CMs were performed as it was mentioned [1]. Sprague-Dawley rats were treated with 20 mg/kg STZ for 5 consecutive days to induce T1D and 12 doses of CMs were intraperitoneally introduced for 4 weeks in accordance with the timeline defined in Figure 1. Therapeutic effects of CMs were comparatively investigated by biochemical, physical, histopathological and immunohistochemical analysis.

Results: At the end of the 2nd week, urinary albumin/creatinine (u-Alb/Cr) ratio and creatinine removal rate (Crr) of diabetes were significantly aggravated compared to control group (p = 0.0001 and p = 0.13 respectively). At the end of the 7th week, u-Alb/Cr ratios of both treatment groups were significantly improved compared to one of diabetes group (p = 0.029 vs p = 0.002). There was no statistical difference among all groups for Crr values. In the post treatment period u-Alb/Cr ratio was exacerbated (p = 0.014) while Crr value was not changed compared to pre-treatment period (p = 0.713). There was no statistical change between the pre- and post-treatment values of u-Alb/Cr ratio and Crr for both treatment groups. Renal mass index of control group was lower than the ones of experimental groups, while weight percent change from pre- to post-treatment period of control group was statistically higher than the ones of experimental groups (p = 0.0001). However, there was no statistical difference for both parameters among the experimental groups (Figure 2). Histopathological evaluations showed that cortical tubular damage (CTD) was significantly ameliorated in only D-+3D-CM group compared to diabetes group (p = 0.012), while there was no statistical change in glomerular fibrosis in both treatment groups (Figure 3.1 and 3.2 respectively). Immunohistochemical analysis indicated that nephrin expression was insignificantly increased in both treatment groups compared to diabetes group (Figure 3.3). Preliminary evaluation of thicknesses of glomerular basal membrane and pedicel with transmission electron microscopy (TEM) showed no clear difference among all the groups (Figure 4).

Conclusion: CM obtained from MSCs in 3D culture conditions could partially ameliorate kidney functions of aT1D by improving CTD and expression of nephrin which is crucial for the integrity of glomerular filtration barrier.

**Background and Aims:** IgA nephropathy (IgAN) may lead to kidney failure. The urinary proteomics biomarker-based classifier (IgAN237) may predict progression at the time of kidney biopsy [1]. We now studied whether IgAN237 predicts disease progression not only at the time of biopsy but also later in the course of IgAN.

**Method:** Urine samples from 103 patients with biopsy-proven IgAN were analyzed using capillary electrophoresis-mass spectrometry at baseline (IgAN237 score-1) and 89 also at follow-up (IgAN237 score-2). Patients were grouped into ‘non-progressors’ (IgAN237 score ≤ 0.38 Units) and ‘progressors’ (IgAN237 score >0.38 Units). Historical and follow-up data included, e.g., estimated glomerular filtration rate (eGFR)-slopes, urinary albumin/creatinine ratio (UACR)-slopes and medication. Multiple logistic regression analysis, using a stepwise model, was done with progressors and non-progressors as dependent factors including explanatory variables age, sex, eGFR- and UACR-slopes.

**Results:** Median age at biopsy was 44 years (range 11-92); 63% were male. Median interval between biopsy and IgAN237 score-1 was 65 months (0-606), and between IgAN237 score-1 and score-2 was 258 days (71-531). IgAN237 score-1 and score-2 values did not differ significantly and were correlated (rho = 0.44, p < 0.001). Twenty-eight and 26% of patients were classified as progressors based on IgAN237 score-1 and score-2, respectively. The IgAN237 score inversely correlated with the chronic eGFR slopes (rho = -0.278, p = 0.02 for score-1; rho = -0.409, p = 0.002 for score-2) and with ±180days eGFR slopes (rho = -0.31, p = 0.009 and rho = -0.439, p = 0.001, respectively) (Figure 1). The ±180days eGFR-slopes were more reduced for progressors than non-progressors (median -5.98 versus -1.22 mL/min/1.73m² per year for score-1, p < 0.001; -3.02 vs 1.08 mL/min/1.73m² per year for score-2, p = 0.047) (Figure 2). The only significant variable maintained in a multiple logistic regression analysis for IgAN237 score-1 (progressor vs non-progressor) was ±180days eGFR slope (p <0.001) and for IgAN237 score-2 the UACR (p = 0.002) and age at baseline (p = 0.016).

**Conclusion:** The urinary IgAN237 classifier represents a risk stratification tool in IgAN not only at the time of biopsy but also later in the course of the disease. It may guide physicians in management and follow-up strategies in an individualized manner.
Figure 1: Correlation between IgAN237 score-1 (A) and IgAN237 score-2 (B) with ±180 days eGFR-slope (eGFR_{180days-slope}).

Figure 2: Boxplot of comparisons of progressors (IgAN237 > 0.38) vs non-progressors (IgAN237 ≤ 0.38) and ±180 days eGFR-slope (eGFR_{180days-slope}) (mL/min/1.73m² per year) in IgAN237 score-1 (A) and IgAN237 score-2 (B).

# KiM-1: A POTENTIAL BIOMARKER OF ACUTE KIDNEY INJURY AND TUBULOINTERSTITIAL INJURY IN PATIENTS WITH ANCA-GLomerulonephritis

**Background and Aims:** Kidney injury molecule 1 (KiM-1) is a transmembrane glycoprotein expressed by proximal tubular cells, recognized as an early, sensitive, and specific urinary biomarker for kidney injury. Blood KiM-1 was recently associated with the severity of acute and chronic kidney damage but its value in ANCA-associated vasculitis with glomerulonephritis (ANCA-GN) has not been studied. Thus, we analyzed its expression at ANCA-GN diagnosis and its relationship with clinical presentation, kidney histopathology, and early outcomes.

**Method:** We assessed KiM-1 levels and other pro-inflammatory molecules (CRP, IL-6, TNF-α, MCP-1 and PTX3) at ANCA-GN diagnosis and after 6 months in patients included in the Maine-Anjou registry, which gathers data from four French Nephrology Centers diagnosed since January 2000.

**Results:** Blood KiM-1 levels were assessed in 58 patients. Levels were elevated at diagnosis and decreased after induction remission therapy. KiM-1 was associated with the severity of renal injury at diagnosis and the need for KRT. In opposition to other pro-inflammatory molecules, KiM-1 correlated with the amount of interstitial fibrosis and tubular atrophy (IF/TA) on kidney biopsy, but not with glomerular involvement. In multivariable analysis, elevated KiM-1 predicted initial eGFR (β = -19 [-31, -7.6], p = 0.002).

**Conclusion:** KiM-1 appears as a potential biomarker for acute kidney injury and for tubulointerstitial injury in ANCA-GN. Whether KiM-1 is only a surrogate marker for IF/TA or a key immune player in ANCA-GN pathogenesis remains to be determined.
A PHENOTYPIC DRIVEN RITUXIMAB MAINTENANCE APPROACH IS EFFECTIVE AND SAFE IN PATIENTS WITH ANCA ASSOCIATED VASCULITIS
Mattia Tonoli1, Stefania Affatato1, Alice Guerini1, Chiara Salviani1, Elisa Dell’Barba1, Alessandra Gina Gregorini2, Francesco Scolari1, Federica Mescia1,3 and Federico Alberici1,3

1ASST-Spedali Civili di Brescia, Nephrology, BS, Italy, 2Independent researcher, Nephrology, BS, Italy and 3Università degli Studi di Brescia - Facoltà di Medicina e Chirurgia, Brescia, Italy

Background and Aims: Rituximab (RTX) has emerged as the first-line treatment to maintain remission in ANCA-Associated Vasculitis (AAV). However, the ideal strategy for RTX re-dosing is still unclear [1].

Method: In this monocentric and retrospective study we evaluated the efficacy and safety of two RTX-based maintenance regimens in patients with AAV. Fixed-dose (FD) RTX dosing, consisting of at least 3 pre-emptive RTX administrations every 6 months, was preferred in patients judged to be at high relapse risk. Instead, a biomarker-guided on-demand (OD) RTX dosing strategy was preferred for patients deemed at lower risk of relapse; this consisted in RTX re-treatment only in case of B-cell repopulation or rise in ANCA titer. The single patient relapse risk was assessed according to the disease phenotype (granulomatous vs vasculitic), the ANCA specificity and the disease status (onset vs relapse). Relapses were defined as increase of disease activity requiring escalation of immunosuppression; major relapses were defined in case of life/organ-threatening manifestations.

Results: The study included 100 patients followed for a median of 24 months (IQR 20-30), 51% treated with an OD and 49% with a FD strategy. The main baseline characteristics of our cohort are shown in the Table; patients treated with a FD strategy were more often GPA, PR3-ANCA positive, with relapsing disease and ENT involvement and less frequent renal involvement. The FD group received a median of 4 (IQR 4-4) administrations of RTX for a median cumulative dose of 2 g (IQR 2-2). Only 6 (11.8%) patients in the OD group received RTX as maintenance therapy with a median of 1 (IQR 1-3) administration of RTX for a median cumulative dose of 0.75 g (IQR 0.5-1.75). Thirteen relapses occurred, 6 in the FD group and 7 in the OD one. Remission rates were comparable in the two cohorts, with respectively 87.6% and 85.9% of the patients in remission at 24 months (Figure 1 - panel A). No significant differences in remission rates across the 2 groups were observed after considering only major flares or after stratification according to clinical diagnosis (MPA/GPA) and ANCA specificity (Figure 1 - panel B to F). Ten and 20 severe infections (p = 0.383) and 3 and 1 cancer (p = 0.581) occurred respectively in the FD and OD group.

Conclusion: In our case series, a phenotypic-driven approach to RTX maintenance showed comparable efficacy and safety between fixed and on-demand dosing, despite different baseline characteristics between the two groups. These results suggest that personalizing RTX maintenance may be a feasible and safe strategy.

The CIRCRNA–MIRNA–MRNAREGULATORY NETWORK AND THE POTENTIAL ASSOCIATIONS WITH THE PATHOGENESIS OF SYSTEMIC LUPUS ERYTHEMATOSUS
Zheng Fengping, Lishan Tan, Guang Yang, Zhiwei Lai, Sanmu Li and Zibo Xiong
Nephrology, Shenzhen, P.R. China

Background and Aims: This study aimed to explore the possible role of plasma and PBMCs circular RNA (circRNA) in systemic lupus erythematosus (SLE).

Method: Total RNA was extracted from blood plasma samples obtained from 10 patients with SLE and 10 healthy controls and subjected to microarray analysis to define the profile of circRNA expression. The quantitative reverse transcription-polymerase chain reaction amplification (qRT-PCR) was conducted. The overlapped circRNA between PBMCs and plasma was performed, the interactions with microRNAs were predicted, the miRNA target mRNA was predicted, and the GEO database was used. The Gene ontology and pathway analysis was performed.

Results: 131 upregulated and 314 significantly downregulated circRNAs were identified in the plasma of patients with SLE by the Fold change criteria (≥2.0) and P<0.05. The qRT-PCR results showed that the expression of has-circRNA-102531, has-circRNA-103984, and has-circRNA-104262 was increased in plasma of SLE, and the expression of has-circRNA-102972, has-circRNA-102006, has-circRNA-104313 was decreased in plasma of SLE. 28 upregulated circRNAs and 119 downregulated circRNAs were overlapped from PBMCs and plasma, and ubiquitination was enriched. Furthermore, the circRNA-miRNA-mRNA network was constructed in SLE after analyzing dataset GSE61635 from GEO. The circRNA-miRNA-mRNA network comprises 54 circRNAs, 41 miRNAs, and 580 mRNAs. In addition, the TNF signaling pathway and the MAPK pathway were enriched from the mRNA of the miRNA target.

Conclusion: We described differentially expressed circRNAs in plasma and PBMCs, and the circRNA-miRNA-mRNA network was constructed. The network’s circRNAs could be a potential diagnostic biomarker and potentially play an important role in the pathogenesis and development of SLE.
Figure 1: The miRNA-mRNA in SLE. A 781 mRNAs were overlapped from the 6603 mRNAs (target 41 miRNAs) and 2524 mRNAs (GSE61635). B 164 mRNAs were upregulated, and 416 were downregulated, the regulation trend consistent with the circRNAs in plasma and PBMCs of SLE. C The biological process terms of GO enrichment analysis of the overlapped mRNAs. D The KEGG pathway of upregulated mRNAs includes the TNF signaling and MAPK pathways.
#2652
ANTIPROTEINURIC EFFECT OF SODIUM-GLUCOSE COTRANSPORTER 2 INHIBITORS IN GLOMERULAR AND SYSTEMIC DISEASES: A REAL-WORLD CLINICAL STUDY
Fernando Caravaca-Fontán¹, Kate Stevens², Andreas Kronbichler³, Hans Joachim Anders⁴, Jürgen Floege⁵, Gema Maria Fernandez Juarez⁶ and Manuel Praga⁷
¹Centro de investigación Hospital Universitario 12 de Octubre, Madrid, Spain, ²Queen Elizabeth University Hospital, United Kingdom, ³Addenbrooke’s Hospital, United Kingdom, ⁴Ludwig Maximilian University of Munich, München, Germany, ⁵University Hospital RWTH Aachen, Aachen, Germany, ⁶La Paz University Hospital, Madrid, Spain and ⁷University Hospital October 12, Madrid, Spain

Background and Aims: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have recently begun to be used in glomerular/systemic autoimmune diseases with glomerular involvement for the treatment of proteinuria, although the information on real-world clinical settings is very scarce.

Method: Retrospective, observational, international cohort study. Adult patients with biopsy-proven glomerular diseases were included. The main outcome was the percentage reduction in 24-hour proteinuria from SGLT2i initiation to 3, 6, 9, 12 months. Secondary outcomes included percentage proteinuria reduction by type of disease and a reduction of proteinuria ≥30% from SGLT2i initiation.

Results: The study group consisted of 493 patients with a median age of 55 years. All patients were on renin-angiotensin system blockade. Geometric mean percentage change of proteinuria from baseline was –35%, –41%, –45% and –48% at 3, 6, 9 and 12 months after SGLT2i initiation, respectively. Geometric mean percentage change of eGFR was –6%, –3%, –8% and –10.5% at 3, 6, 9 and 12 months, respectively. Results were similar irrespective of the underlying disease. However, a significant correlation was found between body mass index (BMI) and percentage proteinuria reduction at last follow-up (R = –0.11; p = 0.02). By mixed-effects binomial logistic regression
model, serum albumin at the onset of SGLT2i emerged as the main predictor of a $\geq 30\%$ proteinuria reduction (odds ratio for albumin $< 3.5$ g/dl: $0.53$; $95\%$ CI $0.30$–$0.91$; $p = 0.02$). Finally, a slower eGFR decline over time was observed in patients achieving a $\geq 30\%$ proteinuria reduction: $-3.7$ versus $-5.3$ ml/min/1.73m$^2$/year ($p = 0.001$).

**Conclusion:** The use of SGLT2i was associated with a significant reduction of proteinuria, irrespective of the underlying glomerular/systemic disease. This percentage change was higher in patients with higher BMI. Higher serum albumin at SGLT2i onset is associated with higher probability of achieving a $\geq 30\%$ proteinuria reduction.
LIMITATIONS AND UNCERTAINTIES OF ASSESSING AND MANAGING OLDER PATIENTS WITH ANCA ASSOCIATED VASCULITIS

Lauren Floyd1,2, Adam Morris1, Choong Ying Wang1, Hon Lin Henry Wu3, Lee Byrne4, Mohamed Elsayed5, Arvind Ponnusamy5, Duduru Geetha1, Andrew Nixon1,2 and Ajay Dhagude1,2

1Lancashire Teaching Hospital NHS Foundation Trust, Renal Medicine, Preston, United Kingdom, 2University of Manchester, Division of Cardiovascular Sciences, Manchester, United Kingdom, 3Kolling Institute of Medical Research, Renal Research Laboratory, Sydney, Australia, 4University of Manchester, Medical School, Manchester, United Kingdom and 5Johns Hopkins University School of Medicine, Division of Nephrology, United States of America.

Background and Aims: ANCA associated vasculitis (AAV) has a peak incidence in 65-74 yr olds. As a result, it affects an ageing population who are vulnerable to co-morbidities, polypharmacy and frailty. Due to the high burden of morbidity and mortality in these patients, it is increasingly recognised that individualised management is needed. Whilst current immunotherapies are effective, there remains caution in treating older patients due to the potential risks. Yet despite AAV being a condition that predominantly affects older people, few studies have looked specifically at the benefit of treating AAV in such age groups, or at frailty assessment tools to guide treatment.

Method: We aimed to evaluate treatment outcomes in older AAV patients, as well as frailty assessment tools to aid prognostication and management. A cohort study evaluating outcomes of induction immunosuppression in patients ≥75yrs was constructed from 2 centres, with subsequent meta-analysis of published data [1]. In addition, studies identifying frail patients, who may be at risk of adverse outcomes, were carried out using the quantitative tools; Hospital Frailty Risk Score (HFRS) [2] and the Clinical Frailty Scale (CFS).

Primary outcomes were mortality and end stage kidney disease (ESKD). The HFRS was calculated using hospital coding data from any hospital admissions between a patient's AAV diagnosis to 2yr follow up. Patients were categorized into low, intermediate and high HFRS groups. CFS scores at presentation were documented prospectively and then repeated a minimum of 6 weeks from diagnosis. A CFS score of ≥5 was used to categorise frailty. Differences in the scores were assessed and compared to clinical outcomes.

Results: Retrospective analysis of our AAV cohort aged ≥75 yrs demonstrated that induction immunosuppression was associated with a significant reduction in the 2yr mortality risk [HR 0.29 (95% CI 0.09–0.93)]. Following systematic review, with a study population of 290 patients, the pooled HR by meta-analysis confirmed a significant reduction in the risk of death with induction treatment [HR 0.31 (95% CI 0.16–0.57)]. Treated patients had a lower rate of ESKD, but this was not statistically significant [HR 0.71 (95% CI 0.15–3.35)]. Looking separately at frailty assessments, mortality and ESKD were assessed according to HFRS and CFS. Thirty-four patients with AAV aged ≥75 yrs were assessed using HFRS and categorised into the low (n = 18), intermediate (n = 13) and high (n = 3) HFRS groups. All patients in the high HFRS groups had ≥1 episodes of hospitalization after diagnosis of AAV. However, there was no difference in frailty at diagnosis and follow-up was 4. There was no significant interval change in CFS (P = 0.16) suggesting that patients did not become frailer. Instead, there was a tendency towards improved frailty scores at reassessment (n = 17, 43%), with some patients going from a CFS of 6 (moderately frail) to 3 (managing well). There was no significant difference in ESKD between those categorised as frail and non-frail (P = 1.0), although crude mortality was higher among those initially categorised as frail (P = 0.03).

Conclusion: Our research shows that older patients with AAV benefit from standard remission-induction therapy and those treated had favourable mortality outcomes compared to those who were not. Furthermore, frailty assessment tools do not correlate clearly with clinical outcomes. Whilst there is evidence to support the use of HFRS and CFS in a many diseases, its utility in determining frailty and potential susceptibility to adverse effects of therapy in patients with multifaceted, autoimmune inflammatory disease remains limited. Patients may present ‘frail’ as a result of significant disease burden, which has the potential to improve with appropriate treatment. We suggest that age alone and frailty at assessment should not be a limiting factor when considering treatment and prospective studies of this population are needed.

Background and Aims: IgA-nephropathy (IgAN) is a slowly progressive disease characterized by mesangial deposition of IgA1 that causes kidney injury and can eventually lead to end stage renal disease. A key factor underlying the development of IgAN is the presence of galactose-deficient IgA1 (Gd-IgA1) in the circulation. The formation of IgA and IgG antibodies against Gd-IgA1 results in the formation of immune complexes which deposit in the kidney mesangium. Production of Gd-IgA1 hints to defects in B cell regulation. However, the exact immunological dysregulation leading to the formation of Gd-IgA1, and the subsequent antibody formation against it, remains elusive.

Here we use single cell RNA sequencing (scRNA-seq) of circulating leukocytes for in depth analysis of immune cell populations in patients with active IgAN to gain a better understanding of the pathogenesis of this disease.

Method: Peripheral blood mononuclear cells were isolated for scRNA-seq from the blood of four patients with active IgAN, and four controls, matched for age and estimated glomerular filtration rate (eGFR). Cell hashing (Biolegend) of individual samples was performed before pooling samples for scRNA-seq. scRNA expression libraries were performed using the chromium X machine (10xgenomics) according to 10XGenomics single cell V2 user guide. Libraries were sequenced on an Illumina Nextseq500 and reads were mapped to GrCh38 using CellRanger. Differential gene expression analysis was performed for each immune cell type (FDR < 0.05). Reactome pathway enrichment analysis was performed on the differentially expressed genes.

Results: Identification of immune cell subtypes in IgAN patients and matched controls did not show a significant difference in cell numbers or ratios. B cells showed only minor changes in gene expression between IgAN patients and controls, and T cell populations showed changes in a limited set of genes, whereas interestingly, most differentially expressed genes were found in monocytes and NK cells (Figure 1A). Analysis of the differentially expressed genes showed enrichment for genes in interferon signaling pathways, mostly in monocytes and NK cells (Figure 1B). Gene enrichment analysis showed differential expression of type 1 IFN genes and antigen presentation genes, mainly in monocytes and NK cells.

Conclusion: Our data shows the specific endotype of circulating immune cells from patients with active IgAN. While gene expression changes in T and B cells are discrete, changes in monocytes and NK cells appear especially prominent. In these cell types, we observed an important role for interferon signaling. Further analysis of scRNA-seq data in a larger patient cohort will follow, as well as analysis of T and B cell receptor clones in IgAN patients, with which we aim to gain new insights into immune dysregulation in IgAN.
Figure 1: Monocytes and NK cells from IgAN patients show large change in gene expression. Single cell RNA sequencing of peripheral blood mononuclear cells from IgAN patients and matched controls, followed by differential gene expression analysis (FDR < 0.05; n=4) shows profound changes in gene expression of monocytes and NK cells, a limited set of genes were changed in T cells, and only minor changes were discovered in B cell gene expression (A). Pathway analysis reveals an enrichment for interferon signalling pathways, mainly in monocytes and NK cells (B).

BLOOD AND URINARY CYTOKINE PROFILES AND CLINICAL OUTCOME IN PRIMARY MEMBRANOUS NEPHROPATHY AND DIABETIC KIDNEY DISEASES
Jorge Enrique Rojas Rivera1, Beatriz Fernandez-Fernandez1, Yuko Saruta2, Takehiro Hasegawa2, Gema Maria Fernandez Juarez3 and Alberto Ortiz1
1IIS-FJD, Spain, 2Sysmex R&D Center Europe, Hamburg, Germany and 3La Paz University Hospital, Madrid, Spain

Background and Aims: Primary membranous nephropathy (MN) is an autoimmune, immune complex-mediated primary glomerulopathy causing podocyte injury and nephrotic syndrome. The results of therapy may be suboptimal and biomarkers are needed that predict the need for immune suppression and the response to different immunosuppression regimens. Diabetic kidney disease (DKD) is the most common cause of kidney failure. It is characterized by non-immune podocyte injury that may lead to nephrotic syndrome. We evaluated the circulating and urine cytokine pattern and pathophysiologic difference between both conditions. For MN, we further aimed at identifying the biomarkers of immunosuppressive treatment response.

Method: 192 MN data-points from the STARMEN trial and 92 DKD from the biobank of IIS-FJD-UAM were included. We analyzed the blood and urine samples by HISCL (Sysmex Inc. Kobe, Japan), a chemiluminescence immunoassay that can afford a high-throughput multiplex cytokine analysis. Sixteen biomarkers were measured and evaluated for the correlation with the clinical outcome (eGFR, uPCR, 24-hour proteinuria). Also, the biomarkers’ concentration at baseline was compared with the treatment response during 6-9 months and the disease status after treatment until 24 months. The treatments evaluated STARMEN were Tacrolimus-Rituximab (TacRt) and alternating therapy with corticosteroids-cyclophosphamide. Box plot and Mann Whitney U test were used to assess subgroup differences and Spearman’s rank correlation to assess correlation between variables.

Results: Median age, baseline eGFR and proteinuria for the MN and DKD cohorts were 53 and 66 years, 74 and 52 ml/min/1.73 m2, and 8.8 and 0.2 g/24h, respectively. Five cytokine markers in blood and 5 in urine from MN and 2 in blood and 2 in urine from DKD showed a significant correlation with proteinuria (Table). Circulating TNFa had been previously related to both MN and DKD pathophysiology and we confirmed its correlation with clinical outcomes in both. CCL20 is one of blood biomarkers correlated with anti-PLA2R (rS = 0.151, p = 0.036) and proteinuria in MN but not DKD. We identified a baseline urinary Protein A whose concentration differed between responders and non-responders to TacRt.

Conclusion: MN and DKD displayed characteristic cytokine patterns. Protein A is related to the progression of chronic inflammation and B cells. Its presence in urine and the differences between TacRt responders and non-responders suggest that high inflammatory progression activities may offset the treatment response. In conclusion, protein A could be the potential prognostic marker of TacRt response. However, additional investigation is needed to confirm and evaluate the possible application to other glomerular diseases.
We identified 22 patients who developed UA and/or renal impairment within 3 months of vaccination. The study aimed to examine the patients who were hospitalized in our Unit between April 2021 and January 2023 and underwent renal biopsy. This report should not highlight the need for pharmacovigilance. However, this report shall not lead to vaccine hesitancy during this pandemic as the benefits of vaccination strongly outweigh the potential risks.

#5747
COVID VACCINATION RELATED GLOMERULOPATHIES AND INTERSTITIAL NEPHRITIS
Martina Marchisio, Stefania Lalloni, Marco Morrone, Gianluca Rabajoli, Andrea Careddu, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

Torino, Italy

Introduction: To date, almost 7 billion doses of the different types of vaccine against SARS-CoV-2 have been administered worldwide. Although the severity of new cases of SARS-CoV-2 has progressively decreased, and the pressure on national health systems has declined, the development of de novo glomerular injuries has been suggested.

Methods: This study aimed to examine the patients who were hospitalized in our Unit between April 2021 and January 2023 and underwent renal biopsy for new-onset urinary abnormalities (UA) and/or renal impairment within 3 months of SARS-CoV-2 vaccination.

Results: We identified 22 patients who developed UA and/or renal insufficiency within 3 months of vaccination. Minimal change disease was the most common disease in our cohort (6 patients, 27.3%) followed by the most common disease in our cohort (6 patients, 27.3%) followed by membranous nephropathy (MN; 5 patients, 22.7%), acute tubulointerstitial nephritis (TIN; 3 patients, 13.6%). The other 5 patients had a diagnosis of ANCA-associated vasculitis (2 patients), membranoproliferative glomerulonephritis (1 patient), systemic lupus erythematosus (1 patient) and tip-variant focal segmental glomerulosclerosis (1 patient), respectively. Nine out of 22 patients (40.9%) developed acute kidney injury. Two patients with acute TIN had to start hemodialysis that was discontinued after 1 and 2 months, respectively, due to the recovery of renal function. Two of the 5 patients who had a diagnosis of MN were positive for anti-PLA2r, while all patients were negative for anti-thrombospondin. All patients underwent treatment with corticosteroids and/or immunosuppressants.

Conclusion: Although it is not possible to conclusively determine whether there is a causal relationship between SARS-CoV-2 vaccination and new-onset nephropathies, based on the appearance of UA and/or renal insufficiency shortly after vaccination, we hypothesize that the immune response to the COVID-19 vaccine may be a trigger of nephropathies. Therefore, our results highlight the need for pharmacovigilance. However, this report should not

#5353
THE IDIOPATICHYPOCRYOGLOBULINEMIA AS AN EMERGING MEMBRANOPROLIFERATIVE GLOMERULONEPHRITIS
Roberta Longo, Cecilia Ceruti, Martina Marchisio, Marco Morrone, Nunziante Caruso, Annalisa Guarino, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

Torino, Italy

Background and Aims: A considerable number of patients with high clinical suspicion for cryoglobulinaemia vasculitis either show negative results for the detection of cryoglobulins or show only trace amounts which cannot be characterized for composition. We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinaemia) or represents a separate entity.

Method: Using a modified precipitation technique in hypo-ionic medium, we prospectively identified between 2008 and 2023 237 patients (median age 60.8 years [22-97], 137 females) having <0.5% cryocrit and clinical suspicion of autoimmune disorder.

Results: 54 out of 237 patients (22.7%) had a history of HCV infection. 169 out of 237 patients (71%) had an established underlying disease, while 68 patients (28.6%) (median age 62.9 years [29-93], 35 females) did not show either laboratory markers or clinical symptoms consonant with an underlying aetiology. These 68 cases with only trace amounts of cryoglobulins were defined as having a putatively idiopathic hypocryoglobulinaemia. Nineteen of these 68 patients (27.9%) had a history of HCV infection. Twenty-four patients out of 68 (35.3%) were positive for rheumatoid factor (RF), while 25 (36.7%) patients had signs of complement consumption, and 36 (52.9%) had increased inflammatory indexes. Seven patients only had arthralgia and constitutional symptoms while 61 out of 68 (89.7%) presented with at least one of the three cardinal signs of cryoglobulinaemia vasculitis including skin lesions, peripheral nerve involvement, and glomerulonephritis. Seventy-five percent of the subjects had type III hypocryoglobulins. In patients with hypocryoglobulinaemia the histologic features of glomerulonephritis (also examined by
electron microscopy) resembled those of mixed cryoglobulinemia-associated glomerulonephritis.

**Conclusion:** In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

**INTENSIFIED B CELL DEPLETION THERAPY IN ANCA-VASCULITIS WITH SEVERE RENAL IMPAIRMENT AS COMPARED TO CONVENTIONAL IMMUNOSUPPRESSION**

Giorgio Amore, Martina Marchisio, Stefania Lalloni, Roberta Longo, Giovanni Geraci, Andrea Careddu, Roberta Fenoglio, Savino Sciascia and Dario Roccioletti

Torino, Italy

**Background and Aims:** Rituximab (RTX) has shown to be an effective induction treatment for small-vessel vasculitides associated with antineutrophil cytoplasm antibodies (AAV) in both newly diagnosed and relapsing patients. However, the role of RTX in the management of the most severe cases of AAV remains to be fully elucidated. The aim of this study was to assess both safety and efficacy of an intensified B-cell depletion therapy (IBCDT) protocol, including RTX, cyclophosphamide (CYC), and methylprednisolone pulses without additional maintenance immunosuppressive therapy in a cohort of 15 AAV patients with the most severe features of AVV renal involvement (as <15 ml/min GFR and histological findings of paucimmune necrotizing glomerulonephritis with more than 50% crescents of non-sclerotic glomeruli at the renal biopsy).

**Method:** Results of the IBCDT regimen have been compared to those obtained in a control cohort of 10 patients with AAV treated with a conventional therapy regimen based on oral CYC and steroids followed by a prolonged maintenance therapy with azathioprine (AZA). Plasma exchange was equally employed in the study and the control group.

**Results:** Complete clinical remission (BVAS 0) was observed at 6 months in 14 of 15 patients treated with IBCDT (93%). All cases who achieved a complete clinical remission experienced a depletion of peripheral blood B cells at the end of therapy. Of the 10 dialysis dependent patients at onset, 6 subjects (60%) experienced a functional recovery allowing the suspension of dialysis treatment. When compared to the control group, no statistically significant difference was observed in patients treated with IBCDT in terms of overall survival, 6-month therapeutic response rate, and 6- and 12-month functional renal recovery. The cumulative total dose of CYC in the case group was on average 1 g/patient while in the control group on average 8.5 g/patient (p = 0.00008).

**Conclusion:** Despite the retrospective design and relative limited sample size, IBCDT appeared to be safe and had the same efficacy profile when compared to the conventional therapy with CYC plus AZA in the management of the most severe patients with AAV. Additionally, this avoided the need of prolonged maintenance therapy for long, and limited the exposure to CYC with consequent reduced toxicity and drug-related side effect rates.

**ASSESSING THE EFFECTIVENESS OF LONG-TERM BELIMUMAB THERAPY IN LUPUS NEPHRITIS: A SINGLE-CENTRE OBSERVATIONAL STUDY**

Francisco Javier Marqués Ortega, Anna Ferri, Manel Gavilà, Iris Viejo Boyano, Ester Cholbi Vives, Francisco José Valero Mena, Ana Peris, Maria Peris-Fernandez, Enrique Garrigos Almerich and Julio Hernandez Jaras

Hospital Universitario y Politécnico La Fe, Valencia, Spain

**Background and Aims:** Lupus nephritis (LN) is a major cause of morbidity and mortality in systemic lupus erythematosus (SLE). Belimumab, a monoclonal antibody that inhibits B-cell activating factor, has demonstrated efficacy in decreasing proteinuria, prevention of flares and achieving renal response after two years. However, data on its long-term efficacy is limited. The aim of this observational study is to assess the efficacy of belimumab in biopsy-proven LN patients over the medium and long term.

**Method:** In this retrospective observational study at our centre, patients with documented history of biopsy-proven LN who received belimumab were selected for analysis. Data on renal function, proteinuria (24 hours) and haematuria were collected. Immunologic activity (Anti-double-stranded-DNA, C3 and C4) was assessed. Data were retrieved at three moments: belimumab initiation, 12 months after the start of therapy and when treatment was discontinued. When treatment had not been discontinued, last available data was used. Renal flares were identified. The observational period was adjusted to be consistent between pre- and post-belimumab treatments. Clinically relevant outcomes such as possible adverse effects or major pathologic events were actively searched in patient records. Finally, the initiation of any additional antiproteinuric treatment was reported. Data analysis was performed using IBM SPSS Statistics 21©. When sample distributions were found to be normal, a parametric T-test was performed. An analysis of outcomes for patients receiving belimumab for more than 24 months was also performed.

**Results:** Seventeen patients diagnosed of LN between 1991 and 2021 began belimumab from 2014 to 2022, ten of whom received belimumab for more than 24 months. Mean treatment duration was 41.8 months. Patient characteristics are presented in Table 1, while analytic results are summarized in Table 2. A statistically significant decrease in proteinuria stands out 12 months after starting treatment with belimumab and a decrease in anti-dsDNA antibodies. As regards the subgroup of extended follow-up, results did not differ in hypothesis contrast tests. Overall, 17 renal flares were identified prior to belimumab initiation, while 9 flares were identified following its initiation (Fisher’s Exact Test: P = 0.092). A patient was diagnosed with acute bacterial meningitis, although the relationship to the drug is unclear since the patient was also receiving other immunosuppressive medications. This event did not lead to drug withdrawal. Only one patient started an angiotensin converting enzyme inhibitor (ACEI) immediately after initiating belimumab.

**Conclusion:** Currently, the optimal treatment duration with belimumab in LN is not known. Despite a decline in median GFR, results from this cohort of patients suggest a tendency to controlling proteinuria, haematuria and immunologic activity, over the middle and long term. A remarkable yet not significant decline in renal flares was observed. Finally, no relevant changes in immunosuppressive or antiproteinuric medication were made, allowing to avoid biases for this reason.

**ADDING 6-MONTH PARAMETERS FOR THE PREDICTION OF RENAL PROGNOSIS IN ANCA-ASSOCIATED GLOMERULONEPHRITIS**

Charlotte Boud’hors¹, Jérémie Riou², Nicolas Fage³, Clément Samoreau¹, Alice Desouche¹, Philippe Gatault¹, Frank Bridoux¹, Cécile Martin⁴, Samuel Wacrenier⁵, Emeline Vinatier⁶, Assia Djema⁷, Nicolas Henry⁸, Anne Croué¹⁰, Giorgina Barbara Piccoli⁶, Marie-Christine Copin⁷,²⁰, Jean-François Augusto¹,² and Benoît Brilland¹,²

**Background and Aims:** Anti-neutrophil-cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with kidney involvement (AAV-GN) frequently evolves to end-stage kidney disease (ESKD) despite aggressive immunosuppressive treatment. Several risk scores have been used to assess renal prognosis.

We aimed to determine whether kidney function and markers of AAV-GN activity after 6 months could improve the prediction of ESKD. **Method:** This retrospective and observational study included adult patients with AAV-GN recruited from 6 French nephrology centers (including from the Maine-Anjou AAV registry). The primary outcome was kidney survival. Analyses were conducted in the whole population and in a sub-population that did not develop ESKD early in the course of the disease. **Results:** 241 patients were included in the whole cohort, with a median follow-up of 59 months. At diagnosis, Berden classification and Renal Risk Score (RRS) were not found better than kidney function (eGFR) alone, at predicting ESKD (C-index = 0.70, 0.79, 0.82, respectively). At 6 months, 20 patients reached ESKD. In the sub-population of 221 patients, 6 months eGFR outperformed Berden classification and RRS (C-index = 0.88, 0.62, 0.69, respectively) to predict ESKD. RRS performed better when it was updated with the eGFR at 6 months instead of the baseline eGFR. While 6-months proteinuria was associated with ESKD and improved ESKD prediction, hematuria and serological remission did not. **Conclusion:** This work suggests the interest of the reassessment of the renal prognosis 6 months after AAV-GN diagnosis. Kidney function at this time remains the most reliable for predicting renal outcome. To improve the long-term prediction of ESKD, there may be a place for repeated kidney biopsy following induction treatment, in order to obtain a precise evaluation of disease activity, discuss the immunosuppressive treatment strategy and improve prognosis scores.
DEVELOPMENT AND VALIDATION OF A PREDICTIVE MORTALITY SCORE IN ANCA-ASSOCIATED VASCULITIS WITH KIDNEY INVOLVEMENT

Background and Aims: Several scores (FFS, JVAS, MVIA, Maldini, NLR, SIRI, PIIVUT and CAR scores) have been developed to predict mortality at ANCA-Associated Vasculitis (AAV) diagnosis. The validity of these scores in AAV with kidney involvement (AAV-KI) remains uncertain. We aimed to evaluate their prognostic value in a large cohort of AAV-KI and to develop and validate a novel and more accurate mortality risk model.

Method: This multicentric retrospective study included patients newly diagnosed with ANCA-KI between January 2000 and January 2021 in 4 nephrology departments (Maine-Anjou Registry). Scores were assessed at diagnosis before any therapeutic intervention. Clinical, biological and histological characteristics at diagnosis were retrieved. A multivariate analysis was performed to determine 2 new predictive models for death. The diagnosis performance (AUROC and C-index) and accuracy (Brier score) of existing scores and the newly developed models were assessed. The RENVAS registry was used as a validation cohort.

Results: Among the 228 patients with AAV-KI included in the registry, 194 had all the data available to determine each score performance. Among all existing scores of the literature, only FFS and JVAS had overall good performances to predict death in AAV-KI. After multivariate analysis, two new models were built, and considered 4 components: age, history of diabetes or hypertension, early need for kidney replacement therapy or eGFR, and hemoglobin level at diagnosis. These models were found to perform better and to be more accurate than the existing scores. Similar results were found using an external validation cohort of 186 patients with AAV-KI.

Conclusion: These novel risk prediction models may be useful to predict the risk of death in AAV-GN patients, with better predictive value than existing scores. It remains to be established, however, whether these new models could be used to assist clinical decisions.
Background and Aims: Currently, the precise mechanism of myeloperoxidase-anti-neutrophil cytoplasmic antibody associated glomerulonephritis (MPO-ANCA-GN) remains elusive. And there is a lack of dependable biomarkers for evaluating disease activity, therapeutic resistance, and risk of relapse. We try to seek valuable biomarkers and explore the mechanism of MPO-ANCA-GN by metabolomics.

Method: Urine and plasma samples from 63 MPO-ANCA-GN, 31 lupus nephritis (LN), 15 IgA nephropathy (IgAN), and 15 minimal change disease (MCD) patients and 30 HC were collected for metabolomics analysis. The samples were analyzed using Ultra Performance Liquid Chromatography (UPLC) and Tandem mass spectrometry (MS/MS). The different groups of samples were compared using Partial Least Squares-Discriminant Analysis. A Receiver Operator Characteristic (ROC) curve was constructed to assess the performance of the metabolite model in identifying active renal vasculitis.

Results: All metabolites in urine and plasma samples including hydrophilic compounds and hydrophobic compounds were identified. Compared with the disease control (DC) and HC, we observed 79 significantly upregulated metabolites (VIP > 1, FDR < 0.05, FC > 1.5) and 32 downregulated metabolites (VIP > 1, FDR < 0.05, FC < 0.67) in the plasma samples of MPO-ANCA-GN patients. KEGG enrichment analysis suggested that these upregulated metabolites were mainly associated with phenylalanine metabolism and galactose metabolism and downregulated metabolites were mainly associated with bile secretion, steroid biosynthesis, and ovarian steroidogenesis. Compared with the DC and HC, we identified a total of 122 differential metabolites in the urine samples of MPO-ANCA-GN patients, 40 of which were significantly upregulated (VIP > 1, FDR < 0.05, FC > 1.5) and 68 of which significantly were downregulated (VIP > 1, FDR < 0.05, FC < 0.67). Subsequently, KEGG analysis revealed that these upregulated metabolites were mainly enriched in glycerolipid metabolism, lipid and atherosclerosis, cholesterol metabolism, insulin resistance, regulation of lipolysis in adipocytes, vitamin digestion and absorption, fat digestion and absorption (Corrected P < 0.05). Downregulated metabolites were mainly enriched in steroid hormone biosynthesis (Corrected P < 0.05).

Nine MPO-ANCA-GN patients with paired plasma and six MPO-ANCA-GN patients with paired urine during the active and remission phase were included in the study. A total of 504 differential metabolites in plasma samples were identified between the active and remission phase based on VIP value > 1, P < 0.05, and FC > 1.5 or FC < 0.6. Of these, 425 metabolites were downregulated, while 79 lipid metabolites were upregulated in the active group. MPO-ANCA-GN patients were divided into two groups according to Mayo Clinic/Renal Pathology Society Chronicity Score: Minimal-mild group and Moderate-severe group. In plasma samples, our data showed that 3-Methoxysalicylic Acid, Carnitine C20:5, and isoanxanthopterin presented good ability in distinguishing between the minimal-mild group and the moderate-severe group, with an AUC > 0.7. In urine samples, cyclohexylamine and arachidonic acid (AUC > 0.8) can distinguish the two groups well. Conclusion: We identified many novel potential metabolic biomarkers in urine and plasma samples for evaluating disease activity, therapeutic resistance, and risk of relapse in patients with MPO-ANCA-GN.

HERPES ZOSTER IN LUPUS NEPHRITIS: AN UNDERESTIMATED COMPLICATION
Francesco Reggiani¹,², Silvia Cardi¹, Fabio Tumminello¹, Marta Calatroni¹,² and Gabriella Luisa Moroni²
¹Humanitas University, Italy and ²Humanitas Research Hospital, Cascina Perseghetto, Italy

Background and Aims: Herpes zoster (HZ) is a known complication of lupus nephritis (LN) because of the drug-related immunosuppression. In fact, high dose corticosteroids (CS) and immunosuppressive (IS) therapy are almost always used in this setting. Our aim is to evaluate the predisposing factors for the development of HZ in patients with LN.

Method: Retrospective cohort study on 292 LN patients. Demographic and clinical data are expressed as numbers or percentages in case of discrete variables, whereas, in case of continuous variables, they are expressed as median and interquartile range (IQR). The demographic characteristics have been analyzed with Mann-Whitney U test and Fisher’s test where appropriate. A univariate and multivariate logistic regression has been performed to identify potential risk factors.

Results: The incidence of HZ in our cohort is 22.6% (66/226). The patients’ characteristics are shown in Table 1. HZ patients are older (54 vs 45 yo, p<0.001). No differences were found in the clinical characteristics at LN diagnosis, except for higher chronicity index in HZ patients (2 vs 1, p = 0.03). No difference was found in the initial IS therapy. Higher cumulative dose of CS was used in patients with HZ (48.9 vs 21.5 grams, p<0.0001). At univariate and multivariate logistic regression (Table 2) age, female sex, the presence of a proliferative form at renal biopsy (class III or IV) and cumulative CS dose greater than 100 grams are linked to a higher risk for HZ.

Conclusion: Incidence of HZ in our LN cohort is high (22.6%). HZ patients are older, while non-significative differences in clinical presentation or initial IS therapy are present. Age, female sex, the presence of a proliferative form at biopsy and greater cumulative CS dose seems to be a risk factor for HZ development in LN patients. According to these data and to the possible evolution of HZ infection in disseminated forms, HZ vaccination should be strongly recommended in LN patients.

Abstracts
Anti-PLA2R antibodies were negative in all three cases. Tissue samples from patients 1 and 2 were positive for FAT1 antigen using laser microdissection and tandem mass spectrometry (MS/MS) of glomeruli. The third patient was negative for FAT1. Clinical and biopsy findings in our cohort of HSCT-associated MN are summarised in Tables 1 and 2.

**Conclusion:** MN can occur at different points in time, sometimes even years, after HSCT. It can be successfully treated with steroids and immunosuppressants, achieving long-term remission. Most patients with HSCT-associated MN are FAT1-positive, although it is not the only antigen associated with MN in HSCT patients. In the future, serum testing for anti-FAT1 antibodies in patients with HSCT could be of similar significance in diagnosing FAT1-associated MN as PLA2R antibodies are for PLA2R-associated MN.

**REFERENCES**

BACKGROUND AND AIM: Urinary albumin:creatinine ratio (UACR) is an important biomarker of active glomerulonephritis, a common complication of antineutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis. In most glomerular diseases, high UACR levels and low estimated glomerular filtration rates are associated with the long-term risk of end-stage kidney disease, cardiovascular disease, and death.[1] In the double-dummy, double-blind, controlled ADVOCATE Phase 3 trial, patients were randomized to receive avacopan, an oral C5a receptor (C5aR) antagonist that blocks C5a-mediated neutrophil activation and migration, or a prednisone taper. All patients received background immunosuppression with either cyclophosphamide followed by azathioprine, or rituximab. Primary endpoints were remission at week 26 and sustained remission at week 52. Prespecified secondary endpoints included the evaluation of kidney function.[2] The effect of avacopan on UACR in patients with ANCA-associated vasculitis is described.

METHOD: This post hoc analysis compared the time to achieve the maximum mean difference in percent change in UACR from baseline between the avacopan and prednisone taper groups using Kaplan-Meier survival analysis. Change in UACR from baseline was a prespecified secondary endpoint but was not adjusted for multiplicity. This analysis included patients from the ADVOCATE trial with kidney involvement (based on the Birmingham Vasculitis Activity Score) and a UACR of at least 10 mg/g at baseline.

RESULTS: The baseline geometric mean UACR mg/g (range) in the avacopan group (n = 125) and the prednisone taper group (n = 128) was 433 (20 to 6461) and 312 (11 to 5367), respectively. A statistically significant UACR reduction (based on least-square means) in the avacopan group compared to the prednisone taper group occurred as early as week 2 (−25% vs. 6%, p = 0.0068, difference between groups: −29%, 95% confidence interval (CI) [−45%, −9%]). UACR continued to decrease at week 4 to the maximum difference between the two groups (−40% vs. 0%, p < 0.0001, difference between groups: −40%, 95% CI [−53%, −22%]) (Figure 1). UACR was
comparable between the two groups by week 13 (−55% vs. −49%, \( p = 0.3028 \), difference between groups: −12%, 95% CI [−32%, 13%]). During the 52-week treatment period, 84% (105/125) of patients in the avacopan group achieved a 40% UACR reduction from baseline within a median time of 29 days (95% CI [29, 88]), compared to 83% (106/128) of patients in the prednisone taper group within a median time of 92 days (95% CI [91, 180]) (logrank \( p = 0.0450 \)) (Figure 2). At week 52, there was a greater overall mean improvement in estimated glomerular filtration rate (eGFR) of 7.6 mL/min/1.73 m² in the avacopan group compared to 4.6 mL/min/1.73 m² in the prednisone taper group (\( p = 0.0432 \)).

**Conclusion:** In the ADVOCATE trial, UACR, an important early indicator of improving kidney function, improved three times faster in the avacopan group compared to the prednisone taper group. The rapid reduction in UACR seen in patients with ANCA-associated vasculitis receiving avacopan suggests more

---

**Figure 1:** Percent Change in UACR from Baseline in the Avacopan vs Prednisone Taper Groups in Patients with Kidney Involvement and UACR ≥ 10 mg/g.

**Figure 2:** Time to 40% Reduction Urinary Albumin:Creatinine Ratio (UACR) in the Avacopan vs Prednisone Taper Groups.
rapid control of glomerular inflammation which may have contributed to the observed subsequent greater improvement in eGFR.

**EFFECT OF IMMUNOSUPPRESSIVE TREATMENTS ON RENAL OUTCOMES AFTER GROSS HEMATURIA-RELATED ACUTE KIDNEY INJURY IN IGA NEPHROPATHY**

Angel Sevillano1, Fernando Caravaca-Fontán1, Eduardo Gutiérrez2 and Manuel Praga3,4

1HU 12 de Octubre, Nephrology, Madrid, Spain and 2Universidad Complutense de Madrid, Medicina, Madrid, Spain

**Background and Aims:** Macroscopic hematuria bouts are one of the most characteristic presentations of IgA nephropathy (IgAN). Acute kidney injury (AKI) is a well-known complication of these episodes of gross hematuria. Although the first descriptions of AKI associated with macroscopic hematuria (AKI-MH) reported a good prognosis in young patients, more recent studies have shown that a substantial number of adult and elderly patients with this unique type of IgAN did not completely recover their baseline kidney function after AKI-MH. Although guidelines recommend a conservative approach for AKI-MH, immunosuppressive therapy (IT) is frequently used in real-world clinical practice. Aim of this study was to analyse the influence of different therapeutic strategies (immunosuppressive or conservative) on kidney function recovery after an episode of biopsy-proven AKI-MH in IgAN patients 40 years.

**Method:** Retrospective study including 91 IgAN patients from 17 nephrology departments who presented with AKI-MH. Secondary types of IgAN and IgA vasculitis were excluded. All the patients had at least one measurement of serum creatinine (Scr) and eGFR before AKI-MH. Kidney function recovery after AKI-MH was defined by the ratio between Scr at a given time after AKI-MH and the last determination of Scr before AKI-MH onset (baseline Scr). No recovery was defined by a Scr > 75% of baseline Scr or the need of kidney replacement therapy (KRT); partial recovery by a Scr <75% and ≥25% of baseline Scr; and complete recovery by a Scr <25% of baseline Scr. End stage kidney disease (ESKD) was defined by an eGFR <15 ml/min/1.73 m² or KRT. Outcomes were the proportion of patients with complete, partial or no recovery of kidney function at 6 and 12 months after MH-AKI and kidney survival (defined as a status free of ESKD or death) at 1, 2 and 5 years and at the end of follow-up. Follow-up was 59±36 months.

**Results:** Mean age was 65±16 years and 72 patients (79%) were men. Mean Scr and eGFR before AKI-MH were 1.2±0.47 mg/dL and 65±24.9 mg/min/1.73 m², respectively, and 37 patients (41%) had CKD (eGFR <60 mg/min/1.73 m²) at baseline. Mean Scr and eGFR at presentation were 4.3±2.8 mg/dL and 19.3±13.4 mg/min/1.73 m², respectively. Thirty-two patients (35%) required acute dialysis at presentation. The most remarkable histological lesions were intratubular erythrocyte casts and tubular necrosis in all the patients. In addition, mesangial proliferation was found in 64%, endocapillary hypercellularity in 25%, segmental glomerulosclerosis in 41%, T1-T2 tubular atrophy/intertubular fibrosis in 33% and crescents in 4%. Sixty-nine patients (76%) were treated with renin-angiotensin blockers. It was prescribed to 52 (57%) patients: corticosteroids alone in 32 (61%), corticosteroids plus mycophenolate in 12 (23%) and corticosteroids plus cyclophosphamide in 8 (15%). Treated patients were significantly older (69.4±20.1 vs 59.9±20.1; p = 0.01), required acute dialysis in a greater proportion (46% vs 20%; p = 0.01) and had more glomerulosclerosis (51% vs 28%; p = 0.02) than non-treated patients. No differences were found in other clinical or histological parameters. There were no significant differences between treated and not treated patients in the number of cases with complete, partial or no recovery of kidney function at 6 months (25%, 33% and 42% vs 26%, 20% and 54% respectively) and 12 months (28%, 30% and 40% vs 35%, 20% and 43% respectively). Kidney survival at 1, 3, 5 years was similar among treated (75.6%, 52%, respectively) and not treated patients (76%, 68%, 50%, respectively). Adverse events occurred in 27% of IT patients: infections (7 patients), diabetes mellitus and cytopenia (2) and vertebral collapse (1). At the end of follow-up, 27 patients (30%) had developed ESKD, with no differences between treated and untreated, and 17 patients had died, 10 among treated patients and 7 among untreated cases.

Conclusion: Prognosis is very poor in IgAN patients > 40 years who present with AKI-MH. IT does not change this unfavorable prognosis, so new therapeutic alternatives are needed.

**LUPUS NEPHRITIS RELAPSE AFTER IMMUNOSUPPRESSION WITHDRAWAL: A SPANISH MULTICENTER STUDY**

Clara Garcia Carro1, Manuel Lopez-Mendoza2, Ana Ávila3, Irene Agraz4, Hernando Trujillo Cuellar5, César Rueda García1, Marian Goicoechea6, Remedios Toledo Rojas7, Begoña Rivas Becerra8, Adoración Martín9, Gema Maria Fernandez Juarez10 and Manuel Praga11

1San Carlos University Clinical Hospital, Nephrology, Madrid, Spain, 2Virgen del Rocio Hospital, Spain, 3Dr Peset Hospital, Spain, 4Vall d’Hebron University Hospital, Spain, 512 Octubre Hospital, Spain, 6Gregorio Marañon Hospital, Spain, 7Carlos Haya Hospital, Spain, 8La Paz Hospital, Spain and 9Poniente Hospital, Spain

**Background and Aims:** In lupus nephritis (LN), therapeutic schemas for remission induction are well known but data about duration of maintenance treatment are limited. There is no agreement between clinical practice guidelines about duration and withdrawal of therapy, and literature regarding this topic is scarce. Recently, a RCT has observed that immunosuppression discontinuation after 2–3 years was related to LN relapse when compared with immunosuppression maintenance. However, immunosuppressive agents are related to severe adverse events and toxicity. We conducted this study with the aim to evaluate the incidence of LN relapse in a cohort of patients with discontinuation of immunosuppressive treatment after a first LN flare. We also aimed to determine factors associated to the presence of renal relapse in this population.

**Method:** Multicenter retrospective observational study including patients with biopsy proven LN who have received immunosuppressive treatment that was subsequently discontinued. Patients on prednisone at doses lower than 5 mg per day were allowed to be included. Patients were diagnosed between 1990 and 2018. The study was conducted in Spain. Relapse was defined according to Malvar et al criteria.

**Results:** 113 patients were included, mean age was 34.1±14.56 years-old and 85.8% were women. Serum creatinine at the time of LN diagnosis was 1.09±0.63 mg/dL, and proteinuria 3.16±2.53g/24h, ANA were positive in 85.4%, and anti-DNA Abs in 69.91%. Serum C3 and C4 levels were 72.51±44.06 and 13.04±11.27 respectively. 55.7% presented with class IV LN, 12.39% with class III or IV LN, and 8.85% with class II. Mixed forms were less frequent. In a follow up period of 172.53±162.95 months, 17.7% (n = 20) presented a renal flare after immunosuppressive drugs withdrawal. Time from LN to relapse was 89.05±39.87 months, and time from immunosuppression discontinuation to relapse was 37.75±32.13 months. There were no differences in baseline characteristics between patients who relapsed and patients who did not, neither in histologic characteristics at the time of LN diagnostic biopsy except for glomerulosclerosis, that was less frequent in the relapse group (20% vs 34.41%, p = 0.0435). However, a tendency to a shorter time under immunosuppression in patients who relapsed was observed (73.55±78.06 vs 110.79±206.87 months). Data about treatment withdrawal in each group are summarized in Figure 1. Interestingly, there were no differences between both groups in steroids withdrawal (75% vs 78.49%, p = 0.7327) and hydroxychloroquine withdrawal (33.33% vs 21.74%, p = 0.3933). At the time of immunosuppression discontinuation, patients who relapsed presented lower serum C3 and C4 levels (78.79±24.89 vs 112.26±35.52, p = 0.0080 and 13.82±6.07 vs 23.09±12.56, p = 0.0333), but there were no differences in terms of renal function at this moment. At the end of follow up, patients who relapsed presented more albuminuria (227.87±259.79 vs 78.65±24.77, p = 0.0289) but creatinine levels were similar in both groups (0.84±0.30 vs 0.84±0.30, 0.530). Only one patient died and two patients required renal replacement therapy, all in the no relapse group.

**Conclusion:** In a cohort of 113 patients with biopsy proven LN who were treated con immunosuppression and subsequently discontinued, 17.7% presented renal relapse at a mean time of 37 months after withdrawal. There was a tendency to a short time on immunosuppressive regimens in patients who relapsed. Also, lower serum C3 and C4 levels at the time of immunosuppression withdrawal were associated to renal relapse. At the end of a follow up of 14 years, patients who relapsed those who did not showed a similar maintained renal function but those who relapsed presented lower albuminuria.
Background and Aims: Macrophage Migration Inhibitory Factor (MIF) is a pleiotropic inflammatory cytokine and a primary counter-regulator of glucocorticoids (GCs) that emerged as a pivotal regulator of immune-mediated disorders including glomerulonephritis (GN). MIF occurs in two immunologically distinct, conformational isoforms: reduced MIF, ubiquitously present in various tissues and the circulation of healthy subjects, and oxidized MIF (oxMIF), described as the pathogenic and druggable isoform of MIF [1]. We previously reported a positive correlation between disease severity and urinary oxMIF levels in patients with acute lupus nephritis, suggesting oxMIF contribution to kidney damage [2]. In this study we evaluated the anti-inflammatory effects of oxMIF neutralization using ON104 antibody during crescentic GN.

Method: By advanced antibody engineering we generated the fully human antibody ON104 that is specific and highly affine for human oxMIF and its orthologs. ON104 was tested for its therapeutic potential in a rodent model of GN. Nephritis was induced in male WYK rats by a single intravenous (i.v.) injection of rabbit anti-rat GBM (glomerular basement membrane) serum. On day 4 and day 6 after GN induction, ON104 was administrated intraperitoneally (i.p.). Body weight, proteinuria, and hematuria were assessed.

Results: Treatment with ON104 substantially attenuated clinical signs of GN by preserving kidney function demonstrated by reduced proteinuria, and reduced hematuria. Furthermore, ON104 significantly reduced tissue injury, reduced crescentic glomerulus formation, and increased the percentage of normal glomeruli. On the cellular level, oxMIF neutralization by ON104 reduced CD68+ macrophage accumulation within the inflamed kidneys compared to untreated and isotype Ig-treated rats.

Conclusion: Our findings substantiate the role of oxMIF in the pathogenesis of experimental GN. Thus, targeting oxMIF may represent a new and promising treatment option for kidney diseases.

CORRELATION OF SYSTEMIC AND IN SITU BIOMARKERS OF COMPLEMENT ACTIVATION WITH HISTOPATHOLOGICAL FEATURES AND PROGNOSIS IN C3 GLOMERULOPATHY

Marie-Sophie Meuleman1, Florent Petitprez2, Anna Duval1, Veronica Fremeaux Bacchi1, Jean-Paul Duong Van Huyen1 and Sophie Chauvet1

1 Centre de Recherche des Cordeliers, Paris, France, 2 Queen’s Medical Research Institute, United Kingdom and 3 Necker Hospital, Paris, France

Background and Aims: C3 glomerulopathy is a rare complement mediated disease, resulting from complement alternative pathway (AP) activation. In addition to AP activation, there are emerging evidence for terminal pathway (TP) implication in kidney damage. A C3G histopathologic index has recently been proposed to evaluate both activity and chronicity parameters. Only a chronicity index > 4 has been independently validated as prognosis factor for end stage kidney disease. We aimed to determine the impact of local activation of the TP on disease phenotype.

Method: C3G histopathological index grading were evaluated via central review of 53 kidney biopsies from 43 patients carrying C3G. C5b-9 staining was performed on 53 FFPE kidney sections and quantified (scoring from grade 0 to 3 for C5b-9 deposits in glomeruli and from 0 to 2 in the tubulointerstitial compartment). Clinical data, C3 and sC5b-9 levels at the time of KB were retrospectively collected.

Results: KB were performed at diagnosis for n = 31. In 22 cases, KB was performed during follow up, under specific treatment (n = 10), without treatment (n = 7), or at disease relapse (n = 5). Twenty-five (47%) were children. Median (Q1-Q3) C3 level at KB was 623 mg/L [236-931] mg/L. Median (Q1-Q3) sC5b-9 level at KB, available in 16, was 374 ng/ml [203-1295]. Median (Q1-Q3) activity and chronicity index were respectively 9[6-12] and 1[0-6]. We confirmed the prognostic impact of chronicity index (p = 0.03) (Figure 1A) without impact of the activity index. Glomerular C5b-9 staining was positive in 47/53 (87%) (grade 1: n = 16 (30%); 2: n = 17 (32%); 3: n = 14 (26%)) and n = 40 (75%) had interstitial C5b-9 staining (grade 1: n = 28 (53%); 2: n = 12 (23%)). Soluble C5b-9 measurement correlated with intensity of C5b-9 glomerular deposit (cof corr = 0.69). As compared to patients with normal C3 level, patients with AP activation had higher proteinuria but kidney function at KB was similar. We found distinct histological features according to C3 plasmatic level (Table 1): patients with low C3 level had higher histological activity index (p = 0.03) and higher glomerular and tubulointerstitial C5b-9 staining (p = 0.001 and p = 0.002 respectively). C5b-9 glomeruli staining allows the identification of 3 groups of KB (1: no or low, 2: medium and 3: high C5b-9 staining) with distinct histological and clinical features. Activity index were higher in groups 2 & 3 (p = 0.05) and chronicity index in groups 1 & 3 (p = 0.003) (Table 2). Renal prognosis was poorer in patients with higher glomerular C5b-9 deposits (Figure 1B). Patients with chronicity index >4 and high C5b-9 staining had the poorest renal survival (Figure 1C).

Conclusion: Our results suggest that TP activation in glomeruli may have an impact on histological features, contributing therefore to renal prognosis. Deeper exploration of correlation between systemic and in situ complement activation and histological features could allow to better identify patients with worst prognosis or who could benefit from emerging complement inhibition therapeutics.

TRAINED INNATE IMMUNITY IN RESPONSE TO NUCLEAR ANTIGENS IN SYSTEMIC LUPUS ERYTHEMATOSUS

Nils Rother1, Cansu Yarginlar1, Tomas Post1, Maaike Jacobs1, Inge Jonkman1, Montsy Brouns2, Maarten van der Sande1, Sybren Rinzema3, Joost Martens3, Michiel Vermeulen3, Leo Joosten1,4, Mihai Netea4, Luuk Hilbrands1, Zaheeb Choudry2, Johan Van Der Vlag1 and Raphael Duivenvoorden1

1Radboud University Nijmegen, Nijmegen, Netherlands, 2Horacio Oduber Hospital, Oranjestad, Aruba, 3Radboud University Nijmegen, Nijmegen, Netherlands and 4Radboud University Medical Center, Internal Medicine, Nijmegen, Netherlands

Background and Aims: Systemic lupus erythematosus (SLE) is an autoimmune disease directed against nuclear antigens, including those derived from apoptotic microparticles (MPs) and neutrophil extracellular traps (NETs). Innate immune cells display an hyperreactive phenotype in patients with SLE, with increased expression of immunostimulatory surface markers and increased production of proinflammatory cytokines. We hypothesize that the hyperreactive phenotype of innate immune cells in SLE is caused by the induction of trained immunity. Trained immunity is a de facto innate immune memory elicited by an initial stimulus that induces metabolic and epigenetic changes and results in a more vigorous inflammatory response to subsequent stimuli. Here we aim to investigate whether nuclear autoantigens derived from MPs and NETs can induce trained immunity in SLE patients.

Method: To investigate the capability of MPs and NETs to induce trained immunity we stimulated healthy PBMCs with isolated NETs and MPs or with plasma from SLE patients for 24 hours, washed and rested the cells for five days. Cells were restimulated with lipopolysaccharide (LPS) and Pam3CSK4. To test the activation status of innate immune cells, PBMCs were isolated from patients with SLE and healthy controls and stimulated the cells with different TLR agonists. Cytokine production was measured using ELISA. Immune cell subsets in SLE patients were analyzed by flow cytometry. We performed RNA sequencing and Chromatin immunoprecipitation (ChIP) sequencing for histone 3 lysine 4 trimethylation (H3K4me3) on monocytes from SLE patients and healthy controls.

Results: We found that in vitro both MPs and NETs, as well as plasma from SLE patients, can induce trained immunity. Initial stimulation with MPs, NETs or SLE plasma resulted in increased production of Tumor necrosis factor (TNF) and Interleukin (IL) 6 upon restimulation with different TLR agonists. Assessment of circulating immune cells showed higher percentages of monocytes in SLE patients compared to healthy controls, and we found that circulating monocytes from SLE patients produce increased levels of pro-inflammatory cytokines (IL-6, IL-1ß, TNF) after stimulation with Toll-like receptor agonists, indicating trained immunity. This is accompanied by increased expression of metabolism and inflammation-related genes, underscoring the hyperreactive phenotype typical in trained innate immune cells. Epigenetic analysis of monocytes revealed major changes in H3K4me3, an epigenetic mark associated with trained immunity.

Conclusion: Our findings provide new insight into the pathogenesis of SLE by showing that trained immunity can be elicited by SLE-related antigens present in MPs and NETs, and demonstrating that circulating monocytes from SLE patients have a trained immunity phenotype. Trained immunity yields a possible biomarker for the risk of SLE flares and offers a new potential target for developing therapeutic strategies.
Figure 1: Monocytes in SLE patients are trained by NETs and MPs. (A) Human PBMCs were isolated and stimulated with Heat-killed *candida albicans* (HKCA) as positive control, only medium as negative control (Untrained) or MPs and NETs for 24 hours. After the resting period, cells were restimulated with Pam3CSK4 for 24 hours. IL-6 production was measured in the supernatant. (B) PBMCs were stimulated with 10% plasma of SLE patients or healthy control for 24 hours. After the resting period cells were restimulated with LPS. IL-6 production was measured in the supernatant. (C) PBMCs were isolated from patients with SLE or healthy controls and stimulated with LPS for 24 hours. IL-6 and IL-18 was measured in the supernatant. Data is shown as mean ± SEM. P-values were calculated using one-way ANOVA with Dunnett’s post-test (in A) and unpaired t-test (in B,C). (D) Gene set enrichment analysis using Hallmark gene set collection on differentially expressed genes between SLE patients and controls (FDR < 0.1). (E) Heatmap of differentially regulated H3K4me3 peaks compared between healthy controls and SLE patients’ monocytes (FDR < 0.1).

NOT JUST AIN? OTHER IMMUNE-CHECKPOINT INHIBITOR LESIONS: A SINGLE INSTITUTION’S EXPERIENCE OVER 12 YEARS
Salvatore Mignano, Raad Chowdhury, Mariam Alexander, Alessia Buglioni and Sandra Herrmann
Mayo Clinic, Rochester, United States of America

**Background and Aims:** Immune-checkpoint inhibitors (ICI) are antineoplastic therapies that unleash the immune-system and have revolutionized cancer outcomes. Though they are a drug class with great potential, their effects are not always limited to the malignant cells and can cause a spectrum of immune-related adverse events (irAEs). Roughly 5% of patients will experience acute kidney injury (AKI) with acute interstitial nephritis (AIN) being the predominant pathologic lesion. Glomerular and vascular lesions are thought to be rare and, as a result, not well-defined. We aim to document glomerular and vascular pathology in this context at our institution.

**Method:** We performed a retrospective review of internal native renal biopsies from 2010-2022 that had known ICI treatment. Standard processing of renal biopsies included light microscopy (LM), immunofluorescence (IF), and electron microscopy (EM). We reviewed the biopsies and pathology reports, as well as clinical data from patient electronic medical records.

**Results:** Our search yielded 32 kidney biopsies; of those, most had AIN (27/32), 8 cases had glomerular pathology, and 1 case had arterial endothelitis. Of the cases with glomerular pathology, 4 had subacute glomerular thrombotic microangiopathy (TMA). Among the cases with TMA, 2 were also treated...
with vascular endothelial growth factor inhibitor (VEGFi), 1 with gemcitabine, and 1 with BRAF-inhibitor therapy. Further, only one of these patients had complement testing, which did not reveal definitive deficiency. One patient had proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID), IgG-κ. One patient had IgA nephropathy (IgAN) and another had membranous nephropathy (MN). Most patients were biopsied for rising serum creatinine (SCr) (median: 1.6 mg/dL; range: 0.55-5.5). I had nephrotic-range proteinuria (median: 1.6 mg/dL; range: 0.55-5.5). I had a history of other known causative drugs. IgAN and MN have been reported in association with neoplasia. PGNMID has been reported in a variety of malignant and nonmalignant conditions, and ICI-use could be a triggering factor. In conclusion, the patterns of glomerular injury reported in a variety of malignant and nonmalignant conditions, and ICI-use and MN have been reported in association with neoplasia. PGNMID has been reported in a variety of malignant and nonmalignant conditions, and ICI-use could be a triggering factor. In conclusion, the patterns of glomerular injury seen in our cohort may be secondary to other concurrent risk factors other than ICI use. Arterial endotheliitis appears to be a rare but significant secondary effect to ICI-use.

MONOCYTE MIGRATION AND ACTIVATION IN ANCA-ASSOCIATED GLOMERULONEPHRITIS
Yosta Vegting1, Katie Hanford2, Aldo Jongejan3, Perry Moerland1, Gayle Gajadin1, Nelly van der Bom-Baylon1, Tamara Dekker1, Liffert Vogt1, Frederike Bemelman2, Jeffrey Kroon2 and Marc Hilhorst1
1. Amsterdam UMC, University of Amsterdam, Nephrology, Amsterdam, Netherlands, 2. Amsterdam UMC, University of Amsterdam, Experimental Vascular Medicine, Amsterdam, Netherlands and 3. Amsterdam UMC, University of Amsterdam, Epidemiology & Data Science (EDS), Bioinformatics Laboratory, Amsterdam, Netherlands

Background and Aims: Glomerular injury in Anti-Neutrophil Cytoplasmic Antibodies (ANCA)-associated glomerulonephritis (AGN) is associated with macrophage infiltration. To date, their role and origin remain to be fully elucidated. Activated blood monocytes likely transmigrate and differentiate into kidney macrophages depending on the local microenvironment. Even in remission, some studies indicate sustained monocyte activation and upregulation of adhesion markers. The aim of this study was to research the intrinsic migration capacity of monocytes in AGN. Targeting monocyte migration might open new therapeutic avenues in the treatment of AGN.

Method: Transendothelial migration of monocytes was tested in AGN patients with active disease (n = 2), in remission (n = 8) and healthy controls (n = 6). To assess their adhesive and migratory capacity, freshly isolated CD14 positive monocytes were added to confluent TNF-α or IL1β overnight-stimulated Human Aortic Endothelial Cell (HAEC) for 30 minutes and subsequently fixed. Monocyte adhesion and transmigration was visualized by phase-contrast microscopy and quantified using ImageJ. To unravel the potential mechanisms driving these differences in monocyte migration, we performed bulk RNA-sequencing of monocytes from AGN patients with active (n = 4) and stable (n = 10) disease, and healthy controls (HC) (n = 6).

Results: Monocyte adhesion, but not migration, was significantly increased during active disease, independently of the stimuli used to mimic the pro-inflammatory phenotype of endothelial cells (EC) (Figure 1). During remission, decreased adhesion was found on the IL1β-stimulated ECs. While CD11b mRNA expression was upregulated, CD11a expression was downregulated in monocytes from active AGN patients compared to HC. Two genes involved in paracellular monocyte transmigration (JAML, PECAM-1) were significantly decreased. Most AGN patients were treated with corticosteroids at time of experiments.

Conclusion: These results suggest a remarkable increase in monocyte adhesion, but lower intrinsic migration capacity, in a 30 minute time-frame during active AGN. Our findings on migration are surprising in the light of theorized enhanced monocyte extravasation towards diseased AGN kidneys. Therefore, it could be speculated that after a longer period of time, a subset of the adherent monocytes would ultimately migrate and differentiate into kidney macrophages. In remission, long-term immunosuppressive treatment or chronic inflammation might decrease monocyte adhesion. This was the first ex-vivo study to research monocyte migration in AGN, further research is required to validate findings and to develop new therapies targeting monocyte migration.

Background and Aims: Interstitial inflammatory infiltrates in ANCA associated glomerulonephritis (AAGN) are frequently observed but their correlation to clinicopathological parameters remains elusive.

Method: Retrospective study of 40 patients with newly diagnosed AAGN. Histological assessments using the presence of interstitial inflammatory cells were performed. Biopsy tissues were investigated by CD3, CD20, CD4, CD8, CD68+(PG-M1), CD138 immunohistochemical staining. We assessed the presence of inflammatory cells in terms of clinical, histopathological parameters as well as the renal prognosis in a large follow-up period [47.87 months (12-216)].

Results: The interstitial infiltrates were consisted of lymphocytes (CD3 T cell> CD 20 B cell) at 83%, followed by plasma cells at 43%, neutrophils at 43%, macrophages at 40% and eosinophils at 20% of the biopsies. CD8 T cells dominated the interstitial area in focal and sclerotic class, while CD8 and CD4 tended to have different expression patterns in the interstitial area (figures 1.2).

Interestingly, we reported that the presence of macrophages was correlated with higher chronicity index [interstitial fibrosis (39% vs 24%, p = 0.015) and creatinine at diagnosis (4.4 vs 2.6 mg/dL, p = 0.011), while the presence of neutrophils, lymphocytes and eosinophils was correlated with higher activity index [cellular crescents (37% vs 6%, p<0.001, 26% vs 9%, p = 0.021, 49% vs 24%, p = 0.021, respectively)]. In terms of short-term renal prognosis, only the macrophages were correlated with worst renal function at the 1st year (Cre 3.2 vs 1.8 mg/dL, p = 0.042). Regarding the long-term renal prognosis, we validated as the most reliably predictive score, amongst Berden classification and Mayo Clinic chronicity score, the ANCA renal risk score (AUC 0.694, p = 0.05) and we found that the low-risk group tended to present less severe inflammation (p = 0.029), while the presence of macrophages and eosinophils was less often present (p = 0.03 and 0.05, respectively) compared to the higher risk groups.

Conclusion: Identifying the differences in histopathological subtypes, in yet underestimated active tubulointerstitial lesions, could be the first step toward improving our understanding of distinct pathophysiological mechanisms and anticipating to specific treatment regimens.

ASSOCIATION BETWEEN INTERLEUKIN-37 RS3811047 POLYMORPHISM AND LUPUS NEPHRITIS IN AN EGYPTIAN POPULATION

Samah Ismaeel1, Hamdy Omar2, Aliia Ellawindy3, Hanan Omar1, Asma Hashem1 and Marwa Tawfeek1

1Suez Canal University, Ismailia, Egypt and 2Suez Canal University, Internal Medicine department, Ismailia, Egypt

Background and Aims: Systemic lupus erythematosus (SLE) is a chronic, clinically heterogeneous, autoimmune disorder with unpredictable course and features ranging from mild skin affection to life-threatening involvement of major organs. Interleukin 37 (IL-37) is a cytokine with anti-inflammatory and immune-suppressive effects; it suppresses both innate and adaptive immune responses, thus protecting against excessive inflammation-induced tissue damage.

Aim: investigate the association of IL-37 (rs3811047) polymorphism with lupus nephritis in Egyptian population.

Method: This case-control study comprised 3 groups: 109 SLE patients without nephritis, 97 SLE patients with LN, and 240 healthy controls. History taking, clinical examination, disease activity in SLE patients was assessed and routine laboratory tests were done. Genotyping of the IL-37 rs3811047 polymorphism was done using real time polymerase chain reaction (PCR).

Results: The AA genotype was more frequently represented in LN patients (21.6%) compared to SLE patients without LN (7.3%) (p = 0.007), and carriers of the AA genotype had four times increased susceptibility to acquire LN compared to GG and GA genotype carriers (OR: 4.1). Likewise, the A allele was more represented in LN patients (43%) than in SLE patients without LN (30%) (p = 0.004), and the carriers of the A allele had nearly two times more risk of developing LN compared to carriers of the G allele (OR: 1.79). Moreover, the AA genotype was associated with LN susceptibility under the recessive genetic model (OR = 3.49, CI: 1.47-8.30) (p = 0.002), but not under other genetic models.

Conclusion: The AA genotype of the IL-37 rs3811047 polymorphism contributes to the development of SLE in Egyptian patients with doubled risk of acquiring LN in carriers of the allele A.
THE PROGNOSTIC VALUE OF DIFFERENT HISTOPATHOLOGIC MODELS OF ANCA-ASSOCIATED VASCULITIDES: A PROSPECTIVE STUDY

Michalis Christodoulou1, Eleni Moysidou1, Georgios Lionoulos1, Stamatia Stal1, Konstantinos Bantis1, Christina Nikolaidou2, Asimina Fylaktou2, Aikaterini Papagianni3 and Maria Stangou4

1Hippokration General Hospital, 54642 Thessaloniki, Greece, Department of Nephrology, School of Medicine, Aristotle University of Thessaloniki, Thessaloniki, Greece, 2Hippokration General Hospital, 54642 Thessaloniki, Greece, Department of Pathology, Thessaloniki, Greece and 3Hippokration General Hospital, 54642, Thessaloniki, Greece, Department of Immunology, National Histocompatibility Center, Thessaloniki, Greece

Background and Aims: Renal histology in ANCA-associated vasculitides-glomerulonephritis (AAV/GN) is characterized by active (inflammation, necrosis, crescents) and chronic lesions (sclerosis, fibrosis), and lately classified by Berden Classification (BC), ANCA renal risk (RRS) and Mayo Chronicity score (MCCS). We aimed to prospectively compare predictive ability of the three classification models in AVV.

Method: 27 AVV/GN patients, 17 females, were estimated at time of diagnosis (T0), based on renal biopsy, commenced on the same treatment protocol, cyclophosphamide+steroids, and followed for 6 months. BC, RRS and MCCS Classification models were initially applied on renal biopsies and results were correlated to renal function at T0, and accordingly, 3 (T3) and 6 (T6) months.

Results: Patients’ median age at presentation was 61.9(18-82) years, ratio BC, RRS and MCCS + a t 3 o r 6 m o n th s o f f o l l o w u p . BC, RRS and MCCS + a t 3 o r 6 m o n th s o f f o l l o w u p .

Conclusion: In the short term follow up, ANCA renal risk could better predict renal function outcome compared to Berden Classification and Mayo Chronicity Score, with high RRS frequently leading to HD. Instead, the sclerotic class in BC was not predictive of poor outcome.

PROPOSAL OF A NOVEL RISK PREDICTION SCORE FOR MAJOR ADVERSE CARDIOVASCULAR EVENTS IN LUPUS NEPHRITIS

Adél Molnár1, Márk Juha1, Klaudia Bulajcsik1, Dejan Dobi2, András Tislér1 and Nóra Ledő1

1Semmelweis University, Department of Internal Medicine and Oncology, Budapest, Hungary and 2Semmelweis University, Department of Pathology, Forensic and Insurance Medicine, Budapest, Hungary

Background and Aims: Patients with systemic lupus erythematosus have an increased risk of cardiovascular diseases (CVD) vastly contributing to morbidity and mortality. Besides traditional risk factors, lupus-related factors also contribute to the overall risk. Our major objective was to identify both traditional and non-traditional factors that could aid the prediction of CVD risk and major adverse cardiovascular events (MACE) in this population.

Method: We conducted a single-center retrospective analysis on lupus nephritis patients. Demographic variables, cardiovascular events, clinical and histological data were collected from patients who underwent kidney biopsy between 2005 and 2020 (Figure 1). Chi-square, Mann-Whitney U-test, and logistic regression analyses were performed to investigate risk factors for MACE (IBM SPSS Statistics v28). Receiver Operating Characteristic (ROC) curve was used to determine optimal cut-off values. The study was approved by the Semmelweis University Regional and Institutional Committee of Science and Research Ethics (SE RKED 225/2018).

Results: 91 patients were enrolled in this period. The mean age was 37.3±12.3 years, 86% females, and the mean follow-up time was 62±48 months. Fourteen patients (15.4%) suffered at least one MACE, of which 13 (14.3%) occurred during follow up lupus and 8 (8.8%) after the biopsy. Two patients deceased of a cardiovascular event. Out of the traditional risk factors, increased age (35.8±11.1 vs 45.5±15.1 years, p = 0.012) entailed a higher occurrence of MACE. Complete white blood cell (3.54±0.41 vs 3.25±0.87 Giga/liter, p = 0.026) and neutrophil count (2.85±0.63 vs 3.11±0.83 Giga/liter, p = 0.001) were higher, while diastolic blood pressure was lower (89.5±10.96 vs 78.43±6.9 mmHg, p<0.001) at the time of the biopsy in patients with MACE complication. Age, neutrophil count, and diastolic blood pressure were proven to be independent predictors of MACE (Table 1). Based on these observations, we proposed a new model (CANDE: Cardiovascular risk –based on Age, Neutrophil count, and Diastolic blood pressure– Estimation score) that is a stronger predictor of MACE and can be used to calculate MACE risk from the time of the biopsy in lupus nephritis patients (Figure 1).

Conclusion: The higher the score was, the more often the MACE cases were present (Table 1). ROC curve analysis demonstrated that at 0.78 cut-off value the score predicts MACE occurrence at the time of the biopsy with a sensitivity of 0.75 and a specificity of 0.61. The analyses of MACE subgroups revealed that neutrophil-lymphocyte ratio was elevated in patients who were hospitalized because of heart failure (5.66±4.61 vs 9.68±6.46, p = 0.046), while neutrophil-thrombocyte ratio was higher in
patients with coronary revascularization in their medical history (0.023±0.015 vs 0.06±0.028, p = 0.02). This also indicates the importance of neutrophils in CVD risk assessment.

Conclusion: Age, neutrophil count, and diastolic blood pressure are demonstrated to be independent risk factors of MACE in lupus nephritis. The score calculated from these parameters (CANDE) is a stronger predictor of MACE at the time of the biopsy. A larger cohort is needed to validate these promising results.

ANCA RENAL RISK SCORE 2023: THE UPDATED AND REVISED ARR

Sebastian Bate1, Dominic Mcgovern2, Francesca Castiglioni3, Marek Myslivecek4, Jennifer Scott5, Gavin Chapman6, Nina Brown7, Lauren Floyd8, Benoit Brilland9, Mehmet Fethullah Aydin10, Duha Ilyas1, Ajay Dhaygude8, Juan-Manuel Mejia11, Jennifer Lees12, Marek Kollar4, Andrea Hinojosa11, Abdulmeccit Yildiz10, Augusto Jean François9, Stephen Roberts13, Thorsten Wiech14, Charles Dickson Pusey15, Rachel Jones2, David Jayne2, Ingeborg Bajema16, Charles Jennette17,
Abstracts

**Background and Aims:** Reliable prediction tools are needed to improve prognostication and personalisation of treatment in anti-neutrophil cytoplasmic antibody (ANCA) glomerulonephritis (GN). We aimed to validate and update the ANCA Renal Risk Score (ARRS) prediction model.

**Method:** The ARRS working group collated a retrospective multicentre international longitudinal cohort from referral centres and registries across the globe to revise the ARRS in a validation and recalibration study. The primary endpoint was end stage kidney disease (ESKD) and patients were censored at last follow-up. Cox proportional hazards models were used to reweight risk factors and develop a modified scoring system. Kaplan-Meier estimates, Harrell’s C statistics and calibration plots were used to assess model performance.

**Results:** Of a total of 1591 patients, 1439 were included in the final analyses (959 in the development cohort, 52% male, median age 64 years). The ARRS demonstrated a discrimination of C = 0.800, comparable to the original cohort. Updating the model found an additional useful cut-off for kidney function (K), and serum creatinine replaced glomerular filtration rate which provided higher reliability (K0: < 250 μmol/l = 0 points, K1: 250-450 μmol/l = 4 points, K2: > 450 μmol/l = 11 points). The risk points for the percentage of normal glomeruli (N) and interstitial fibrosis and tubular atrophy (T) were also reweighted (N0: > 25% = 0 points, N1: 10-25% = 4, N2: < 10% = 7, T0: none, mild or < 25% = 0 points, T1: ≥ mild-moderate or ≥ 25% = 3 points). We created four risk groups based on the sum of points: low (0 – 4 points), moderate (5 – 11), high (12 – 18) and an additional very high-risk (21). The model discrimination was C = 0.831 and a supplemental continuous model was developed to supply a patient-specific annual risk. Three-year kidney survival was 96%, 79%, 54%, and 19%, respectively. The ARRS23 performed similarly well in the validation cohort with excellent calibration.

**Conclusion:** We demonstrated the out-of-sample validity of the ARRS and present here the modified and improved score to optimise prognostication and risk stratification for clinical practice and trials.

**SARS-COV-2 VACCINATION AS A TRIGGER FOR AUTOIMMUNE GLOMERULOPATHIES, CHANCE OR REALITY?**

Jorge Ivan Zamora Carrillo, Marina Lopez, Marc Patricio, Juan Carlos Leon, Sheila Bermejo Garcia, Irene Agraz Pamplona, Natália Ramos Terrades, Maria Azancot, Néstor Toapanta Gaibor and María José Soler Romeo

Vall d’Hebron University Hospital 119, Nephrology, Barcelona, Spain

**Background and Aims:** The administration of vaccines, such as influenza or pneumococcus, is a known trigger for the appearance of autoimmune glomerulopathies (AIG). Since the start of vaccination against SARS-CoV-2, publications described the appearance of AIG after SARS-CoV-2 vaccine administration. The timing that has been established associated with causality reaches up to 6 weeks after vaccination. Our aim is to analyse the incidence of AIG flares before and after the start of vaccination against SARS-CoV-2 in our center.

---

**Table 1: Incidence of AIG, IgAN, vasculitis and INS before and after start of Spanish vaccination.**

</tbody>
</table>

The percentages correspond to the initial sample size of 386 patients.

AIG: Autoimmune glomerulopathies, IgAN: IgA nephropaty, INS: Idiopathic Nephrotic Syndrome.

**Method:** All persons with a kidney biopsy from January 2019 to March 2022 in our center were included in the study. We compared the incidence of AIG before and after Spanish vaccination (SV) initiation and determined the time-lapse from vaccine and SARS-CoV-2 infection to kidney biopsy. We established 6 weeks as the time limit to associate AIG with vaccine or SARS-CoV-2 infection. We also evaluated the analytical characteristics of the outbreaks. Idiopathic nephritic syndrome (INS) which comprehended minimal change disease (MCD) and primary focal and segmental glomerulosclerosis (GSFS), IgA nephropathy (IgAN) and vasculitis were studied as subgroups. Minimal changes disease (MCD) flares in patients with and without kidney biopsy in that period were also studied.

**Results:** A total of 386 biopsies were studied. Of them, 86/218(39.4%) were AIG performed pre- and 85/168(50.6%) post- national vaccination (p = 0.029). From the group with kidney biopsy after SV, 31 (36.5%) presented with acute renal failure or chronic kidney disease with acute exacerbation, peak of creatinine 3.09 mg/dL (IQ range: 2.01–4.97), serum albumin 3.5 g/dL (IQ range: 2.9–3.9), proteinuria 1959mg/g (IQ range: 563–5558) and 53% with hematuria. The incidence of idiopathic nephritic syndrome (INS) studied separately was also significantly higher post-SV (18-10.7%) than pre-SV (11-5.0%) (p = 0.036). There were no differences in the incidence of vasculitis or IgA nephropathy. Regarding time-lapse between either SARS-CoV-2 vaccine or infection to AIG diagnosis, a total of 17 (20%) took place in the first 6 weeks after SARS-CoV-2 vaccine and only 2 (2.4%) before 6 weeks after SARS-CoV-2 infection. Within those 17 flares, the most common diagnosis was of IgAN (5-29.4%), 14 (82.4%) received an mRNA vaccine and 9 (52.9%) took place after the 1st vaccine dose. We observed a significantly increase of MCD flares post-SV (n = 20) as compared with pre-SV (n = 13) (p = 0.002).

**Conclusion:** The incidence of AIG, INS and MCD flares in our center increased significantly after Spanish vaccination against SARS-CoV-2. Importantly, 20% of AIG flares took place in the first 6 weeks after receiving a vaccine dose, being the first dose the most risky one and IgAN the most frequent diagnosis. Although causality cannot be demonstrated solely with temporal association and general COVID-19 vaccination, further investigation and prospective studies could be of great interest.
RELATION OF KIDNEY BIOPSY FINDINGS TO CLINICAL OUTCOMES IN PATIENTS WITH LUPUS NEPHRITIS TREATED WITH AN ANTAGONISTIC ANTI-CD40 ANTIBODY (BI 655064)

Ingeborg Bajema¹, Helmut Schumacher², Jürgen Steffen³, Simone Deutschel⁴ and David Jayne⁵

¹University Medical Center Groningen, Pathology and Medical Biology, Netherlands, ²Statistical Consultant, Germany, ³Boehringer Ingelheim International GmbH, Germany, ⁴Boehringer Ingelheim RCV GmbH & Co KG, Austria and ⁵Department of Medicine, University of Cambridge, United Kingdom

Background and Aims: Lupus nephritis (LN) is the most serious complication of systemic lupus erythematosus with a high risk of end-stage kidney disease and a high need of better treatment. A recent randomized, double-blind, placebo-controlled, phase II trial tested doses of 120, 180 and 240 mg of the anti-CD40 monoclonal antibody BI 655064 as add-on to standard of care (MMF + glucocorticoids), in patients with active LN (proteinuria > 1 g/day) for 52 weeks. Although the trial did not demonstrate a dose-response relationship for the primary endpoint determined by complete renal response, a potential efficacy benefit of BI 655064 180 mg and 240 mg was found in a post-hoc analysis. We investigated whether a treatment effect was related to findings in the pre-treatment renal biopsy.

Method: Biopsies from 101 patients with LN class III or IV, confirmed in a central review conducted according to a previously established protocol, were included. Protein/creatinine ratio (UPCR, based on spot urine) and eGFR were determined at every visit. For each, the last available UPCR and the last available eGFR values, linear regressions (based on the respective baselines) of all patients irrespective of therapy were calculated, and subjects were classified according to their individual performance, “Better” or “Worse” than the average. The modified activity and chronicity indices as well as all biopsy parameters, which are not already contained in the indices, were compared for differences between the “Better” and “Worse”. Parameters with p < 0.1 in the univariate analyses were entered into a multivariate logistic regression model, and a routine model selection procedure (with p < 0.2) was used to identify parameters predictive for clinical outcome. As monocytes express CD40, which is the target of BI 655064, a further question was whether high dose treatment with BI 655064 (180/240 mg) was beneficial when monocytes were present in the biopsy, using a model which adjusted for all predictors identified in the multivariate model.

Results: The results of the univariate and the multivariate analysis of biopsy parameters are shown in Table 1. Improvement in UPCR was better if the

¹Chi² or Wilcoxon test, only parameters with p<0.1 presented

Logistic Regression, only parameters with p<0.2 included

“per unit increase”

for “Better” outcome
modified chronicity index was low. In addition, LN class IV subjects had a marginally better prognosis than class III. The effect of high-dose treatment with BI 655064 was better when monocytes were present. eGFR outcome was better if the modified chronicity index was low and, conversely, the modified activity index was high. Further, the presence of synechia/adesions was a negative predictor for positive outcome. There was no indication for an effect of high-dose treatment with 655064 on eGFR when monocytes were present.

Conclusion: This post-hoc analysis of the BI 655064 trial used a novel approach which investigated whether specific histological lesions in renal biopsies were related to treatment outcome. Although the number of patients was limited, our results suggest that treatment with higher dose anti-CD40 may improve the reduction of proteinuria when monocytes are present in the biopsy. This indicates that specific information from renal biopsies could ultimately improve the choice of treatment for individual LN patients.

#5207
CENTRAL NERVOUS SYSTEM INVOLVEMENT IN EOSINOPHILIC GRANULOMATOsis WITH POLYANGIITIS: A DIAGNOSTIC DILEMMA
Carla Nicolau1, Rui Barata2, Miguel Bigotte Vieira1, Tiago Assis Pereira1, Mário Góis1, Helena Viana1, João Sousa1, Francisco Ribeiro1 and Fernando Nolasco1
1Hospital Curry Cabral, Nephrology, Lisboa, Portugal and 2Hospital Curry Cabral, Lisboa, Portugal

Background: Central nervous system involvement is extremely rare in eosinophilic granulomatosis with polyangiitis, and associated with very poor prognosis. A high index of suspicion is needed to diagnose this entity and initiate prompt treatment for this life-threatening condition.

Case presentation: A 71-year-old man was admitted to our hospital with lower limb weakness, loss of vision in the left eye and diplopia for four weeks. Four months prior to admission he reported unintentional weight loss and wheezing. Laboratory studies revealed anemia, eosinophilia and high antineutrophil cytoplasmic antibodies (ANCA) anti myeloperoxidase (MPO) levels. Brain computerized tomography (CT) was normal. Although corticosteroids were started, addition of other immunosuppressants was delayed due to ongoing infection. During the next three days, the patient presented with worsening kidney function and was drowsy, agitated and combative. Lumbar puncture and brain CT scan showed no acute abnormalities. Therefore, plasmapheresis was started. During the third session of plasmapheresis, the patient became drowsy and non-responsive. Brain CT scan revealed subdural hematoma with uncal herniation. Trepanation and initiation of hemodialysis were required. Kidney biopsy revealed focal proliferative glomerulonephritis with fibrocellular crescents. Magnetic resonance imaging and ophthalmological evaluation showed abnormalities compatible with vasculitic disease. Cyclophosphamide was added to prednisolone, with renal and extra renal manifestations improvement. One year later, the patient is autonomous, with right hand paresis, stable kidney function (serum creatinine 2.5 mg/dL) and negative ANCA MPO serology.

Conclusion: Neurological involvement in GEA is heterogeneous and requires differential diagnosis with central nervous system infections, adverse effects of corticosteroids and complication of plasmapheresis. The diagnosis is challenging and demands a high level of suspicion. Otherwise, it may lead to delayed, erroneous diagnosis and worse survival.

NETOSIS IS A PREVALENT IMMUNE PROCESS IN LUPUS NEPHRITIS AND NEUTROPHIL ELASTASE SCORING EXPRESSES THE ACTIVITY AND SEVERITY IN DIFFERENT CLASSES
Shaimaa Zaki Abdelmegied1, Manal Salman2, Heba Mahmoud2 and Aya Elgendy3
1Internal Medicine and Nephrology Department, Faculty of Medicine Ain Shams University Cairo, Egypt, 2Pathology Department, Faculty of Medicine Ain Shams University Cairo, Egypt and 3Internal Medicine/Allergy and Clinical Immunology Department, Faculty of medicine Ain Shams University Cairo, Egypt

Background: NETosis is a prevalent immune process in lupus nephritis and its presentation in different lupus classes.

Methods: A cross-sectional study included 45 patients with lupus nephritis who underwent renal biopsy and were classified according to lupus class. NE was done for the detection of NETosis by immunohistochemistry.

Results: The prevalence of (NE) was 88.8% (40/45 cases). NE combined score with cut-off (>3) expresses moderate to severe NETosis. It allowed the detection of active proliferative lupus class III-IV with a sensitivity: 80.0%, specificity: 60.0%, PPV: 58.71%, and NPV: 60.0%. In class III-IV (N = 34 cases): NE combined score >3 was 83.3% (25/30 cases) with features: glomerular deposition >25% of the glomeruli in 60% (19/30 cases), strong intensity (+2) in 63.3% (19/30 cases), diffuse (>50% of the number of the glomeruli) 67.8% (19/28 cases). In non-proliferative lupus class II-V (N = 11 cases) NE combined score >3 was 20% (2/10 cases) and score <3 was 80% (8/10 cases) with features: glomerular deposition <25%/ faint intensity (+1) focal. On comparing both groups as regard NE combined score, distribution, intensity, and focal/diffuse p-value was 0.0002, 0.099, 0.013, and 0.94 respectively. On redistribution of biopsies according to NE combined score >3 vs <3 there was a significant difference in activity index, distribution, intensity, and focal/diffuse p-value 0.0011, 0.0001, 0.0002, 0.0006 while non-significant for chronicity index p-value 0.08914.

Conclusion: NETOSIS is a prevalent immune process in lupus nephritis and NE combined score is a sensitive marker of proliferation that increases with class severity and activity.

MICROVASCULAR LESIONS IN LUPUS NEPHRITIS
Tamara Knezevic1, Ivan Padjen2,3, Vanja Ivkovic4,5, Mario Laganovic1,6, Stela Bulimbasic2,7, Ana Luka2, Marijana Ćorić1,7 and Branimir Anić2,3
1University Hospital Centre Zagreb, Division of Nephrology, Hypertension, Dialysis and Transplantation, ZAGREB, Croatia, 2University Hospital Centre Zagreb, Division of Clinical Immunology and Rheumatology, Zagreb, Croatia, 3University of Zagreb, School of Medicine, Zagreb, Croatia, 4University Hospital Centre Zagreb, Division of Nephrology, Hypertension, Dialysis and Transplantation, Zagreb, Croatia, 5University of Rijeka, Faculty of Health Studies, Rijeka, Croatia, 6Clinical Hospital Merkur, Renal Division, Department of Medicine, Zagreb, Croatia and 7University Hospital Centre Zagreb, Department of Pathology and Cytology, Zagreb, Croatia

Background and Aims: Microvascular lesions (MVL) can be found in the kidneys of lupus nephritis (LN) patients and might be associated with worse outcomes. There are very few studies which evaluated MVLs in these patients and we aimed to provide a comprehensive evaluation of all MVLs, their frequency, characteristics and association with renal outcomes one year after kidney biopsy.

Method: We have conducted a retrospective cohort study to evaluate the characteristics and prognostic significance of MVLs in the kidney of subjects with LN. We have collected data on demographics, clinical and laboratory parameters and histopathology (light, immunofluorescent and electron microscopy). MVLs were characterized according to previous classifications. SLE was diagnosed using the American College of Rheumatology criteria.

Results: A total of 56 patients with biopsy-proven LN were followed up for at least one year after kidney biopsy (79% women, mean age at biopsy 38±13 years). Forty patients (71%) had MVLs in the kidney. The most common MVLs were arteriolar endotheliocyte swelling (54%), arteriolar hyalinosis (25%) and endothelialitis (8%) and the frequency distribution of all microvascular lesions is shown in Figure. Median number of lesions in the MVL group was 1 (interquartile range 1 to 2) and subjects had up to 6 MVLs. There was no difference in the median number of MVLs across LN classes (p=0.05). Proteinuria was highest in class V (5.5 g/day, p = 0.06 vs. all other classes). Subjects with MVLs had lower baseline proteinuria compared with those with no lesions (3.6 vs. 5.4 g/day, p = 0.037), but there was no difference in serum creatinine (92 vs. 119 umol/L, p = 0.25). There were no differences in the occurrence or number of MVLs across LN classes (p = 0.63). The number of MVLs was not correlated with proteinuria (p=0.05). There was no difference in the frequency of proliferative lupus between MVL and no MVL groups (79% vs. 60%, p = 0.15). A total of 48% of subjects achieved complete response (CR), 27% achieved partial response (PR) and 25% had no response (NR). MVLs were not associated with response (defined as CR or PR) in a multivariate regression model (OR 3.5 [0.5, 24.6]).

Conclusion: MVLs are common in LN. They were associated with lower baseline proteinuria, but not with proliferative LN or renal outcomes. The association with proteinuria warrants further research.

CHANGING PATTERNS IN CLINICAL-HISTOLOGICAL PRESENTATION AND OUTCOMES OVER THE LAST FOUR DECADES IN PATIENTS WITH MICROSCOPIC POLYANGIITIS (MPA)
Martina Uzzo1,2, Filippo Sala1,3, Francesco Reggiani1,4, Vincenzo L’imperio5, Marta Calatroni2,4, Umberto Maggiore6, Gabriella Luisa Moroni1,2 and Renato Alberto Sinico1,4
1University of Milano-Bicocca, Department of clinical and sperimental sciences, Milano, Italy, 2Humanitas Research Hospital, Nephrology and Dialysis Unit, Monza, Italy, 3Humanitas Research Hospital, Nephrology and Dialysis Unit, Cusca Perseghetto, Italy, 4Ospedale San Gerardo, Nephrology and Dialysis Unit, Monza, Italy, 5Ospedale San Gerardo, Department of Medicine and Surgery, Pathology Unit, Monza, Italy and 6University of Parma, Department of Medicine and Surgery, Nephrology and Dialysis Unit, Parma, Italy

Background and Aims: Recent data seem to indicate an increasing age of patients affected by MPA over the last decades, which may result from the wider availability of anti-neutrophil cytoplasmic antibody (ANCA) testing and to a greater awareness of the disease. It is not known whether the changing MPA has been mirrored by a change in the pattern of clinical outcomes. We aimed at assessing the changes in demographic, clinical and histological presentation, and outcomes of MPA patients over a 42-year period.

Method: We performed a multicenter retrospective cohort study. Patients diagnosed with MPA between 1980 and the 31st of January 2022 were grouped in two periods (p), based on the year of diagnosis: p1980-2001 and p2002-2022. We tested the baseline differences using the Mann-Whitney test and the Fisher’s exact. We estimated the crude patient survival using the Kaplan-Meier
Figure 1: Crude cumulative incidence curves (Aalen–Johansen estimator) computed with the time from MPA diagnosis to the first event as absorbing state (ESKD or death, whichever came first).

Figure 2: Crude probability of each outcome at each time point since MPA diagnosis, that results from fitting the multiple state model. Unlike the model in which ESKD is an absorbing state (Figure 1), the multistate model allows that patients starting dialysis remain at risk of dying.
estimator and the cumulative incidence of competing events death/dialysis using Aalen-Johansen estimator. The probability of end-stage kidney disease (ESKD) and death at each time point since MPA diagnosis was estimated through a multistate model, which accounted for patients who died after starting dialysis. We used Cox proportional hazards, Fine-Gray regression, and multistate regression models to adjust for potential confounding factors such as age, kidney function and clinical symptoms at the time of diagnosis.

Results: Out of 201 patients, 187 had non-missing follow-up to ESKD and/or death and could be included in the study. There were 77 patients in p1980-2001, and 110 patients in p2002-2022. Compared to p1980-2001, patients in p2002-2022 were older (66.2 (14.0) vs 57.7 (15.8); P < 0.001) and had better kidney function (eGFR (MDRD), mL/min/1.73m²: 25.9 (24.8) vs 21.5 (28.2); P = 0.0011). The prevalence of the sclerotic class according to the Berden histopathological classification was lower in p2002-2022 (4.8 vs 18.2%; P = 0.0016). There were mild differences in the pattern of clinical symptoms, with a lower prevalence of constitutional symptoms (83.6 vs 94.8%; P = 0.021) and a higher prevalence of pulmonary disease (40 vs 20.8%; P = 0.040) and peripheral neuropathy (17.3 vs 5.2%; P = 0.013) in p2002-2022. Crude and adjusted patient survival was similar. However, the risk of ESKD decreased during p2002-2002 compared to p1980-2001 (Figure 1; crude Subhazard ratio of ESKD: 6.30 [95%CI: 0.16 to 0.57; P < 0.001]). The difference in the probability of ESKD remained significant even after accounting for death after ESKD (Figure 2), and after adjusting for potential confounders (Hazard ratio of ESKD since MPA diagnosis in multistate models: 0.33 [95%CI: 0.18 to 0.63; P < 0.001]).

Conclusion: Clinical presentation of MPA has become less severe in the last decades, leading to a reduced risk of ESKD, despite a comparable risk of death. Older age, changing clinical patterns and better kidney function at the time of diagnosis do not fully account for the reduction in ESKD, which may be instead related to new induction and maintenance therapies as well as to a greater awareness of the disease.

618yearswithbiopsy-provenpureormixedISN/RPS

Background and Aims: A significant number of patients with anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) with glomerulonephritis (AAV-GN) still progress to end-stage kidney disease (ESKD, eGFR <15mL/min/1.73m²) despite advances in remission-induction treatment.

Method: A retrospective cohort study on MPO- or PR3-ANCA positive patients with AAV (MPA or GPA) and ESKD at presentation. Renal recovery, treatment.

Results: We analyzed 166 patients with biopsy proven active kidney involvement and eGFR <15mL/min/1.73m² at the time of AAV-GN diagnosis. Patients received glucocorticoids with CYC (n = 84) or with RTX (n = 72) for remission-induction, and 49 also received PLEX. The predictors of renal recovery were erythrocyte sedimentation rate, SCr at diagnosis and minimal or mild chronicity changes. We analyzed 71 patients who started dialysis with or without PLEX within 4 weeks from AAV-GN diagnosis. The predictors for dialysis discontinuation were minimal chronicity changes in kidney biopsy at the time of diagnosis (OR 6.138, [95%CI 1.389-27.118]; P = 0.017) and focal glomerular involvement (OR 5.017,[95%CI 1.287-19.567];p = 0.020). Predictors for maintenance in ESKD at 12 months included higher serum creatinine (SCr) at the time of diagnosis (IRR 1.086, [95%CI 1.005-1.173],p = 0.037), moderate (IRR 3.797,[95%CI 1.090-13.225],p = 0.036), or severe chronicity changes in kidney biopsies (IRR 5.883,[95%CI 1.542-22.439],p = 0.009).

Conclusion: In our cohort, kidney recovery, dialysis discontinuation, and maintenance of ESKD in patients with AAV-GN and eGFR<15mL/min/1.73m² depended on SCr and histologic findings on kidney biopsies at the time of diagnosis and was not affected by the addition of PLEX.

Figure 1: Thematic overview of prominent themes that emerged through qualitative analysis. Representative quotes are included to punctuate the main findings.
Background and Aims: SLE is a chronic autoimmune disorder that can affect all organ systems. Clinically evident renal disease known as Lupus Nephritis (LN) occurs in up to 50% patients of SLE and up to 10% of LN patients develop ESRD. LN carries a significant morbidity and mortality and requires an early aggressive management. Our Aim is to study the effect of IV Cyclophosphamide (CYC) vs Mycophenolate Mofetil (MMF) as Induction regimen in proliferative Lupus Nephritis patients of North- East India.

Method: This is a prospective observational study conducted in the department of Nephrology, Gauhati Medical College, over a period of 1 year. Haematological and biochemical assay including serum creatinine, blood urea, serum albumin, ANA, Anti ds DNA, C3 and C4,24h urine protein, estimated glomerular filtration rate (eGFR) of all patients were taken into account. Renal biopsy was performed under ultrasonographic guidance. SLEDAI Score and Activity and Chronicity Indexes were calculated for all patients. Statistical analysis was done by SPSS Version 22 for windows. Two tailed p<0.05 was considered to be statistically significant. A total of 64 biopsy proven LN patients of Class III, Class IV and Class V (Plus Class III/ Class IV) were enrolled in the study. We randomly assigned 34 patients with Class III through IV lupus nephritis to IV CYC (NIH protocol/monthly) and 30 patients to MMF (2 gm/day) for 24 weeks as Induction Regimen. Both the groups received prednisone, tapered from a maximum starting dosage of 60 mg/day.

All the patients were followed up for 6 months. Complete Response (CR) was considered when proteinuria<0.5g and Partial Response (PR) when 0.5g<proteinuria<3g or there is reduction in proteinuria by at least 50%. Baseline characteristics and CR and PR were compared between the two groups.

Results: Of the total 64 patients, 57 patients (89%) were female, and 7 patients were male (11%) with the mean age of 31±9.45 years. 24% patients had Class III LN and 76% had class IV LN. Complete Response was achieved in 13 patients (43%) in the MMF group and in 15 patients (44%) in CYC group. Partial Response was achieved in 11 patients (36.67%) in CYC group and 6 patients (20%) in MMF group. No response was seen in 7 patients (20.6%) in MMF group and 6 patients (18.7%) in CYC group.

Conclusion: The Northeastern population of India consists of various ethnic groups and there are records of variation in response to the Regimens in different geographical areas. In our study from North-east India, IV Cyclophosphamide and Mycophenolate Mofetil showed similar efficacy as Induction Regimen in proliferative Lupus Nephritis. However, there were higher rates of infection in the Cyclophosphamide group.

Figure 1: Intersection immune associated genes of arsenic trioxide in systemic lupus erythematosus (SLE). (A) The heatmap showed the transcriptional expression of differentially expressed genes (DEGs) in both GSE144390 and GSE50772 dataset (merged dataset). (B) Venn diagram indicated 476 total predicted targets of Arsenic Trioxide (ATO) using four databases. (C) The transcription expression of 12 intersection genes (DEGs genes, immune related genes, and arsenic trioxide targeted genes) in SLE. *p<0.05, **p<0.01, ***p<0.001.

Figure 2: Single-sample GSEA (ssGSEA) analysis of eight intersection genes in the infiltration of immune cells in systemic lupus erythematosus (SLE). The heatmap showing a total of 8 types of immune cells had significant associations with intersection genes expression in SLE. aDCs, activated Dendritic Cells; DCs, Dendritic Cells; iDCs, immature Dendritic Cells; pDCs, plasmacytoid Dendritic Cells; Tfh cell, Follicular helper T cell; Th1 cells, T helper1 cells; Th2 cells, T helper2 cells; Treg cell, Regulatory T cell; TIL, Tumor-Infiltrating Lymphocytes.
NOD-like receptor signalling pathway (p = 1.93E-09). Ten types of immune cells showed significant difference with intersection genes expression in SLE using ssGSEA approach. MMP9 was the most significantly associated with immune cells and showed positive correlations with macrophages and neutrophils. A significant TF-MMP9-miRNA regulatory network was constructed using cytoscape software. Pilot data from our in vitro studies suggested that ATO might down regulate MMP9 expression in PBMCs obtained from LN patients during disease remission (n = 3).

Conclusion: ATO interacts with immune cells in LN patients via different inflammatory pathways and may downregulate MMP9 expression in PBMCs.

PROTEINURIA AND PROGRESSION OF IGA NEPHROPATHY. HAVE WE REACHED THE POINT OF NO RETURN?

Carolina Isabel Movilla Echeverri, Cristina Andrades Gómez, Macarena Naranjo Arellano, Carmen Alarcón Garcelán, Fátima Cazalla Cárdenas, Virginia Cabello Chaves, Manuel López Mendoza, Inmaculada Gómez Couñago, Paula Batalha and Miguel Ángel Pérez Valdivia

Virgen del Rocio Hospital, Nephrology, Seville, Spain

Background and Aims: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide, associated with an incidence of 2.5/100,000 cases per year and progression to end-stage kidney disease (ESKD) in 20% patients within 10 years. Proteinuria has been identified as the greatest risk factor for ESKD in IgAN. The aim was to evaluate the correlation between proteinuria and major adverse renal events (MARE). We define MARE as 40% decline in glomerular filtration rate (eGFR), initiation of kidney replacement therapy (either dialysis or kidney transplantation) or death whether from renal cause or cardiovascular-related.

Method: In this retrospective observational single-center study, we included all biopsy-proven IgAN patients older than 18 years with proteinuria >500 mg/24h, diagnosed between 2006-2017 and followed up to January 2022. Clinical, analytical, and histological findings were collected at time of diagnosis and during follow-up. Uni and multivariable Cox regression were performed to establish correlation between our data and the main event. A linear mixed-effects model was used to estimate eGFR slope.

Results: A total of 124 patients were included. Mean age and eGFR were 40 ±15 years and 59 ml/min (IQR: 33-94 ml/min) respectively, with a median proteinuria of 1.44 g/24h (IQR: 0.7-2.3). 64% of patients were treated with corticosteroids. In the multivariate analysis, we found that IFTA >25% had a statistically significant risk of MARE (IFTA T1 HR 3.1; 95% CI 1.52-6.6; p = 0.002; IFTA T2 HR 6.6; 95% CI 1.46-16.12; p <0.001), history of cardiovascular disease presented 3.7 times higher risk of MARE (HR 3.7; 95% CI 1.46-9.6 p = 0.015). Patients with proteinuria >3 g/24h showed significantly higher hazard ratio (HR 2.36 95%CI 1.16-4.8 p = 0.01) for MARE. In the 3-year linear mixed-effects model, patients with proteinuria above 3 g/24h had an annual eGFR slope of -6.3 ml/min (-9.6 to -3.1 95% CI). Nevertheless, proteinuria between 1.5 to 3 g/24h had a similar behaviour as our reference group (proteinuria <1.5 g/24h). These results might provide new evidence supporting a more conservative approach and start receiving glucocorticoids if proteinuria is >3 g/24h.

SERUM BIOMARKERS AS PREDICTORS OF RENAL DAMAGE IN ANCA-ASSOCIATED VASCULITIDES
António Silva Inácio1, Patricia Domingues1, Ana Piedade1, Teresa Furtado1, Beatriz Mendes1, Ricardo Verde1, Jesuïna Duarte2, Patricia Valério Santos1, Ana Farinha1, Miriam Karina Soto Rios1 and Liliana Cunha1
1Centro Hospitalar De Setúbal E.P.E., Nephrology, Setúbal, Portugal and 2Centro Hospitalar De Setúbal E.P.E., Clinical Pathology, Setúbal, Portugal

Background and aims: Despite therapeutic advances, anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) carry poor renal and survival outcomes. Prognostic elements are needed to guide treatment. Several studies explored determinants of AAV outcomes, but predictive factors are not well established. Poor prognosis factors have been lower glomerular filtration rate, lower serum C3, C3 deposition on immunofluorescence (IF), and recently platelet count below 250 × 109/L. Histopathological lesions have also been related to renal outcomes. In this study we aim to correlate serum immune and inflammatory biomarkers with renal histological lesions' severity.

Methods: We retrospectively analysed histopathological findings of adults with biopsy-proven AAV renal involvement through Berden's histopathological classification (BHC) classes, Brix's renal risk score (BRS), interstitial fibrosis and tubular atrophy (IFTA) and crescentic glomeruli percentages (%), C3 positive IF and presence of interstitial hemorrhage (IH). Patients' ANCA titer (ANCAD) measured by ELISA, serum C3 and C-reactive protein (CRP) were documented at diagnosis. ANCA titer was also registered at last follow-up date (ANCAF). Univariate statistical analysis was used to correlate every biomarker with every histologic variable mentioned. C3 and CRP were used as continuous variables and ANCA titers as continuous and categorical variables. As a continuous variable, ANCA titers above laboratorial detection values, proliferative classes and the activity index at kidney biopsy (Table 2). Variables included in Table 1 with values of antiC1q antibodies and we found significant correlation for serum creatinine, active urinary sediment, C3 and C4 values, proliferative classes and the activity index at kidney biopsy (Table 2).

Results: We included 46 patients with biopsy-proven AAV kidney involvement from January 2006 to January 2023, 65.2% male (n = 30), median age 66.5 (60.75-74.5), 78.3% (36) MPO, 15.2% (7) PR3 and 6.5% (3) seronegative; and 12.8% (5) 100-134 and 43.6% (20) > 134. According to BHC, biopsies were: 17.4% (8) global sclerotic, 28.3% (13) mixed, 39.1% (18) crescentic, and 15.2% (7) 100-134 and 43.6% (> 134). ANCA positive biopsies were 28.3% (16) global sclerotic, 28.3% (13) mixed, 39.1% (18) crescentic, and 15.2% (7) 100-134 and 43.6% (> 134).

Conclusions: ANCA titer at diagnosis, serum C3 and CRP did not correlate with histological severity and chronicity lesions in our population. Nonetheless, larger cohorts, systematization of biopsy findings and studies on newer biomarkers might bring helpful information to expected prognosis and initial Furtapace approaches. A positive correlation between ANCA levels at the last follow-up date and medium and high-risk BRS groups on initial biopsy might be further explored in larger studies.

#5081

THE VALUE OF ANTI-C1Q ANTIBODIES IN PREDICTING THE CLINICAL-HISTOLOGICAL FEATURES OF LUPUS NEPHRITIS PATIENTS AT TIME OF KIDNEY BIOPSY

Marta Calatróni1, Emanuele Conte2, Francesco Reggiani3, Federica de Lisi1 and Gabriella Luisa Moron1
1Humanitas University, Nephrology, Milan, Italy, 2University of Milano Bicocca, Italy, 3Humanitas Research Hospital, Rozzano Milan, Italy, 4Fondazione IRCCS Ca' Grande PoliClinico Maggiore, Milan, Italy and 5Humanitas Research Hospital, Nephrology, Rozzano Milan, Italy

Background and Aims: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with renal involvement in around 50% of patients. Delayed diagnosis of lupus nephritis (LN) is associated with higher risk of end-stage kidney disease (EKD) and mortality. Kidney biopsy remains the gold standard for diagnosis and management of LN, but in the last decades there is an interest for new serum biomarkers. Anti-C1q antibodies are autoantibodies associated with LN. Nevertheless, few studies have correlated the association of anti-C1q antibodies with active LN with focus on renal histology.

Method: We evaluated clinical and histological data of 59 patients with biopsy proven LN. Kidney biopsies were categorized according to the ISN/RNP Classification. We evaluated the correlation of the main clinicopathologic features with values of anti-C1q antibodies, measured by a commercial kit with a clinically validated ELISA test. Normal values of anti-C1q were < 20 UA, medium values were between 20 and 80 UA and high values were > 80 UA. Demographic and clinical data were expressed as numbers or percentage for discrete variables and as continuous variables as mean and standard deviation. The correlation between anti-C1q levels and clinicopathological characteristics have been explored using Spearman's test.

Results: At the presentation of 59 patients with LN, the mean age was 34 years and the time of SLE disease before the onset of LN was 73.2 months. 9 patients were male, mean serum creatinine was 1 mg/dL, glomerular filtration rate (eGFR) was 88.53 ml/min, proteinuria was 4.35 g/day and microscopic hematuria was present in 79% of pts. Kidney biopsies were classified as non-proliferative (class II and V) in 18.4% of patients and proliferative (class III and IV) in 77.6% of patients. We evaluated the correlation between all variables included in Table 1 with values of antiC1q antibodies and we found significant results for serum creatinine, active urinary sediment, C3 and C4 values, proliferative classes and the activity index at kidney biopsy (Table 2).

Table 1: Clinical and histological characteristics at presentation of LN in 59 patients. RSP/ISN Classification for kidney biopsy classes.

| Time of SLE before LN (months) | 73.2 ± 89.9 |
| Male sex, n (%) | 9 (18) |
| Age (years) | 34 ± 13.21 |
| Serum Creatinine (mg/dL) | 1 ± 0.41 |
| eGFR CKD-EPI (ml/min) | 88.53 ± 31.16 |
| Proteinuria (g/24 h) | 4.35 ± 3.43 |
| RBC in the Urinary Sediment n./HPF | 17 ± 24 |
| Arterial hypertension (%) | 49.15 |
| Hematocrit (%) | 31.11 ± 7.09 |
| White blood cells /ul | 5558 ± 2367.52 |
| Platelets /ul | 232100 ± 96.310 |
| Class II n° (%) | 3 (6.1) |
| Class III n° (%) | 5 (10.2) |
| Class IV n° (%) | 19 (38.8) |
| Class V n° (%) | 6 (12.2) |
| Class VI n° (%) | 1 (2) |
| Class V + III n° (%) | 7 (14.3) |
| Class V + IV n° (%) | 8 (16.3) |
| Activity Index (n) | 7.84 ± 5.69 |
| Chronicity index (n) | 2.02 ± 2.1 |
| Antiphospholipid antibodies, n° (%) | 41 (69.5) |
| C3 (mg/dL) | 50.32 ± 27.56 |
| C4 (mg/dL) | 8.33 ± 6.21 |
| ANA positivity, n° (%) | 59 (100%) |
| Anti-DNA positivity, n° (%) | 53 (89.8) |
| Anti Ro antibodies, n° (%) | 18 (30.5) |
| Anti Sm antibodies, n° (%) | 18 (30.5) |
| Anti RNP antibodies, n° (%) | 22 (37.3) |

THE EFFECTS OF RITUXIMAB IN NON-HCV-RELATED MIXED CRYOglobulINEMIC VASCULITIS

Annalisa Guarino, Nunziante Caruso, Giovanni Geraci, Roberta Longo, Giorgio Amore, Gianluca Rabajoli, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

Torino, Italy

**Background and Aims:** Remarkable results in severe HCV-related cryoglobulinemic vasculitis have been obtained with Rituximab. Details of the clinical characteristics and effective treatment of non-HCV-related cryoglobulinemic syndrome are presently lacking.

**Method:** This paper reports on a prospective single-Center open study aimed at evaluating the clinical presentation and effects of Rituximab administered alone in patients with severe non-HCV-related cryoglobulinemic syndrome.

**Results:** The study group included 11 patients followed for at least 6 months. Three patients had type 1 cryoglobulinemia, 6 had type II and the remaining 2 patients had type III. Mean cryocrit was 2.5%. Four out of 11 patients had symptomatic sicca complex with anti-SSA (Ro/anti SSB (La) antibodies. All 11 patients presented with biopsy-proven renal involvement, 4 out of 11 with leukocytoclastic vasculitis, 8 with involvement of the peripheral nervous system. Renal biopsy revealed diffuse membranoproliferative glomerulonephritis (MPGN) in 9 out of 11 patients. Extracapillary proliferation and necrosis of the glomerular tuft was observed in 1 of these 9 cases. Intermittent nephritis together with mesangial expansion and capillary immune deposits were observed in 1 patient. Prevalent interstitial fibrosis and glomerular sclerosis were detected in the remaining case. Patients underwent treatment with rituximab alone. After 6 months we observed a remarkable improvement in the necrotizing skin ulcers and a substantial amelioration of the electrophysiological parameters of motor and sensory peripheral neuropathy. Improvement in both renal function (from 2.8 to 1.4 mg/dl, p < 0.001) and proteinuria (from 4.2 g/24 to 0.4 g/24 h, p < 0.001) was found in 10 out of 11 patients, while 1 could not be fully treated because of a severe infusion reaction and sudden development of anti-Rituximab antibodies. Good renal response was confirmed at the end of follow-up (38.4 months). Three patients had a relapse at 6, 12, and 48 months, respectively.

**Conclusion:** In our cohort the administration of 4 once-weekly infusions of Rituximab followed by 2 more infusions after 1 and 2 months proved to be effective in the management of these rare patients.

ONCO-NEPHROLOGY: THE ROLE OF KIDNEY BIOPSY IN THE MANAGEMENT OF SIDE EFFECTS OF TARGETED THERAPIES

Nunziante Caruso, Stefania Lalloni, Martina Marchisio, Marco Morrone, Gianluca Rabajoli, Andrea Careddu, Giovanni Geraci, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

Torino, Italy

**Background and Aims:** The introduction of innovative therapies, resulting from revisiting cancer as a disease of the immune system, has changed the scenario of complications. These new classes of drugs, such as targeted therapies and immune checkpoint inhibitors, assure substantial advantages in cancer therapy, despite some side affecting various organs, including the kidney. Histological evaluations of kidney disorders induced by targeted/immunotherapy are limited.

**Method:** In this study we examined the histological features of patients treated with new cancer agents who underwent kidney biopsy for new onset kidney failure and/or urinary abnormalities.

**Results:** The cohort included 30 adult patients. The most frequently administered therapies were immunotherapy (30%), targeted therapy (26.7%), immunotherapy plus targeted therapy (13.3%), immunotherapy plus chemotherapy (13.3%), targeted therapy plus chemotherapy (16.7%). The most common histological finding was tubular interstitial nephritis (30%) that was associated with acute tubular necrosis in 4 cases, and thrombotic microangiopathy (23.3%). After kidney biopsy, 16 of the 30 patients were treated according to the histological diagnosis. Fourteen patients were treated with steroids. One patient with membranous nephropathy was treated with a single dose of rituximab. A patient with severe thrombotic microangiopathy requiring dialysis received a treatment with eculizumab for 3 months. Overall some renal response was obtained in all patients treated with glucocorticoids, while complete kidney response was achieved in the patient treated with rituximab. Cancer treatment was resumed without change in 21 out of 30 patients.

**Conclusion:** Kidney biopsy is critical for the management of kidney toxicities and should be strongly encouraged for patients showing adverse kidney effects of novel cancer agents.

PATIENT OUTCOME IN A SWEDISH SINGLE-CENTRE COHORT OF ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT

Ylva Ostdlund, Aso Saeed and Karlo Mihovilovic

Sahlgrenska Academy, Sweden

**Background and Aims:** End-stage kidney disease and premature death are common in patients with antineutrophil cytoplasmic antibody (ANCA) - associated vasculitis (AAV) with renal involvement. Poor patient outcome is attributed to multiple factors comprising a delay in diagnosis and treatment, inadequate efficacy of treatments, and complications due to toxic effects of given immunosuppressive therapy. The aim of the present study was to evaluate clinical and prognostic features of a Swedish cohort of patients with renal AAV and to investigate the pattern of immunosuppressive treatment and predictors of renal and patient survival.

**Method:** Ninety-one patients diagnosed with AAV with renal involvement between 01 March 2002 and 30 October 2018 in a single-centre were included in the present retrospective study.

**Results:** Among these ninety-one patients, 52 (57%) were diagnosed with PR3-ANCA, and 39 (43%) with MPO-ANCA. Patients with PR3-ANCA and MPO-ANCA were received comparable induction therapy. However, the frequency of PLEX was significantly higher in patients with PR3-ANCA versus MPO-ANCA (44% vs. 21% respectively; P = 0.025). Overall renal survival at 1- and 5-year was 91% and 69% respectively with no significant differences between patients with PR3-ANCA and MPO-ANCA. Overall, 1-year and 5-year patient survival were 92% and 77% respectively. The overall survival time was 11.5 years and 95% confidence interval (CI) of 9.9 to 13.0 years. Mean survival time in patients with PR3-ANCA was 10.8; 95% CI 8.8 to 12.7 years versus 11.7; 95% CI 9.6 to 13.8 years in those with PR3-ANCA. Cox regression analysis showed that advancing age significantly predicted higher mortality risk, whereas MPO-ANCA subtype significantly predicted lower mortality risk (Figure 1). Infection (25%), malignancy (22%), and cardiovascular events (16%) were the major causes of death in the present cohort. In a subgroup of thirty-two patients with eGFR <15 ml/min per 1.73 m² or undergoing dialysis at time of diagnosis. Twenty-three patients (72%) were treated with PLEX, whereas 9 patients (28%) did not receive PLEX as a part of remission induction therapy. Treatment with PLEX had no effects on overall 1-year patient and renal survival.

**Conclusion:** In this cohort of patients with AAV with renal involvement the overall 1-year renal and patient survival were high. Advancing age significantly predicted higher mortality risk, while MPO-ANCA subtype significantly predicted lower mortality risk. Treatment with PLEX had no effects on 1-year patient and renal survival in a subgroup of patients with severe renal involvement with AAV.

NEW-ONSET OR EXACERBATIONS OF GLOMERULONEPHRITIS FOLLOWING SARSCOV2 VACCINE: A REVIEW OF THE LITERATURE
Chiara Rimoldi1, Lucia Del Vecchio1, Mariag Giulia Magatti1,2, Marco Allinovi3, Beniamina Gallelli1, Marco D'amico1,2, Giulio Pucci Bella1,2 and Gianvincenzo Melfa1

1Sant'Anna Hospital, ASST Lariana, San Fermo della Battaglia (CO), Italy, 2University of Milano-Bicocca, Department of Medicine and Surgery, Monza, Italy and 3Careggi University Hospital, Florence, Italy

Background and Aims: Following vaccination against SarsCoV2 several cases of new-onset glomerulonephritis or exacerbations of glomerular diseases have been reported [1, 2]. No literature review has been published yet on the subject.

Method: We searched for single case or case series through the PubMed portal search and through the abstract search submitted to the EDTA and the American Society of Nephrology in 2021 and 2022 (last view on the 15th of December 2022).

Results: A total of 138 cases were analyzed, of which 127 complete for all the variables. The mean age was 52.6±20.75 years (min 12, max 99), M/F 67/63. The majority of patients received mRNA vaccine (BNT16b2 Pfizer (n = 70, 51%), mRNA-1273 Moderna (n = 42, 30.7%), followed by AZD1222 AstraZeneca (n = 10, 7.3%) and Ad26.COV2.S Johnson & Johnson (n = 4, 2.9%). A minority of cases were associate with Covaxin and Sinovac (Figure 1).

Most cases were reported from the European continent (39.4%, n = 54), followed by North America (35.8%, n = 49) and Asia (21.9%, n = 30). A minority of cases were reported from Australia and Central/South America. The onset of glomerulonephritis occurred after a mean of 17.8 days±22.82 (min 1, max 89). In 37.4% of cases (n = 49), glomerulonephritis occurred after the first dose, in 61.8% after the second (n = 81), only 1 case after the third one. Regarding mRNA vaccine, in most cases, the disease occurred after the second dose (n = 78, 70.9% of cases, p < 0.001). Gross hematuria as the initial symptom was significantly related to mRNA vaccination (27/27 cases), 30 cases (24.8%) showed nephrotic syndrome at onset. The most prevalent diagnosis was IgA nephropathy (n = 36, 26.3%), followed by vasculitis (n = 33, 24%), Minimal Change Disease (n = 26, 19%), and membranous nephropathy (n = 14, 10.2%) (Figure 2). Interesting, 6 cases (4.4%) of anti-GBM GN were reported. Compared to patients with glomerulonephritis, those with systemic vasculitis were older (59.84±19.43 vs 49.21±21.21 years), with a slightly shorter onset time (14.9±12.67 days, vs 16.6±24.14 days). Both vasculitis and glomerulonephritis generally occurred more frequently following mRNA vaccination. For vasculitis, ANCA-MPO was more frequent (n = 15, 45.45%), followed by ANCA PR3 (n = 10, 30.3%), and finally IgA vasculitis (n = 3, 9%). Two cases (6.06%) were ANCA negative. New-onset glomerulonephritis accounted for 78.8% (n = 108), while relapses accounted for 21.2% (n = 29). There was no significant difference between the type of vaccine and de-novo or relapse glomerulonephritis. Patients were treated with steroid only (43.4%, n = 56), steroid and immunosuppressant (n = 21, 61.3%), rituximab alone or in combination (n = 26, 20.15%), conservative therapy (24, 18.6%). 6 patients (4.4%) underwent dialysis, 2.9% (n = 4) received plasmapheresis. 80 patients (69%) responded effectively to therapy, achieving complete remission, 19% (n = 22) achieved partial remission, while 2.1% (n = 14) did not respond to therapy. Evolution towards ESKD occurred in 11 cases (8%).

Conclusion: New-onset glomerulonephritis or exacerbations of glomerular diseases that were in remission is a possible complication of SarsCov2 vaccination. Most patients received mRNA vaccine; more than half of the patient developed or worsened the GN after the second dose.

Background and Aims: ANCA-Associated vasculitis (AAV) is an autoimmune disease with necrotizing inflammation of small vessels as the main manifestation. AAV is a severe disease with high level of mortality. Severity markers are needed to better tailor treatment. ANCA titers have not always been correlated with disease severity and mortality. Other inflammation markers have also been used such as C3 and C-reactive protein (CRP). The aim of this study is to correlate ANCA titers, C3 and CRP values with mortality in patients with renal vasculitis.

Method: We retrospectively analyzed all adult patients between June 2006 and December 2022 with a renal AAV in the nephrology department of São Bernardo Hospital. Demographic, clinical and laboratory findings of all patients were recorded. ANCA titers at the time of diagnosis (ANCAd), remission (ANCArm), relapse (ANCArl) and last follow-up (ANCAf) dates were registered. C3 levels were measured at diagnosis (dC3) and at the last follow-up (fC3) dates. CRP was measured at diagnosis (CRPd), remission (CRPrm) and last follow-up (CRPf). ANCA titers was analysed as continuous and categorical variables. C3 and CRP were used as continuous variables. We analyse the association between ANCA titers, C3, CPR values and mortality with univariate analysis. Multivariable adjusted cox regression analysis was performed for assessing predictive variables associated with mortality.

Results: We included 58 AAV patients with kidney involvement, with mean age of 69±10 years old, 54.4% were male (n = 31), 82.7% (n = 48) MPO-ANCA+, 12.1% (n = 7) PR3-ANCA+ and 5.2% (n = 3) seronegative. Median follow-up was 32.2 months. 20 (34.5%) patients died. At admission, categorization by ANCA titer revealed 5.2% (3) 0-19 UI/mL, 10.3% (6) 20-39,
and CT scan showed features of small bowel obstruction with transition at stercoralis (Figure 1). Bronchoesophageal lavage was done which revealed biopsy was taken. The duodenal biopsy showed features of strongyloidiasis revealed diffused edema, erythema, and superficial ulceration in duodenum and bilateral raised Eco pattern in kidneys rest were normal. Upper GI endoscopy showed features of strongyloidosis.

HRCT chest revealed bilateral ground glass opacities and a calcified nodule 8mm3, urea-92mg/dL, creatinine-2mg/dL. ECG showed sinus tachycardia, and total leucocyte count-8600, eosinophilia with absolute eosinophil count 1900/μL. The laboratory investigations on admission showed hemoglobin-15 g/dL, platelet 31.2 vs 52.1 ± 29.3 ml/min, respectively; p = 0.78). 17.6% of patients reached the composite endpoint, while 12.3% progressed to ESRD. Those with SARS-CoV-2 infection were more likely to reach the composite endpoint compared to those without infection [prevalence of composite endpoint, 26.7% vs. 14.8%, p = 0.006; OR, 2.1 (95%CI, 1.23-3.58), p = 0.006 (Figure 1). Similarly, there was a significant decline of eGFR in the first year of follow-up between the two study groups [-2.24 (-24.8; 20.9) vs. +2.31 (-16.8; 27.5) ml/min, respectively, p = 0.004]. In multivariate Cox proportional hazards regression analysis, the independent predictors of the composite endpoint were baseline eGFR (HR, 0.94; 95%CI, 0.92-0.96, p < 0.05), age (HR, 1.02-4.29, p = 0.04) (Figure 2). The results remained consistent when restricting the analysis to ESRD as an endpoint. When taking into account the severity of SARS-CoV-2 infection, a severe infection was the most important predictor of the composite endpoint (HR, 2.1; 95%CI, 1.02-4.29, p = 0.04) (Figure 2). The results remained consistent when restricting the analysis to ESRD as an endpoint. When taking into account the severity of SARS-CoV-2 infection, a severe infection was the most important predictor of the composite endpoint (HR, 2.1; 95%CI, 1.02-4.29, p = 0.04) (Figure 2). The results remained consistent when restricting the analysis to ESRD as an endpoint. When taking into account the severity of SARS-CoV-2 infection, a severe infection was the most important predictor of the composite endpoint (HR, 2.1; 95%CI, 1.02-4.29, p = 0.04) (Figure 2). The results remained consistent when restricting the analysis to ESRD as an endpoint. When taking into account the severity of SARS-CoV-2 infection, a severe infection was the most important predictor of the composite endpoint (HR, 2.1; 95%CI, 1.02-4.29, p = 0.04) (Figure 2).
EXPLAINABILITY OF A DEEP LEARNING BASED CLASSIFICATION MODEL FOR ANCA-ASSOCIATED GLOMERULONEPHRITIS

Maria Wester Trejo1, Maryam Sadeghi1, Shivam Singh2, Andreas Kronbichler2, Zdenka Hruskova4, Xavier Puéchal5, Georg Goebel2 and Ingeborg Bajema1

1Netherlands, 2Austria, 3United Kingdom, 4Czech Republic and 5France

Background and Aims: The histopathological classification for ANCA-associated glomerulonephritis (ANCA-GN) is a well-established tool to reflect the variety of patterns and severity of lesions that can occur in renal biopsies of patients with ANCA-associated vasculitis. As with many fields, medicine saw a rapid emergence of Artificial Intelligence (AI) and Deep learning (DL) approaches. In the field of digital pathology AI can now serve as decision-support for pathologists, with the potential for gains in productivity and time-saving. It was demonstrated previously that AI can aid in identifying histopathological classes of renal diseases, e.g. of diabetic nephropathy. Although these models reach high prediction accuracies, their black box structure makes them very non-transparent. The disadvantage is that the networks' decisions are not easily interpretable by humans and it is not clear what information in the input data underlies their decisions. This necessitates the use of Explainable AI (XAI), so that decisions made by AI models become accessible for validation by a human expert.

Method: Renal biopsy slides of 80 patients with ANCA-GN from 3 European centers, who underwent a diagnostic renal biopsy between 1991 and 2011, were included. On the scanned slides glomeruli were labelled as ‘normal’, ‘sclerotic’, ‘crescentic’ or ‘abnormal - other’. We developed a DL-based computational pipeline, which detects and classifies the glomeruli. We investigated the explainability of our model, using XAI techniques to shed light on the decision-making criteria of our trained DL classifier using saliency maps. These maps were analyzed by pathologists to compare the decision-making criteria of humans and the DL model.

Results: Our DL model shows a prediction accuracy of 93% for classifying glomeruli. The saliency maps from our trained DL models help us to better understand the decision-making criteria of the DL black box.

Conclusion: AI and DL play an increasingly important role in (nephro)pathology. To ultimately enable safe implementation of these models in clinical practice, validation of their decisions is needed. To achieve this, we used XAI techniques, which showed great potential for illuminating the decision-making criteria of the DL black box.

THE VALUE OF THE HISTOLOGICAL CLASSIFICATIONS OF ANCA ASSOCIATED VASCULITIS IN PREDICTING LONG TERM KIDNEY SURVIVAL

Matteo Stella1,2, Laura Locatelli2, Filippo Maria Sala3, Marta Calatroni1,2, Francesco Reggiani1,2, Gabriella Luisa Moroni1,2 and Renato Alberto Sinico2

1Humanitas University, Department of Biomedical Science, Pieve Emanuele MI, Italy, 2IRCCS Humanitas Research Hospital, Nephrology and Dialysis Division, Rozzano, Italy and 3OspedalediVimercate, ASSTBrianza, Nephrology and Dialysis Division, Vimercate, MB, Italy

Background and Aims: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are a group of multisystemic autoimmune diseases characterized by necrotizing inflammation of small vessels, with a predilection for the kidney. The prognostic value of histological classification of ANCA-glomerulonephritis (ANCA-GN) is discussed. In 2010, Berden and colleagues proposed a prognostic classification based on glomerular involvement; in 2018, Brix et al. introduced the ANCA Renal Risk Score, which includes histological features and glomerular filtration rate; in 2017 the Mayo Clinic Chronicity Score, that considers chronic histological lesions, was designed and assessed in ANCA-GN. We aimed to identify which score is the best tool to predict end-stage kidney disease or death in a cohort of ANCA-GN patients.

Method: Patients who underwent kidney biopsy in two Italian centers within 32 years were retrospectively collected. Inclusion criteria: age >18 years, and at least one year of follow-up. A minimum of 10 glomeruli was considered adequate for a biopsy. Renal biopsies were classified according to Berden’s classification, Renal Risk Score and Mayo Clinic Chronicity Score. The primary end point of the study was the development of end-stage kidney disease (ESKD) at 5 years, defined as the chronic need of renal replacement therapy (RRT) or glomerular filtration rate (GFR) <15 ml/min. The secondary endpoint was a composite endpoint of ESKD or death for all causes.

Results: Of the 152 patients 84 were male, the median age was 63.8 years (Figure 1). Mean eGFR at diagnosis was 21.32 ml/min/1.73 m². 32.2% of patients were PR-3 positive, 50.6% were MPO positive, 17.2% were ANCA-negative. After a mean follow-up of 71.7 ± 66.7 months, 59 patients (38.8%) were on chronic dialysis or with a GFR <15 ml/min; among them, 20 patients died. The pure kidney survival rate (without ESKD or GFR <15 ml/min) was 79% at 1 year, 65% at 5 years, 59.8% at 10 years. Figure 2 reported the pure kidney survival rates of the patients assigned to every class of the three scores that we considered in this study. Fig. 3, Fig. 4, Fig. 5 show Kaplan-Meyer curves for the secondary outcome (ESKD+death); patients are classified according to the Berden’s score (Fig. 2), the Renal Risk Score (Fig. 3) and Mayo Clinic Chronicity Score (Fig. 4).

Conclusion: Berden histopathological classification and Renal Risk Score are predictive of renal prognosis when we consider the primary outcome (ESKD or GFR <15 ml/min) and when we consider the composite outcome (ESKD + death). The Mayo Clinic Chronicity Score allows a reliable stratification of the patients only when we consider the composite outcome (ESKD and death).

Figure 5:
CLINICAL CHARACTERISTICS OF PATIENTS WITH LUPUS NEPHRITIS CLASS III–V: ANALYSIS OF INTERNATIONAL REAL-WORLD DATA

Seth Anderson¹, Ana Delgado², Xin He³, Zhiliu Tang³, Jack Milligan⁴ and Marguerite Bracher⁵

¹GSK, Global Value Evidence and Outcomes, Philadelphia, PA, United States of America, ²GSK, Global Medical Affairs, Brentford, United Kingdom, ³GSK, Value Evidence and Outcomes, Shanghai, P.R.China, ⁴Adelphi Real World, Rheumatology, Bollington, United Kingdom and ⁵GSK, Value Evidence and Outcomes, Stevenage, United Kingdom

Background and Aims: Lupus nephritis (LN) is a severe renal manifestation of systemic lupus erythematosus (SLE) that negatively impacts morbidity and mortality; however, real-world data for LN is scarce. This study describes: the proportion of patients with SLE managed by rheumatologists (rheum-managed) and by nephrologists (neph-managed) with LN class III–V; the proportion of patients with a Safety of Estrogens in Lupus Erythematosus National Assessment - SLE Disease Activity Index (SELENA-SLEDAI) score ≥ 8 by region; extra-renal organ systems involvement by region; flaring by region; and EQ-5D and EQ-visual analogue scale (VAS) scores by estimated glomerular filtration rate (eGFR).

Method: Data were drawn from the Adelphi Lupus Disease Specific Programme, a cross-sectional, multi-subscriber survey of physicians and their consulting patients conducted April 2021–May 2022 in China, Japan, EU5 (France, Germany, Italy, Spain and the UK) and the USA. Physicians provided demographic and clinical data for 5–6 consecutive adult patients consulting for SLE/LN. LN class III–V was assessed by the physician at data collection. SELENA-SLEDAI scores were derived by physician assessment of patients’ current clinical manifestations. Patients had the opportunity to complete an EQ-5D form. All analyses were descriptive.

Results: Overall, 9% (183/2148) of rheum- and 48% (364/766) of neph-managed patients had LN. Most patients with LN had a SELENA-SLEDAI score ≥ 8 (70% of rheum- and 76% of neph-managed; Table 1), compared with 48% (1032/2148) of rheum-managed patients with SLE alone. The proportion of neph-managed patients with LN with a SELENA-SLEDAI score ≥ 8 varied by region, from 58% in the USA to 87% in China. In total, 62% of rheum- and 43% of neph-managed patients with LN had ever flared (any organ system; Table 1). The proportion of rheum-managed patients with LN who had ever flared ranged from 52% in China + Japan to 75% in EU5. The proportion of patients with LN currently experiencing a flare was similar between rheum- (31%) and neph-managed (35%) patients, but varied by region, with the highest proportion for rheum-managed patients in China (59%) and lowest in the USA (18%). In subgroups with ≥15 patients, EQ-5D and EQ-VAS scores generally worsened as eGFR lowered (Figure 1).

Conclusion: Patients with LN class III–V had high disease burden (SELENA-SLEDAI scores ≥ 8) and flaring that varied by region, suggesting a need for more efficacious treatments for patients with LN.

Table 1: Summary of outcomes among patients with LN by region and management.

CLINICAL UTILITY OF SEROLOGICAL TEST AT TIME OF BIOPSY
Mårten Segelmark1,2, Maria Weiner3 and Björn Peters4
1Lund University, Clinical Sciences, Lund, Sweden, 2Skane University Hospital, Nephrology, Lund, Sweden, 3Linköping University, Health, medicine and caring sciences, Linköping, Sweden and 4Skaraborgs Sjukhus, Njurmedicin, Skövde, Sweden

Background and Aims: It is common practice to order serological tests at time of renal biopsy, but the diagnostic value in different clinical settings is largely unknown. We utilized data from the national Swedish Renal Biopsy Registry to analyze the positive and negative post-test likelihood of four common diagnoses depending on the results of frequently used serological tests.

Method: Data on all biopsies performed during the period 2015-01-01 – 2020-12-31 was retrieved from the Swedish Renal Biopsy Registry. All biopsies are classified into one of the following five biopsy indications: the nephrotic syndrome (nephrosis), acute/subacute nephritic syndrome (nephritis), other acute kidney injury (AKI), chronic kidney disease stage 1-2 (CKD 1-2), and CKD 3-5. Biopsy results are given as SNOMED codes by the pathologist and a clinical diagnosis using the ERA coding system by the nephrologist. Results from the following serological tests were analyzed: C3, C4, ANA, anti-dsDNA, ANCA (PR3 and/or MPO-ANCA) and anti-phospholipid antibodies. Pre-test likelihood, positive post-test (PPL) and negative post-test likelihood (NPL) for the diagnoses IgA nephropathy (IgAN), diabetic nephropathy (DN), ANCA-associated vasculitis (AAV) and lupus nephritis (LN) were analyzed. The diagnostic yield was defined as the ratio between the PPL and NPL.

Results: Out of a total of 3165 individuals that had undergone kidney biopsy, there were 694 (21.9%) patients assigned a diagnosis of IgAN, 378 (11.9%) with DN, 342 (10.8%) with AAV and 117 (3.7%) with LN. The proportion of patients being tested varied from 17% for anti-phospholipid antibodies to 77% for ANCA. The highest diagnostic yield was found for ANCA in AAV where the PPL/NPL ratio was 154. In patients with nephrosis the ratio went up to 290 mainly because of a very low NPL (0.2%). The next best diagnostic yield was seen in SLE were both ANA and anti-dsDNA exhibited a PPL/NPL ratio of 26. The best yield for ANA was found when the biopsy indication was nephrosis where the PPL was 33% and the NPL 0.54% and the ratio 61. For anti-dsDNA the best yield was in AKI with a ratio of 46 (PPL 55%, NPL 1.1%). The best test to make a diagnosis less likely was anti-phospholipid antibodies in diabetic nephropathy. The test was never positive in any of the 42 patients with this diagnosis however the same result slightly increased the likelihood of AAV. A positive result for C3(reduced levels) also reduced the likelihood of DN and the likelihood av diabetic nephropathy, the PPL / NPL ratio was 13. C4 and ANCA being, on the other hand, reduced the likelihood for IgAN with a ratio in the same range.

Conclusion: While the utility of ANCA, ANA and anti-dsDNA is well known, it is less known when a positive test substantially reduced the likelihood of a disease. Here we present data showing that a positive test for C3 decreases the likelihood of DN, while the likelihood is much less affected by C4. The opposite is seen for IgAN.

Figure 1: EQ-5D (A) and EQ-VAS (B) scores by eGFR* among rheum- and neph-managed patients with LN†
* eGFR was inferred by chronic kidney disease stage: stage 1/2 = eGFR ≥ 60 ml/min/1.73 m²; stage 3a/b = eGFR 30–59 ml/min/1.73 m²; stage 4 = eGFR 15–29 ml/min/1.73 m²; stage 5 = eGFR <15 ml/min/1.73 m²; † included only patients with a chronic kidney disease stage.

SYSTEMATIC HISTOLOGICAL SCORING OF TUBULOINTERSTITIAL LESIONS CORRELATE WITH CLINICAL PARAMETERS IN ANCA-ASSOCIATED GLOMERULONEPHRITIS
Björn Tampe
University Medical Center Göttingen, Department of Nephrology and Rheumatology, Göttingen, Germany

Background and Aims: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Small vessels in the kidney include small-sized arteries (interlobular artery, afferent and efferent arteriole), capillaries (glomerular and peritubular capillary) and venules. Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis. Therefore, we here aimed to expand our current knowledge focusing on interstitial vasculitis in ANCA GN by systematic histological scoring of vascular lesions analogous to Banff.

Method: A total number of 49 kidney biopsies with confirmed renal involvement of AAV at the University Medical Center Göttingen were retrospectively included between 2015 till 2020. A renal pathologist evaluated all biopsies and was blinded to clinical data collection and analysis. A detailed methodological section is provided in the Supplementary material and methods section.

Results: Since previous studies established that crescentic ANCA GN associates with severe kidney injury and acute deterioration of kidney function in AAV, we first systematically scored interstitial vasculitis in association with requirement of renal replacement therapy (RRT). Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring RRT was observed for interstitial vasculitis in AAV reflected by peritubular capillaritis (ptc) and arteritis (v, p = 0.0002) and arteritis (v, p = 0.0069), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Since it is known that severe deterioration of kidney function also correlates with crescentic ANCA GN, we next directly compared glomerular and tubulointerstitial lesions. The fraction of normal glomeruli was inversely associated with interstitial fibrosis (ci), total (t) and inflammation in IFTA (i-IFTA), whereas glomerular crescents were associated with interstitial inflammation (i), tubulitis (t) and total inflammation (ti). In contrast, global glomerular sclerosis associated with less interstitial inflammation (i) but correlated with interstitial fibrosis (ci) and tubular atrophy (ct), confirming established mechanisms that chronic glomerular injury leads to tubular atrophy and interstitial fibrosis. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from RRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.

Conclusion: Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV. Furthermore, our findings that interstitial vasculitis did not correlate with crescentic ANCA GN implicate that the characteristics of each vasculitis manifestation are independent and could further improve our understanding of mechanisms contributing to renal injury. These observations suggest that interstitial vasculitis in AAV may also affect long-term prognosis requiring further investigation.

RISK OF CKD IN LUPUS NEPHRITIS: CORRELATION WITH DURATION OF REMISSION AND DEVELOPMENT OF RENAL AND EXTRArenal FLARES
Giulia Frontini1, Silvana Quaglini1, Mariele Gatto1, Michela Gasparotto1, Marta Calatroni4,5, Francesco Reggiani1,5, Mario Gennaro Cozzolino1, Renato Alberto Sinico1, Andrea Doria1 and Gabriella Luisa Moroni1,5
1 ASST Santi Paolo e Carlo, Ospedale San Paolo, Unit of Nephrology and Dialysis, Milano, Italy, 2 University of Pavia, Department of Electrical, Computer and Biomedical Engineering, Pavia, Italy, 3 Padova University Hospital, Unit of Rheumatology, DIMED, Padova, Italy, 4 Humanitas University, Department of Biomedical Sciences, Pieve Emanuele, Italy and 5 IRCCS Humanitas Research Hospital, Nephrology and Dialysis Division, Rozzano, Italy

Background and Aims: Achievement of remission and prevention of SLE flares are important therapy targets in patients with SLE in order to avoid the development of systemic chronic damage. In patients with lupus nephritis, the correlation between the duration of remission, the occurrence of SLE flares and the development of CKD is unclear. The aims of this study are to investigate a) the risk of CKD in patients with lupus nephritis b) the correlation between the risk of CKD and the development of renal and extrarenal SLE flares c)
the correlation between the risk of CKD and the achievement and duration of remission and the probability and predictors of renal and extra-renal remission.

**Method:** This is a retrospective multicentric study of prospectively collected data. Patients were included if they were >18 years old, they had a histological diagnosis of lupus nephritis and they had at least 5 years of follow up after the diagnosis. CKD was defined as eGFR <60 ml/min/1.73m² without active urinary sediment for at least 3 months. Remission was defined as normal renal function (serum creatinine <1.0 mg/dl, eGFR >60 ml/min/1.73m²), proteinuria <0.5 g/24h and cSLEDAI = 0 for at least 1 year. The probability of developing flares and achieving remission was estimated using Cox regression analysis.

**Results:** CKD developed in 57 patients out of the 303 included in the study (18.8%) during a median follow-up of 14.8 years. During the observation 257 patients achieved remission in a median time of 1.4 (0.7-3.6) years, while 46 patients never achieved it. 115 patients maintained remission until the end of follow-up (9.5 (5.8-14.5) years), while 142 developed a flare after a median time of 3.6 (2.3-5.9) years from the beginning of remission. Altogether, in these 142 patients, 174 SLE flares developed during a median follow-up of 17.8 (13.3-24.2) years: 132 renal flares (20 with serum creatinine increase, 112 with proteinuria) and 42 extra-renal flares. CKD developed in 11 patients with creatinine flares (55%), 19 patients with proteinuric flares (16.9%) and 1 patient with extra-renal flares (2.4%) (p<0.0001). The longer was the duration of remission, the lower the probability that remission was interrupted (Figure 1A) by the development of a SLE flare: the risk of flare reduced from 10% when the remission lasted less than 5 years, to 5% if the remission lasted 5-10 years and to 2% if the remission lasted more than 10 years (Figure 1B). CKD developed in 26 out of the 46 patients who never achieved remission (56%), in 31 patients among those who achieved remission but developed SLE flares (21.8%) and in none among those who maintained remission until the end of the observation (p<0.0001). We found that 3 years of persistent remission significantly reduced the risk of CKD development (Figure 2). At multivariate Cox regression analysis, age >40 years (OR: 1.017; 95% CI: 1.005-1.028; p = 0.004), therapy with hydroxychloroquine (OR: 1.384; 95% CI: 1.109-1.661; p = 0.021) and absence of arterial hypertension (OR: 0.699; 95% CI: 0.425-0.975; p = 0.011) were independent predictors of remission.

**Conclusion:** in patients with lupus nephritis, the risk of CKD is significantly higher if renal-extrarenal remission is not achieved or if it is interrupted by SLE flares. In particular, the risk of CKD is very high in patients who develop renal flares with creatinine increase. A longer duration of remission is related to a lower risk of SLE flares and of CKD: in particular, 3 years of remission protect from the development of CKD. Age older than 40 years, therapy with hydroxychloroquine and absence of arterial hypertension are associated with the achievement of remission.

![Figure 1](image1.png) **Figure 1:** A) probability of persistence of remission in relation to the duration of remission. B) risk of SLE flares in relation to the duration of remission.

![Figure 2](image2.png) **Figure 2:** CKD free survival in patients with at least 3 years of remission and in patients without 3 years of remission.
LONG-TERM CLINICAL OUTCOMES OF PATIENTS WITH LUPUS NEPHRITIS TREATED WITH AN INTENSIFIED B-CELL DEPLETION PROTOCOL WITHOUT MAINTENANCE THERAPY

Cecilia Ceruti, Giorgio Amore, Nunziante Caruso, Annalisa Guarino, Roberta Longo, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

Torino, Italy

Background and Aims: The aim of this prospective study is to investigate the long term safety and efficacy of intensified B-cell depletion therapy (IBCDT) in patients with active lupus nephritis (LN), in comparison to a conventional immunosuppressant therapy, followed by a 3 year maintenance micophenolate mofetil (MMF) regimen.

Method: Thirty patients were administered an IBCDT (4 weekly rituximab [RTX] 375 mg/m2 and 2 more doses after 1 and 2 months; 2 infusions of 10 mg/kg cyclophosphamide [CYC], 3 methylprednisolone pulses), followed by oral prednisone (tapered to 5 mg/d by the third month). No immunosuppressant maintenance therapy was given. Thirty patients matched for LN class and age were selected as controls: 20 received 3 methylprednisolone pulses days followed by oral prednisone and micophenolate mofetil (MMF) 2 to 3 g/d, whereas 10 were given the Euro Lupus CYC, MMF (1-2 g/daily) or azathioprine (AZA, 1-2 mg/kg/day) were given for > 3 years as a maintenance therapy.

Results: At 12 months, complete renal remission was observed in 93% of patients on IBCDT, in 62.7% on MMF, and in 75% on CYC (P = 0.001). The dose of oral prednisone was lower in the IBCDT group (mean ± SD 2.9 ± 5.0 mg/d) than MMF (10.5 ± 8.0 mg/d, P = 0.01) or CYC group (7.5 ± 9.0 mg/d, P = 0.01). Mean follow-up after treatment was 45 months (interquartile range [IQR] 36-120 months), 48.6 months (IQR 36-120 months), and 45.3 (IQR 36-120 months) months for IBCDT, MMF, and CYC, respectively. At their last follow-up visit, we observed no significant differences in proteinuria and serum creatinine, nor in the frequency of new flares among the 3 groups.

Conclusion: In biopsy-proven LN, the IBCDT without further immunosuppressive maintenance therapy was shown to be as effective as conventional regimen of MMF or CYC followed by >3-year maintenance either MMF or AZA regimen. Moreover, the use of IBCDT was associated with a marked reduction of glaucoma levels at cumulative dose.

MULTICENTER STUDY TO ASSESS THE FREQUENCY OF ADVERSE EVENTS FROM VACCINATION AGAINST SARS-COV2 IN PATIENTS WITH PAUCI-IMMUNE GLOMERULONEPHRITIS

Angeliki Sardeli1, Evangelia Ntounousi2, Dimitri Galitsiou3, Konstantina Kantartzii4, Pelagia Kriki4, Vassilios Liakopoulos5, Smaragdi Marinaki6, Vasilios Vaios2, Dimitra Petrou1, Roberta Longo, Roberta Fenoglio, Savino Sciascia and Dario Roccatello

1Department of Nephrology, Medical School, Democritus University of Thrace, Alexandroupolis, Greece, 2Department of Nephrology, University Hospital of Ioannina, Ioannina, Greece, 3Department of Nephrology and Renal Transplantation, Medical School, National and Kapodistrian University of Athens, General Hospital of Athens Laiko, Athens, Greece, 4Department of Nephrology, Medical School, Democritus University of Thrace, Alexandroupolis, Greece, 5Division of Nephrology and Hypertension, 1st Department of Internal Medicine, School of Medicine, Aristotle University of Thessaloniki, AHEPA Hospital, Thessaloniki, Greece and 6Department of Nephrology and Renal Transplantation, Medical School, National and Kapodistrian University of Athens, General Hospital of Athens Laiko, Athens, Greece

Background and Aims: The present study aims to investigate the frequency of adverse events of SARS-CoV2 vaccination in patients with pauci-immune glomerulonephritis with a median age of 46±18 years and 71% male were included. 15% of patients were hypertensive and 4% were diabetic. 90% had antihypertensive treatment, and 44% immunosuppressive treatment. In renal biopsy according to Oxford classification: M1: 11.4%, E1:8.8%, S1:22%; T1:10.5%. The basal creatinine was 1.3 ± 0.47 mg/dl (eGFR 16 ± 116 ml/min/1.73m2), and proteinuria (uPCR) 500 mg/g (IQR 30-3220). The patients were followed for a median of 83 months (IQR 0-111 months). Seven patients progressed, defined as a loss of >40% of glomerular filtration rate (GFR), FH and FHR-1 plasma levels were significantly higher in IgAN cases (FH: cases 2400±659 nM vs controls 1980±573 nM, P = 0.002), (FHR-1: cases 97±256 vs controls 379±152 nM, P = 0.011), but the patients had a lowest FH/FHR-1 ratio (FH/FHR-1 cases 5.4±2.58 vs controls 6.3±3.67, p = 0.061). The levels of FH-2 and FHR-4A were also elevated in IgAN cases (FH-2: cases 214±127 vs controls 132±71 nM, P < 0.0001), (FHR-4A: cases 45±22 vs controls 31±14 nM, P < 0.001), while protein levels of FHR-1 and FHR-5 are higher in plasma samples from IgAN patients than in controls. The contribution of other FH proteins to IgAN is so far unknown. The objective of this study is to determine the role of FH and FHR proteins in the renal progression of IgAN, and to establish whether plasma levels of these proteins could at least partially explain the heterogeneity observed in the patients.

Method: Plasma levels of FH, FHR-1, FHR-2, FHR-4A and FHR-5 was carried out in patients diagnosed with IgAN by renal biopsy (n = 45), and compared with a control group (n = 45). Protein levels observed in the IgAN patients were subsequently compared according to renal progression.

Results: Forty-five IgAN patients with a mean age of 46±18 years and 71% male were included. 15% of patients were hypertensive and 4% were diabetic. 90% had antihypertensive treatment, and 44% immunosuppressive treatment. In renal biopsy according to Oxford classification: M1: 11.4%, E1:8.8%, S1:22%; T1:10.5%. The basal creatinine was 1.3 ± 0.47 mg/dl (eGFR 16 ± 116 ml/min/1.73m2), and proteinuria (uPCR) 500 mg/g (IQR 30-3220). The patients were followed for a median of 83 months (IQR 0-111 months). Seven patients progressed, defined as a loss of >40% of glomerular filtration rate (GFR), FH and FHR-1 plasma levels were significantly higher in IgAN cases (FH: cases 2400±659 nM vs controls 1980±573 nM, P = 0.002), (FHR-1: cases 97±256 vs controls 379±152 nM, P = 0.011), but the patients had a lowest FH/FHR-1 ratio (FH/FHR-1 cases 5.4±2.58 vs controls 6.3±3.67, p = 0.061). The levels of FH-2 and FHR-4A were also elevated in IgAN cases (FH-2: cases 214±127 vs controls 132±71 nM, P < 0.0001), (FHR-4A: cases 45±22 vs controls 31±14 nM, P < 0.001), while no differences in FHR-5 levels were found (FHR-5: cases 25.7 ± 17 vs controls 27 ± 15, p = 0.7). When the patients who progressed and those who did not progressed were compared, it was observed that, as previously described, FH-1 levels showed a tendency to be higher in progressing patients (566±333 vs 451±203 nM, p = 0.2), and a lower FH/FHR-1 ratio (4.1±2.4 vs 5.8±2.6, p = 0.1). Moreover, we also observed a similar trend in the other FHR proteins: (FHR-2: 304±106 vs 195±118 nM, p = 0.043); (FHR-4: 53±26 vs 43±21, p = 0.29); (FHR-5: 41±35 vs 23±8.9 nM, p = 0.2).

Conclusion: We observed increased levels of several FH proteins and FHRs/FH ratios in our IgAN cohort. We confirm that FH-1 is implicated in renal progression, and we also show that other proteins of the family (FHR-2, FHR-4, and FHR-5) also contribute, suggesting that dysregulation of the alternative Complement pathway by FHR proteins is involved in IgAN. Genetic studies in the CFH-CFHR region may provide additional evidence to our protein findings.
#6193 MULTICENTER RETROSPECTIVE STUDY EVALUATING THE CLINICAL PICTURE AND OUTCOME OF THE SARS-COV2 INFECTION AMONG PATIENTS WITH GLOMERULAR DISEASES

Background and Aims: This is a retrospective study aiming to describe the clinical picture and outcome of sars-cov2 infection in patients with glomerular diseases (GD) and its impact in the probability of relapse of the primary disease.

Methods: Patients with biopsy-proven GD, who had been infected by sars-cov2 were studied. Patients who ended up in end-stage kidney disease prior to infection were excluded. We recorded demographics, histopathological diagnosis, past medical history, immunosuppressive regimens which were given for the GD, status of GD at the time of infection, clinical picture and outcome of the infection including specific symptoms, requirement for hospitalization, duration of hospitalization and outcome of Covid-19. The probability of relapse following Covid-19 was also estimated in patients who were infected and those who did not.

Results: To date 312 patients have been included in the study, of whom 214 (68.5%) were diagnosed with Covid-19, while the remaining 98 did not. Infected patients were younger compared with those not infected [44 (28-59,75) vs. 53 (38-64) years, p < 0.001]. The mean time from the diagnostic biopsy to Covid-19 was 67,6±(±9,3) months. 82.5% of the infected patients were vaccinated against sars-cov2 and 49.1% were treated with immunosuppressive therapy at vaccination. 28(13%) of the infected patients required admission to hospital, with a mean duration of 8,3±(±5,1) days. 84.2% of the infected patients experienced complete recovery of the infection, 4 (1.5%) due to Covid-19 and 24 (11%) had Covid-19 related symptoms for more than 3 months. Among patients who had achieved remission of the GD prior to the infection, the frequency of relapse of the primary disease was higher in patients with Covid-19 versus not infected patients (11.9% vs. 2.1%, p = 0.007).

Conclusions: According to our findings, the sars-cov2 infection appears to have a significant impact in patients with GD not only due to the increased morbidity but also by increasing the probability for relapse of the primary disease.

#6325 A LONG TERM EXPERIENCE OF MANAGEMENT OF BIOPSY-PROVEN RENAL AL AMYLOIDOSIS WITH DARATUMUMAB MONOTHERAPY
Gianluca Rabajoli, Andrea Careddu, Martina Marchisio, Stefania Lalloni, Marco Morrone, Roberta Fenoglio, Savino Sciascia and Dario Roccatello
Torino, Italy

Background and Aims: Daratumumab is an anti-CD38 monoclonal antibody recently approved as a first-line therapy on top of standard therapy for the treatment of multiple myeloma and AL amyloidosis. The mechanism of action of Daratumumab is based on its ability to bind CD38, a transmembrane receptor expressed in particular by pathogenic plasma cells, inducing their death through multiple intra and extracellular signaling mechanisms and thus interrupting the production of monoclonal light chains and consequently the deposition of new amyloid substance. The following data describe the good results reported by our group and the long-term experience achieved in recent years on the efficacy of daratumumab used in monotherapy.

Methods: This paper describes 17 patients affected by AL amyloidosis who were treated with Daratumumab alone, 24 iv administrations and a dose of 16 mg/kg. All of them had an histological confirmation and staging of renal involvement before treatment was started and were ineligible for ASCT. A bone marrow biopsy excluded overt multiple myeloma and the patient could either be naïve or refractory. Haematological and organ response was evaluated every 4 infusions by checking NTproBNP, dFLC and FLC ratio, serum creatinine, Upt (24h), serum and urine IF; responses were defined by using the International Society for Amyloidosis extended criteria. When feasible, the patient who underwent the whole cycle of therapy underwent a second kidney biopsy at the end of the treatment.

Results: 1 mean age at diagnosis was 73 years. 16 out of 17 patients had proteinuria (in the nephrotic range in 11) that was associated with renal function impairment in 11. Two patients were on dialysis at the time of therapy initiation, the patient completed the treatment: 13 over 17 underwent at least 12 infusions. At this time, the 12 th administrations 11 out of 13 pts (84.6%) had an overall hematological response. 6 pts (46.5%) achieved a complete hematological response, 5 pts had a very good partial response (38%), and 2 were non responders (15.3%). As regard to renal response 5/13 had already achieved an organ response; 6 didn’t meet renal response criteria yet; the 2 patients who were in dialysis at the time of therapy initiation, remained on dialysis. 1 of them had a complete hematological and cardiac responses, the remaining pt didn’t have any response. 7/9 achieved a renal response; the 2 remaining patients who were in dialysis at the time of therapy initiation, remained on dialysis. A significant decrease in 24-hour proteinuria from 6,02 g/24 hours (range 0.8 – 16,8) to 1,28 g/die (range 0.9 – 3,6 g/die, p < 0.005) with stabilization or improvement of sCr (from 1.66 mg/dl to 1.1 mg/dl, p = 0.17) were observed. 8/9 patients with cardiac involvement obtained at least amelioration. At the end of follow-up (mean 30 months, range 19–46) 5 patients have persistent hematological and renal response. One patient with initial partial response had a relapse and initiated a treatment with Bortezomib plus cyclophosphamide and dexamethasone. Two patients died to COVD infection and cardiovascular disease respectively. The last patient is still alive and is currently being treated with a second line of therapy, because no hematologic or organ response was achieved with Daratumumab. 7 patients underwent a second kidney biopsy at the end of the treatment. Histological findings showed stable deposits in 6 over 7 cases, while the last one showed a reduction in the extent and amount of amyloid deposits.

Conclusion: The optimal management of patients with AL amyloidosis remains to be defined. In particular patients who are ineligible for transplant continue to have a poor outcome. In recent years daratumumab has emerged as an appealing therapeutic alternative as shown by several reports. However, in clinical trials daratumumab was always added to bortezomib, cyclophosphamide and dexamethasone. Two patients died to COVD infection and cardiovascular disease respectively. The last patient is still alive and is currently being treated with a second line of therapy, because no hematologic or organ response was achieved with Daratumumab. 7 patients underwent a second kidney biopsy at the end of the treatment. Histological findings showed stable deposits in 6 over 7 cases, while the last one showed a reduction in the extent and amount of amyloid deposits.

#6452 SEVERE INFECTIONS AND IMMUNOSUPPRESSIVE MAINTENANCE THERAPY IN PATIENTS WITH LUPUS NEPHRITIS: DATA FROM A SINGLE CENTER PROSPECTIVE STUDY
Anna Mirela Stroie1, Mireca Penescu1,2 and Balanescu Paul3
1Dr. Carol Davila” Teaching Hospital of Nephrology, Clinical Nephrology II, Bucharest, Romania, 2“Carol Davila” University of Medicine and Pharmacy, Internal Medicine and Nephrology, Bucharest, Romania and 3“Carol Davila” University of Medicine and Pharmacy, Clinical Research Methodology, Bucharest, Romania

Background and Aims: Systemic lupus erythematosus is a multi-organ, multi-systemic autoimmune disease with significant burden on generally young patients. Renal involvement is relatively frequent, recent studies cite a prevalence of 15–60% of patients, and 25% develop end-stage renal disease after 10 years of disease onset. We studied the incidence of severe infections in 67 lupic patients with biopsy proven lupus nephritis treated with immunosuppressive maintenance therapy: mycophenolate mofetil, azathioprine, calcineurin inhibitors associated with corticosteroids. Severe infections are a major cause of death in lupic patients.

Methods: We concluded a single center prospective study to assess the incidence of severe infections in patients with biopsy proven lupus nephritis. Patients received standard induction therapy (Euro lupus, NIH, MMF, CNIs induction regimens) and were assigned to maintenance therapy to either AZA, MMF, CNIs or patients who received both AZA and MMF in the course of the disease (a switch in therapy was made), alongside standard doses of
corticosteroids. We used SPSS version 16 for the statistical analysis and data was extracted from the electronic medical records.

**Results:** We included patients diagnosed with systemic lupus erythematosus who had renal biopsy performed between January 2008 – December 2018. Patients were followed-up until May 2020. We included 67 patients, out of which 58 patients were female (86.5%). Median age at diagnosis of lupus disease was 29 years (min 10 years, max 62 years). Median duration of the disease was 10 years (min 1.5 years, max 30 years). Median duration of corticosteroid treatment was 10.1 years (min 1.58 years, max 29). 1 patient had class I, 2 had class II, 12 had class III, 32 had class IV, 12 had class V, 1 had class VI, 1 had classes III+V, 1 had classes IV+V of lupus nephritis (ISN classification of lupus nephritis). The induction regimens received by the patients were: Eurovalop (21 patients), NIH (23 patients), MMF (14 patients) and CNIs (9 patients). Treatments administered for the maintenance period were MMF (5 patients), AZA (5 patients), CNIs (9 patients), and patients who had a switch in therapy, receiving both MMF and AZA during the study (26 patients) due to financial reasons, pregnancies, adverse effects, patient preference. We registered severe infections in 16 patients – 3 patients had severe viral infections, 9 had bacterial and 4 had both viral and bacterial severe infections. We did not obtain statistical significance (Chi square statistic = 1.568, p = 0.06) for the association of a specific immunosuppressive treatment modality with infection development. In our study, the duration of administration of each immunosuppressive therapy expressed in years was not associated with the number of severe infections (Independent-Samples Mann-Whitney U Test, p<0.05).

**Conclusion:** We could not identify significant differences regarding infection rates in patients treated with MMF or AZA, CNIs, MMF and AZA. We therefore suggest that all patients receiving the immunosuppressive regimens described should be considered at equal risk of severe infections.

**TUBULOINTERSTITIAL NEPHRITIS AND UVETIS (TINU) SYNDROME: A REPORT OF 6 CASES WITH RENAL BIOPSY AND ELECTRON MICROSCOPY EVALUATION.**

Kostas Palamaris, Ioannis Petrikas, Kleio Dermitzaki, Christos Pleros, Nikos Kroustalakis, Maria Destouni, Anastasios Stofas, Christos Palouras, Irene Theochari, Panagiota Sarantis, Eleni Theodoropoulou, Kostas Stylianou and Harikleia Gakiopoulou

1National Kapodistrian University of Athens, Pathology, Athens, Greece, 2University General Hospital of Heraklion, Nephrology, Heraklion, Greece, 3Rhodes General Hospital, Nephrology, Rhodes, Greece, 4National Kapodistrian University of Athens, Department of Biological Chemistry, Athens, Greece and 5Izanio General Hospital, Nephrology, Greece

**Background and Aims:** Tubulointerstitial nephritis with uveitis (TINU) syndrome is a rare, but probably under-diagnosed, immune-mediated clinical entity, characterized by simultaneous renal and ocular manifestations. Diagnosis requires exclusion of all other causes of tubulointerstitial nephritis (TIN). We present six patients with clinical, laboratory and renal biopsy findings consistent with TINU syndrome.

**Method:** Medical records review. All patients underwent renal biopsy. Histochemical (pas, masson, silver, Congo-red) and immunohistochemical stains for immune cell populations (CD3, CD20, CD4, CD8, PGM1, CD138) and for the assessment of β2-microglobulin were conducted. Electron microscopy (EM) was also performed.

**Results:** All our patients experienced ocular and renal manifestations, defined by bilateral uveitis, photosensitivity, and decline of renal function. In all patients, increased serum creatinine was accompanied by non-nephrotic range proteinuria, glucosuria or “full blown” Fanconi syndrome. The rest of the laboratory evaluation was normal apart from the presence of elevated erythrocyte sedimentation rate and urine β2-microglobulin. Follow-up, ranged from 18 months to 10 years. Histological evaluation revealed interstitial inflammatory infiltration consisting of lymphocytes, with a T-cell predominance, along with several macrophages. Inflammation severity varied, with some showing scarce foci of immune cell clusters, while others demonstrated a dense, diffuse interstitial infiltration. Interestingly, in two cases, non-necrotic, ill-defined granulomas were detected. Tubulitis was also encountered in some patients. A divergence was noted regarding chronicity index, with different levels of tubular atrophy, interstitial fibrosis and global glomerulosclerosis among different cases. β2-Microglobulin immunohistochemical evaluation revealed diminution of cytoplasmic staining in tubular epithelial cells compared to control kidneys. A notable finding derived from EM was the presence, in one patient, of scattered granular electron-dense-deposits along tubular basement membranes. First-line treatment included steroids, supplemented in some cases by additional immunosuppressive agents. Three patients experienced partial or complete response. Progressive renal damage was observed in a case with severe chronic lesions and persistence of inflammation-triggering factor (β2-microglobulin).

**Conclusion:** Our cases seem to represent progressive stages within the continuum of disease evolution. Patients with more prominent inflammation might represent a more initial state, while those with more severe chronicity index, probably depict more advanced stages. While the predominance of T-cells predicates a cell-mediated autoimmune mechanism, as the driving force of the disease occurrence, the presence of immune-complexes in more advanced stages might contribute to the involvement of humoral immunity as a late event during disease course.

**SECONDARY MEMBRANOUS NEPHROPATHY WITH IGA DEPOSITS IN A PATIENT WITH PRIMARY CILIARY DYSKINESIA.**

Denise Maria Do Nascimento Costa 1,2, Camila Oliveira 1, Gisele Vajgel 1, Thais Clazone 2 and Lucila Valente 2

1Hospital das Clínicas, EBSERH/Universidade Federal de Pernambuco, Recife, Brazil and 2Faculdade de Medicina do Recife-CCM/Universidade Federal de Pernambuco, Clínica Médica, RECIFE, Brazil

**Background and Aims:** Membranous nephropathy and IgA nephropathy are two types of common glomerulonephritis worldwide. There are reports of the coexistence of these glomerulopathies, mostly with mesangial expansion and IgA deposits. Furthermore, primary ciliary dyskinesia is rarely associated to glomerulopathy. Thus, we report a case of a patient with primary ciliary dyskinesia demonstrating membranous glomerulopathy associated with IgA and IgG deposits exclusively in glomerular basement membrane, without complement deposition.

**Method:** Case report.

**Results:** A 18 years-old man was referred from the nephroepidiatric outpatient clinic with subnephrotic hematuria and proteinuria. His medical history included a clinical diagnosis of primary ciliary dyskinesia due to a history of several respiratory infections since birth, asthma, rhinitis and bronchiectasis and a 15 years-old brother with a similar history. He was diagnosed with idiopathic thrombocytopenic purpura at age of one year-old and received prednison. At 3 years-old he presented with nephrotic syndrome, hematuria and hypertension, and was treated with intravenous methylprednisolone and oral cyclophosphamide for three months. Renal biopsy demonstrated mesangial expansion and thickening of the glomerular basement membrane (GBM), without adequate material for immunofluorescence. Because proteinuria and hematuria persisted, the prednison dose was increased to 2 mg/kg/day and cyclosporine was started. After 5 years on these medications, persisting with proteinuria, a second biopsy was performed and showed 16 glomeruli, three globally sclerosed and the others with diffuse thickening of the GBM, without other alterations, focal interstitial fibrosis and tubular atrophy and diffuse granular deposits of IgA 1+ and IgG 2+ along the GBM. Cyclosporine and prednison were discontinued. At age of 18 years-old, he was admitted to adult glomerulonephritis clinic with significant developmental delay (weight 28.6kg and height 1.29m), no edema and normal arterial blood pressure with RAAS inhibition. Laboratory tests: Hb 8.9 g/dL, serum iron 12 mcg/dL, Creatinine 0.51 mg/dL, albumine 2.3 g/dL. Serologies were negative for syphilis, hepatitis B and C, HIV, ANA and anti-DNA, with normal complement C3, C4 and C1q. Urinalysis revealed proteinuria 1+, hematuria 16.000/mL and proteinuria 1.400 mg/dL. CT scan showed symmetrical bronchiectasis in both lungs, with mucoid endobronchial impingement and diffuse bronchial parietal thickening; and chronic post-thrombotic changes with calcified thrombi in the left renal vein, extending into the inferior vena cava. A third renal biopsy was performed showing 38 of 45 (84%) globally sclerosed glomeruli without mesangial matrix changes or capular adhesions. GBM was thickened with spikes and holes and reactive podocytes. The tubulointerstitial compartment showed moderate atrophy and fibrosis (40-50%). Immunofluorescence microscopy evidenced strong immunoreactivity of IgG 3+/3+, IgA 3+/3+, Kappa 3+/3+ and Lambda 2+/3+, in granular pattern exclusively in GBM, without C3. Electron microscopy showed four sclerosed glomeruli, without deposits. Immunohistochemistry staining for IgG1 2+/3+, and it was negative for PLA2R, NELL-1, THSD7A, Exostosin-1 and 2, IgG 2, IgG3 and IgG4. The patient was maintained with supportive treatment, with RAAS inhibition and SGLT2 inhibitors, without immunosuppression.

**Conclusion:** This case highlights the codominance of IgG1 and IgA deposits along the GBM, without proliferation or mesangial deposition and without complement activation, in a patient with membranous nephropathy and primary ciliary dyskinesia, a condition rarely associated with glomerulopathies. Although rare, such renal biopsy findings reinforce the need for a better understanding of the different mechanisms of membranous nephritis, in
addition to better understanding and management of treatment in this situation.

#2898

UNMET NEEDS AND POOR LONG-TERM RENAL OUTCOMES IN EUROPEAN PATIENTS WITH LUPUS NEPHRITIS

Jonathan Barratt¹, Janice Ma², Konrad Pisarczyk³, Eunmi Park⁴, Kiruthi Palaniswamy⁵ and Richard Leff⁶

¹University of Leicester, Cardiovascular Sciences, United Kingdom, ²Maple Health Group, LLC, New York, United States of America, ³Maple Health Group, LLC, Krakow, Poland and ⁴Keeza Life Sciences, Inc., South San Francisco, United States of America

Background and Aims: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), associated with substantial morbidity and increased risk of end-stage renal disease (ESRD). Despite currently used therapies, a notable proportion of patients may not achieve sustained remission, leading to adverse disease outcomes. This study aims to summarize evidence on the long-term outcomes, burden of comorbidities, and real-world (RW) effectiveness of therapy in European patients with LN.

Method: A targeted literature review was conducted using MEDLINE/Pubmed and Embase to identify studies in patients with LN. Search strategies were developed for each database to identify relevant peer-reviewed articles published in English from March 2012 - March 2022 and conference abstracts from 2019 – March 2022. All records were screened according to pre-specified inclusion/exclusion criteria. Only studies conducted in a European setting were summarized here.

Results: Of 4,216 total records, 55 studies reported long-term outcomes of LN and RW effectiveness of treatment in European adults. Up to 36% of patients with SLE developed LN, and nearly all LN cases occurred within 5 years of SLE diagnosis. Patients with LN often suffered from serious infection (19-35%), cardiovascular disease (CVD) (26%), chronic kidney disease (CKD)/ESRD (6-22%) and were more likely to experience cardio- and cerebrovascular events than patients with SLE only (p < 0.001). Patients with LN had a higher risk of mortality compared to those with SLE only or other lupus manifestations (p < 0.001), and deaths were often due to infections (8-32%), CVD (22-58%), or malignancies (5-27%). CKD/ESRD also contributed to poor survival – patients with ESRD had 3-times higher risk of death compared to those with LN only (p < 0.001). The majority of RW studies evaluated effectiveness of standard of care (SOC) induction and/or maintenance therapy, mostly with mycophenolate mofetil and cyclophosphamide. Treatment response rates varied across the studies likely due to heterogeneity in study design, drug dosing, and patient population; comparative studies did not find significant differences in response rates between the regimens. Overall, 30-86% of patients with LN achieved complete renal response/remission (CRR) within the first year of starting SOC therapy. However, one study reported that only 38% of patients maintained CRR while on SOC over a 5-year period, suggesting inadequate long-term maintenance on existing therapies. Patients who were non-responders (NR) after 1 year had a significantly increased risk of mortality and CKD compared to responders (p < 0.005). Patients achieving CRR had significantly longer survival compared to NR patients (95 vs 55%, p < 0.0001), further highlighting the value of achieving response in terms of long-term renal outcomes. Despite initial response to current therapies, 20-35% of patients experienced a renal relapse/flare while on maintenance therapy, with one study noting significantly increased risk of proteinuric flares with azathioprine compared to other maintenance therapies (p = 0.001). Limited studies focused on patients with severe refractory LN.

Conclusion: European adults with LN have considerable comorbidity burden and poor long-term renal outcomes. Few patients achieve and maintain renal remission with SOC, and a notable proportion of patients experience renal relapse despite initial response to therapy. Given the impact that achieving CRR has on long-term outcomes, there is a need for effective therapies that provide sustained remission, especially for patients with severe/refractory LN.

#5769

MEASURING PROTEINURIA AT 12 MONTHS IN LUPUS NEPHRITIS: A USEFUL TOOL?

Beatriz Gil Braga¹, Ana Cunha², Sofia Sousa², Sofia Ventura², Sofia Correia³, Andreia Campos³ and Josefa Santos³

¹Centro Hospitalar Universitário do Porto, Nephrology, Porto, Portugal and ²Hospital Do Divino Espírito Santo, Ponta Delgada, Portugal

Background and Aims: Lupus nephritis is a well known manifestation of systemic lupus erythematosus (SLE) and it can progress to end stage kidney disease (ESKD) in 10-30% of patients [1]. Several studies have been conducted to find out whether proteinuria detected earlier in the course of lupus nephritis is associated with worse kidney related outcomes, such as progression to chronic kidney disease [2].

Method: We retrospectively reviewed a cohort of 67 patients referred to our center with the diagnosis of lupus nephritis until 2019. We evaluated proteinuria (g/g) in a random urine sample measured 12 months after diagnosis and beginning of treatment of lupus nephritis and divided patients into two groups: those with proteinuria less than or equal to 0.3 g/g – group 1 (n = 11; 35%) and those with proteinuria superior to 0.3 g/g – group 2 (n = 20; 65%) that had measures of our variables of interest. These groups were compared regarding a continuous variable: serum creatinine measured in the first year of follow up, as evaluated in previous studies [3]. We compared the median of serum creatinine values between group 1 and group 2 using Mann-Whitney test, due to the absence of normal distribution of serum creatinine. We also compared the median of serum creatinine in the 7th year to proteinuria measured at 3 and 6 months.

Results: Mean follow up was 13.36 ± 7.8 years and 81.7% (n = 57) were women, with a median age of 33.0 ±12.85 years. A total of 8 patients (11.9%) progressed to ESKD defined by the need for renal replacement therapy or being surviving to renal transplantation. Only 1 patient died due to a nosocomial infection. We had a sample of 31 patients, 26 women and 5 men (p = 0.591) (missing n = 36). Baseline median serum creatinine in group 1 was 0.95 mg/dl and in group 2 was 0.78 mg/dl (p = 0.086). We obtained a median serum creatinine of 0.69 mg/dl (Interquartile range (IQR): 0.61-0.87) in group 1 versus 0.92 mg/dl (IQR: 0.66-1.25) in group 2 (p = 0.04). Medians of serum creatinine in the 7th year regarding proteinuria measured at 3 and 6 months were not significantly different (p = 0.05).

Conclusion: In our cohort, the group with a higher persistent proteinuria (>0.3 g/g), one year after lupus nephritis diagnosis, had a significantly higher serum creatinine (7 years after diagnosis). Although previous studies have shown that reducing proteinuria to less than 0.3–0.8/g.d⁻¹ by 1 year of treatment predicts good long-term kidney outcomes, our particular data suggest that further reducing to less than 0.3 g/g may provide additional benefit in the long run [2], even though, due to our reduced sample, more investigation is required. From the above mentioned, one may consider 12 months proteinuria
as a potential predictor to long-term renal outcomes with lupus nephritis. More studies are necessary to validate this hypothesis.

#6612 ACUTE KIDNEY INJURY ASSOCIATED WITH IMMUNE CHECKPOINT INHIBITOR THERAPY: REPORT OF 4 CASES

Angeliki Sardeli1, Dimitra Petrou1, Petros Kalogeropoulos1, Petros Nikolopoulos1, George Liapis2 and Sophia Lionaki1

1Department of Nephrology, 2nd Propaedeutic Internal Medicine, Medical School, National and Kapodistrian University of Athens, “Attikon” University Hospital, Athens, Greece and 3Department of Pathology, Medical School, National & Kapodistrian University of Athens, Athens, Greece

Background and Aims: Immunotheapy using immune checkpoint inhibitors (ICIs) is the cornerstone of modern cancer therapy. Despite significant clinical benefits, ICIs are associated with remarkable adverse events of autoimmune nature involving various organs. Acute Kidney Injury (AKI) occurs more rarely, mainly with the appearance of acute interstitial nephritis. We present a series of patients with AKI after administration of immunotherapy with ICIs.

Method: Patient 1 with metastatic small cell lung cancer on immunotherapy with atezolizumab presented with purpura on the trunk and lower extremities, AKI, microscopic glomerular hematuria, and proteinuria. Patient 2 with esophageal malignancy on immunotherapy with pembrolizumab and worsening renal function. Patient 3 with endometrial malignancy on immunotherapy with pembrolizumab developed AKI, nephrotic syndrome and microscopic hematuria. Patient 4 with melanoma on immunotherapy with pembrolizumab presented with microscopic hematuria and rash.

Results: A kidney biopsy was performed in all 4 patients unraveling the following: Patient 1: pauci-immune necrotizing glomerulonephritis with fibrinoid necrosis and inflammation in the wall of a vessel. Patient 2: acute interstitial nephritis with intense inflammation. Patient 3: findings consistent with focal segmental glomerulosclerosis (FSGS, NOS), without evidence of immune complex disease. Patient 4: focal segmental glomerulosclerosis, moderate interstitial fibrosis and interstitial nephritis in remission. The patient had already been treated with glucocorticoid. In all 4 patients immunotherapy was temporarily discontinued and they were treated with intravenous pulses of methyl-prednisolone followed by oral glucocorticoids, with significant improvement of kidney function and resolution of all extra renal manifestation i.e skin rash etc. Escalation of immunosuppressive therapy with the addition of another agent was avoided in order not to cause relapse of the malignancy.

Conclusion: AKI is a rare but potentially serious complication of ICIs. Temporal discontinuation of the implicated agent is of major importance while treatment with glucocorticoids may be critical for kidney function. Yet, constant vigilance and sustained collaboration among medical specialists are becoming essential in the increasing use of immunotherapy.

#6663 PRIMARY SJÖGREN SYNDROME WITH BIOPSY PROVEN RENAL INVOLVEMENT: A SINGLE CENTER EXPERIENCE

Adria Tinoco1, Yolanda Arcé2, Ana Domínguez Guasch1, Jonas El Bachouti Khalil2, Beatriz Bardaji1, Carolt Arana Alliaga4, Xoana Barros1, Helena Marco1 and Montserrat Diaz Encarnacion1

1Fundació Puigvert, Nephrology, Barcelona, Spain, 2Fundació Puigvert, Pathology, Barcelona, Spain, 3Fundació Puigvert, Barcelona, Spain and 4Hospital Clinic, Nephrology, Spain

Background and Aims: Primary Sjögren’s syndrome (pSS) is a chronic systemic autoimmune disease characterized by inflammation and destruction of the exocrine glands and the involvement of multiple organs. A wide variety of kidney manifestations associated with pSS have been described. The prevalence of kidney involvement is not clear. Our aim was to describe the renal involvement of patients with pSS diagnosed by kidney biopsy (KB). We also analyzed the clinical manifestations, laboratory and immunological characteristics, clinical outcomes, treatments received in patients with pSS referred to a specialized kidney centre.

Method: Observational, retrospective study of adult patients (age > 18 years) diagnosed with pSS (EULAR criteria) referred and treated at a kidney referral centre (Fundació Puigvert) in Barcelona, Spain. We collected data from the clinical records registry including demographic variables, laboratory parameters, biopsy results and adverse outcomes, defined by the need of renal replacement therapy (RRT) and/or death. Absolute frequencies, percentages, means and standard deviations were used for statistical analysis. Multivariate analysis was performed as appropriate in SPSS V28.0

Results: A total of 27 patients with pSS underwent KB from January 1994 to July 2022; all patients were female, with a median age of 58.4 years (SD ± 12.4); 85% were Caucasian. The mean baseline glomerular filtration rate (eGFR) was 65.9 mL/min (SD ± 16) (before nephrologist referral), with 8 of 27 patients (29.6%) having eGFR less than 60 mL/min at baseline. The main indication for nephrological evaluation was acute kidney injury (AKI) (63%), followed by the presence of non-nephrotic proteinuria with dysmorphic haematuria (29.6%). The most common finding in KB was acute interstitial nephritis (AIN) (55.6%), as an isolated AIN kidney lesion in twelve patients (44.4%). Mild interstitial nephritis was noted in the context of a predominant glomerular lesion in three other patients (one membranoproliferative glomerulonephritis, one IgA nephropathy and one AA amyloidosis). Nine patients (33.3%) had glomerular lesion (see Table 1). In 18.5% of patients, the diagnosis of pSS was made after the renal biopsy. The percentage of patients receiving ACEI/ARB was 77.8%. A total of 25 patients received some type of immunosuppression (IS). Corticosteroids being the most frequently used (77.8%), followed by the combination IS treatment (44%) and rituximab (33.3%). At the time of the KB, the mean eGFR was 46.3 mL/min (SD ± 24), compared to eGFR of 45.2 mL/min (SD ± 22) one-year after KB. During follow-up, seven patients (25.9%) required RRT and three (11.1%) died from non-renal causes, mainly by infections associated with immunosuppression. Factors associated with adverse renal outcomes were AKI (p = 0.01), baseline eGFR CKD-EPI less than 60 mL/min (p = 0.005), presence of anti-Ro60 antibodies (p = 0.046), use of plasmapheresis (p = 0.013), use of cyclophosphamide (p = 0.013) and the presence of tubulointerstitial atrophy with glomerular sclerosis on kidney biopsy (p = 0.010).

Conclusion: Our study included a larger cohort than previously reported before in a single centre. In our cohort of patients with pSS who were evaluated by KB, AIN was the leading cause of renal involvement, as has been seen in other studies. The presence of eGFR below 60 mL/min at baseline and the finding of chronicity in the KB are associated with an adverse outcome, as well as is the presence of AKI. Early referral to nephrologist may be important for prognosis, and KB is necessary for accurate diagnosis of kidney involvement to allow targeted treatment.
#6809
PULSE VERSUS DAILY ORAL CYCLOPHOSPHAMIDE IN ANCA-ASSOCIATED VASCULITIS WITH RENAL INVOLVEMENT: A SINGLE CENTER EXPERIENCE
Joana Pereira Dias, Maria Victoria Vaz Da Rocha Paes de Faria, Catarina Almeida, Daniela Alferes, Rute Carmo, Maria Clara Santos and Clara Almeida
Vila Nova de Gaia Hospital Center, Nephrology, Portugal

Background and Aims: We aimed to compare the risk of death, relapse and infections requiring hospital admission of ANCA-associated vasculitis (AAV) patients according to the induction of remission scheme used: daily oral (PO) cyclophosphamide or pulse intravenous (IV) cyclophosphamide.

Method: We identified all newly diagnosed AAV patients treated with PO or IV cyclophosphamide between January 1998 and December 2022 admitted to the CHVNGe Nephrology Department. Data were analyzed with SPSS v28© using parametric and non-parametric tests and Kaplan Meyer survival analysis.

Results: We identified 74 cases of de novo vasculitis, 50 of them received PO cyclophosphamide and 24 received IV cyclophosphamide. Median age at presentation was 68,30 ± 16,06 years PO and 68,00 ± 10,41 years IV. Median duration of follow-up was 3,8 years ± 2,98 for both groups, 6,21 years PO and 3,88 years IV. One-year survival was 84% in PO and 91,3% in IV patients; 15 (30%) PO and 5 (20,8%) IV patients had at least one relapse. Neoplasms occurred in 3 (6%) patients in the PO group and 1 (4,2%) patient in the IV group. The number of patients admitted with one or more infections was 22 (44%) in the PO group and 9 (37,5%) in the IV group. Renal survival was 26 (52%) PO and 15 (62,5%) IV. There was no difference in survival (p = 0,176), renal survival (p = 0,113), risk of relapse (p = 0,283) and infection (p = 0,196) between the two groups.

Conclusion: There was no difference in renal or overall survival, confirming the previous published data. Contrasting with CYCLOPS, our analysis does not confirm an increased risk of relapse in the IV group. One particularly interesting data is that the number of infections in IV route was lower than PO, corroborating the data on lower cumulative doses and therefore lower risk of infection in previous studies. Potential bias of this study is the small sample of patients enrolled in the two groups and the duration of follow up. Despite the reduction in the cumulative dose of cyclophosphamide, we continue to have significant adverse effects, which can also be explained by the dose of corticosteroid previously used, therefore strategies to reduce the toxicity associated with treatment without compromising efficacy are important goals for future research. Treatments need to be optimized and customized according to the severity of the patient's disease and the risk of recurrence.

#3741
A CASE OF PODOCYTIC INFOLDING GLOMERULOPATHY WITH DIABETES MELLITUS, NEPHROTIC RANGE PROTEINURIA AND POSITIVE ANTI-PLA2R IN SERUM
Paraskevi Eva Andronikidi1, Kostas Palamaris2, Virginia Athanasiadou1, Styliani Flavoukou1, Dimitrios Panokostas2, Harikleia Gakiopoulou2 and Eirini Grapsa2
1Aretaieion University Hospital, Nephrology Department, Athina, Greece, 2National and Kapodistrian University of Athens, First Department of Pathology, Medical School, Athens, Greece and 3Aretaieion University Hospital, Nephrology Department, Athens, Greece

Background and Aims: Podocytic infolding glomerulopathy (PIG) is a rare glomerular abnormality which was first proposed as a new disease entity in 2008. It is characterized by glomerular basement membrane (GBM) bubbling viewable by light microscopy, due to extensive trapping of podocytic cytoplasm fragments and cell membrane projections within the GBM. Electron microscopy reveals podocyte infolding and invagination into the glomerular basement membranes (GBMs). Most of the cases reported worldwide, indicate that PIG usually co-exists with autoimmune diseases. In this case we present a diabetic patient with no other autoimmune disease in his medical history, whose biopsy was characterized as PIG.

Method: A 60-year-old Caucasian man with a 5-year history of type II diabetes mellitus, hyperlipidemia, hypertension, hyperuricemia and benign colon polyps, was noted by his family physician to have proteinuria. He had been treated with an angiotensin II receptor blocker, statin, and allopurinol for 5 years and he was well regulated. At the point of admission, his 24-h urine collection showed 4,5gr of urine protein. His creatinine at the time was normal (0,89mg/dl), no hypoalbuminemia, no edema or deregulation of hyperlipidemia was noted. His fundoscopy at this point had no diabetic lesions. In the immunological work up, we found normal values of autoantibodies ANA, anti-dsDNA, anti-ENA, complement screening C3, C4, serum and urine protein electrophoresis - immunofixation. Everything was within normal limits except from serum autoantibodies to PhospholipaseA2 Receptor of podocytes which was tested with ELISA and valued 35 RU/mL (<20RU/mL).

In the following 9 months his proteinuria remained at the same levels. Due to the persistent nephrotic range proteinuria (>3.5gr/24h) a kidney biopsy was performed. Biopsy was evaluated under light microscope (histochemistry for Congo-Red and immunohistochemistry for C4d, PLA2R and DNAJB9 included), immunofluorescence and electron microscope.

Results: The renal biopsy included 8 glomeruli, 3 of them globally sclerosed (37.5%), the rest enlarged with mild to moderate mesangial matrix increase and thickening of the GBMs, without spikes, pin holes or reduplications. Immunohistochemistry for C4d, PLAR2 and DNAJB9 was negative. Immunofluorescence revealed nothing noticeable (no staining of IgG, IgA, IgM, C3, C1q, C4, κ-λ chains) apart from a moderate linear albumin staining. Without electron microscopy the whole picture was rather reminiscent of mild to moderate lesions of diabetic nephropathy.

On electron microscopy, no classical electron-dense deposits were found. Effacement of podocytes' foot processes was multi-segmental. More importantly, podocytic cytoplasmic processes invaginating into the GBMs were observed, accompanied by scattered endomembranous, partially microspherulif microstructures, sometimes with adjacent unclear small pyknotic areas. The biopsy report concluded that although light microscopy and immunofluorescence findings could indicate diabetic nephropathy, the electron microscopy lesions suggest the diagnosis of PIG.

Conclusion: To our knowledge, this is the first reported case with PIG and anti-PLA2R antibodies detected in the serum, without clear histological evidence of membranous nephropathy. Our patient was diabetic for five years with no diabetic lesions in fundoscopy. Although PIG has been reported mainly in the context of autoimmune diseases, the coexistence with diabetes or its possible role in PIG’s pathogenesis has not been addressed. The treatment of this peculiar morphologically disease, still remains an open query for physicians.
Efficacy and Safety of Monthly-steroid Pulse Therapy and Tonsillectomy in Patients with IgA Nephropathy

Takayuki Fujii, Noriko Terasaki, Takahiro Matsunaga, Junya Koshizaka, Mayu Morimoto, Nobuki Yamauchi, Hiroaki Tanaka and Satoshi Suzuki

Seirei Sakura Citizen Hospital, Kidney center, Sakura City, Japan

Background and Aims: In Japan, tonsillectomy and corticosteroid therapy is widely performed in patients with IgA nephropathy, to improve kidney outcomes and reduce proteinuria and hematuria. Over the last decade, tonsillectomy and corticosteroid therapy monthly for 3 consecutive months and tonsillectomy without post-treatment. Thereafter, the effects and adverse events were evaluated.

Method: Forty-two patients diagnosed with IgA nephropathy on biopsy at our hospital, with ≥0.3g/day of proteinuria, and who had undergone tonsillectomy and steroid pulse therapy were included in the study. Of these patients, 16 were treated with three months of consecutive steroid pulse therapy without follow-up steroid administration (MSP); the remaining patients were administrated the conventional steroid pulse therapy (SP), including modified Pozzi’s (Lancet 1999) and Hotta’s (AJKD 2001) regimens. We evaluated and compared the time to proteinuria remission and both hematuria and proteinuria remission between the two groups using Kaplan-Meier curve and log-rank test. Remission of proteinuria was defined as three consecutive results of <0.3g/day over 6 months, and that of hematuria was defined as three consecutive results of <5 RBCs/high-power field in the urinary sediment. In addition to efficacy, we compared the incidence rates of adverse events between the two groups.

Results: There were no significant differences in the age, sex, time to diagnosis, histopathological findings according to the Oxford classification, or RAS inhibitor use between the MSP and SP groups. The eGFR(ml/min/1.73m^2) was 81.3 and 78.5, and the urinary protein excretion (g/day) was 1.18, in the MSP and SP groups, respectively. The proteinuria remission rates in the MSP and SP groups were 81% and 69% after one year and 94% and 81% after two years, respectively, with no significant difference. The remission rates of both hematuria and proteinuria were 47% and 46% after one year and 77% and 58% after two years, respectively, with no significant differences. The incident rates of adverse events, including diabetes and infections, was 13% and 54% in the MSP and SP groups, respectively, and was significantly lower in the MSP group (p = 0.005).

Conclusion: Tonsillectomy with monthly steroid pulse therapy was effective and safer than the conventional steroid pulse therapy in patients with IgA nephropathy.

CORONARY ARTERY CALCIFICATION IN AN SLE PATIENT WITH RENAL: IS IT PATIENT OR DISEASE RELATED?
Noureldabah Mohamed1,2, Ayman Refaie1,2, Kareem Zayed1 and Mohamed Sobh3
1 Mansoura, urology and nephrology center, Mansoura, Egypt and 2 Mansoura, nephrology department, Mansoura, Egypt

Background and Aims: Cardiovascular disease is one of the leading causes of death in SLE patients (Fors Nieves CE, et al. 2016). Coronary artery calcium scores can be used as a predictor CVD events, independent of traditional risk factors. CAC scores quantify the presence and extent of calcified plaque in the coronary arteries. A CAC>0 in the general population is an independent predictor of CVD mortality (Platekani AN, et al. 2015) patients with SLE, especially those aged >45 years, have an increased prevalence of CAC and the presence of renal affection obviously increases this risk. Patients with SLE aged ≤45 years have an increased prevalence of detectable CAC compared with the general population (Yevgeniya Garshkeyn, et al. 2019). We evaluated CAC in SLE with predominantly renal affection.

Method: In this observational study we identified 86 patients with SLE and documented lupus nephritis by renal biopsy ISN/RPS classification 2004, without known coronary artery disease and who had a non-contrast chest CT performed as part of their clinical care, with images retrievable for calculation of CAC scores. Demographics, disease characteristics and comorbidities were ascertained and adjusted for.

Results: 15.1% of patients with SLE, LN (mean age 43±41 years, 84%female,) had CAC>0, 53.8% for age ≤45 years and 46.2% for age >45. Patients with SLE with CAC>0 were older and had longer disease duration and higher disease activity than patients with normal CAC (p.value 0.004, 0.004 and 0.02 respectively). Furthermore, DM was at higher incidence in normal CAC patient and all patients with CAC>0 were hypertensive.

Conclusion: Patients with SLE and LN have an increased prevalence of detectable CAC. Our data suggest that subclinical atherosclerosis in SLE may develop early and it is directly related to disease factors as its duration and pathological activity. Although, patient age is an important risk factor for developing coronary artery calcification. This need a close monitoring and even some cardioprotective interventions.

ZETOMIPZOMIB DEMONSTRATES CLINICALLY MEANINGFUL IMPROVEMENT IN UPCR IN NPHROTIC RANGE PROTEINURIA PATIENTS: RESULTS FROM THE OPEN-LABEL MISSION STUDY
Samir Parikh1, Amit Saxena2, Richard Leff3, Steven Hua4, Eunmi Park3 and Noreen Henig5
1 The Ohio State University Wexner Medical Center, United States of America, 2 NYU School of Medicine, United States of America and 3 Kezar Life Sciences, United States of America

Background and Aims: Prospective cohorts have shown that patients with LN and nephrotic range proteinuria at baseline have a lower probability of achieving renal response [1]. These patients may require more time due to slower proteinuria recovery. Results previously reported on the Phase 2, open-label MISSION study evaluating the safety and tolerability of zetomipzomib in active proliferative LN including patients with nephrotic range proteinuria, demonstrated clinically meaningful renal responses [2]. A post-hoc analysis of MISSION patients with nephrotic range proteinuria is presented here.

Method: In the MISSION Phase 2 study, patients with active proliferative LN (Class III or IV ± V) with 24-hour urine protein to creatinine ratios (UPCR) ≥1.0 mg/mg despite stable background therapy received 60 mg of zetomipzomib subcutaneously once weekly (first dose: 30 mg) in addition to stable background therapy for 24 weeks. End of treatment (EOT) was at Week (W) 25, and end of study (EOS) occurred at W37. The primary endpoint was the number of patients with ≥50% reduction in UPCR from baseline after 24 weeks of treatment. Nephrotic range proteinuria was defined as UPCR ≥3.0 mg/mg at baseline (as per KDIGO 2012 Clinical Practice Guideline for the Management of Glomerular Diseases).

Results: Of 17 evaluable patients who reached EOT, 4 patients had nephrotic range proteinuria, with 3 having hypoalbuminemia (serum albumin ≤3.5 g/dL) at baseline. Patients with nephrotic range proteinuria had mean LN duration of 4.14 years with mean 24-hour UPCR of 5.78 mg/mg, mean serum albumin of 3.0 g/dL, mean blood pressure of 124/81 mmHg and mean eGFR of 122.5 mL/min/1.73 m2. All 4 patients were on concomitant corticosteroids (mean dose: 19.81 mg/d), mycophenolate mofetil, hydroxychloroquine and antihypertensives. After 24 weeks of zetomipzomib treatment, 3/4 patients with nephrotic range proteinuria achieved ≥50% reduction in UPCR at W25 (EOT) and W37 (EOS, 12 weeks post-treatment) (Table 1). Serum albumin levels also improved and normalized by EOS in all 3 patients with hypoalbuminemia at baseline (Table 1). eGFR levels generally remained stable throughout the study. Reduction of daily steroid dose to 10 mg/day was observed in all 4 patients as early as W13 and at EOT/EOS while other background therapy doses

Spearman rank correlation was performed.

**Correlation significant at 0.01 level (two-tailed).
related to the diagnosis and management of glomerulonephritis (PG)

**Method:** In this post-hoc subgroup analysis of MISSION Phase 2 study, zetomipzomib treatment demonstrated clinically meaningful improvement in UPCR and normalization of albumin levels in patients with nephrotic range proteinuria and hypoalbuminemia. These results further support the potential activity of zetomipzomib in hard-to-treat LN patients.

**GLOMERULONEPHRITIS DIAGNOSIS AND MANAGEMENT: IMPROVING KNOWLEDGE AND COMPETENCE AMONGST NEPHROLOGISTS THROUGH ONLINE CME CASE CHALLENGES**

Sukhbir Bahra¹, Adriana Stan¹, Peter Schoonheim ¹, Rita Moreira Da Silva¹ and David Kavanagh²

¹Medscape, Den Haag, Netherlands and ²Newcastle upon Tyne Hospitals, Newcastle upon Tyne, United Kingdom

**Background and Aims:** Continuing medical education (CME) aims at modeling best practice in promoting positive behavior. We hypothesized that participation in the case-based medical education "Challenging Cases of Glomerulonephritis: How Would You Diagnose and Manage These Patients?" would lead to improved knowledge and competence of nephrologists in the diagnosis and management of glomerulonephritis.

**Method:** The online CME activity consisted of 2 patient case scenarios, and it was delivered as an interactive, text-based format. Using a "test and teach" methodology to elicit cognitive dissonance, clinicians completed multiple-choice questions to test their application of evidence-based recommendations. Each response was followed by detailed, referenced, feedback to improve learners’ knowledge, competence, and confidence on the diagnosis and management of glomerulonephritis. The educational effect was assessed using a repeated-pairs design with pre-/post-assessment, where 3 multiple choice questions assessed knowledge/competence and 1 question assessed confidence. Significance was assessed using paired samples t-test for overall average number of correct responses and for confidence rating, and the McNemar’s test for individual questions (5% significance level, P < 0.05). Cohen’s d estimated the effect size impact on number of correct responses (r<.20 modest, .20-.49 small,.50-.79 moderate, ≥.80 large). Data were collected between July 15 2022 and September 27 2022.

**Results:** Comparison of responses to questions before and after education demonstrated a large educational effect for nephrologists (n = 119; d = 1.36; P < .001). Overall 84% nephrologists improved their knowledge/competence related to the diagnosis and management of glomerulonephritis (P < .001), showing a 76% relative increase in correct responses from pre- to post-CME (51% pre, 90% post). Significant increases in knowledge/competence on rare complement-mediated kidney diseases were reported (P < .001 for all comparison) for:

- Clinical manifestations (64% pre; 97% post)
- Diagnosis (18% pre; 84% post)
- Management (71% pre; 90% post)

**Conclusion:** Around 55% of nephrologists showed a measurable confidence increase (P <.001) in their ability to recognize clinical information suggestive of rare complement-mediated kidney diseases.

### #4709

**PERSONALISED INDUCTION THERAPY IN ANCA GLOMERULONEPHRITIS**

Laura Hamburger¹, Wing Yin Leung¹, Ian Bruce² and Silke Brix³
¹Manchester Royal Infirmary, Manchester, United Kingdom and ²The University of Manchester, Manchester, United Kingdom

**Background and Aims:** Patient and kidney outcome in ANCA glomerulonephritis (GN) remains unsatisfactory. Rituximab use failed to reduce the rate of infectious complications and demonstrates a significant rate of hypogammaglobulinaemia in ANCA vasculitis. Adjusting the rituximab dosage to the individual patient’s need promises a reduction in treatment toxicity.

**Method:** Retrospective analysis of a single centre cohort of ANCA GN patients with disease flares between 2019 – 2022 using a stratified induction immunosuppression with rituximab and cyclophosphamide. Treatment intensity was adjusted to reduce the rate of systemic inflammation and microscopic haematuria, peripheral CD19 cell count depletion and immunoglobulin G (IgG) levels.

**Results:** 45 patients (median age 57 years, 55.7% female, median eGFR 27 mls/min) were treated with a median dose of 1.5 grams Rituximab during induction (interquartile range, IQR 1 – 2 grams). 18 patients received concomitant intravenous cyclophosphamide pulses to control the acute inflammation (median cumulative dose of 2 grams, IQR 1.65 – 3 grams). Peripheral B cell depletion was 91.4% at 3 months and 90.3% at 6 months (<3 CD19 cells/ul). During the initial 12 months treatment, IgG level fell below 7g/l in 20 patients, below 5g/l in nine patients and below 3g/l in one patient. Seven patients required renal replacement therapy at diagnosis (15.6%). Five patients recovered kidney function and three patients developed end stage kidney disease (6.7%). Twelve infections were reported requiring antibiotic treatment (26.7%), seven severe infections were documented requiring hospitalisation (13.3%) and one patient died (2.2%).

**Conclusion:** An early assessment of treatment response assists adjusting vasculitis therapy. Adjusting management to the patient’s individual immunological and treatment response may result in better outcome with less treatment toxicity.

**GLUCOCORTICOID-RELATED ADVERSE EFFECTS IN THE TREATMENT OF ANCA-ASSOCIATED VASCUITIS**

David Plappert, Markus Ketteler, Moritz Schanz and Nico Schmid
RBK Stuttgart, Department of General Internal Medicine and Nephrology, Stuttgart, Germany

**Background and Aims:** Upcoming glucocorticoid (GC)-sparing treatment strategies like avacopan could potentially diminish or replace the need of GC therapy for ANCA-associated-vasculitis (AAV) in the future. Therefore, a proper assessment of GC-related morbidity in AAV is required to provide further justification of such therapies. The aim of this study was therefore to assess the incidence of common toxicities and to further investigate the effect of GC-treatment on the incidence and management of diabetes mellitus, arterial hypertension and hypercholesterolemia.

**Method:** In this single-centre-cohort-study we screened medical records for patients with a diagnosis of AAV admitted to the Robert-Bosch-hospital (RBK) in Stuttgart, Germany on a regular basis. We assessed the dosage and duration of immunosuppressive therapy used to treat AAV, as well as the incidence and therapies of arterial hypertension, diabetes mellitus and hypercholesterolemia.
For this study, we observed the vasculitis time course during the acute phase (180 days) after either the initial diagnosis or relapse for each patient.

Results: We included 74 patients admitted to the RBK since 2004 up to the current date. Most common subtype of AAV was GPA (n = 48 patients), followed by MPA (n = 22) and EGPA (n = 4). Including relapses, a total of 127 events were observed. We followed patients for a mean time of 8 years (SD 3.9, 0.9 - 18.0 years). Mean duration of glucocorticoid therapy in total was 4.2 years (SD 3.6, 0.3-14.7 years). All of the patients received prednisolone, whereas 73% of the patients furthermore were administered methylprednisolone for induction therapy. Overall, 34% of the patients were diabetes mellitus (20% pre-existing diabetes, 20% new-onset diabetes). Daily and accumulated GC-dose did not differ between patients with or without diabetes. However, there was a significant higher accumulated GC dose in patients requiring insulin-therapy for diabetes management in comparison to those with oral anti-diabetics (p-value = 0.0214). 89% of the patients were treated with antihypertensive therapy (38% pre-existing hypertension, 51% new-onset hypertension). We found that the accumulated dose of prednisolone within the first 180 days after a vasculitis event was not significantly higher for patients with documented hypertension. However, we detected that the mean accumulated GC dose after a vasculitis event was significantly higher for the subgroup of patients in whom an escalation of antihypertensive therapy was initiated in comparison to the patients whose therapy was stable or even deescalated (p-value = 0.0001). With regard to hypercholesterolaemia, there was no statistical difference in the accumulated GC-dose during the acute course between patients requiring statin-therapy and those who did not.

Conclusion: GC related toxicities are common in patients with AAV. This study provides additional evidence about the incidence of treatment related harms in AAV to further promote importance of alternative reduced dose or GC free treatment approaches. This may be relevant in detecting risk groups for whom upcoming GC-sparing treatment strategies such as avacopan are essential to reduce treatment-related harm.

#5076 MONOCLONAL GAMMOPATHY IN C3 GLOMERULOPATHY: DOES THE BUCKET STOP THERE? Pedro Fragoso1, Luis Rodrigues1,2, Andreia Borges1, Ana Belmira1 and Rui Alves1,2

1Coimbra Hospital and University Centre, Nephrology Department, Coimbra, Portugal and 2Faculty of Medicine, University of Coimbra, University Clinic of Nephrology, Coimbra, Portugal

Background and Aims: C3 glomerulopathy (C3G) is a rare diagnosis, characterized by dysregulation of the alternative pathway of complement, classically presenting in children and young adults. Recently, it has been reported the association between the production of a monoclonal protein and the development of C3G, affecting a larger age span.

Method: We report the case of a 53-year-old male patient, that attended the emergency department due to persistent holocranial headache. He was an IV drug abuser with a history of treated Hepatitis C infection and free lancing with a chain monomolecular protein, identified by the Laboratory Department. On admission, he was hypertensive (187/98 mmHg), and labs showed an acute on chronic kidney disease (serum creatinine 2.35 mg/dl from a basal of 1.5 mg/dl) with an active urinary sediment (38 erythrocytes/field, with dysmorphia), a urinary protein/creatinine ratio of 626 mg/g, and C3 consumption (0.52 g/L). The patient was admitted, and a kidney biopsy was performed.

Results: Further lab results confirmed a serum IgG Lambda monomolecular protein. Autoantibodies screening (ANCA, ANAs, Anti-GBM), ASLO and Rheumatoid Factor were negative. Cryoglobulonemia was detected, and the cryoprecipitate’s immunofixation revealed monoclonal proteins IgG Lambda. HCV viral load was negative. Bone marrow biopsy revealed a small per cent (< 3%) of plasma cells with Lambda light chain restriction. Kidney biopsy’s light microscopy showed increased mesangial matrix and cells, endocapillary hypercellularity, and some glomeruli with lobulated appearance. Five out of 15 glomeruli presented fibrocellular crescents. Immunofluorescence showed C3 dominant staining on capillary walls and in the mesangium, with absent IgG and light chain deposits. A presumptive diagnosis of C3 glomerulopathy was made and the patient was empirically started on corticosteroids (3 pulses of intravenous methylprednisolone, followed by oral prednisolone 1mg/Kg/day), which was followed by paraproein-directed chemotherapy with bortezomib, cyclophosphamide and dexamethasone (VCD). The patient is currently on the third VCD cycle, presenting both renal and haematological responses: recovery of serum creatinine to basal levels (1.54 mg/dl), resolution of haematuria and proteinuria, normalisation of C3 levels. Serum immunofixation is currently negative for monomolecular protein, with normal serum immunoglobulin levels. Electron microscopy revealed electron-dense deposits in the mesangium, and mesangium-capillary transition, supporting the diagnosis of C3 glomerulonephritis. Genetic testing of complement-related genes revealed a rare missense variation of unknown significance (c.4855A>C) on the C3 gene, that has previously been reported in association with C3 glomerulopathy and atypical Haemolytic-Uremic syndrome.

Conclusion: This case represents a monoclonal gammopathy associated- C3 glomerulonephritis with a favourable response to paraprotein-directed chemotherapy. Although the association between monoclonal gammopathy and C3G rests on epidemiologic findings, experimental evidence suggests that several monoclonal proteins have complement dysregulation features, which may enhance alternate complement pathway activation.

Our patient’s response is in line with observational data that have shown improved renal outcomes in patients who achieve a haematological response following monoclonal protein-directed chemotherapy, which further supports the role of monoclonal gammopathy in C3G pathogenesis [1].

Interestingly, the genetic variation identified in our patient might have provided a favourable genetic background for the development of C3G, which is thought to rely upon a complex interaction of triggering events, such as a monoclonal gammopathy, and underlying complement abnormalities, such as genetic variants in complement genes.

Background and Aims: Patients with chronic kidney disease (CKD) are at an increased risk of cognitive dysfunction, which is characterized by deficits in executive functions, memory and attention. Previous studies have suggested that albuminuria and lower estimated glomerular filtration rate (eGFR) are related to mild cognitive impairment (MCI) and dementia. There are no studies that have noticed connection between glomerular activity presented by dysmorphic red blood cells (RBC) count and cognitive evaluation results. The aim of the study was to investigate the association of cognitive decline with renal function and other potential risk factors such as albuminuria, proteinuria, and hematuria in patients with immunoglobulin A nephropathy (IgAN).

Method: A prospective study that took place from January 2020 till January 2022 at Pauls Stradins Clinical University Hospital Nephrology center included patients with IgAN. Diabetes mellitus, oncology, acute inflammation processes, transplantation in anamnesis were exclusion criteria. Demographic, anamnestic, clinical, laboratory data for renal function evaluation were collected. GFR was calculated using CKD-EPI Creatinine Equation. Urine spot protein/creatinine ratio was used for proteinuria measurement. Urine microscopy was performed by a nephrologist. Patients were assessed with a MoCA. Results of MoCA have been compared with potential risk factors.

Results: Sixty-five patients were included in the study. The mean age of the participants was 42.06 ± 10.71 years (IQR 35.47-75, range 21-65), with predominance of male sex (62.1%), mainly with higher education (45.5%). Dialysis was performed in 7 patients. The average duration of illness was 89.97 months ± 97.95 (IQR 31.5-120, range 1-456 months/38 years). Average GFR was 59.26 ± 38.66 (IQR 20.25-91.75, range 3-131) ml/min/1.73m2, urea 12.57±9.88 (IQR 6.3-15.45, range 4-62). Patients did not have anemia, average hemoglobin 135.20±14.8. Average proteinuria was 0.53±0.99 g/g (IQR 0.06-0.52, range 0.06-6.20), albuminuria - 69.34±107.3 g/mol (IQR 10.95-69.4, range 0.45-620). Average hematuria was 116.68±239.67 RBC/mlk (IQR 9.99-92.1, range 1.5-1421.3), while dysmorphic RBC count was 4.02±9.88 (IQR 6.3-15.45, range 4-62). Patients did not have anemia, average hemoglobin 135.20±14.8. Average proteinuria was 0.53±0.99 g/g (IQR 0.06-0.52, range 0.06-6.20), albuminuria - 69.34±107.3 g/mol (IQR 10.95-69.4, range 0.45-620). Average hematuria was 116.68±239.67 RBC/mlk (IQR 9.99-92.1, range 1.5-1421.3), while dysmorphic RBC count was 4.02±9.88 (IQR 6.3-15.45, range 4-62). Average hematuria was 116.68±239.67 RBC/mlk (IQR 9.99-92.1, range 1.5-1421.3), while dysmorphic RBC count was 4.02±9.88 (IQR 6.3-15.45, range 4-62). Average hematuria was 116.68±239.67 RBC/mlk (IQR 9.99-92.1, range 1.5-1421.3), while dysmorphic RBC count was 4.02±9.88 (IQR 6.3-15.45, range 4-62).
Patients age correlated with memory task score (p = 0.002, r = -0.42). Dysmorphic RBC count in urine sediment correlated with attention task (p = 0.002, r = -0.42).

Conclusion: Mild cognitive impairment is frequent even in our young age IgAN patient's cohort. Even small age difference plays role in MoCA evaluation score. No correlations have been found between proteinuria or albuminuria and MoCA score. Association between dysmorphic RBC and cognitive decline should be studied in bigger cohorts’ studies.

RE-ASSESSMENT OF PATHOLOGICAL DATA OF VASCULITIS PATIENTS WITH RENAL INVOLVEMENT ACCORDING TO CURRENT SCORING SYSTEMS AND CLINICAL CORRELATION

Deniz Eräl1, Dilek Barutcu Atas2, Murat Tuğcu1, Arzu Velioğlu1, Izzet Hakkı Arikân1, Fatma Alibaz-Oner1, Haner Direskeneli3, Ebru Asicioglu2 and Z. Serhan Tuglular2

1 Marmara University School of Medicine, Internal Medicine, Istanbul, Turkey, 2 Marmara University School of Medicine, Nephrology, Istanbul, Turkey and 3 Marmara University School of Medicine, Rheumatology, Istanbul, Turkey

Background and Aims: Renal involvement is responsible for substantial morbidity and mortality in ANCA associated vasculitis (AAV) patients. Predicting renal prognosis in AAV patients with renal involvement has been a challenge over the last decade. To date Berden Classification which focuses on glomerular lesions at renal biopsy proposed in 2010, Mayo Clinic Chronicity Score also including non-glomerular histopathological chronicity findings proposed in 2017 and adding eGFR at diagnosis to glomerular and non-glomerular chronicity findings at renal biopsy constructing ANCA Renal Risk Score (ARRS) proposed in 2018 have all addressed the latter challenge. In this study, we aimed to validate the impact of these 3 classification systems on the renal and patient survival in our ANCA associated glomerulonephritis (AAGN) patient population.

Method: Thirty-seven AAV patients with biopsy proven renal involvement who have been treated and followed-up at our multidisciplinary vasculitis clinic at Marmara University School of Medicine, Istanbul, Turkey between 2000-2020 were included in the study. Renal biopsies were re-evaluated by our pathologist and patients were grouped according to Berden Classification, Mayo Chronicity Score and ARRS. Renal survival and mortality analyses were carried out for 3 classification systems in order to evaluate their success at predicting prognosis and survival.

Results: Evaluated according to Berden Classification, 40.5% (n = 15) were classified as focal, 8.1% (n = 3) were sclerotic, 40.5% (n = 15) were crescentic and 10.8% (n = 4) were mixed. Focal group was associated with best renal prognosis and patients in mixed group had poorest renal prognosis. Differences in renal survival rates (p = 0.111) and patient survival rates (p = 0.129) among Berden Classification groups were not statistically significant. According to Mayo Chronicity Score, 16.2% of the patients were scored as minimal, 51.4% were as mild and 32.4 were in medium group. None of the patients were classified as severe. Compared to minimal group, mild and medium groups were found to be significantly associated with CKD development (p = 0.002). Mortality rates were similar between the groups according to Mayo Chronicity Score (p = 0.143). In renal survival analysis, mild and medium groups were associated with decreased renal survival (p = 0.046). When evaluated for ARRS, 29.4% of the patients were in low risk group, 45.9% of the patients were in medium risk group and 24.3% of the patients were in high risk group. Medium and high risk groups were associated with higher probability of progression to CKD (p = 0.000). Renal survival was found to be poorest in high risk group and best in low risk group (p = 0.017). Although mortality rates were higher in medium risk group than lower and higher risk groups, the difference has not reached statistical significance (0(0%) vs. 7 (38.9%) vs. 2 (22.2%); p = 0.067). Renal survival in AAGN patients according to Berden Classification, Mayo Chronicity Score and ARRS parameters are shown in Figure 1.

Conclusion: Recent classification systems were evaluated among our AAGN patients and our results showed that addition of eGFR at diagnosis to glomerular and non-glomerular histopathological findings were predictive of renal prognosis. Mayo Chronicity Score and ARRS systems can be used to predict patients’ renal reserve at diagnosis and also they can be used as a prognostic tool to predict patients’ probability of progressing to chronic kidney disease, end stage kidney disease.

Figure 1: Renal survival in AAGN patients according to Berden Classification, Mayo Chronicity Score and ARRS parameters.
THE PREDICTIVE VALUE OF URINARY CONGOPHILIA AS A BIOMARKER IN PREGNANT AND NON-PREGNANT WOMEN WITH LUPUS NEPHRITIS

Dalia Younis1, Rasha Samir Shemies1, Ghada El-Kannishy1, Alaa Mosbah1, Mahmoud Zakaria2, Amira Awadalla2 and Sherouk Elnagar1

1Faculty of Medicine Mansoura University, Egypt and 2Urology and Nephrology Center, Egypt

Background and Aims: Endoplasmic reticulum (ER) stress with protein misfolding has been introduced as a key pathogenetic mechanism in patients with lupus nephritis (LN). Pregnancy is thought to exaggerate ER stress in conjunction with autophagy inhibition. This probably explains disease flares during pregnancy; however, this is not fully addressed. The detection of the abnormally misfolded proteins is made using the Congo red stain, which is referred to as congophilia. This study aimed to assess the predictive value of urinary congophilia as a marker of protein misfolding in pregnant and non-pregnant women with lupus nephritis.

Method: Urine samples from non-pregnant lupus nephritis patients (n = 45) and pregnant women with lupus nephritis (n = 12), as well as pregnant healthy controls (n = 38) were collected. Urinary congophilia was assessed by Congo Red Dot Blot assay. The disease activity was defined according to SLE Disease Activity Index (SLEDAI) criteria. Renal biopsy was done for 26 adults of non-pregnant lupus nephritis patients at time of urine sampling as it was clinically indicated and modified NIH activity index was assessed.

Results: The median and range values for SLEDAI score were 14(4-34) for non-pregnant LN patients, and 4(0-6) for pregnant women with LN (Table 1). Congo red retention (CRR) was significantly higher for non-pregnant LN patients (24.18%(0.75-126.29%)), in comparison with pregnant LN patients (0.67%(0.31-27.69%), P = 0.001), and healthy controls (0.33%(0.18-2.7%), P≤0.001). There was a significant positive correlation between CRR on one hand, and anti-ds-DNA (r = 0.791, P≤0.001), as well as SLEDAI score (r = 0.623, P≤0.001) on the other hand. However, no significant correlation has been found between CRR with renal histopathological activity index (r = 0.2, P = 0.425). CRR at a cut point ≥ 21.85% had 83% sensitivity, and 58% specificity to capture high LN activity status (NIH-AI > 10) versus lower LN activity status (Fig. 1).

Conclusion: Urinary congophilia may add diagnostic value in patients with lupus nephritis and can be a reliable marker of disease activity. CRR is related to disease activity rather than pregnancy.

Figure 1: ROC curve to test the diagnostic accuracy assessment of CRR to capture high LN activity status (NIH-AI >10) versus lower LN activity status (NIH-AI ≤10). CRR at a cut point ≥ 21.85% had 83% sensitivity, and 58% specificity to capture high LN activity status (NIH-AI >10) versus lower LN activity status.

Background and Aims: The spectrum of glomerular lesion that occurs in the context of plasma cell dyscrasias (PCD) is wide, including type I and type II membranoproliferative glomerulonephritis (MPGN), focal proliferative GN, membranous nephropathy (MN), minimal change disease and amyloidosis. A clear-cut link between hematological dyscrasias and glomerulopathy is often offered by the finding of paraproteins in the kidney or by kidney leucocytic infiltration and, in these scenarios, malignancy treatment is often found to be also effective towards the glomerulopathy. In the context of PCD in which proliferation of the B-cell clone does not lead to plasma-cell terminal differentiation such as chronic lymphocytic leukemia (CLL), the physiopathological link with glomerulonephritis is not well established and it’s hard to determine whether the combination of these two disorders is fortuitous. With regarding to MN, it’s now well established that this histopathological pattern must be related to the presence of circulating autoantibodies, where anti-PLA2R antibodies usually been associated with primary MN. To our knowledge association between LLC and anti-PLA2R associated MN has not been described.

Case report: We report the case of a 76-year-old man who was admitted in February 2022 with anasarca and acute kidney injury. He had recently been evaluated by a hematologist in the context of suspected chronic lymphocytic leukemia (CLL). Laboratory findings, along with typical CLL white blood cell count, showed decreased kidney function from baseline and were compatible with nephrotic syndrome, with proteinuria progressively increasing up to 27 gr/24 h in the following weeks. CLL was confirmed by lymphocyte typing. A total body CT scan showed mediastinal, abdominal and inguinal lymphadenopathies, but no suspected neoplastic lesions. Screening for autoimmunity tested completely negative, as well as infectious screening for common hepatic viruses (HBV, HAV, HCV), EBV, CMV, HIV, Parvovirus B19. Lymph node biopsy showed no aspects of aggressive lymphoproliferative disease and hematological consultation only indicated clinical and laboratory follow-up of LLC, with no further indication to specific therapies. A kidney biopsy was performed showing diffuse thickening of the basement membrane (Fig. 1) with granular deposition of Ig (+++) and C3 (+++) along the glomerular capillary walls at immunofluorescence. Electron microscopy revealed subepithelial immune deposits (Fig. 2) with initial incorporation from the glomerular basement membrane (GBM). Anti PLAS antibodies, found negative at first determination, subsequently tested positive at high titre (ELISA 1356.4 U/ml). A diagnosis of stage two membranous nephropathy was made, and the patient was treated with Rituximab 375 mg/m2 every week for four weeks. Clinical stability was obtained with repeated intravenous administration of diuretics (furosemide 60 mg + canrenone 200 mg) along with albumin. Nevertheless, nephrotic syndrome persisted, and kidney function progressively decreased with serum creatinine up to 2.8 mg/dL. Immunophenotype, which showed reduction but no suppression of CD19+ lymphocytes, was again repeated on November 2022 and showed typical LLC findings (CD 19+, CD 20+, CD 23+, CD 5+). Anti PLASR antibodies gradually decreased instead, reaching a value of ELISA 1.8 U/ml in November 2022 and persisted negative until present. The patient recovered from nephrotic syndrome in Autumn 2022 and is currently on stage G3B chronic kidney disease with persistent sub-nephrotic proteinuria in supportive treatment.

Conclusion: Simultaneous diagnosis of primary MN and LLC led us to ask ourselves whether this patient could benefit from LLC-specific chemotherapy, even though there were no signs of aggressive hematological disease and no clear link with the nephropathy. We think that further investigations are required to deeply understand the connection between hematological and renal disorders, in order to identify whether there are two diseases to treat separately or two sides of the same disease to treat as one.

COVID-19 INFECTION MODIFIES GLOMERULAR DISEASE EVOLUTION
Felipe Ignacio Ojeda1, Miguel Giovanni Uriol Rivera1, Estela de Los Angeles Mas Rodenas4, Paloma Livianos Arias-Camison3, Aina Obrador Mulet1, Gemma Arrufat2, Maria Gomez Zamora2 and Sonia Cleofe Jimenez Mendoza1
1Hospital Universitari Son Espases, Nephrology, Palma, Spain and 2Hospital Universitari Son Espases, Pharmacy, Palma, Spain

Background and Aims: A fibrotic effect of the SARS-CoV2 virus (Covid-19) has been described and the risk for acute renal failure in glomerular disease (GD) patients; however, the long-term renal effect in these patients is unknown. We evaluate the impact of the Covid-19 infection on eGFR, the influence of proteinuria, the effect of the drugs used to control glomerulonephritis and the use of Paxlovid (nirmatrelvir/ritonavir) for covid infection control.

Method: We retrospectively evaluate the eGFR (mL/min/1.73m2) at month 12 and 6 before infection (pre-infection period), during infection, 6 months after infection and at the last visit post-infection in renal biopsy-proven glomerulonephritis patients. Patients were included from January/2020 to July/2022. All patients were followed up for six months or more from infection.

Results: Forty-seven patients were included. The mean follow-up was 13 months (min: 6–max = 33). Sex Female 24 (52%), Age (mean[SD]) = 47 (14) years. 39(85%) were vaccinated before infection. At infection time, 31(66%) of the patients presented proteinuria (protein/creatinine ratio > 0.2 mg/mg), 27(54%) received oral steroids, 27(54%) mycophenolate, 24(51%) prednisone, and 27(54%) renin-angiotensin system inhibitors (RASi). Four (8%) started chronic renal replacement therapy during the follow-up, and 12(25%) required hospital admission. During the pre-infection period, eGFR remained stable (mean change (95%CI): -2.2 (-8.2 to 3.7) mL/min/1.73m2, P = 1. Compared with month six before infection, eGFR decreased at the end of the follow-up by 9.1 (95% CI: 0.96 to 17.2) mL/min/1.73m2, P = 0.019. After stratifying by the presence of proteinuria, eGFR decreased only in those with proteinuria 14.5 (95%CI: 3.7 to 25.4) mL/min/1.73m2, while no changes were observed in those without proteinuria. No changes in proteinuria level after infection were observed. No interaction between drugs used, hospitalisation requirements and eGFR evolution was observed. In the sub-group of patients treated with Paxlovid (all previously vaccinated) after six months of follow-up, no patients observed.

Abstracts
required hospitalisation; however, eGFR evolution was similar to the whole group, which decreased only in those with proteinuria at baseline.

**Conclusion:** The Covid-19 infection in proteinuric GD patients changed the renal function evolution dramatically. The medication used (mycophenolate, steroid and RASi), including Paxlovid, did not influence this evolution. At the end of the follow-up, the accelerated renal function deterioration continues. Urgent therapeutic measures for controlling eGFR decline in these patients are needed.

**KIDNEY INVOLVEMENT IN HAEMATOLOGICAL MALIGNANCIES: THE IMPORTANCE OF EARLY NEPHROLOGICAL REFERRAL**

Vittorio Di Maso1,2, Brigitta Perencin2, Alberto Zacchi3, Ahmad Yazbek2, Federico Toffoli2, Fabrizio Zanconati2 and Francesco Bianco2

1SS Nefrologia Clinica - SC Anatomia Patologica - ASUGI - Ospedale di Trieste, Trieste, Italy, 2SC Nefrologia e Dialisi - ASUGI - Ospedale di Trieste, Trieste, Italy and 3SC Anatomia Patologica - ASUGI - Ospedale di Trieste, Trieste, Italy

**Background and Aims:** Kidney is often injured in the setting of hematological malignancies. Although, kidney involvement negatively influences the prognosis of these patients, often the referral to clinical nephrology is late. The aims of this study were to investigate the long-term outcomes of haematological diseases with renal involvement demonstrated by kidney biopsy and the association between nephrological referral earliness and survival.

**Method:** Monocentric retrospective study evaluating overall survival (OS) (time to death) and renal free survival (RFS) (time to renal replacement therapy) in patients affected by hematologic malignancies with renal involvement demonstrated by kidney biopsy. Data have been collected by January 1st 2009 to December 30th 2021. Results reported as median (min-max) and percentage (%).

**Results:** 46 patients; M/F = 1.3; age: 70 years (39.5-91.2). Follow-up: 17.8 months (0.13-125.4). Data at kidney biopsy: creatinine was 3.13 mg/dL (0.6-14), eGFR was 20 ml/min/1.73 m2 (3-110), proteinuria was 5.1 g/24h (0.15-38.6), Bence-Jones proteinuria detected in 74% of patients. Clinical presentations: AKI (63.1%), Nephrotic syndrome (26.1%), General Practitioner (21.7%); Emergency Department (17.4%). The most frequent histological diagnosis was amyloidosis (32.7%), followed by cast nephropathy (19.2%). Renal Replacement Therapy was required in 41.3% patients. Treatment: 38 patients underwent chemotherapy (56.4% complete/very good hematologic response; 12.8% partial and 30.6% without response). Overall Survival at 24 months was 63.8% and it was reduced in patients with AKI at presentation (Fig. 1) and in patients without treatment response (Fig. 2). RFS was shorter in patients who presented with AKI and affected by Myeloma Cast. Early nephrological referral was associated with a better RFS (Fig. 3).

**Conclusion:** Haematological malignancies with renal involvement causing AKI have the worst prognosis. Kidney biopsy has a prognostic significance and early nephrological referral associated with haematological treatment response correlate with a better renal outcome. These data point to the central role of a multidisciplinary team aimed to the detection and treatment of renal damage due to hematologic malignancies.

A CASE REPORT OF MEMBRANOUS NEPHROPATHY SECONDARY TO SYPHILIS: A STEROID-RESPONSIVE DISEASE?

Vittorio DI Maso1, Ahmad Yazbek1, Brigitta Perencin1, Claudia Colli2, Elisa Oivo3, Alberto Zacchi4, Fabrizio Zanconati4 and Francesco Bianco1

1SC Nefrologia e Dialisi - ASUGI - Ospedale di Trieste, Trieste, Italy, 2Clinica Dermatologica - ASUGI - Ospedale di Trieste, Trieste, Italy, 3S.C. Nefrologia e Dialisi, AUSL-IRCCS Reggio Emilia, Reggio Emilia, Italy and 4SC Anatomia Patologica - ASUGI - Ospedale di Trieste, Trieste, Italy

Background and Aims: Membranous Nephropathy (MN) is among the most common forms of nephrotic syndrome in the adults. MN in adults is most often primary (75-80%) and caused by circulating autoantibodies against podocyte antigens being PLA2R the most important target. In the remaining 20-25% of cases, the MN lesion is associated with various disorders, including infections, autoimmune diseases, thyroiditis, malignancies, and the use of certain drugs. Syphilis is a chronic bacterial infection caused by Treponema Pallidum that can present in the primary, secondary or tertiary forms. Kidneys can be involved during either the secondary or the tertiary phase and the most frequent clinical presentation is nephrotic syndrome underlying membranous nephropathy. Here, we present the case of a 47-year-old man who developed rapidly progressive acute kidney injury, nephrotic syndrome and a blotchy diffuse macular rash secondary to Treponema Pallidum infection.

Method: Data review and collection of clinical records, kidney biopsy evaluation, treatment and outcomes description.

Results: A 47-year-old man presented to our hospital complaining about asthenia and dizziness. He reported recent use of both antinflammatory drugs and antibiotics to treat an anal fissure. His past medical history was notable for previous drug abuse and alcohol consumption. Physical examination highlighted peripheral edema and a diffuse macular rash. Serum analysis showed serum creatinine of 2.06 mg/dL, urea 84 mg/dL, haemoglobin 13.8 g/dL, albumin 4 g/dL and protein/creatinine ratio of 17741 mg/g; urinary dipstick was positive for haemoglobinuria and proteinuria. Urine collection revealed 22 g proteins/24h. Kidney ultrasound showed normal kidneys with a preserved cortico-medullary differentiation and thickness. In the next days kidney function worsened (serum creatinine 3 mg/dL and urea 100 mg/dL) and daily proteinuria reached a peak of 35 g/24h. A complete panel of antibodies was searched. IgG4 against PLA2R were negative. ANA, ENA and ANCA were absent, C3 and C4 were in the normal range. Serologic testing for HBV, HCV and HIV were negative. Empircic steroid therapy with prednisone 1 mg/kg/day was started obtaining a rapid improvement in terms of proteinuria and asthenia.

Abstracts i343
and kidney function (Fig. 1), the cutaneous rash faded. Kidney biopsy was performed and demonstrated a membranous nephropathy. Serological testing for syphilis revealed positive TPHA (titer, 1:2560; normal value, <1:80) and a positive Veneral Disease Research Laboratory test (VDRL) (titer, 1:32; normal value, <1:2). The presentation suggested the diagnosis of anti-PLA2R negative membranous nephropathy secondary to systemic syphilis. Because of the serious clinical manifestation and the unknown duration of the infection we decided to treat the patient with Benzathine penicillin G 2.4 million units administered as three doses over one week intervals (Schön & Bertich, 2016). Oral steroid was maintained at a dose of 1mg/kg/body weight and desacalation started after 30 days. The proteinuria also improved with a reduction in the 24-hour collection from 30 g to 200 mg and serum creatinine went back to normal. Clinical course according to treatment phases are summarized in Fig. 1.

Conclusion: As far as we know, this is the first case of PLA2R negative membranous nephropathy secondary to syphilis. Although, antibiotic therapy is pivotal in syphilis treatment, our patient showed a fast improvement of kidney function, proteinuria and fading of the cutaneous erythema after steroid therapy and before starting antibiotic therapy. This suggested the possible role of steroids in treatment of secondary T. Pallidium infection complicated by anti-PLA2R negative membranous nephropathy. Further researches are needed to better define the possible role of steroids in the context of an infective but immune-complex mediated nephropathy.

#3121
THE EFFECTIVENESS OF A GLUTEN-FREE DIET IN PATIENTS WITH IGA NEPHROPATHY
Mariya Mantsaeva and Alexey Borisov

Russian Medical Academy of continuous education, Department of General Medicine and Therapeutics and Outpatient Therapy, Moscow, Russia

Background and Aims: Modern data from the world literature confirm the association of IgA nephropathy (IgAN) and celiac disease. The inclusion of a gluten-free diet (GFD) in the diet has a beneficial effect not only on gastrointestinal symptoms, but also reduces the clinical and laboratory activity of IgAN. The aim of this study was to evaluate the effect of a gluten-free diet on the course of IgAN using general clinical and immunological tests 6 months after the start of its use.

Methods: In patients with IgA nephropathy, with morphologically confirmed IgAN were included in the study. To detect a violation of gluten metabolism, screening determination of the level of IgA antibodies to tissue transglutaminase (Anti-TTG IgA) and IgA antibodies to deamidated gliadin peptides (Anti-DPG IgA) was performed. According to the results of the screening examination, a group of patients with the level of antibodies exceeding the reference values were formed (group 1, n = 13) and a group of patients in whose blood did not exceed the reference values, or were absent at all (group 2, n = 52). Patients of both groups were recommended GFD for a period of at least 6 months. The effectiveness of GFD was evaluated by the following indicators: protein in urine (g/l); red blood cells in urine (RBCs) (hp); daily proteinuria (g/day); blood creatinine (mmol/l), GFR calculated by the formula CKD-EPI (ml/min/1.73 m²) at the beginning of the study and 6 months after the inclusion of dietary recommendations. Statistical analysis of the data obtained was carried out using the statistical program SPSS Statistics 26.0 (IBM, USA). When comparing quantitative indicators, the distribution of which differed from normal in two related groups, the Wilcoxon criterion was used. Then the statistical hypothesis about the absence of differences and connections was rejected at p<0.05.

Results: among the examined patients there were 61 men (93.8%), 4 women (6.2%). The average age of men was 39.0±8.2 years, women - 34.7±9.7 years. The duration of the underlying disease at the time of inclusion in the study was 55.98 [40.67-71.28] months. 57 people (85.1%) received ACE inhibitors/sartans in therapeutic doses as the main therapy, 8 people (11.9%) did not receive drug therapy. It was possible to evaluate the effectiveness of GFD in patients from group 1 in 9 people. During the follow-up period 2 patients from group 1 showed progression of the disease to the End-Stage Renal Disease (GFR according to CKD-EPI <15 ml/min/1.73 m²), which required their exclusion from the study, in 2 more patients it was not possible to evaluate the effectiveness of GFD due to insufficient follow-up periods (less than 6 months.) GFD was also recommended to patients from group 2. Dietary restrictions were applied to patients with daily protein loss > 0.5 g/day and/or anti-TTG IgA and anti-DPG IgA levels in the reference values, thus it was possible to evaluate the effectiveness of GFD in patients of group 2 in 21 people. According to the results of the analysis, a statistically significant decrease in daily proteinuria (p = 0.028) and microscopic hematuria (p = 0.018) was revealed. After 6 months from the start of compliance with GFD, daily proteinuria decreased in 66.7%; microscopic hematuria – in 77.8% in group 1 patients. Among group 2 patients, a statistically significant decrease in microscopic hematuria (p = 0.05) was observed in 76.2% of those included in the study.

Conclusion: the inclusion of GFD in the diet of patients with IgAN is justified in patients with the presence of gluten antibodies in the blood serum, as it allows to significantly reduce the severity of proteinuria, microscopic hematuria in these patients. Screening examination of patients with IgAN for gluten metabolism disorders will expand therapeutic possibilities, and GFD can become part of a nephroprotective strategy.

#5339
TRANSTHYRETIN AMYLOIDOSIS WITH BIOPSY PROVEN RENAL INVOLVEMENT
Andrea Caredu, Stefania Lalloni, Martina Marchisio, Marco Morrone, Gianluca Rabajoli, Cecilia Ceruti, Roberta Fenoglio, Savino Sciaccia and Dario Roccatello

Torino, Italy

Background and Aims: Systemic amyloidosis is a cluster of disorders characterized by tissue deposition of amyloid (highly ordered fibrils composed of low molecular weight subunits of a variety of proteins). Transthyretin (TTR) amyloidosis (ATTR) is either an autosomal dominant inherited condition (ATTRv, where v stands for "variant") or a non hereditary disease due to misfolding of wild-type TTR (ATTRwt). ATTR is likely underdiagnosed due to its clinical variability and lack of specific symptoms or biomarkers. The first aim of the study is to emphasise the importance of suspecting ATTR when facing certain clinical manifestations in association with renal impairment and urinary abnormalities. Furthermore, renal biopsy provides crucial information for a correct diagnosis and treatment approach.

Method: We report 5 cases of biopsy-proven renal ATTR deposition in patients presenting with mild to moderate renal impairment and mild urinary abnormalities. The ATTRv precursor has been confirmed in kidney specimens by immunohistochemistry. Genotyping was carried out in every patient.

Results: The presence of amyloid was found in all patients, with different distribution (#1-3 pericapsular and vascular; #2 vascular; #4 mesangial, vascular, in tubular basement membrane and in the interstitium of cortex and medulla; #5 pericapsular, vascular and interstitial). On genetic analysis three patients were wild-type (#1-2-5), one carried the c.424G>A (p.Val142Ile) mutation (#3) and the last one the Val30Met mutation (#4).

Conclusion: Suspection of ATTR should be considered in patients with increase in serum creatinine, mild proteinuria and cardiac and peripheral nerve symptoms. This can be of utmost importance in elderly patients in whom a monoclonal gammapathy of undetermined significance can co-exist and drive a wrong diagnosis of primary light chain amyloidosis (AL), that could lead the clinician to undertake inappropriate treatments. Renal biopsy and genetic sequencing are both critical in diagnosing ATTR. Finally, we suggest distinguishing in the context of the ATTR deposition disease an ATTR nephropathy characterized by mesangial accumulation of amyloid, that impacts functional and urinary assessment, from isolated deposition in small vessels without specific clinical consequences, albeit critical for ATTR diagnosis.

#5163
RATIONAL USE OF ECULIZUMAB IN SECONDARY ATYPICAL HAEMOLYTIC UREMIC SYNDROME
Lucia Cordero García-Galán, Teresa Cavero Escribano, Eduardo Gutiérrez, Justo César Sandino Pérez, Hernando Trujillo Cuadra, Pilar Auñón, Marta Rivero Martínez, Celia González, Paúl Hernández and Enrique Morales

Hospital Universitario 12 de Octubre, Neftrología, Madrid, Spain

Background and Aims: Secondary atypical hemolytic uremic syndrome (secondary aHUS) is a heterogeneous group of thrombotic microangiopathies (TMA) associated with various underlying conditions. Unlike primary aHUS, there is still no hard evidence on the efficacy of complement blockade in treating secondary aHUS since the two main series in the literature that investigate this subject show discrepant results. Our work aims to reassess Eculizumab’s efficacy in treating secondary aHUS.

Method: Observational, retrospective, single-center study, in which we analyzed the hematological and renal evolution of 24 patients diagnosed with secondary aHUS who received treatment with Eculizumab compared with a control cohort of 14 patients who did not receive Eculizumab. Complete renal response was defined as the recovery of renal function before the event, partial renal response as a recovery of 50% of lost glomerular filtration rate, and hematological response as normalization of hemoglobin and platelets.

Abstracts
Results: We found no statistically significant differences in baseline character-istics between the two groups. After a median of 5 doses of Eculizumab, the group of patients who received complement blockade presented a significant difference in renal response (complete in 47.8% of patients and partial in 17.4%) compared to the control cohort (complete response 14.3% and partial of 14.3%). Rates of hematological remission were similar in both groups (87% in the eculizumab cohort and 85.7% in the control cohort).

Conclusion: Rational and early use of Eculizumab in patients with secondary aHUS could be an effective and safe therapeutic option, guaranteeing better renal recovery compared to patients who do not receive complement blockade.

#5091 RITUXIMAB IN MANAGEMENT OF RELAPSING AND STEROID DEPENDANT C1Q NEPHROPATHY: A TALE OF THREE PATIENTS
Panagoula Gkargkoula and Farid Ghalli
Royal Sussex County Hospital, Sussex kidney Unit, Brighton, United Kingdom

Background and Aims: C1q nephropathy is an immune glomerular disease in which dominant C1q electron-dense deposits are identified in the mesangium. It commonly presents with nephrotic syndrome, while nephritic syndrome or isolated haematuria are less common. Biopsy findings vary; from no glomerular lesion identified as in minimal change disease (MCD) to focal segmental glomerulosclerosis (FSGS) and immune-mediated proliferative glomerulonephritis. Steroids are the main therapeutic agents that have been tried.

Rituximab is an anti-CD20 human/mouse chimeric monoclonal antibody and one of the drugs used in managing C1q nephropathy. We present 3 cases of biopsy-proven C1q nephropathy that presented with nephrotic syndrome. They responded initially to steroids and achieved remission after treatment with rituximab.

Method: Case Scenarios: Case (1): A 30-year-old man had been diagnosed with steroid sensitive nephrotic syndrome since he was 18 months. Renal biopsy confirmed the diagnosis of C1q nephropathy, more in the spectrum of MCD. He was managed with steroids, and rituximab in 2011 and achieved remission for the last 7 years after 5 doses. His renal function had always remained normal. He presented to our department in 2020 with another relapse and heavy proteinuria (urine protein creatinine ratio (UPCR) was 1300 mg/mmol) but unchanged renal function. Repeat kidney biopsy showed C1q nephropathy in the spectrum of FSGS. He showed good response to oral steroids. On relapse while weaning steroids, Rituximab was considered. He had 2 doses of rituximab of 1 gram 2 weeks apart in July 2021. He achieved full remission over the last 2 years. Case (2): A 77-year-old female presented in 2020 with nephrotic syndrome (UPCR of 660 mg/mmol) and acute kidney injury (AKI) (creatinine 400 μmol/l). Her kidney biopsy showed C1q nephropathy with FSGS features. She was started on haemodialysis due to continuous kidney function deterioration. She recovered on steroid therapy to normal kidney function and negative proteinuria, but she relapsed with weaning steroids. So steroid dose was increased and tacrolimus was added. Her renal function remained intact. Following that she had another flare in May 2022 with mild kidney impairment and worse proteinuria (UPCR 500 mg/mmol) while she was on small dose steroid and tacrolimus. She was then started on rituximab. After 2 doses 1 gm 2 weeks apart she achieved remission and her kidney function normalised. She received 2 more doses of 1 gram rituximab 6 months apart with excellent response. She has been in complete remission since. Case (3): A 28-year-old male presented to our department in July 2020 with nephrotic syndrome (urine PCR > 900 mg/mmol) and preserved renal function. His kidney biopsy was initially reported as MCD and he was managed with oral steroids. He showed a good response with complete resolution of his proteinuria 3 weeks later and remained in remission for 2 years. However, in August 2022- he suffered a second severe relapse (UPCR 4000 mg/mmol) with preserved renal function. His kidney biopsy was therefore reevaluated and immunofluorescence was added which revealed C1q nephropathy. He had another course of steroids and was initiated on rituximab infusions. He showed full remission after 2 doses (1 gram IV 2 weeks apart) and is on ongoing 6 monthly infusions.

Results: Rituximab was effective in inducing remission in our patients with nephrotic syndrome due to C1q nephropathy. They were all steroid sensitive. It was effective in both steroid-sensitive and steroid-dependent cases. The first and second cases had biopsy findings in the spectrum of FSGS while the third case histological picture in the spectrum of MCD. They all achieved full resolution of their proteinuria and preserved their renal function finally.

Conclusion: Rituximab was effective in inducing remission in both steroid-responsive and steroid dependent relapsed patients with C1q nephropathy, despite differences in biopsy results. Kidney function was preserved. More solidified data, including multi-centre randomized controlled trials, are needed to establish clear guidelines for the position of rituximab in the management of the disease and the proper dose to use.
One of two main antigens are targeted in this condition, either proteinase 3 (PR3) or myeloperoxidase (MPO). Uncommonly, both antigens can be targeted in specific situations such as during levisamole use, propylthiouracil use, hydralazine use or infections. Herein, we illustrate a case of a patient who presented with progressively worsening kidney function in the setting of recent COVID booster.

**Method:** A 79 year old female with a history of hypertension, hyperlipidemia, acid reflux and hypothyroidism was admitted to our facility from her outpatient nephrologist due to abnormal labs. This was the first time the patient had seen a nephrologist, although she was told that her serum creatinine (Scr) was elevated to ~3 mg/dL three months earlier. At that time, she noted blood tinged urine as well as frothiness of urine that had since resolved. She also endorsed a raised erythematous rash that also resolved. She did mention that she had increasing fatigue over the past week prior to presentation along with weight loss over the past few months. She denied ear pain, sinus pain, epistaxis, hemoptysis or specific joint pain. She denied any kidney stones or NSAID use. She was a former smoker, having quit decades ago. She denied any current tobacco or illicit drug use, including cocaine as well as any herbal supplements or medications that were not otherwise prescribed to her by a medical provider. She did note recent COVID booster prior to being told of a Scr ~3 mg/dL. She had a repeat kidney function test one month prior to presentation, at which time she was told her Scr was 5 mg/dL. In our Emergency Department, Scr was elevated to 8.45 mg/dL with a BUN of 68 mg/dL. Computed tomography of the abdomen and pelvis ruled out any hydronephrosis or kidney stones. Urinalysis was revealing for 509 RBCs, 39 WBCs, and some granular casts. Spot urine protein to creatinine ratio was found to be elevated at 6925 mg/g. Serologies were pertinent for WBCs, casts as well as granular casts. Spot urine protein to creatinine ratio was found to be elevated at 6925 mg/g. Serologies were pertinent for a positive ANA as well as ANCA. Interestingly, both MPO and PR3 titres were elevated at 72 AU/mL and 391 AU/mL, respectively. Kidney biopsy was performed and revealed a pauci-immune glomerulonephritis with crescents along with mixed interstitial inflammatory infiltrate (Figure 1). The diagnosis of dual positive ANCA glomerulonephritis was made. Computed tomography of the chest revealed scattered ground glass opacities and subpleural nodules which was consistent with a vasculitis. She started treatment with Rituximab and steroids on Day 5 of hospitalization.

**Results:** Although evidence linking ANCA vasculitis to COVID infection and vaccine has been starting to develop, the association with dual positive ANCA is something that has been elusive. Having titres for both MPO and PR3 ANCA is uncommon and has traditionally been attributed to very few causes; as COVID infection and vaccination has been a fairly recent development, this has not historically been considered a cause to think of in such patients. In the case presentation above, our patient had no other identifiable risk factors for presenting with a dual positive ANCA vasculitis. She did endorse recent booster vaccination which was subsequently followed by elevated Scr and positive serologies.

**Conclusion:** Dual positive ANCA vasculitis is an uncommon finding and should trigger a high clinical suspicion for implicated drugs, infections as well as COVID vaccination.

---

**MONOCLONAL GAMMOPATHY OF RENAL SIGNIFICANCE: A SINGLE CENTER EXPERIENCE**

Kishan A1, Sravani Muske1, Haritha Harindrath1, Mahesa Vankalakunti2 and Sreedhara CG1

1Institute of Nephro-Urology, Nephrology, Bangalore, India and 2Manipal Hospitals, Nephropathology, Bangalore, India

**Background and Aims:** Monoclonal gammopathy of renal significance is an organ-threatening manifestation of paraproteinemia. It can be secondary to the clonal proliferation of either plasma cells or mature B-lymphocytes. The underlying clonal disorder does not meet the current hematologic criteria for immediate myeloma-specific therapy. With the advent of routine use of light chain detection by immunofluorescence technique in tissue biopsy, more cases of monoclonal gammopathy of renal significance are being diagnosed but there remains a therapeutic uncertainty. Data regarding the prognosis and outcomes of the various clinical manifestations of monoclonal gammopathy of renal significance is limited due to its rarity and under diagnosis. MGRS if left untreated can lead to end-stage renal disease and premature death.

**Method:** This is a retrospective study conducted at the Institute of Nephro-urology, Bangalore by retrieving the data from the digital medical records of our institute. Demographic and clinical details of the patients diagnosed with monoclonal gammopathy of renal significance from 1st January 2018 to 31st October 2022 were collected. Myeloma related light chain cast nephropathy was excluded from the study. Follow-up data were collected using out patient data base, through telephone, and from the records at the cancer institute where the patient was referred post-diagnosis at our institute. The data collected was entered in excel and analyzed using SPSS software version 27.0.

**Results:** Fifty eight patients (n = 52) were diagnosed with the disease during the study period. MGRS contributed to 1.27% of all the renal biopsies conducted at our institute during the study period. The mean age of the study population was 52.1 with 95% CI [48.3 to 55.6] with a male: female ratio of 1.36:1 and 36.5% (n = 19) of study cohort aged above 60 years. Among clinical presentations CKD (n = 23) was the main clinical presentation followed by AKI, Nephrotic syndrome, Nephritic syndrome and RPGN as the other presentations. Dialysis requirement was noted in 35% at initial presentation. Most common histiopathological presentation was Amyloidosis (n = 15) followed by Light chain deposition disease LCDD (n = 14), monoclonal non-amyloid deposition disease NADD (n = 6), Light chain proximal tubulopathy LCPT (n = 5), Proliferative glomerulonephritis with monoclonal immunoglobulin deposition disease PGNMIDD (n = 9) and others (n = 3). The patient survival at the time of analysis was 22.7% and death censored renal survival was 80%.

**Conclusion:** MGRS contributed to 1.27% of all the renal biopsies conducted at our institute during the study period. Because of its variable clinical presentation, one needs high degree of clinical suspicion for early diagnosis. MGRS unlike MGUS carries significant morbidity and mortality.
Background and Aims: Development of SARS-CoV-2 vaccination has altered the natural course of the related infection and the pandemic. The present study aims to explore the frequency of adverse events in patients with glomerular diseases (GD).

Methods: Patients with biopsy-confirmed GD, who received at least one dose of the vaccine against SARS-CoV-2 were studied retrospectively. Patients who ended up in ESKD prior to vaccination were excluded. We recorded demographics, histopathological diagnosis, past medical history, immunosuppressive regimens which were given at diagnosis and thereafter, outcome of the GD and adverse events associated with the vaccine, both systemic and local. We also estimated the rate of GD relapse post vaccination in patients in remission of the primary diseases compared with patients who decided not to receive the vaccine.

Results: To date 280 patients with GD have been included in the study with a mean age of 47.6 (±17.8) years, of whom 111 (39.6%) are males. Patients received in total 3.0 (±0.9) vaccine doses with the mean time from the diagnostic kidney biopsy to the 1st dose being 76.5 (±61.5) months. 47.1% of the patients were on immunosuppressive therapy at the time of vaccination. 27.1% of the patients reported systemic side effects (fever, arthralgias, myalgias) and 50.7% reported local side effects (pain, swelling, itching, edema). Renal function and 24-hour proteinuria remained stable after vaccination. Among patients who were in remission of the GD at the time of vaccination 19 (8.2%) patients experienced a relapse of the primary disease after vaccination, versus 5% of patients not vaccinated (p = 0.99).

Conclusions: According to our findings the vaccine against SARS-CoV-2 appears safe for patients with GD with no significant impact in renal function or the probability for relapse.

Renal function and 24-hour proteinuria remained stable after vaccination. Among patients who were in remission of the GD at the time of vaccination 19 (8.2%) patients experienced a relapse of the primary disease after vaccination, versus 5% of patients not vaccinated (p = 0.99).

Conclusions: According to our findings the vaccine against SARS-CoV-2 appears safe for patients with GD with no significant impact in renal function or the probability for relapse.

#6517
CLINICOHISTOLOGICAL CHARACTERISTICS, THERAPEUTIC APPROACH AND RENAL OUTCOME IN PATIENTS WITH C3 GLOMERULOPATHY: A SINGLE-CENTER EXPERIENCE
Eleonora Kapsia1, Zoe Kleznik1, Ioannis Michelakis2, Stathis Tsiaakis1, Chrysanthe Skaloti1, Evangelia Rokka1, George Liapis2, Ioannis Boletis3 and Smaragdi Marinaki1
1National and Kapodistrian University of Athens Medical School, Laiko General Hospital, Department of Nephrology and Renal Transplantation, Athens, Greece, 2National and Kapodistrian University of Athens Medical School, Athens, Greece and 3National and Kapodistrian University of Athens Medical School, Laiko General Hospital, Department of Pathology, Athens, Greece

Background and Aims: C3 glomerulopathy has been identified as a distinct disease in the last decade but it has already been associated with a high burden of end stage renal disease (ESRD). Due to the rarity and heterogeneity of the disease, data regarding the prognosis and optimal treatment are still lacking. We aimed to describe the clinical and histological phenotype of patients with C3 glomerulopathy followed at our center, the treatment regimens applied and their long-term renal outcome.

Method: We conducted a retrospective medical chart review of 19 patients with C3 glomerulopathy followed at our center and we reported clinical, histological and therapeutic parameters as well as their long-term renal outcome.

Results: Median age of patients at the time of diagnosis was 23 years (IQR 28), median proteinuria 2.6 g/d (IQR 2.8) and median eGFR 63ml/min (IQR 63). 26% of patients (5/19) presented with an eGFR <30ml/min. Low serum C3 levels were reported in 11/19 patients (58%). A monoclonal paraprotein was detected in three patients and pathogenous mutations of CFH/CFI genes in 4 out of 10 patients who underwent genetic testing. 41% of patients (7/17) were treated with RAAS inhibitors only, while 59% (10/17) received immunosuppressive treatment. Immunosuppressive treatment consisted of different combinations of steroids with mycophenolic acid, cyclophosphamide, cyclosporine or rituximab and steroid monotherapy in one patient. Treatment data were not available for two patients. There was a significant difference in baseline proteinuria between patients treated with RAAS inhibitors only (median 1.5g/d, IQR 1.14) and those who were treated with immunosuppressants (median 3.95g/d, IQR 4.8) (p = 0.003). Remission (complete or partial) was achieved by 43% of patients at 6 months and by 50% at 12 months. Median follow up time was 45 months (IQR 66). Eight patients (42%) reached ESRD in a median time of 58.5 months (IQR 62.5) while other three patients (16%) ended up with a GFR decline >30%. Among patients with adverse renal outcome (ESRD, GFR decline >30%), 54.5% (6/11) had baseline proteinuria >3g/d, 73% (8/11) had low serum C3 and 54.5% (6/11) had interstitial fibrosis/tubular atrophy >25%, while the median percentage of glomerulosclerosis was 33% (IQR 58). On the contrary, in the group of patients with favorable renal outcome, baseline proteinuria >3g/d was reported in only 25% (2/8), low serum C3 in 37.5% (3/8), interstitial fibrosis/tubular atrophy >25% in 25% (2/8), while median glomerulosclerosis was only 8% (IQR 15). Attainment of complete remission was associated with favorable renal outcome (p = 0.001). Five of eight patients who reached ESRD underwent kidney transplantation from a living related donor. All of them received basiliximab,
mycopHENolic acid, tACROMLin and steroids. Recurrence of C3 glomerulopathy was observed in four of these patients and one of two of them.

Graft loss due to disease recurrence was observed in one patient.

Conclusion: The present case series of patients with C3 glomerulopathy highlights the great heterogeneity in the clinical phenotype, therapeutic approach and renal prognosis of the disease. It also underscores the importance of attainment of complete remission regarding the long-term renal survival. Large studies are needed in order to better define clinical and histological predictors of adverse renal outcome as well as the optimal treatment regimens.

Background and Aims: Myelodysplastic syndromes (MDS) are hematologic disorders characterized by ineffective and dysplastic hematopoiesis that can be associated with systemic inflammatory and autoimmune diseases. The objective of this study was to describe kidney involvement in MDS patients, their treatments, and outcomes.

Method: We conducted a French and American multicenter retrospective observational study in nine centers, identifying MDS patients with acute kidney injury (AKI), chronic kidney disease (CKD), and urine abnormalities.

Results: Seventeen patients (males n = 11, median age 76 [70-79]) developed a kidney disease 6 months [0-31] after the diagnosis of MDS. Median urinary protein to creatinine ratio was 1.93g/g [0.8-3.3], and median serum creatinine was 3.5mg/dL [1.5-4.7]. Twelve patients (70%) had AKI at presentation, and a kidney disease 6 months [0-31] after the diagnosis of MDS. Median urinary protein to creatinine ratio was 1.93g/g [0.8-3.3], and median serum creatinine was 3.5mg/dL [1.5-4.7].

Conclusion: The spectrum of kidney injuries associated with MDS is mostly represented by vasculitis, and especially ANCA vasculitis. A diagnosis of ANCA vasculitis in an elderly patient, or with a cutaneous manifestation, or without ANCA positivity, should lead to the search for a possible MDS.

MESENCHYMAL STEM CELLS FOR THE TREATMENT OF SYSTEMIC LUPUS ERYTHEMatosus WITH NEPHRITIS

Lina Zaripova1, Akerke Dildabekova2, Fariza Mendibe3, Aliazamalmatov4, Nurayya Krivoruchko5, Nurzhamal Imanbayeva1 and Saltanat Tuganbekova2

1National Scientific Medical Center, Astana, Kazakhstan and 2Astana Medical University, Astana, Kazakhstan

Background and Aims: Systemic lupus erythematosus (SLE) is a chronic multisystem autoimmune disease of unknown aetiology affecting various organs and tissues. In the last decade, alternative therapeutic methods for SLE refractory to immunosuppressive therapy have been actively studied. Of interest are the data of transplantation of mesenchymal stem cells (MSCs) that demonstrated immunomodulatory properties, as well as the ability to self-renewal and multi-lineage differentiation.

Objective: to evaluate the efficacy and safety of MSCs in patients with severe refractory SLE.

Method: The search was conducted on PubMed and Google Scholar platforms using the following strategy: “Systemic lupus erythematosus” plus “Mesenchymal stem cells”. All articles presented in these domains published before 01.12.2022 in the format of case reports, clinical studies, clinical trials, multicentre studies were analysed. The effectiveness of MSCs was evaluated using the systemic lupus erythematosus activity index SELENA-SLEDAI, renal functional parameters (daily proteinuria, creatinine, glomerular filtration rate (GFR), and serum albumin), immunological parameters (anti-nuclear antibodies (ANA), anti-double-stranded DNA (anti-dsDNA)). The safety assessment included registration of various adverse events during and after transplantation.

Results: A total of 201 publications were retrieved for the period from 2000-2022, and 24 records about MSCs treatment in SLE patients met the above criteria and were included in the study. The analysed publications included data on the transplantation of MSCs obtained from various biological sources such as bone marrow, adipose tissue, and umbilical cord. In total, the results of MSCs transplantations in 806 patients were analysed. The average age of patients was 30.5±8.53 years old (from 12 to 62 years). The results obtained suggested that there was a significant decrease in the activity of SLE: 2.5-fold reduce in SELENA-SLEDAI score after 12 months (from 12.43±3.06 to 5.02±2.12). Anti-dsDNA titer dropped from 99.05±477.86 to 227.65±130.76. Some research also revealed decrease in ANA titer from 309.6±412.75 to 187.8±146.60. The improvement of kidney function was assessed by the 2.17-fold reduction of daily proteinuria from 2.48±0.66 to 1.14±0.56 g/l and an increase in GFR from 66.84±42.2 to 83.25±44.90 ml/min.

Conclusion: According to the analysis of currently available research data MSCs demonstrated a significant therapeutic effect in SLE with kidney injury: the decrease in the activity index SELENA-SLEDAI, the improvement in kidney function and the decrease in immunological indicators. According to the data from follow-up studies there were no serious adverse events, or tumor-related effects after MSCs transplantation in SLE patients.
the prognosis of this group of patients. Plasmic score have been shown to predict severe ADAMTS-13 deficiency; however, its role as a prognostic factor of CO in TMA-13n is unknown.

**Method:** We retrospectively evaluate the potential factors associated with the risk of CO. Patients diagnosed with TMA-13n (defined by microangiopathic anemia, thrombocytopenia, organ damage and ADAMTS-13 activity ≥ 10%) from January 2008 to May 2018 in our centre were included in the study.

**Results:** Forty-two consecutive patients were included. Mean (SD) age: 42 (20) years. Twenty-five (60%) were females. Mean (SD) ADAMTS-13 activity: 69 (24%). Twenty-six (62%) patients required dialysis at admission. Nineteen (45%) met CO (10 patients died). Higher age, lower lactate dehydrogenase, PLASMIC score values ≤ 4, neuroradiological damage and early eculizumab use [median (IQR): 4 (0-16) days from hospital admission: 5] were factors associated with the risk for developing CO. Only three factors were independently associated with CO mortality by logistic regression: early use of eculizumab (OR: 0.14; 95% CI: 0.02-0.94) and neuroradiological damage (OR: 6.67; 95% CI: 1.12-39.80) and PLASMIC score ≤ 4 (OR: 7.39; 95% CI: 1.18-46.11).

**Conclusion:** In TMA-13n patients, neuroradiological damage, low PLASMIC score and early use of eculizumab were independent prognostic factors of death and chronic renal replacement therapy requirements.

**#3512 GLOMERULOPATHIES DURING PREGNANCY: A TEN-YEAR SINGLE CENTER EXPERIENCE**

Estela Nogueira 1, Rita Afonso 2, Iolanda Godinho 1, Mónica Centeno 1, Luisa Pinto 1 and José António Lopes 1

1 Centro Hospitalar Universitário Lisboa Norte, EPE, Nephrology and Renal Transplantation, Lisbon, Portugal. 2 University Hospital Center of Algarve, Faro, Portugal. 3 Centro Hospitalar Universitário Lisboa Norte, EPE, Obstetric, Gynecology and Reproductive Medicine Department, Lisbon, Portugal

**Background and Aims:** Literature regarding pregnancy management and outcomes in women with glomerulopathies is still sparse. Specific guidelines for each glomerulopathy are still lacking which impairs a more homogeneous approach. The authors describe the multidisciplinary approach and the outcomes of pregnant women with primary and genetic glomerulopathies.

**Method:** Retrospective observational study in which the authors reviewed maternal, obstetric and perinatal outcomes in pregnant women with primary and genetic glomerulopathies surveilled at our nephro-obstetric clinic from 2011 to 2021.

**Results:** We evaluated 23 gestations in 20 patients (two pregnancies still ongoing). Mean age was 32.4 ± 5.4 years (18-41). 17 women were caucasian, 3 black African, 10/23 nulliparous and 5/20 had chronic hypertension. Mean baseline SCr was 0.8 ± 0.3mg/dl (0.5-1.8) and proteinuria was 1360 ± 2199.6 mg/day (150-8615), with 13/6/2 patients being on CKD stage 1/2/3, before pregnancy, respectively (unknown in 2 patients). The most frequent CKD etiologies were IgA nephropathy (6/20), Focal Segmental Glomerulosclerosis (FSGS; 3/20) and Membranous nephropathy (2/20). Exposure to teratogenic etiologies were IgA nephropathy (6/20), Focal Segmental Glomerulosclerosis (FSGS; 3/20) and Membranous nephropathy (2/20). Exposure to teratogenic

**Conclusion:** In our series, glomerulopathies with proteinuria or nephrotic syndrome were not associated with poor renal and perinatal outcome, with only one patient developing PE and renal function deterioration, probably associated to with CKD stage 3. In patients with nephrotic syndrome, immunosuppression with calcineurin inhibitor and low dose prednisone was associated with complete or partial remission in all patients.

---

**#4323 A RARE CASE OF MEMBRANOUS NEPHROPATHY AS THE INITIAL PRESENTATION OF SJÖGREN SYNDROME**

Harinarasudan Natarajan 1, Bibi Maryam 1, Aditya Shrikhande 1 and Zahid B. Ahmad 2

1 University of Oklahoma Medical Center, Oklahoma City, United States of America and 2 University of Oklahoma Medical Center, Nephrology, Oklahoma City, United States of America

**Introduction:** Primary Sjögren’s syndrome (pSS) is an autoimmune disorder characterized by lymphocytic infiltrates in exocrine glands, most commonly manifesting as dry eyes and mouth. Even though extra glomerular involvement can occur in Sjögren, renal involvement is rare. It affects less than 10% of the patient population, with tubulointerstitial nephritis being the usual presentation. Glomerular involvement and, in particular, membranous nephropathy are not commonly encountered. We describe a rare case of membranous nephropathy as the initial presentation of Primary Sjögren’s syndrome.

**Case history:** A 21-year-old female with a history of sickle cell trait presented to our emergency department with one week history of anasarca. Vital signs were unremarkable, and the physical exam was significant for a 2+ pitting edema of bilateral upper and lower extremities. Initial investigation revealed acute kidney injury (Creatinine 2.9 mg/dl from normal baseline), nephrotic range proteinuria of 6 grams on 24-hour urine collection, and hypoalbuminemia (serum albumin 1.5 mg/dl). Immunological workup showed positive ANA (speckled), strongly positive anti-SSA, borderline elevated anti-SR, negative anti-PLA2R, negative cryoglobulins, negative anti-dsDNA, and negative anti-Smith antibody (Figure 1). Renal biopsy (Figure 2) revealed membranous nephropathy with acute tubular necrosis (ATN). PLA2R staining was negative. We attributed acute kidney injury to ATN and proteinuria to membranous nephropathy. Negative serologies and renal biopsy findings ruled out systemic Lupus. The patient was therefore diagnosed with membranous nephropathy secondary to pSS. The patient was started on Mycophenolate mofetil and steroid taper with an improvement of proteinuria and anasarca and currently follows at our clinic.

**Discussion:** Glomerular involvement is rare, and when involved, it is membranoproliferative glomerulonephritis (MPGN) associated with B-cell activation and positive cryoglobulins. Membranous nephropathy is rare with primary Sjögren syndrome. In our patient, a negative anti-PLA2R goes against primary membranous nephropathy. A negative anti-dsDNA and anti-Smith and biopsy findings essentially rule out Lupus nephritis, leaving Sjögren induced secondary membranous nephropathy as the most likely diagnosis. A literature search revealed few described cases of membranous nephropathy as the presenting feature of pSS with later development of sicca symptoms and progression of renal disease to MPGN. Interestingly, our patient had no sicca symptoms at the presentation time. Occult salivary gland involvement has been described in some of these patients; however, our patient deferred salivary gland biopsy. The management of renal disease in pSS has yet to be well described because of its rarity. Rituximab has shown the most benefit in patients with pSS who have positive cryoglobulins and associated MPGN. Steroids and mycophenolate mofetil (MMF) are other possible agents that can be tried. Given that experience, we started on steroids and MMF with an excellent response to treatment indicated by improvement in proteinuria.

**Conclusion:** This case adds to the limited available literature on membranous nephropathy as the initial manifestation of pSS. Although the European Alliance of Associations for Rheumatology (EULAR) criteria strongly emphasizes sicca symptoms and glandular involvement in pSS, the possibility of a small subset of pSS patients who present with early renal involvement with latent glandular findings needs to be recognized.
OLD BIOPSY IS ALWAYS GOLD, REVISITING MEMBRANOPROLIFERATIVE GN DIAGNOSIS IN A RENAL TRANSPLANT PATIENT
Nihal Bashir1, Suhail Abdullah2 and Ahmad Chaaban3
1Seha Kidney Care, Nephrology, AlAin, United Arab Emirates, 2United Arab Emirates University, Pathology, Alain, United Arab Emirates and 3Seha Kidney Care, Nephrology, Alain, United Arab Emirates

Background and Aims: MPGN resulting from hepatitis C virus (HCV) infection typically shows granular deposition of immunoglobulin M (IgM), C3, and both kappa and lambda light chains. Immunoglobulin G (IgG) may or may not be present, and C1q is typically negative, the same pathology can be found in other viral infections. The recurrence rate post-transplantation is high, with 33% of immune-complex MPGN. Graft loss is even higher 65%, especially among patients with idiopathic MPGN. Treatment of a patient with significant proteinuria can be tricky, as no proven treatment is described yet, but plasmapheresis and induction with cyclophosphamide were described for heavy proteinuria >3.5 g/day.

Method: 79 year old female patient, known case of live unrelated renal transplantation in December 2013, primary renal disease is unknown. She had a history of equivocal hepatitis C virus antibodies, but Hepatitis C virus RNA was not detected. She is also known to have Type II Diabetes Mellitus and hypertension. The patient had baseline creatinine of 100-120 micromol/L. 24 hr urine protein was 0.8 g/Day but started rising quickly to reach a peak of 9.2 g/g seven months post-transplantation to nephrotic range proteinuria but her serum albumin level was always above 35 g/L. Serum protein electrophoresis showed no M band, a kappa/ Lambda ratio 1.21 within a normal range (0.260-1.65). Anti- nuclear antibody (ANA), P-ANCA, C-ANCA, and Double-stranded DNA all were negative. Complements were within normal range C3 1.39 g/L (0.79 -1.52), C4 0.44 g/L(0.17-0.57) rheumatoid factor and Anti- citrullinated peptide antibodies were negative. Hepatitis b Virus surface antigen and core antibodies were not reactive, HIV screening was negative. Urine analysis showed RBCs but no RBC casts. Renal biopsy showed mild mesangial expansion and mild l increase in mesangial cells and matrix. Some glomeruli show increased lobulation with increase in mesangial cells and matrix with segmental endocapillary proliferation There is double contour of the glomerular basement membrane with scattered spikes and holes within the basement membrane seen best with silver stain. There is mild increase in the thickness of glomerular basement membrane. There is focal mild lymphocytic infiltration. Tubulitis is not seen in the examined material. One Focal area of mild interstitial fibrosis. Sampled blood vessels are unremarkable. The stain for C4d is negative. Immunofluorescence showed granular capillary wall immunoreactivity to IgM (+2), C4 (+1), C1q (+1), and Lambda light chain (+2). The glomeruli show no immunoreactivity to IgG, IgA, C3, Kappa and fibrin. The glomeruli show (+) staining for albumin. Tubular protein reabsorption droplets showed immunoreactivity for albumin, IgG, IgM, C3, kappa and lambda light chains. Electron microscopy showed many subendothelial, and mesangial electron-dense deposits. The patient was on maintenance immunosuppression medications inform of mycophenolic acid 720 mg, cyclosporine; 250mg BID, and Prednisolone 5 mg daily.Revisiting the new classification of membranoproliferative glomerulonephritis is challenging in this patient, since there is the dominance of IgM deposition by immunofluorescence and C4 but not C3 makes it challenging, the negative monoclonal band in serum electrophoresis and negative autoimmune workup excludes immune complex mediate MPGN, leave idiopathic MPGN a possibility,
keeping in mind that hepatitis C virus infection was never confirmed. On the other hand, IF showed IgM with C4 subendothelial and mesangial dense deposits that excludes away the C4 glomerulopathy.

**Results:** Whether this is a recurrence of glomerular disease early on post-transplantation or denovo membranoproliferative disease, she responded well to the addition of losartan 100 mg daily, with a reduction of her urinary protein to less than 1 g/g: the patient never received treatment for the hepatitis C virus.

**Conclusion:** In our patient, it is difficult to conclude if the cause of MPGN is recurrence or denovo GN, especially with severe proteinuria that responded well to ACEi treatment. The pathological findings can be tricky.

**HYPOCOMPLEMENTEMIA AT DIAGNOSIS OF ANCA-ASSOCIATED VASCULITIS IS ASSOCIATED WITH SEVERITY AND OUTCOMES**

Maria Lanau, Loretto Fernandez Lorente, Mario Perez Arnedo and Joaquin Manrique

Hospital Universitario de Navarra, Nephrology, Pamplona, Spain

**Background and Aims:** A relationship between antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and complement has been shown, and complement has an important role in the pathogenesis of AAV [1]. Low serum complement levels (sC3) at diagnosis of AAV has been previously described although clinical characteristics and outcomes of AAV with hypocomplementemia still remain unclear [2]. The aim of this study was to investigate what proportion of patients with AAV have low sC3 at diagnosis, and whether they have different clinical and histological features or experience different outcomes compared to patients with normal sC3.

**Method:** A total of 93 patients with AAV diagnosed (81.3% Anti-MPO and 18.7% anti-PR3) were included in the study from 2000-2022. 12% of them had sC3 values below limit of normal range (i.e., <90 mg/dl). Patients were categorized according to sC3 levels into 2 groups, hypocomplementemic (G1; mean C3: 73.1mg/dl) and normocomplementemic (G2; mean C3: 123.3mg/dl).

**Conclusion:** Based on the Berden score and correlated with clinical features, main outcomes of interest included severity of acute kidney injury at diagnosis (AKI), histopathological patterns, end-stage kidney disease (ESKD) and death in the long term.

**REFERENCES**

assess the prognosis. The aim of this work was to evaluate the prognostic value of this anatomopathological classification.

**Method:** We conducted a single-center retrospective descriptive and analytical study of patients diagnosed with histologically confirmed GAA in our Nephrology Department during the period from 2016 to 2022.

**Results:** We collected 20 patients, median age 52 years (21-77 years). The sex ratio (M/F) was 0.8. Histological confirmation of GAA was based on renal biopsies in 100% of cases. Rapidly progressive glomerulonephritis was the nephrological presentation in 15 patients. One patient had no hematuria and one had no proteinuria and renal failure was present in all cases. Good Pasture syndrome was present in 7 cases. The Berden classification was applied to the renal biopsies: the focal form (2 cases), the cellular form (7 cases), the mixed form (7 cases) and the sclerotic form (4 cases). The evolution was marked by a partial remission for 11 patients. After an evolution of 1 year, end-stage renal failure (ESRD) was retained in 13 patients. The sclerotic form was not associated with a poor prognosis in our population (p = 0.642).

**Conclusion:** Of course, our sample size was small and in our population we found a predominance of the mixed and cellular forms compared to the sclerotic form, contrasting with poor therapy with a rapid evolution towards CKD.

**Background and Aims:** The present study aims to describe the clinical presentation and outcome of SARS-CoV2 infection in patients with systemic lupus erythematosus (SLE) and renal involvement (LN).

**Method:** 82 patients with biopsy-proven LN were retrospectively studied. 56 (68.3%) had a positive test for SARS-CoV2 at some point during the follow-up time and were compared with 26 patients with SLE patients who had LN but were not infected with SARS-CoV2 in order to compare the impact of SARS-CoV2 infection in the outcome of LN. Patients who had reached end-stage kidney disease before infection were excluded. Biopsy data, treatment, outcome of LN, clinical presentation of SARS-CoV2 infection and outcome were recorded.

**Results:** The mean age of the patients was 33 (±12.7) years and 85.3% were females. In the histopathological diagnosis there was proliferative LN in 43 (76.8%) cases. All patients had received immunosuppressive therapy and 89.2% had achieved remission of LN. 66.1% of patients were treated with immunosuppressive agent at the time of diagnosis of the SARS-CoV2 infection. 96.4% of patients were tested due to symptoms while gradually all of the patients became symptomatic. 5 (9.01%) of patients required hospitalization mainly due to hypoxemia. 11 (19.6%) of patients received specific treatment for SARS-CoV2 infection, 91.6% of patients experienced complete recovery, 2 (3.57%) experienced prolonged symptomatology, and 1 (1.78%) died. 10.9% of patients with SARS-CoV2 infection, who were in remission before infection, experienced a relapse of LN in a mean time of 2.7 ± 2.1 months after the infection, while none of the patients without SARS-CoV2 infection relapsed in the same time period (p = 0.09).

**Conclusion:** SARS-CoV2 infection affects the morbidity of patients with SLE who have renal involvement and possibly the likelihood of relapse in those who have achieved remission prior to infection.

**GLOMERULAR LESIONS IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME**

Daniela Valentinova Monova1, Todor Todorov2 and Simeon Monov3

1Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria, 2Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria and 3Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria

**Background and Aims:** Antiphospholipid syndrome (APS) is a complex autoimmune systemic disease, characterized by the presence of circulating antibodies directed against anionic phospholipids and the protein bound to them (aPL), leading to recurrent thrombosis and/or obstetrical complications. Renal manifestation of antiphospholipid syndrome conform a wide spectrum of disease renal syndrome. APS nephropathy (APSN) is considered a renal small-vessels vasculopathy, that can present acutely or chronically. The aim of the study is to identify glomerular lesions in patients with APSN.

**Method:** We studied retrospectively 114 patients (51 male, 63 female; age between 19 and 58 years; duration of follow-up was between 2 and 16 years) fulfilling classification criteria for APS. Renal and extra-renal symptoms were analyzed. None of the patients developed SLE in follow up. 18 patients with evidence of renal involvement underwent renal biopsy. All cases had proteinuria and five of them presented nephrotic syndrome.

**Results:** Of 18 patients with kidney biopsy, 8 (44.4%) were male and 10 (55.6%) - female. Four of patients with renal biopsy had membranous glomerulonephritis, two had diffuse proliferative glomerulonephritis, 2 - mesangial C3 nephropathy, 2 - minimal change disease, 1- focal segmental glomerulosclerosis, the other seven had classic pathologic findings consistent with APSN. Chronic lesions with fibrous intimal hyperplasia being the most common. Thrombotic microangiopathy (TMA) in glomeruli was characterized by fibrin thrombi without inflammatory cells or immune complexes. Double contour of the glomerular basement membrane was associated with mesangiolysis and endothelial cell swelling in 5 patients with APSN. Electron microscopy confirmed subendothelial edema. Segmental glomerulosclerosis was observed in 4 patients. Tubulointerstitial was injured with interstitial fibrosis and tubular atrophy. Patients with APS and renal involvement were older (p < 0.05), had LA positive test (p < 0.005) and low complement levels (p < 0.05). Hypertension is present in all cases with APSN, reduced glomerular filtration rate – in 4. All cases had proteinuria and five of them presented with nephrotic syndrome. Microscopic hematuria is observed in 4 patients. The treatment of APSN includes standard anticoagulant treatment for APS, inhibitors of the angiotensin system in patients with hypertension and proteinuria, steroids, intravenous immunoglobulin, cyclophosphamide and azathioprine.

**Conclusion:** Of 18 patients with kidney biopsy, 8 (44.4%) were male and 10 (55.6%) - female. Four of patients with renal biopsy had membranous glomerulonephritis, two had diffuse proliferative glomerulonephritis, 2 - mesangial C3 nephropathy, 2 - minimal change disease, 1- focal segmental glomerulosclerosis, the other seven had classic pathologic findings consistent with APSN. Chronic lesions with fibrous intimal hyperplasia being the most common. Thrombotic microangiopathy (TMA) in glomeruli was characterized by fibrin thrombi without inflammatory cells or immune complexes. Double contour of the glomerular basement membrane was associated with mesangiolysis and endothelial cell swelling in 5 patients with APSN. Electron microscopy confirmed subendothelial edema. Segmental glomerulosclerosis was observed in 4 patients. Tubulointerstitial was injured with interstitial fibrosis and tubular atrophy. Patients with APS and renal involvement were older (p < 0.05), had LA positive test (p < 0.005) and low complement levels (p < 0.05). Hypertension is present in all cases with APSN, reduced glomerular filtration rate – in 4. All cases had proteinuria and five of them presented with nephrotic syndrome. Microscopic hematuria is observed in 4 patients. The treatment of APSN includes standard anticoagulant treatment for APS, inhibitors of the angiotensin system in patients with hypertension and proteinuria, steroids, intravenous immunoglobulin, cyclophosphamide and azathioprine.

**DOUBLE GLOMERULOPATHY OF THIN BASEMENT MEMBRANE DISEASE AND IGA NEPHROPATHY PRESENTING WITH NEPHROTIC SYNDROME IN AN ADULT WOMAN**

Johannes Kepler Polito1 and Erastothenes Polito3

1Perpetual Succour Hospital, Internal Medicine, Cebu, Philippines and 2The Perpetual Succour Hospital, Internal Medicine, Section of Adult Nephrology, Cebu, Philippines

**Background and Aims:** We report a case of a 44-year-old woman with no known comorbid conditions who, eventually was diagnosed to have simultaneous occurrence of IgA nephropathy and thin basement membrane disease atypically presenting with heavy proteinuria, hypoalbuminemia, bipedal edema, ascites, bilateral pleural effusion, and hemodynamic instability, but with a surprisingly normal light microscopic findings and an Oxford MEST score of 0 on renal biopsy who, clinically improved with immunosuppression and angiotensin II receptor blocker therapy. Physical exam revealed an
overweight female, with facial swelling, no rash, periorbital and a Grade II "p" bidental pitting edema. The presence of decreased breath sounds and dullness on percussion on both lower lung fields were also observed. Shifting dullness and fluid wave on abdominal exam. The patient was afebrile, no desaturation at room air and a palpatory blood pressure of 70 mmHg. Secondary causes of glomerulonephritis such as Hepatitis B and Hepatitis C infection were ruled out. Antinuclear antibody (ANA) test, compliment (C3 and C4) with anti-dsDNA determination to rule out SLE were unremarkable as well. Serum creatinine was elevated at 2.63 with estimated GFR of 22 mL/min. Further work-up with 24-hour total urine protein was 22,026.2 grams/day. The patient underwent percutaneous kidney biopsy which showed IgA Nephropathy with a MEST C score of 0 with simultaneous occurrence of thin basement membrane disease.

Method/Treatment: Pulse steroid therapy was started with Methylprednisone 1 gram intravenous infusion once daily for 3 days followed with Prednisone (1mg/kg/day) 60 mg a day and a low-dose of Angiotensin receptor blocker, Candesartan, 4mg once daily for the proteinuria.

Results: After 8 weeks of corticosteroid and ARB therapy, patient was seen at the clinic with resolution of bidental edema, no demonstrable ascites and clear breath sounds on chest and lungs auscultation. Blood pressure was 130/80 with no proteinuria on dipstick, random urine protein: creatinine ratio (UPCR)
of 0.07, creatinine of 0.97 mg/dl and BUN of 17 mg/dl. Prednisone was then reduced with the goal to taper the dose for a period of 6 months. 

**Conclusion/Significance:** Both IgA nephropathy and thin basement membrane disease usually present with hematuria, hypertension, and varying degrees of proteinuria. However, nephrotic syndrome as its presentation has not been well characterized to date, and whether this adds to the mortality is not yet established. Although the most widely accepted system, the Oxford MEST-C scores is utilized in predicting renal outcomes, its role in double glomerulopathies has not been validated. Even though many investigators have indicated that the presence of heavy proteinuria at the initial evaluations was almost always associated with progressive renal failure and that there is no effective medical treatment aside from supportive care, in this study, a trial of immunosuppression yielded improved clinical outcomes.
#3564

**DIAGNOSTIC AND PROGNOSTIC SIGNIFICANCE OF INTERLEUKIN-6 IN LUPUS NEPHRITIS**

Deba Kar and Bishwa Mohanty

IMS & Sum Hospital, Nephrology, Bhubaneswar, India

**Background and Aims:** Lupus nephritis is a frequent and potentially serious complication of SLE. The present study is aimed to evaluate the usefulness of urinary IL-6 as a non-invasive diagnostic & prognostic biomarkers of disease activity in LN.

**Method:** The study was done in IMS and Sum hospital, Bhubaneswar, India from January, 2018 to July 2022. The study included 20 healthy controls and 32 patients of SLE diagnosed based of Systemic Lupus International Collaborating Clinic (SLICC) criteria, who presented with renal involvement. The exclusion criteria was inability to obtain informed consent and SLE patients without renal involvement. Urinary IL-6 levels were assessed in patients before initiation of therapy and in controls by quantitative sandwich EASIA technique using human IL-6 EASIA kit (DIA Source Belgium). All patients underwent ultrasound guided renal biopsy and the results were classified according to the ISN/RPS classification of LN. Treatment was started in all patients according to class of LN as per KDIGO guidelines. Urinary IL-6 levels were again assessed in all patients after 6 months of induction phase treatment.

**Results:** In our 32 patients, female to male ratio was 7:1 with a mean age of 28.68 ± 9.28 years. In our study, ANA was positive in 96.8%, anti-dsDNA Ab in 78%, C3 was low in 78% & C4 was low in 72% of LN patients. Based on renal biopsy findings, there were 2 cases of Class II LN, 6 cases of Class III LN, 19 cases of Class IV LN and 5 cases of Class V LN. In our study, patients with LN have significantly higher urinary IL-6 levels (301.58 ± 483.96 pg/ml) as compared to 20 healthy controls (4.7 ± 2.282 pg/ml) with a p-value of 0.001. The mean urinary IL-6 levels in different ISN/RPS classes of LN patients based on renal biopsy showed a statistically significant difference between different classes (p-value = 0.005). Highest values of urinary IL-6 (473.126 ± 580.90 pg/ml) was seen in Class-IV LN which is most active form of LN and lowest values (28.28 ± 7.30pg/ml) were seen in Class-IILN. In our study, a significant correlation was found between serum creatinine & presence of active urinary sediment with urinary IL-6 levels but there was no correlation between 24 hour urinary protein with urinary IL-6 levels in patients of LN (p = 0.799). In our study 2 patients (6.25%) died, 3 patients (9.37%) lost follow up, 16 patients (50%) achieved complete remission, 8 patients (25%) achieved partial remission and 3 patients (9.37%) did not show any improvement after 6 months treatment. Urinary IL-6 levels were near normal among 12 patients (75%) out of 16 patients who achieved remission after 6 months of induction treatment (p-value = 0.001). Urinary IL-6 levels remained elevated in all 8 patients (100%) who achieved partial remission (p-value = 0.028, and also remained elevated in all 3 patients who had no remission at all (p-value = 0.109).

**Conclusion:** Urinary IL-6 may provide a simple non-invasive potential biomarker of disease activity of renal involvement in patients with SLE and may be used to monitor therapy.

**#3041 DNAJB9 POSITIVE PRIMARY FIBRILLARY GLOMERULONEPHRITIS: TREATMENT WITH CORTICOSTEROID PULSES EXPERIENCE**

Diana Oleas
Consorti Sanitari de Terrassa, Nephrology, Barcelona, Spain

**Background and Aims:** Fibrillar glomerulonephritis (FGN) is a rare histological pattern. Electron microscopy is needed for diagnostic confirmation where predominantly mesangial fibrils are observed. To support the diagnosis, DNAJB9 is a biomarker that is 100% sensitive and 100% specific for FGN. To date, there is no defined therapeutic approach. Various immunosuppressants have been implemented to treat FGN showing poor renal response and approximately 50% progression to chronic kidney disease.

**Method:** Ambispective observational study. A protocol based on a bibliographic review was developed. The protocol included an induction therapy with methylprednisolone pulses (MTP), 300 mg a day for three days. Followed by oral prednisone at a dose of one mg/kg with an individual titration period considering the clinical evolution. Demographic, clinical, and pathological variables were extracted from the electronic health record.

**Results:** Case 1. Seventy-eight-year-old female. History of arterial hypertension (HT) treated with an angiotensin-converting enzyme inhibitor (ACEI). She debuted with a nephrotic syndrome characterized by proteinuria of 15 grams/day, hyperalbuminemia, and altered kidney function with creatinine (Cr) of 2.7 mg/dL. Secondary causes were rule out. The kidney biopsy showed mesangial expansion with mesangial deposition of IgG and C3 on the immunofluorescence. Congo red was negative. Positivity for DNAJB9 was observed. The electron microscopy (EM) showed 20-nanometer fibrils in the mesangium. The patient was initiated on the treatment protocol with a subsequent reduction of prednisone over a period of 24 weeks. Complete remission, defined as proteinuria <0.5g/day and reduction >50% of Cr was achieved after 20 weeks of treatment. Case 2. Forty-seven-year-old female with a history of hypertension treated with ACEI. The patient presented with proteinuria 3.5g/d with a normal kidney function. Secondary causes were rule out. The kidney biopsy showed mesangial thickening with IgG, C3, C1q, Kappa, and lambda positivity on immunofluorescence. Congo red was negative. DNAJB9 was positive. An electron microscopy study showed randomly arranged mesangial fibrils. The treatment protocol was started. Prednisone was titrated over a period of 20 weeks. Partial remission was observed, defined by >50% reduction of proteinuria. Kidney function remained preserved.

**Conclusion:** Induction treatment based on steroid pulses followed by prednisone titration in patients with FGN with predominantly mesangial remission was associated with a substantial reduction of proteinuria and stabilization of kidney function.

**#5891 REPEAT RENAL BIOPSIES IN ADULT LUPUS NEPHRITIS PATIENTS**

Zakia Majd, Rania Afifi, Najoua Mikdam, Nawal Mitoui Chkaari, Salma El Khayat, Mohamed Ali Zamd, Ghislaine Medkouri and M Benghanem
CHU Ibn Roch, Nephrology, Casablanca, Morocco

**Background and Aims:** The role of repeat renal biopsy in lupus nephritis (LN) to guide treatment or predict prognosis has been controversial. The objective of this work is to evaluate the causes were requiring the use of a second renal biopsy, as well as to describe the histological results and the therapeutic management according to the results.

**Method:** This is a descriptive retrospective study, covering 450 renal biopsy performed between January 1, 2020 and December 31, 2022 at the nephrology department of the Casablanca University Hospital. The patients were selected from the kidney biopsy register.

**Results:** Thirty patients followed for lupus nephritis had benefited from a 2nd renal biopsy. The average age of our patients was 36.4 years with a sex ratio of 0.8. The average time from first to second biopsy was 2.1 years. The indications for a second renal biopsy was included a suspected flare (76.6%), of which had worsening proteinuria with or without rising serum creatinine (90%), or lack of treatment response (23.4%). Twenty-two patients (73.3%) had proliferative class on their first renal biopsy. When comparing first and second renal biopsy, 26 patients (86.6%) switched histological classes. When categorized as proliferative versus non-proliferative, 21 (95.4%) patients with proliferative class on the first biopsy remained similar on the second biopsy. The mean chronicity index (CI) was significantly different for 10 consecutive biopsies with worsening CI noted with increased number of renal flares. 11 patients (36.6%) required intensification in immunosuppressive therapy after the second renal biopsy whereas 3 patients (10%) experienced a reduction in immunosuppression. 16 patients (53.3%) did not experience any change in immunosuppression.

**Conclusion:** A 2nd renal biopsy was justified in most cases, making it possible to establish a precise diagnosis, to identify the evolution of the histological lesions, and to guide the therapeutic management.

**#6260 PREDICTING KIDNEY FUNCTION AND END-STAGE KIDNEY DISEASE IN ANCA-ASSOCIATED VASCULITIS USING ANCA, C-REACTIVE PROTEIN AND C3**

Patricia Domingues1, António Silva Inácio1, Ana Piedade1, Ricardo Verde1, Jesuina Duarte2, Patricia Valério Santos1, Karina Soto1 and Liliana Cunha1
1Centro Hospitalar de Setúbal, Nephrology, Setúbal, Portugal and 2Centro Hospitalar de Setúbal, Pathology, Setúbal, Portugal

**Background and Aims:** Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are systemic autoimmune diseases that involve small- and medium-sized blood vessels. AAV compromises the overall survival of patients, and its kidney involvement can lead to end-stage kidney disease (ESKD). Our aim was to determine whether the serum C3, C-reactive protein (CRP) and ANCA levels could predict kidney survival.

**Method:** We retrospectively reviewed patients with AAV and kidney involvement (n = 62) from 2006 to 2022. Demographic, clinical and laboratory data were collected. Patients’ ANCA title were measured by ELISA, and Glomerular Filtration Rate (GFR) was estimate by CKD-EPI equation. ANCA, C3 and CRP were measure at diagnosis, remission, and last follow-up. ANCA was analyzed as continuous and categorical variable. We analyzed factors associated with dialysis dependency at diagnosis and evolution to ESKD. Multivariable adjusted Cox regression analysis was performed for assessing predictive variables associated with dialysis outcome.

**Results:** The cohort included 62 total patients, with median age of 69 (63-77) years old, 44% were female, 35.5% (n = 22) presented with alveolar haemorrhage, 82.3% (n = 51) were MPO-ANCA+ and 4 patients had concomitant anti-GBM+. At admission, the median ANCA title was 80.5 UI/mL (36.75-112.25), C3 was 108.5 mg/dL (90-130.25) and CRP 7.5 mg/dL (2.14-14.34). The GFR was 11.7±11.6 at admission and 24% of patients required dialysis at admission (n = 15). At 3 months 30% (n = 19) required dialysis, 10% at 6 months (n = 6) and 5% at 1 year (n = 3). The median time until dialysis was 488.98 (0-5702) days. Twenty (32.3%) patients died during the study period. The title of ANCA at admission, as categorical variable, did not associate with requirement of kidney replacement therapy during follow-up (p = 0.523). Considering C3 and CRP, only low C3 at last follow-up correlates with ESKD (p = 0.028). Median C3 at last follow-up was 91.5 mg/dL (79.5-107) in ESKD patients and 114.5 mg/dL (92-142.75) in patients that do not require dialysis. In a multivariate analysis, including age and gender, C3 levels at last follow-up lost significance to predict time until ESKD (p = 0.083, model p = 0.005). Initial GFR was not correlated with ANCA title at admission (r = 0.220, p = 0.205) nor as a categorical variable (p = 0.592). At remission, GFR was not correlated with ANCA title (r = 0.383, p = 0.349). Considering factors associated with the need for dialysis at admission, only CRP levels at admission were significantly significant.
higher (p = 0.035) in those who required dialysis. ANCA title and C3 at admission did not correlate with dialysis at admission (p = 0.875, p = 0.702). In multivariate analysis, including age and gender, CRP maintain its significance (p = 0.036, model p = 0.044).

Conclusion: C3 and CRP levels have been studied as possible factors predicting kidney survival, however, results are not consistent. CRP is a marker of inflammation and C3 represents complement activity, these serological markers could be important to identify patients at risk for ESKD. In our study CRP levels seems to be related to dialysis requirement at admission. These patients should be followed more closely and carefully to improve kidney survival.

#6470

PATIENT SURVIVAL IN AN ASSOCIATED VASCULITIS COHORT – DATA FROM A REFERRER CENTER

Matija Crnogora1, Patricia Kacinar1, Luka Toric1, Dino Kasumovic1, Ana Zivic1, Miroslav Tlšjar1, Danica Galesič Ljubanović3, Kresimir Galesić1 and Ivica Horvatić1

1Dubrava Clinical hospital, Department of nephrology and dialysis, Zagreb, Croatia. 2Galway university hospital, Department of internal medicine, Galway, Ireland and 3Dubrava Clinical hospital, Department of clinical pathology, Zagreb, Croatia

Background and Aims: Patients with ANCA associated vasculitis (AAV) have variable survival rates depending on disease activity, complications and sometimes the choice of treatment. Still today there are a lot of differences between various cohorts regardless of similarities in clinical presentation, serology or histology. Understanding risk factors for various outcomes in cohorts from different geographical areas might help build better and more uniform prediction models. We present data on patient survival from our referrer center.

Method: This study included 106 consecutive AAV patients with biopsy proven renal involvement in the period from 2007-2017. We analyzed clinical, laboratory and pathohistological data as predictors for death of the patients. Survival univariate analysis was performed using Kaplan-Meier method and log-rank (Mantel-Cox) test. Variables that had p<0.1 in univariate analysis were alongside age and gender included in multivariate Cox proportional hazard model.

Results: The study included 106 AAV patients with renal involvement: 66 (61.1%) MPA, 20 (18.5%) GPA, 20 (18.5%) RLV. There were 14 (13%) PR3-ANCA positive patients, 57 (52.8%) MPO ANCA positive, 5 (4.6%) PR3-ANCA+MPO-ANCA and 32 (29.6%) ANCA negative patients. Average SCr was 316.5 μmol/l (IQR 207.0-548.5), 24-hour proteinuria median was 1,7g/24h (IQR 0.8-2.8). Histologically (Berden classification) 43 (39.8%) patients had crescentic, 19 (17.6%) focal, 34 (31.5%) mixed and 12 (11.1%) sclerotic class. Follow up time was 1 to 127 months with median 21 months (IQR = 7 - 44) and medium follow up time of 28.6 months (SD = 26.6). All the patients recieved the same induction treatment (cyclophosphamide and glucocorticoids +/- acute haemodialysis and plasma exchange treatment) and remission maintenance treatment (azathioprine). During the follow up 21 patient (19.8%) died. Out of those 13 were females. Main causes of death were either infections or cardiovascular diseases. In follow up period patient survival was 83.9,81.2,79-74,7% at 12-24-36-60 months. There were no differences in survival rates between clinical, histological or serological phenotypes. In univariate analysis significant predictors for death of patients were: age (>68 years; p = 0.002), anaemia (Haemoglobin <96 g/l; p = 0.001), increased CRP levels (CRP > 63mg/l; p = 0.001), lower serum C3 levels (p = 0.001), BVAS > 18 (p = 0.003) and the need for dialysis (p = 0.06). In multivariate analysis however significant predictors for the death of patients were age (HR = 1.059, 95% CI = 1.001-1.120; p = 0.046), anaemia (HR = 0.952, 95% CI = 0.908-0.998; p = 0.040) and BVAS (HR = 1.093, 95% CI = 1.030-1.159; p = 0.003).

Interestingly in additional analysis PLEX was, alongside acute haemodialysis, significant predictor in combined ESRD/death outcome (as well as for ESRD and relapse rate) but not for death alone.

Conclusion: In our data disease activity as defined by BVAS and anaemia alongside the patient age are predictors for the patient survival. Anaemia is not included either in BVAS or in other disease activity scores or prediction models. Considering its potential impact on multiple organ functions perhaps anaemia levels should be included either in BVAS or perhaps in VDI though anaemia itself is mostly not autoimmune phenomenon in AAV patients. Also in our cohort PLEX wasn’t a significant predictor for patient survival.

MPO ANCA-ASSOCIATED VASCULITIS IN A PATIENT WITH A HISTORY OF METHAMPHETAMINE ABUSE

Jesús Alejandro Rico Sánchez1 and Yuliana López Arreguin2

1General Hospital No. 50 IMSS, Nephrology, San Luis Potosi, Mexico and 2General Hospital No. 50 IMSS, Internal Medicine, San Luis Potosi, Mexico

Background and Aims: Methamphetamines cause kidney damage by different mechanisms. The most common is the tubular lesion associated with myoglobinuria secondary to rhabdomyolysis. Other renal effects include prerenal azotemia, acute tubular necrosis, malignant hypertension, and necrotizing vasculitis have been reported. It is important to consider this drug as a possible cause of glomerulonephritis.

Method: We present the case report of a patient with suspected MPO ANCA-associated vasculitis from methamphetamines.

Results: A 24-year-old male, he was admitted to nephrology due to hematuria and proteinuria accompanied by serum creatinine elevation (2.5 mg/dl). He reported inhaled methamphetamine abuse since the age of 14, smoking and occasional ethylism. His symptoms began in October 2022 with asthenia and anemia, accompanied by generalized pallor and edema in both malleoli. At admission with normal blood pressure (112/70 mmHg), Laboratory tests revealed: leukocytes 6.35 thousand/UL, hemoglobin 7.7 g/dl, platelets 698,000 thousand/UL, urea 70.81 mg/dl, sodium 137 mmol/L, potassium 4.72 mmol/L, albumin 3.85 g/dl, urine test with proteinuria 25 mg/dl, hemoglobinuria 250 eri/microl. Leukocytes 15-20 field and countless erythrocytes, albuminuria 450.87 mg/day, globular sedimentation rate 18 mm/hr, reactive protein C 37 mg/L. Complement levels were normal, negative serologies for hepatitis B, C, human immunodeficiency viruses, antinuclear antibodies, double-stranded anti DNA and anti-proteinase 3, but was positive for IgG anti myeloperoxidase (anti-MPO) 33.6 U/ml. Urinary sediment showed the presence of dysmorphic erythrocytes, as well as abundant erytrocyte and granular casts. Ultrasound-guided renal biopsy was performed; light microscopy reported 21 glomeruli, 6 globally sclerosed, 4 with irregular segmental sclerosis, 4 with destruction and granuloma formation. Immunofluorescence showed traces of mesangial IgM, the rest negative for IgG, IgA, C3, C1q, fibrinogen, kappa and lambda. The patient received 3 pulses of methylprednisolone 300 mg followed by oral prednisone and rituximab. Baseline creatinine decreased to 1.88 mg/dl.

Conclusion: Inhaled methamphetamine is commonly used in young people, it is important to consider this drug as a possible cause of crescentic and necrotizing glomerulonephritis.
Urinary sediment shows erythrocyte cast, light microscopy 40x

Urinary sediment shows granular cast, light microscopy 40x
KIDNEY INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS
Daniela Valentinova Monova1, Todor Todorov2 and Simeon Monov2
1Medical Institute, Medical University - Sofia, Department of Internal Medicine, Sofia, Bulgaria, 2Medical University - Sofia, Department of General and Clinical Pathology, Sofia, Bulgaria and 3Medical University - Sofia, Department of Rheumatology, Sofia, Bulgaria

Background and Aims: In rheumatoid arthritis (RA) kidney is commonly affected organ with clinical presentation characterized by proteinuria and microalbuminuria, followed by chronic renal failure. RA is associated with reduced kidney function, possibly due to chronic inflammation or the use of nephrotoxic therapies. Renal diseases occurring in patients with RA may have a variable clinicopathological picture. Little is known about the effects of using the novel biological agents on the risk of kidney diseases.

The aim of this study was to determine the relationship between effect of therapy and kidney involvement in patients with RA and evaluated the histopathological findings and associated clinical manifestation.

Method: In this retrospective study 275 patients with diagnosis of RA were included. In 48 patients renal biopsy was performed. The patients were divided in three groups according to changes in management of RA: 1991-2001, 2002-2011 and 2012-2022 year. Data of demographic characteristics, clinical symptoms and pathological diagnosis were extracted from medical records and pathological reports.

Results: In our study amyloidosis was the most common histologic pattern, followed by chronic glomerulonephritis (GN) and tubulointerstitial nephritis. Renal amyloidosis was diagnosed in 13 patients, membranous GN – in 9, mesangio proliferative GN – in 7 patients, focal segmental necrotizing GN – in 5, focal segmental sclerosis – in 4, minimal change disease – in 3, tubulointerstitial nephritis – in 7 patients. Between 1991 and 2001 year the most common clinical manifestation was nephrotic syndrome and the most common histopathological findings – renal amyloidosis, followed by...
membranous GN and focal segmental necrotizing GN. The membranous GN was the leading cause of kidney disease between 2002–2011 years and focal segmental sclerosis – between 2012–2022. In our study 68 patients had a decrease of glomerular filtration rate (GFR) < 60 mL/min/m². No kidney biopsies were performed in these cases because no urine abnormalities were detected. We found that age, duration of the disease, arterial hypertension, C-reactive protein were significant risk factors for disease, arterial hypertension, C-reactive protein were significant risk factors for

Conclusion: In all patients with RA, renal function should be monitored and in the case of pathologic results, renal biopsy should be performed. In RA patients with renal disorder, suspected causal drug should be removed from the treatment and specific immunosuppressive therapy initiated. Improved pain management associated with biologic treatment may help to reduce the need for potentially nephrotoxic anti-inflammatory agents such as NSAIDs and certain types of non-biologic DMARDs, which could consequently reduce the risk of drug-induced nephrotoxicity and thereby contribute to the lower risk of renal diseases.

SPONTANEOUS REMISSION OF MEMBRANOUS VARIANT OF PGNMID WITH MONOCLONAL IgG2κ

Hui Zhan Tan1, Alwin Hwai Liang Loh3, Chee Woon Tan1 and Jason Choo1

1 Singapore General Hospital, Department of Renal Medicine, Singapore, Singapore and 2 Singapore General Hospital, Department of Anatomical Pathology, Singapore, Singapore

Background and Aims: The clinical significance of the morphological patterns of glomerular injury and each IgG subclass in proliferative glomerulonephritis (GN) with monoclonal immunoglobulin deposits (PGNMID) is not well understood. Literature suggests that PGNMID with certain histological features such as membranous or mesangio-proliferative features or non-IgG3 subclass staining may be associated with a more favourable renal prognosis. We present a patient with membranous variant of PGNMID with monoclonal IgG2κ who had spontaneous remission without recurrence over a 2-year follow-up.

Method: Not applicable

Results: A 62-year-old Malay gentleman presented with new onset nephrotic range proteinuria, on a background of type 2 diabetes mellitus with diabetic duration of 5 years, hypertension and hyperlipidaemia. He was mildly hypertensive (blood pressure 148/87) and non-edematous at presentation. Investigations revealed preserved kidney function [serum creatinine (sCr) 66μmol/L], bland urinalysis, and 24-hour urinary total protein (UPT) of 3.74g/day. Serum albumin (sAlb) was 35g/L. Serum complements were not low. Autoimmune markers inclusive of anti-double stranded DNA antibodies, anti-neutrophil cytoplasmic antibodies, and anti-phospholipase A2 receptor (PLA2R) antibodies were negative. Viral serologies were also unremarkable. No monoclonal band was detected on serum electrophoresis, while serum immunofixation was not performed. Kidneys were normal sized. Renal biopsy performed demonstrated 28 glomeruli, of which only 1 was globally sclerosed. Glomeruli capillary walls were diffusely thickened by vacuolations. Capillary loops were mostly single contoured although occasional focal double contouring was seen. Masson trichome stain revealed fuchsinophilic subepithelial immune deposits while periodic acid methenamine silver stain showed argyrophilic basement membrane spikes. Variable mesangial expansion and hypercellularity was observed, as well as mesangiolysis. Focal leucocyte margination was present, but significant endocapillary proliferation was not seen. There were no Kimmelstiel-Wilson lesions. Tubular atrophy with interstitial fibrosis was overall mild (10% of parenchymal area) and there were no tubulointerstitial infiltrates. Immunofluorescence showed granular staining of IgG (1-2+), C3 (2-3+) along glomerular capillary walls, as well as presence of kappa light chain restriction (k 1-2+; λ negative in glomeruli). Immunostaining for PLA2R was negative. IgG subclass analysis performed in view of kappa light chain restriction revealed isolated deposition of IgG2κ. Electron microscopy was not available. Overall findings were most consistent with membranous variant of PGNMID with monoclonal IgG2κ. Age-appropriate and symptom-directed malignancy screening did not reveal significant abnormalities. Given that the patient was minimally symptomatic, a trial of conservative therapy was initiated with optimized non-immunosuppressive anti-proteinuric therapy using renin-angiotensin-aldosterone and sodium-glucose co-transporter-2 inhibitors. Gradual spontaneous remission was observed without recurrence over 2 years of follow-up (sCr 77μmol/L; sAlb 40g/L; 24-hour UPT 0.22g/day).

Conclusion: Our case adds to the literature that a membranous variant of PGNMID with monoclonal IgG2κ may be associated with better renal outcomes. Despite the lack of proliferative changes, it is possible that membranous variants may share similar underlying disease mechanisms as the other proliferative variants. Large international registries to allow the correlation of morphological features and IgG subclasses with clinical outcomes are required to confirm our observation.

#2885

DYNAMICS OF URINARY SYNDROME IN PATIENTS WITH CHRONIC GLOMERULONEPHRITIS DEPENDING ON THE USE OF ANTICOAGULANT

Asalya Abduvakhtinta

Tashkent Pediatric Medical Institute, Internal Disease, Nephrology and Hemodialysis, Tashkent, Uzbekistan

Background and Aims: to study the dynamics of urinary syndrome in patients with chronic glomerulonephritis (CGN) against the background of the use of rivaroxaban.

Method: 108 patients with chronic glomerulonephritis (CGN), on the background of 3-month basic therapy with the inclusion of anti-coagulant rivaroxaban 55 patients and without anti-coagulant 53 patient. Initially and after 3 months, the composition of the urinary sediment was assessed.

Results: Patients with CGN had significant proteinuria (3.2±0.12g/l versus 0.01±0.004 control group (CG), p<0.001), hematuria (42.58±2.10 erythrocytes in the field of vision, against 0.75±0.25 cells in the field of vision, p<0.001), leukocyturia (38.25±0.80 leukocytes in the field of vision, against 1.70±0.24 cells in the field of view in CG, p<0.001) and cylindruria (38.11±1.04 cylinders in the field of view, versus 0.10±0.07 cylinders in the field of view in CG, p<0.001). Albuminuria contributed to an increase in the specific gravity of urine (1021.64±0.44 g/l versus 1017.45±0.65g/l in CG, p<0.001). By the end of the hospitalization period, there was a significant improvement in urinary syndrome: the relative dynamics of urinary syndrome indicators was more than 30%. Thus, the degree of proteinuria decreased to 1.98±0.10 g/l (p<0.001 the reliability of the difference with the initial data), hematuria – to 26.38±1.43 cells in the field of vision (p<0.001), leukocyturia – to 22.04±0.88 cells in the field of vision (p<0.001), cylindruria – to 25.45±0.79 cylinders in the field of view (p<0.001). Against the background of a decrease in proteinuria and diuretic therapy, there was a decrease in the specific density of urine by 0.73% (up to 1014.15 ± 0.45g/L, reliability with baseline data - p<0.001).

Conclusion: Rivaroxaban is an effective oral anticoagulant, the long – term use of which as part of the basic therapy of patients with CGN is safe, well tolerated and pathogenetically justified. The inclusion of rivaroxaban in the basic therapy of patients with CGN is associated with the achievement of more favorable values of proteinuria, hematuria and leukocyturia by the end of the 3rd month of therapy.

#3412

THE THROMBOTIC EVENTS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS: A RETROSPECTIVE COHORT STUDY AND MENDELIAN RANDOMIZATION ANALYSIS

Xin Chen, Shuo Zhang, Ruilian You, Peng Xia, Xiaoxiao Shi, Wuhai Ting, Yu-Bing Wen, Yan Qin and Limeng Chen

Peking Union Medical College Hospital, Nephrology, Dongcheng-qi, PR. China

Background and Aims: Thrombotic event in ANCA-associated vasculitis (AAV) was prevalent but not clarified in the causal relationship between AAV and thrombotic events. We tried to identify the clinical characteristics and risk factors of thrombotic events in a large sample-size retrospective cohort and investigate the causal relationship by Mendelian randomization (MR) analysis.

Method: In this retrospective, observational study, all hospitalized AAV patients were included in a single-center tertiary hospital in China from Jan 2013 to April 2022. Clinical data were collected for multivariate regression analysis to determine the risk factors of thrombotic events. As for MR analysis, we selected single nucleotide polymorphisms (SNPs) related to AAV from published genome-wide association studies. The outcome data containing deep vein thrombosis (DVT) and pulmonary embolism (PE) were extracted from the UK biobank. The inverse variance weighted (IVW) method and weighted median (WM) were performed in MR analysis.

Results: A total of 1203 primary AAV patients were enrolled, with 11.3% developing thrombotic events, with the average age of 49 (ranging from 43.75 to 59.75), and males occupied 36.3%. AAV patients with thrombosis were older (>65 years, 44.9% vs. 29.9%, P<0.001) and with more commodities

Abstracts
like chronic kidney disease (CKD, 22.8%) or artery disease (CAD, 11.8%). The thrombotic incidences were more common in eosinophilic granulomatosis with polyangiitis (EGPA, 19.5%), with prolonged hospitalization without significant difference in hospital mortality. Multivariate regression suggested that age over 65 years (OR = 1.574, P = 0.029), EGPA (OR = 3.686, P = 0.029), elevated D-dimer (>2 mg/L, OR = 7.119, P < 0.001), and end-stage renal disease (ESRD) status were associated with thrombosis events in patients with AAV. In addition, MR analysis showed that EGPA could increase the risk of developing DVT and PE (OR = 1.0038, 95% CI = 1.0035-1.0041, P = 0.009).

Conclusion: Thrombotic events were not rare in Chinese patients with AAV with independent risk factors such as highly elevated D-dimer and EGPA, which served as a causal risk factor for DVT and PE.

LARGE B CELL RENAL INFILTRATION IN A PATIENT WITH WALDESTRÖM MACROGLOBULINEMIA: A CASE REPORT
Federica Allegretta1, Campolo Gesualdo2, Olivieri Antonella1, Sarah Ercoletti1, Marco Allinovi3, Leonardo Caroti3, Giulia Antognoli3, Raffaella Santi4, Luca Novelli4 and Fiammetta Ravaglia2

1Università degli Studi di Firenze, Scienza Biomediche Sperimentali e Cliniche “Mario Serio”, Firenze, Italy, 2Nuovo Ospedale di Prato - S. Stefano, Nefrologia, Dialisi e Trapianti, Prato, Italy, 3Careggi University Hospital, Nefrologia, Dialisi e Trapianti, Firenze, Italy and 4Careggi University Hospital, Istologia Patologica e Diagnostica Molecolare, Firenze, Italy

Background and Aims: Waldeström Macroglobulinemia (WM) is a clinicopathologic entity demonstrating lymphoplasmacytic lymphoma (LPL) in the bone marrow with an IgM monoclonal gammopathy in the blood. Only 15% of patients with WM may develop a renal insufficiency due to either glomerular or tubulointerstitial pathologies. Most common findings include deposits of IgM in the glomerular basement membrane and infiltration of lymphocytes or plasmacytoid cells; light chain cast nephropathy; nephrotic syndrome led by AL amyloid deposition; immune-mediated glomerulonephritis (typically due to IgM deposition or cryoglobulinemia) and non-amyloid nephrotic syndrome (minimal change-like). Moreover, WM may evolve in hematological malignancies with renal localization. Therefore, a renal biopsy may be needed in patients who have recent unexplained renal dysfunction.

Method: A 72-year-old male with a history of WM is referred to our nephrology center for declining renal function. He had been diagnosed with Waldemström Macroglobulinemia IgM Kappa 4 years prior to presentation, at onset serum protein electrophoresis showed an M spike of 4900. After diagnosis confirmation, he underwent treatment with 6 cycles of rituximab and bendamustine resulting in a complete response and M spike at serum protein electrophoresis lowering to 23. At WM diagnosis his renal function was normal, he had no proteinuria nor urinary Bence-Jones. His medical background also included hypertension and diabetes mellitus type 2, both in good pharmacologic control and Sars-Cov2 infection. Two years later, we witnessed to progressive presentation of anemia, fatigue and cough along with hepatomegaly, axillary lymphomegaly, pulmonary basal thickenings and IgM levels elevation. Serum creatinine was 1.47 mg/dl, proteinuria 1.75 g/die, no urinary Bence-Jones proteinuria. A renal ultrasound showed poor corticomedullary differentiation in both kidneys and a left kidney slightly bigger than the other one. Respiratory symptoms and pulmonary thickenings persisted after antibiotics therapy, also cytology and culturing exams performed on broncho-alveolar lavage resulted negative. To exclude a possible relapse of WM, a BOM and a lymphnodal mass biopsy were performed. Both exams showed no disease progression. Due to lack of WM progression, the patient is referred to renal biopsy execution.

Results: Renal biopsy showed morpho-phenotypic findings for localization of mainly large B peripheral cells, partial plasmocytic differentiation and high proliferation levels. Further exams revealed a double monoclonal component IgM Kappa with normal Kappa/Lambda, also a total Body TC was performed, and it evidenced a possible renal and pulmonary lymphoproliferative disease involvement. In the figure an image of the patient’s renal biopsy showing IgM immunofluorescence. Our patient is still fulfilling all the supplementary analysis needed to evaluate the best therapeutic strategies. We also reviewed all renal biopsies performed in our center in patients with hematological diseases in the last 10 years and a neoplastic renal infiltration was documented in just 6 cases out of 650 biopsies.

Conclusion: Although lymphomatous infiltration of the kidney in WM is a rare event, it should be considered in patients presenting with abnormal renal function. It is important during follow-up to monitor kidney function in patients with plasma cell dyscrasias, even if patients appear to have stable lymphoproliferative disease.

Figure 1: Renal biopsy - IgM immunofluorescence.
Background and Aims: Henoch - Schönlein purpura (HSP) is an immunemediated small-vessel vasculitis that manifests as non—thrombocytopenic purpura, arthritis or arthralgia, abdominal pain and/or kidney involvement. HSP nephritis can presented as micro- or macroscopic hematuria, proteinuria, nephrotic or nephritic syndrome, as well as acute renal failure. The aim of the study is to identify risk factors associated with unfavorable outcomes in patients with HSP nephritis.

Method: This retrospective study enrolled 68 patients with HSP nephritis. Renal and extra-renal symptoms were analyzed. A diagnosis of HSP nephritis was made when hematuria and/or proteinuria, and/or renal failure was associated with a palpable purpuric eruption or abdominal or joint pains (at least two of these three clinical signs) and predominant mesangial IgA immune deposits, confirmed by renal biopsy. The patients were subdivided into five classes according to the renal manifestation at onset of disease: 1) micro- or macroscopic hematuria; 2) mild proteinuria (<1 g/L); 3) acute nephritic syndrome, defined as moderate proteinuria, hematuria, increased serum creatinine and/or hypertension; 4) nephrotic syndrome; 5) mixed nephritic-nephrotic syndrome.

Results: Of 68 patients with HSP nephritis, diagnosed by kidney biopsy, 41 (60,29%) were male and 27 (39,71%) - female. Age of onset was between 18 and 66 years (mean 37,28 ± 9,34). Duration of follow-up was between 2 and 28 years. 29 patients had histories of infection preceding presentation. At onset all patients had palpable purpura and urinary abnormalities (only hematuria - in 16,18%; mild proteinuria ± hematuria - in 44,12%; moderate or severe proteinuria and hematuria – in 39,70%). Arthralgias were present in 49 patients (72,06%), gastrointestinal involvement – in 32 patients (47,05%). Renal function was impaired in 26,47% of patients, and 51,47% were hypertensive. Mesangial hypercellularity lesions were found in most patients (97,06%), endocapillary proliferation – in 20,58%, segmental sclerosis – in 32,35%, tubular atrophy/interstitial fibrosis – in 38,23%. Corticosteroids and cyclophosphamide were prescribed in patients who presented with severe infection, active malignancy, those with prior explosion seen at Kasturba Hospital and Medical College, Manipal. Exclusion: Patients with active/recent infection, active malignancy, those with prior explosion to immunosuppression. Outcome measures, 1. To detect correlation if any, between peripheral blood lymphocyte subset and clinical remission achieved at six months. 2. To determine correlation if any, between peripheral blood lymphocyte subset and clinical remission achieved following immunosuppressive regimens at the end of six months of initial intensive treatment phase.

Results: 22 patients were taken for study. Relationship between SLEDAI score, lymphocyte subset characters, and clinical outcome given in Table 1 and 2. There was good correlation between lymphocyte subset characters, inflammatory markers and SLEDAI score, indicating ability of lymphocyte subset characters to characterize the severity of lupus nephritis. We found significant difference in lymphocyte subset characters between baseline and at the end of 6 months treatment. But there was no significant correlation for remission attainment with lymphocyte subset characters and SLEDAI score.

Conclusion: 1. Correlation found between peripheral blood lymphocyte subset, serum inflammatory markers and disease activity score at presentation and 6 months of treatment of lupus nephritis. 2. Peripheral blood Lymphocyte subset analysis was not found useful in predicting clinical outcome in lupus nephritis at the end of 6 months of intensive treatment.
Background and Aims: Impaired renal function is one of the most relevant factors associated to crescentic glomerulonephritis (CGN) prognosis. However, renal remission has not yet been defined and clinicians are required to use systemic scores (such as BVAS) to predict severity. In this retrospective study, we aim to describe the associated factors to long-term chronic dialysis incidence and survival in CGN.

Method: We included all biopsy-proven CGN of our center between 2004 and 2022. At baseline, demographics, treatments, and comorbidities were collected. Renal function was assessed by glomerular filtration rate (GFR) using CKD-EPI equation, quantification of proteinuria and demonstration of hematuria. During follow-up (median 1486, interquartile range [25-3082] days) renal and vital status was evaluated. Factors associated to dialysis requirement were assessed using Cox regression models. A combined endpoint of death and dialysis was established. Factors associated to the combined endpoint were assessed.

Results: We included 47 CGN (77% female, 67±15 years). Of them, 35 (75%) presented positive ANCA antibodies, 8 (17%) ANCA and GBM antibodies and one (2%) presented negative autoimmunity. Induction treatment was based on prednisone and cyclophosphamide in 43 patients (91%), prednisone and rituximab in 3 (6%) and prednisone alone in one (2%). At admission, median CKD-EPI was 11 (11-21) ml/min/1.73 m², proteinuria was 1030 (552-1872) mg/g and 43 (91%) patients presented hematuria. Nineteen patients (40%) required dialysis at admission. Following the definition of KDIGO guidelines for renal remission, 28 (64%) patients achieve it at 6 months.

During follow-up, fifteen patients (36%) started chronic dialysis. Factors associated to chronic dialysis were the type on CGN (dual ANCA and GBM and GBM (+) vs ANCA (+), p = 0.003), CKD-EPI at admission (p = 0.001), AKIN (p = 0.050), requirement of dialysis at admission (p<0.001), percentage of crescents (p = 0.037), proteinuria at admission (p = 0.046) and remission after induction treatment (p<0.001). Twenty-four patients (53%) died or needed dialysis during follow-up. Factors associated to this combined endpoint were CKD-EPI at admission (p = 0.017), type on CGN (dual ANCA and GBM vs others, p = 0.003) (Figure 1), debut in dialysis (p<0.001), remission after induction treatment (p<0.001). An adjusted Cox regression model demonstrated that the need for dialysis or death during follow-up was independently associated to not achieving remission after induction (i.e. 6 months) (HR 8.78, 95%CI [2.88-26.7], p<0.001) and requirement of dialysis at debut (HR 3.96, 95%CI [1.15-13.6], p = 0.029).

Conclusion: The requirement of dialysis at debut and not achieving remission after induction are independent predictors of death or need for chronic dialysis in CGN.

**Background and Aims:** Impaired renal function is one of the most relevant factors associated to crescentic glomerulonephritis (CGN) prognosis. However, renal remission has not yet been defined and clinicians are required to use systemic scores (such as BVAS) to predict severity. In this retrospective study, we aim to describe the associated factors to long-term chronic dialysis incidence and survival in CGN.

**Method:** We included all biopsy-proven CGN of our center between 2004 and 2022. At baseline, demographics, treatments, and comorbidities were collected. Renal function was assessed by glomerular filtration rate (GFR) using CKD-EPI equation, quantification of proteinuria and demonstration of hematuria. During follow-up (median 1486, interquartile range [25-3082] days) renal and vital status was evaluated. Factors associated to dialysis requirement were assessed using Cox regression models. A combined endpoint of death and dialysis was established. Factors associated to the combined endpoint were assessed.

**Results:** We included 47 CGN (77% female, 67±15 years). Of them, 35 (75%) presented positive ANCA antibodies, 8 (17%) ANCA and GBM antibodies and one (2%) presented negative autoimmunity. Induction treatment was based on prednisone and cyclophosphamide in 43 patients (91%), prednisone and rituximab in 3 (6%) and prednisone alone in one (2%). At admission, median CKD-EPI was 11 (11-21) ml/min/1.73 m², proteinuria was 1030 (552-1872) mg/g and 43 (91%) patients presented hematuria. Nineteen patients (40%) required dialysis at admission. Following the definition of KDIGO guidelines for renal remission, 28 (64%) patients achieve it at 6 months.

During follow-up, fifteen patients (36%) started chronic dialysis. Factors associated to chronic dialysis were the type on CGN (dual ANCA and GBM and GBM (+) vs ANCA (+), p = 0.003), CKD-EPI at admission (p = 0.001), AKIN (p = 0.050), requirement of dialysis at admission (p<0.001), percentage of crescents (p = 0.037), proteinuria at admission (p = 0.046) and remission after induction treatment (p<0.001). Twenty-four patients (53%) died or needed dialysis during follow-up. Factors associated to this combined endpoint were CKD-EPI at admission (p = 0.017), type on CGN (dual ANCA and GBM vs others, p = 0.003) (Figure 1), debut in dialysis (p<0.001), remission after induction treatment (p<0.001). An adjusted Cox regression model demonstrated that the need for dialysis or death during follow-up was independently associated to not achieving remission after induction (i.e. 6 months) (HR 8.78, 95%CI [2.88-26.7], p<0.001) and requirement of dialysis at debut (HR 3.96, 95%CI [1.15-13.6], p = 0.029).

**Conclusion:** The requirement of dialysis at debut and not achieving remission after induction are independent predictors of death or need for chronic dialysis in CGN.

Figure 1: Survival plot for combined endpoint regarding serology.
Background and Aims: Belimumab (BLM) has been approved for the treatment of active systemic lupus erythematosus (SLE) and active lupus nephritis (LN). Multitarget therapy (MT) consisting of tacrolimus (FK506), mycophenolate mofetil (MMF), and steroid has been proved that can provide good curative effect as induction therapy for LN. Because of the limitations of BLM’s phase III clinical trails, the exact curative effect in severe active LN of BLM is not clear yet. To assess the safety and generate preliminary efficacy data on MT followed by BLM for severe active Chinese LN patients, a case series were investigated.

Method: Six patients with severe active LN were reported. Among the 6 patients, 2 were treated with MT followed by BLM infusions, 2 were treated with MMF / (FK506) followed by BLM infusions, and 2 were treated with MT. BLM was given 10 mg/kg every 2 weeks for 3 times, then every 4 weeks till Week 24. Primary renal response index, SLEDAI, and safety data were analyzed.

Results: The patients affected by LN ISN/RNP Class III/IV±V with high disease activity are 3 de no LN and 3 refractory LN (each regimen included 1 de no LN and 1 refractory LN). At baseline, the SLEDAI score were 15,20,17,16,15,15 respectively. 4 of the 6 patients (case 1, case 2, case 3, and case 5) accepted intravenous (IV) methylprednisolone, followed by MT/MMF/FK506 after admission. The initial oral prednisone was 30-45 mg/day. Within 2 weeks of starting treatment, IV BLM was introduced. At Week 24, the SLEDAI score decreased to 2,8,8,10,8,10 respectively. 2 patients accepted BLM and MT achieved complete renal remission, and the other 4 patients achieved partial renal remission (Fig. 1). MT and BLM therapy reduced SLEDAI more rapidly than MMF/FK 506 +BLM or MT (Fig. 2). Prednisone was reduced to 10-15 mg/d. No adverse events occurred.

Conclusion: The addition of BLM to basic immunosuppressants was effective and safe for severe active LN. The BLM and MT regimen seems to lead a faster and more pronounced remission. Further prospective clinical studies with larger samples are needed to evaluate the benefits of belimumab combined with MT in severe active LN.
Figure 2: The details of the 6 patients’ Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). The graph shows the patients’ overall scores along with the SLEDAI components with their respective weights during the treatment. 0 week is the time to start the belimumab in cases 1-4 and is the time to start therapy in cases 5-6. Case 1 and Case 2 accepted belimumab and multitarget therapy. Case 3 accepted belimumab and mycophenolate mofetil. Case 4 accepted belimumab and tacrolimus. Case 5 and Case 6 accepted multitarget therapy.

CHARACTERIZATION OF RESPONSE TO TREATMENT WITH RITUXIMAB IN PATIENTS WITH PRIMARY GLOMERULOPATIES
Roxana Bury¹, Maria Larrosa García², Bruno Montoro³, Sheila Bermejo García¹, Ander Vergara¹, Marina López¹, María José Soler Romeo¹, Anguita Danae², Sanz María¹, Martínez Monica¹ and Irene Agraz Pamplona¹

¹Vall D Hebron University Hospital, Nephrology, Barcelona, Spain, ²Vall D Hebron University Hospital, Pharmacy, Barcelona, Spain and ³Vall D Hebron University Hospital, Immunology, Barcelona, Spain

Background and Aims: Rituximab (RTX) is an anti-CD20 monoclonal antibody used in renal diseases with glomerular involvement, which usually present with proteinuria. The doses used in this pathologies are extrapolated from other diseases such as rheumatoid arthritis, but the optimal regimen in this population has not been well defined.

Objective: To describe the behavior of RITUXIMAB in patients with primary glomerulopathies in whom its use is indicated.

Method: Descriptive low-intervention single-center clinical trial approved by the Spanish Medicines Agency (NEFRX, EUDRACT 2020-000484-23). Patients treated with rituximab were included according to medical criteria, prior approval by the Pharmacy Commission. The regimen used was 1g every 15 days, or only 1gr dose with premedication according to clinical practice guidelines. 24-hour blood and urine samples were collected on days 1 (post-rituximab), 7, 15 (pre and post-rituximab), 28, and 45. Serum rituximab was determined using ELISA (Lisa-Traker®, TheraTrak®). Clinical and pharmacokinetic data analyzes were performed considering a single compartment model by non-linear regression with Winnolin® to obtain clearance (Cl), half-life (t1/2), maximum concentration (Cmax) and volume of distribution (Vd). Some quantitative results are expressed as mean ± standard deviation. Linear regression was used to establish correlations.

Results: The results of 5 patients were analyzed, 2 women and 3 men, with a mean age of 68.8 ± 17.02 years of 72 years and a diagnosis of membranous GN (3), ANCA MPO GN (1), focal and segmental GN (1). Renal function CKD EPI: GFR between 45- 60 ml/min N=2 GFR >60 ml/min N=3. According to clinical practice guidelines, patients received 1g doses, 2/5 patients received a second dose on day 15. The evaluation parameters were: proteinuria, CD19+ lymphocyte depletion, Antibodies titers and histological characteristics as appropriate. Levels of rituximab in urine samples after the rituximab administration (15, 30, 180, 365 days after) were determined. All the patients presented proteinuria, with a mean of 11 ± 14.6 g in 24 h urine.

Mean Rituximab clearance was 0.676 ± 0.431 ml/h/kg, distribution volume was 222.35 ± 140.52 mL/Kg and Cmax 69.66 ± 26.14 mcg/mL and t1/2 269.66 ± 229.71 h (11 days approximately). There is a correlation between proteinuria and rituximab half-life (p = 0.077), as well as between proteinuria and clearance creatinine (p = 0.975) suggesting that half-life of rituximab is lower if proteinuria increases (Fig. 1). All presented lymphocyte depletion of CD 19 at 45 days. However, those with more proteinuria >2.5 g (N = 3) in those 45 days, after 6 months of exposure to RTX, progressive repopulation of CD19 was observed, which persisted in the year of follow-up.

Conclusion: In patients with high proteinuria, rituximab has a t1/2 lower than the 21–28 days described in the data sheet, which may suggest that patients with nephrotic syndrome may require higher doses to ensure the effectiveness of treatment with rituximab. Repopulation of CD19 in 45 days could be a reliable indicator of non-response in patients with nephrotic proteinuria.
NEW ONSET OR RECURRENT GLOMERULONEPHRITIS FOLLOWING SARS-CoV2 VACCINATION: A MULTICENTER EXPERIENCE

Chiara Rimoldi1, Marica Gilberti2, Loreto Gesualdo2, Giulia Sossai1, Renato Alberto Sinico4, Elisa Giglio5, Marta Calatroni6, Davide Raimondo7, Beniamina Gallelli1, Lucia Del Vecchio1 and Sara Visca1

Background and Aims: In general, vaccination is a well-known trigger for the onset or recurrence of glomerulonephritis or more in general autoimmune disease. Starting from the beginning of 2021 millions of people worldwide have received a vaccination of SARS-CoV2. Over the months, several cases of glomerulonephritis with a clear temporal association with the vaccine have been described [1,2].

Method: To better understand the characteristics, pattern of presentation, temporal and qualitative association with SARS-CoV2 vaccination and outcome, we designed a retrospective, multicenter, nationwide study aimed at collecting information on new onset or recurrence of primary or secondary vaccination following SARS-CoV2 infection. We present the preliminary findings from the first seven participating centers that completed data collection. For inclusion patients needed to be ≥16 years, have either a biopsy-proven glomerulonephritis or gross haematuria without urological explanation in close relationship with the vaccine. For outcome definition, partial remission was proteinuria > 300 mg/day, complete remission proteinuria 300–3500 g/day.

Results: We report 57 cases (M/F 22/35, mean age 48.59±18.99 years, median follow-up of 11.8 months (min 1.1, max 22.5). Of these, 25 (44%) were new onset glomerulonephritis, the remaining 32 (56%) were recurrence of already known cases (1/3 in complete remission, 2/3 in partial remission). Table 1 summarises the diagnosis new-onset or recurrent glomerulonephritis. 37 (65%) were primary glomerulonephritis, the other 20 (35%) kidney involvement of systemic diseases. The most frequent diagnosis was IgA nephropathy (IgAN, n = 17, 30%), followed by lupus nephritis (n = 9, 16%) and membranous nephropathy (n = 7, 12%). Compared to recurrence, patients with new-onset glomerulonephritis had a higher prevalence of minimal change disease (4 vs 1 case), Henoch Shoenlein purpura (3 vs 0) and FSGS (2 vs 0). Conversely, in patients with recurrence, we observed a higher rate of IgAN (14 vs 3), microscopic polyangiitis (5 vs 1) and lupus nephritis (7 vs 2). Most of the cases occurred following an mRNA vaccine (n = 42, 90%). The median time of onset was of 18 days. The onset was related more to the second dose of vaccine (n = 27, 47.4%), followed by the first dose (n = 14, 25%) and then the third dose (n = 12, 21.1%), with an imbalance between new-onset vs recurrence (C2, 11.18; p = 0.011) Fig.1). The information is missing in 4 cases. Most of the patients presented with nephrotic proteinuria (n = 24, 42%). Following treatment, 15 (26.3%) patients obtained partial remission, 18 (31.6%) had complete remission and the remaining 21 (36.8%) had no response. The information is missing for 3 patients.

Conclusion: Following SARS-CoV2 vaccine, de novo or recurrent glomerulonephritis can occur. The majority of the cases were related to mRNA vaccines. However, the vaccine policy in Italy could have influenced this finding.

UTILITY OF REPEAT KIDNEY BIOPSY IN LUPUS NEPHRITIS PATIENTS: A SINGLE CENTRE EXPERIENCE
Alexandra Vornicu, Bogdan Obrisca, Alexandru Procop, Vlad Herlea, George Terinte-Balcan, Mihaela Gherghiceanu, Nicu Caceaune and Gener Ismail

Background and Aims: Given the accumulating evidence of discrepancies between the clinical features and histological lesions in lupus nephritis patients, there is an increasing need for a histology-guided approach in order to optimise the management of these patients.

Method: 13 adult patients with a diagnosis of systemic lupus erythematosus and biopsy-proven lupus nephritis, followed up in the Nephrology Department of Fundeni Clinical Institute in Bucharest, Romania from 2015 to 2022, which had undergone a repeat per-protocol biopsy at 6 months were included in this retrospective, single-centre study. The objectives of the study were to determine the evolution of the clinical and histological parameters at first and at 6-months repeat-biopsy, their possible associations and their relationship with the primary efficacy renal response (PERR) at 12 months. The National Institutes of Health activity index (AI) and chronicity index (CI) scores were assessed in all biopsies. PERR was defined as proteinuria ≤ 0.7 g/24 h and eGFR ≥ 60 ml/min/1.73 m².

Results: The median (IQR) follow-up was 20 (13.5-34) months. 53.8% were class IV lupus nephritis at the first biopsy. Repeat biopsies were performed after a median time (IQR) of 6 (6-9) months. The majority of the patients received cyclophosphamide and corticosteroids as induction regimen (69.2%) and mycophenolate mofetil and corticosteroids as maintenance regimen (92.3%). PERR was achieved in 61.5% of cases at 12 months. Proteinuria (g/24 h) decreased from the median value (IQR) of 2.3 (1.55-4.3) to 0.4 (0.2-3.1) at biopsy 2 (p 0.02), hematuria (red blood cells/μl) decreased from 33 (11.5-178.5) to 10 (1.75-62) at biopsy 2 (p 0.017) and serum creatinine decreased from 1.18 (0.81-1.48) to 0.9 (0.73-1.07) at biopsy 2 (p <0.001). Serum C3 (mg/dl) increased from 56 (41-76.5) to 103 (84-126) (p <0.001), whereas serum C4 (mg/dl) increased from 10 (4-19) to 22 (11-31) (p <0.001). AI scores decreased from 10 (8.5-13.5) to 3 (2.5-7) (p <0.001) and CI scores increased from 2 (2-3) to 3 (3-5.5) (p <0.001). At repeat biopsy, CI increased in 8 patients (61.5%). Its increase was not predicted by baseline or at the moment of repeat biopsy values of activity and chronicity indices, renal function, hematuria, proteinuria and complement fractions. The type of induction regimen used did not protect against CI increase (p 0.506). The baseline value – median (IQR) of AI (9 (6.5-14.5) vs 10.5 (9-13.75), p 0.596), CI (2 (1.5-2.5) vs 3 (2-4.5), p 0.127), serum creatinine (mg/dl)(1.18 (0.96-1.66) vs 1.03 (0.75-1.36), p 0.316), hematuria (red blood cells/μl) (78 (10.9-1086) vs 29 (7.25-111.5), p 0.622) and complement fractions C3 (mg/dl) (74 (40-104) vs 48.5 (41-71.5), p 0.33) and C4 (mg/dl) (18 (6-23.5) vs 8 (3-15.75), p 0.36) were not associated with the PERR at 12 months. The median value (IQR) of AI (3 (2.9-3.5) vs 3.5 (2.25-7), p 0.943) and CI (3 (2.5-5) vs 5 (3-5.5), p 0.42), hematuria (red blood cells/μl) (26 (2.25-85.5) vs 6.5 (1.4-48.25), p 0.35) and serum creatinine (mg/dl) (1.18 (0.89-1.12) vs 0.77 (0.7-0.9), p 0.13) at the second biopsy were also not associated with the PERR at 12 months. Proteinuria at baseline (g/24 h) (4.6 (2.37-8.1) vs 1.85 (1.16-2.6), p 0.019) and proteinuria at repeat biopsy (g/24 h) (4.6 (1.45-6.1) vs 0.23 (0.17-0.36), p 0.002) were associated with PERR at 12 months. Lower complement fraction C3 at the second biopsy (mg/dl) (123 (104-142) vs 88.5 (74.75-106.5), p 0.036) was associated with the PERR at 12 months and lower serum C4 at the second biopsy (mg/dl) (26 (21-34.5) vs 16 (7-29), p 0.082), had a trend to associate with the PERR at 12 months.
Conclusion: At the second biopsy, the chronicity index increase was not predicted by baseline or at the moment of repeat biopsy values of activity and chronicity indices, renal function, hematuria, proteinuria or the values of complement fractions. The type of induction regimen used did not protect against chronicity index increase. Proteinuria at baseline and at repeat biopsy was associated with PERR at 12 months. Lower complement fraction C3 at the second biopsy was associated with the PERR at 12 months and lower serum C4 at the second biopsy had a trend to associate with the PERR at 12 months.

ROLE OF THERAPEUTIC PLASMATHERAPY IN PAUCI-IMMUNE VASCULITIS – A SINGLE CENTRE EXPERIENCE

Nidia Marques1, Núria Lopes Figueiredo de Carvalho Paulo1, Filipa Ferreira1, Ana Nunes1, Ricardo Neto1, Edite Pereira1, Eva Mariz1 and Inês Castro Ferreiro1

1Hospital São João, Nephrology, Porto, Portugal, 2Hospital São João, Internal Medicine, Porto, Portugal and 3Hospital São João, Rheumatology, Porto, Portugal

Background and Aims: The indication for plasmapheresis (PLF) in pauci-immune vasculitis (PIV) is controversial. This study aimed to characterize the population and renal outcome of patients with PIV undergoing PLF in a hospital in the north of Portugal.

Method: We conduct a retrospective cohort study of patients followed by a multidisciplinary team, from diagnosis to death or May/22. Two groups were defined: patients undergoing PLF (group A, GA) and not undergoing PLF (group B, GB). Demographic variables, comorbidities, serological subtype, clinical presentation, histological classification and therapeutic were evaluated. Recorded outcomes were death and ESRD (end-stage renal disease) (eGFR<15 ml/min per 1.73 m², dialysis, or transplantation). Renal survival was estimated using the Kaplan-Meier analysis and differences between curves were evaluated using the log-rank test.

Results: A total of 72 patients, 26 (36.1%) in group A and 46 (63.9%) in group B were included. In both groups the most frequent serotype was myeloperoxidase (MPO) (n = 23, GA; n = 38, GB). In both groups, most patients were male (61.5% in GA and 56.5% in GB), with a mean age at admission of 64 (SD±11.5) and 66.5 years (SD±12.2) in GA and GB, respectively (p = 0.362). Most GA patients had pulmonary and renal involvement on admission (80.7%, n = 21), versus GB (36.9%, n = 17), p<0.05. Mean serum creatinine was superior in GA (7.64 mg/dl, SD ±2.75) versus GB (3.82 mg/dl, SD±2.95), p<0.05. Twenty patients from GA (76.9%) and 7 from GB (15.2%) required dialysis upon admission, p<0.05. In both groups, almost all patients underwent immunosuppression with cyclophosphamide (mean cumulative dose of 4.4 grams (SD ± 2.6) and 5.9 grams (SD ± 2.7), in GA and GB, respectively) and azathioprine in the maintenance phase, with a rapid corticosteroid weaning scheme in both phases. Median follow-up time (months) of GA and GB was 11 (IQR [4.8-37.5]) and 58.5 (IQR [14.5-92]) months. Regarding renal prognosis, 9 of 20 patients in GA and 3 of 7 patients in GB who needed dialysis on admission, partial recovery of renal function (p = 1.00). About 37% (n = 17) of patients of GB and 73% (n = 19) of patients of GA reached the composite renal outcome, with a median time of 0 (IQR 0 - 21.8) and 38.5 months (IQR 5.3-92), respectively. GA showed worse renal survival, with a mean of 30.9 months vs. 116.5 months in GB, p = 0.01. Renal survival at 2 years was 68.7% in GB and 24% at GA. Patients in both groups with admission serum creatinine ≥ 5.7 mg/dl had similar renal survival (GA 39.9 and GB 32 months, p = 0.714). Regarding the histological classification, 91.7% and 38.9% in GA and GB belonged to the crescentic class, (p = 0.009). Renal survival in the subgroup of patients with crescentic class was worse in GA (16.6±10.2 vs 83.3±16.1, p = 0.015). The analysis of the Renal Risk Score showed no statistically significant difference between the groups, and between patients with crescentic class in both groups, p = 0.274. Mortality and hospitalization rate due to infection were similar in both groups (p>0.05).

Conclusion: Patients undergoing PLF had a worse renal outcome, consistent with the higher proportion of patients with severe azotemia and requiring dialysis at admission, in a sample that was mostly ANCA MPO. As described in the literature, the experience of our centre did not demonstrate benefit in the addition of PLF, despite the limitations inherent to an observational, retrospective study and the modest sample size. A better knowledge of etiopathogenesis is essential for the optimization of the therapeutic strategy, together with the implementation of measures that allow timely referral, an early diagnosis and consequent improvement of renal prognosis.
**Results:** A total of 1227 VTE cases were identified in the hospitalized NS population and the detection rate was 1.56%. Detection rate of VTE varied significantly in patients with different pathologic types of NS. Patients with membranous nephropathy (MN) had a significantly increased risk of VTE [Odds ratio [OR] 2.11 [95% confidence interval (CI) 1.12–4.36]]. While patients with focal segmental glomerulosclerosis (FSGS) did not show a significant high risk [OR 0.93 (95% CI 0.29–2.60)] compared with minimal change disease. We also found that male [OR 1.44 (95% CI 1.15–1.80)], age [OR 1.09 (95% CI 1.02–1.17)], anemia [OR 1.50 (95% CI 1.15–1.95)], cerebral bleeding [OR 3.23 (95% CI 1.69–6.10)], respiratory tract infection [OR 2.05 (95% CI 1.60–2.63)], respiratory failure [OR 2.24 (95% CI 1.42–3.53)], use of proton pump inhibitors (PPIs) [OR 2.19 (95% CI 1.54–3.12)], use of glucocorticoids [OR 1.46 (95% CI 1.03–2.09)] and immunosuppressants [OR 1.48 (95% CI 1.14–1.93)], orthopedic operations [OR 1.97 (95% CI 1.22–3.18)], high-level D-dimer (>0.55 mg/L) [OR 2.62 (95% CI 1.87–3.65)] were associated with increased risk of VTE detection. While 24-hour urine protein quantification >10 g/d [OR 1.24 (95% CI 0.90–1.70)] showed little significant correlation with VTE. Hypertension [OR 0.74 (95% CI 0.58–0.95)] and the use of diuretics [OR 0.72 (95% CI 0.53–0.97)] were found to have a negative correlation with VTE detection.

**Conclusion:** The detection rate of VTE among patients with NS during hospitalization was 1.56%. Male, age, MN, anemia, cerebral bleeding, respiratory tract infection, respiratory failure, and use of PPIs, glucocorticoids and immunosuppressants, high D-dimer concentration were associated with VTE detection in NS. While 24-hour proteinuria did not show a significant association with VTE identification.

Results: Baseline features, treatment characteristics and outcomes were detailed in Table 1. Median follow-up duration was 36 (12-60) months. Overall, 19 patients (25.7%) experienced the study outcome over a median of 24 (6-51) months. Three patients died due to infections (n = 2) and unknown causes (n = 1) including a patient who died shortly after becoming dialysis-dependent. Median TCS was 3 (1-5). Univariate analyses showed that IF, hemoglobin, serum creatinine and serum albumin levels were associated with the outcome, but only grade 3 IF predicted the outcome in the multivariate Cox regression (HR: 6.623, 95% CI: 1.269-34.564, p = 0.025). Since the median follow-up was 36 months, separate analyses for the outcome at 3 years were conducted. IF, TA, TCS, hemoglobin, serum creatinine and albumin were associated with the outcome in univariate analyses. In a multivariate Cox regression model encompassing IF, TA, hemoglobin, serum creatinine and albumin, only hemoglobin was identified as a predictor. A second model including TCS instead of IF and TA demonstrated that TCS (HR: 1.288, 1.021-1.626, p = 0.033) and hemoglobin (HR: 0.617, 0.407-0.935, p = 0.025) predicted the study outcome. Kaplan-Meier analysis showed that 3-year kidney survival was lower in patients with TCS ≥4 (72.4%) compared to TCS <4 (91.1%) (p = 0.036 with log-rank test).

Background and Aims: The relapsing-remitting, multi-system pattern of disease in ANCA vasculitis (AAV) results in incremental tissue injury. For those with renal involvement, there is a 9-fold increased risk of end-stage kidney disease after renal relapse. Relapse is defined by the Birmingham Vasculitis Activity Score (BVASv3) >0, particularly in the clinical trial setting. However, this metric may be missing or incorrectly scored in real world registry data, resulting in incomplete or inaccurate ascertainment of this key outcome. Our aim was the development, internal validation and evaluation of a pragmatic data-driven algorithm to automate the retrospective identification of AAV relapse in real-world data.

Method: The Rare Kidney Disease (RKD) Registry is a national longitudinal, multi-centre cohort study, including 663 patients with AAV, of whom those with ≥6 months follow up post diagnosis were eligible for inclusion. We followed five steps to develop and validate the algorithm: 1) independent expert adjudication of encounters using primary medical record information to assign the reference probability of relapse (ground truth), 2) selection of data elements and corresponding value sets using literature review, expert opinion and with a consideration of likely data availability, 3) development
of a computable phenotype definition, with an embedded logistic multi-level regression model using complete case analysis, 4) internal validation, 5) development of additional models (using the same method) to account for combinations of variable missingness (models described in Fig. 1). We also developed a Shiny web application to implement the final algorithm, which determines the appropriate model based on available variables, outputting an individualised probability of relapse, with a suggested binary interpretation.

Results: In the first step of the algorithm, encounters with diagnostic histopathology were labelled as relapse. For encounters without histopathological confirmation, we selected five objective data elements to build the model: change in ANCA level, suggestive blood/urine tests, suggestive imaging, immunosuppressive (IS) status at the time of the encounter and the change of this IS in response (‘IS response’) (Fig. 2). Development and validation datasets comprised 1209 and 377 separate encounters, respectively. An optimal cut-point of 0.48 was determined by maximising the F1-Score (0.85) for the complete 5-variable model. Sensitivity and specificity were 0.91 and 0.95 respectively. Performance metrics were stable across fifty random-split resamples. Calibration-in-the-large was satisfied. Where ‘IS response’ was missing, ‘suggestive bloods/urine’ (Data Element [DE]2) with at least either ‘ANCA level’ (DE1) or ‘suggestive imaging’ (DE3) was required to achieve an accuracy as good as gold standard BVAS (Fig. 1).

Conclusion: In settings where accurate BVAS may not be available, this algorithm accurately quantifies the individualised probability of AAV relapse using objective, readily accessible registry data. In addition to our web application, the model can be directly embedded in a registry database. This framework could serve as an exemplar for other relapsing-remitting diseases and for automating the identification of other key outcomes or cohorts in registry data.
THE NATURAL HISTORY OF IGA NEPHROPATHY IN THE GERMAN CHRONIC KIDNEY DISEASE (GCKD) COHORT

Eleni Stamellou1, Jennifer Nadal2, Claudia Seikrit3, Bruce Hendry3, Alex Mercer4, Markus Johannes Müller4, Matthias Schmidt5, Mario Schifo4, Kai-Uwe Eckardt6,7 and Jürgen Floege8

1RWTH Aachen University Hospital, Division of Nephrology and Rheumatology, Germany; 2Faculty of Medicine, University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Germany; 3Traverce Therapeutics, Inc., San Diego, United States of America; 4JAMCO, Pharma Consulting, Sweden; 5Friedrich-Alexander University Erlangen-Nuremberg, Department of Nephrology and Hypertension, Erlangen, Germany and 6Charité-Universitätsmedizin Berlin, Department of Nephrology and Critical Care Medicine, Germany.

Background and Aims: Primary IgA nephropathy (IgAN) is the most common form of glomerulonephritis and a major cause of kidney failure. Here we describe the natural history of individuals with IgAN in the German Chronic Kidney Disease (GCKD) cohort.

Method: From 2010 to 2012, 421 patients with biopsy-proven IgAN have been enrolled into the GCKD study, a prospective observational cohort study (N = 5217). Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30-60 mL/min/1.73 m² or overt proteinuria in the presence of an eGFR < 60 mL/min/1.73 m². The adjudicated composite renal endpoint (Major Adverse Kidney Events; MAKE) was defined as eGFR decline 40%, eGFR < 15 mL/min or initiation of kidney replacement therapy. The associations between the incidence of MAKE and baseline risk factors were analyzed using the Cox proportional hazards regression model. Data relating to baseline demographics, laboratory, comorbidity, and mortality were used.

Results: The mean age at baseline of IgAN patients was 51.6 years (±13.6) and 67% were male. Duration of disease at baseline was 5.9 ± 8.1 years. Baseline median UACR was 0.4 g/g (0.1-0.8) and mean eGFR was 52.5 ± 22.4 mL/min/1.73m². Over a follow-up of 6.5 years, 53 (12.6%) initiated kidney replacement therapy, 64 (15.2%) experienced eGFR decline >40%, eGFR < 15 mL/min or initiation of kidney replacement therapy. The associations between the incidence of MAKE and baseline risk factors were analyzed using the Cox proportional hazards regression model. Data relating to baseline demographics, laboratory, comorbidity, and mortality were used.

Conclusions: The GCKD study reflects a large cohort with long follow up allowing for a thorough analysis of the natural history of IgAN. More than every fourth patient experienced a MAKE event within 6.5 years. Our findings support the use of albuminuria as a surrogate for poor kidney outcomes.

REFERENCES
Methods: A single-center retrospective cross-sectional study was conducted to compare the time spent on the procedure and the number of glomeruli obtained in a group using the SIGN technique (n = 81) and a group using the standard ultrasound-guided renal biopsy technique with a needle guide (n = 143). Biopsies were performed by four board-certified nephrologists of the Japanese Society of Nephrology and four fellows. It was left to the operator to decide whether to use the standard technique or the SIGN technique. In the standard technique, an operator inserted a biopsy gun through a needle guide attached to the ultrasound probe and obtained a biopsy core from the lower pole of the kidney. In the SIGN technique, after local anesthesia, an operator inserted a 17-gauge guide needle (TSK Laboratory, Tochigi, Japan) through the needle guide without making a skin incision. The guide needle was placed in the fascia of the posterior abdominal wall. Then the operator inserted a biopsy gun through the guide needle into the lower pole of the kidney and obtained the biopsy core. The puncture time was calculated by subtracting the minute of the last puncture from the first. The number of glomeruli in the specimen for light and fluorescence microscopy was counted by kidney pathologists who did not have procedural information.

Results: The proportion of fellows using the SIGN method was significantly higher than that of specialists (56.9% and 27.7%, respectively, P = 0.001). The median age of subjects in the SIGN group (58 years old) was younger than that of subjects in the standard technique group (64 years old) (P = 0.009). There was no significant difference between the two groups in gender, BMI, clinical diagnosis, kidney depth, kidney volume, eGFR, or hemoglobin level. The median puncture time in the SIGN group (2 min, IQR: 1–3 min) was significantly shorter than that in the standard technique group (3 min, IQR: 2–4 min) (P < 0.001). The number of glomeruli obtained in the SIGN group (29 ± 15) was significantly larger than that in the standard technique group (24 ± 12) (P = 0.008). The prevalence of major complications in the SIGN group (1.2%) was similar to that in the standard technique group (2.1%) (P = 1.0). Logistic regression analysis with adjustment for age, gender, BMI, kidney depth, kidney volume, and the operator's experience showed that the use of the SIGN technique was independently associated with the puncture time ≤ 2 min (odds ratio: 5.84, 95% CI 3.0–11.4). In addition, multiple linear regression analysis with adjustment for age, gender, BMI, number of punctures, use of an 11 mm stroke biopsy gun, kidney depth, kidney volume, and operator's experience showed use of SIGN method was independently associated with a significantly larger number of glomeruli to be obtained (P = 0.015).

Conclusion: Use of the SIGN technique reduces the procedure time and enables adequate biopsy tissue to be obtained with complication rates comparable to those of the standard technique regardless of the operator's experience. Since the biopsy procedures in the current study were performed by multiple nephrologists, including fellows, the SIGN technique can be applied in a nephrology training program and can be used as the standard biopsy procedure.

INCREASED RISK OF CARDIOVASCULAR DISEASE PRECEDING DIAGNOSIS OF INCIDENT ANCA-ASSOCIATED VASCULITIS: A DANISH NATIONWIDE STUDY

Louis Ngaarda Pedersen 1, Christoffer Polcwiartek 2, Karl-Emil Nelvey-Kristensen 1, Nicholas Carlson 3, Salome Kristensen 1, Christian Torp 4 and Jon Waarst Gregersen 1

1 Aalborg University Hospital, Center for SLE and Vasculitis, Aalborg, Denmark, 2 Aalborg University Hospital, Department of Cardiology, Aalborg, Denmark, 3 Copenhagen University Hospital, Rigshospitalet, Department of Nephrology, Kobenhavn, Denmark and 4 North Zealand Hospital - Hillerød, Department of Cardiology, Hillerød, Denmark

Background and Aims: ANCA-associated vasculitis (AAV) is associated with an increased risk of cardiovascular disease (CVD). The risk of CVD seems to be increased shortly after initial diagnosis as well as in the long-term setting. However, no studies have addressed the risk of CVD in the period preceding an AAV diagnosis. Since the diagnosis of AAV often is associated with a substantial diagnostic delay, we hypothesize that patients with AAV consistently are at an increased risk of developing CVD already before they even are diagnosed with AAV.

Method: Using a nested case-control framework, patients with AAV were identified through the Danish Nationwide Registries from 1996-2021 and matched 1:3 with age- and sex-matched controls without AAV. Each control was assigned the same index date (date of AAV-diagnosis) as their corresponding case. Conditional logistic regression was used to compute age, sex and comorbidity adjusted Hazard Ratios (HRs) for major adverse cardiovascular events (MACE), ischemic heart disease, heart failure, venous thromboembolism, atrial fibrillation, ischemic stroke, pericarditis, and ventricular arrhythmias/ICD-implantation/cardiac arrest (VA/ICD/CA) within 12 months, 6 months, 3 months, 2 months and 1 month before the index date.

Results: A total of 2371 patients with AAV (median age: 63 yrs, 53.7% male) were matched with 7113 controls. In patients with AAV, 10.33% had a cardiovascular outcome within 12 months preceding diagnosis as compared to 3.84% of controls (HR 3.05 [95% CI, 2.48–3.75]). The associated risk of cardiovascular outcomes was similarly increased in the temporal proximity of the diagnosis, with the highest HR at 1 month prior to index date (HR 10.73 [95% CI, 7.05–16.32], Fig. 1). In individual analysis, a significantly higher HR was observed for all outcomes (excluding VA/ICD/CA), Fig. 2.

Conclusion: AAV disease is associated with an increased risk of CVD in the months preceding diagnosis, which underlines the importance of early clinical vigilance toward CVD starting in the diagnostic phase of AAV.
Figure 1: Conditional logistic regression of the association between AAV and having any cardiovascular outcome in close proximity to AAV diagnosis. Any cardiovascular outcome was defined as having either ischemic heart disease, acute myocardial infarction/percutaneous coronary intervention/coronary-artery bypass graft surgery, coronary angiogram, heart failure, venous thromboembolism, atrial fibrillation, ischemic stroke, pericarditis, VA/ICD/CA, or any combination thereof. HRs were adjusted for age, sex, chronic kidney disease, hypertension, hyperlipidemia, peripheral artery disease, diabetes, chronic obstructive pulmonary disease, malignancies, chronic liver disease and a previous history of cardiovascular disease.

Figure 2: Logarithmic radar chart of cardiovascular outcomes expressed as HRs of the association between AAV, and cardiovascular outcomes compared to age- and sex-matched controls preceding AAV diagnosis. HRs are adjusted for age, sex, and comorbidities. HRs of pericarditis and venous thromboembolism are not available at 1 month preceding index date, due to no events in the control group. MI, myocardial infarction, PCI, Percutaneous coronary intervention; CAGB, Coronary artery bypass graft surgery, VA/ICD/CA, ventricular arrhythmia and/or implantable cardioverter-defibrillator and/or in-hospital cardiac arrest with subsequent recirculation.

THERAPEUTIC AND PROGNOSTIC IMPACT OF KIDNEY BIOPSY FINDINGS IN PATIENTS AGED 80 YEARS AND OLDER: A MULTICENTER RETROSPECTIVE COHORT STUDY (KB-OLD)
Aghiles Hamroun, Rémi Lenain, Paul Nicolazzi, Sébastien Gomis, Mehdi Maanaoui, Jean-Baptiste Gibier and Francois Glowacki
Lille University, Lille University Hospital Center, Nephrology, France

Background and Aims: The great phenotypic heterogeneity in the presentation of kidney diseases makes the diagnostic strategy all the more complex in the elderly. While kidney biopsy should play a pivotal role, its non-negligible risk of bleeding complications (2-5% in the general population) justifies a certain reluctance to its application in the elderly. To date, however, there is little data on the benefit-risk ratio of kidney biopsy in the elderly. Most of these studies have focused on a relatively young population (60-70 years old) and on a limited number of patients. Concerning patients aged 80 years and older, very few studies have described the real therapeutic influence of kidney biopsy findings with regard to the rate of complications. Moreover, none of these studies have evaluated the long-term prognostic impact of therapeutic changes induced by the results of the kidney biopsy. The main objectives of this study are to describe the indications, diagnoses, complication rate, therapeutic influence and the prognostic impact of a change in therapeutic management after native kidney biopsies performed in patients aged 80 years and older.

Method: The KB-Old study (Kidney Biopsy for Old) is a retrospective multicenter cohort that consecutively included all patients aged 80 years and older who underwent percutaneous native kidney biopsy in 17 centers in the northern region of France, between 2010 and 2020. Clinical, biological and anatomopathological data as well as post-biopsy follow-up (therapeutic strategy, occurrence of complications) were collected from medical records. All pathology examinations were analyzed centrally by a team of experienced nephropathologists. Events of death or kidney failure were identified by specific registry cross-linking. To analyze the prognostic impact of therapeutic management following kidney biopsy (either initiation of a specific treatment or simple nephroprotection) on the risk of kidney failure and death, we performed Cox models weighted by propensity score (Inverse Probability of Treatment Weighting - IPTW-) in the population potentially eligible for treatment (exclusion of diseases without specific treatment). The areas under Kaplan Meier curves were calculated up to 6 years of follow-up (Restricted Mean Survival Time - RMST) and compared according to the initiation of a specific treatment after the kidney biopsy. This study was approved by Institutional Review Board (#AUG-20-707).

Results: Overall, the cohort included 453 patients (54% men, median age 83 years), half of whom underwent biopsy in the context of acute kidney injury (median serum creatinine level 3.0 mg/dl). The main diagnoses were nephroangiosclerosis (15%), renal involvement of hematological malignancies (13%), acute tubulointerstitial nephritis (12%) and vasculitis (10%). The complication rate was approximately 10%, with only 2.8% of serious complications requiring therapeutic intervention (mostly transfusion). The kidney biopsy identified a disease potentially accessible to a specific treatment in 73% of cases. After exclusion of patients with ineligible diseases, a specific treatment was initiated in about one out of two cases (163/332, 49%). After weighting on propensity score, the two treatment groups were globally balanced. A beneficial effect of treatment on dialysis-free survival was observed (HR = 0.51 [0.28-0.92], p = 0.02), without any major influence on mortality (Figure 1). Over a 6-year follow-up period, there was a gain in dialysis-free survival in the treated group estimated by the delta RMST at +10.46 months [3.39 - 17.54] compared with the untreated group (p = 0.004), with no difference in overall life expectancy.

Conclusion: To the best of our knowledge, this is the largest multicenter cohort of patients aged 80 years and over who have undergone kidney biopsy. It seems to confirm the interest and safety of this examination for specific indications, and a potentially important benefit on the prognosis when it leads to an adapted therapeutic management.

Figure 1: Dialysis-free survival and mortality by treatment group (weighted Kaplan Meier curves).
#3618

CLINICAL SIGNIFICANCE OF MILD ABNORMALITIES IN GLOMERULAR FILTRATION BARRIER (GBM) DIAGNOSED BY RENAL BIOPSY

Julee You and Ho Jun Chin

1Seoul National University Bundang Hospital, Seongnam-si, Rep. of South Korea and 2Seoul National University College of Medicine, Seoul, Rep. of South Korea

Background and Aims: The well-known GBM abnormalities without immunological reaction are Alport syndrome (ALPORT) and thin basement membrane disease (TMD). Two diseases occasionally share common genetic abnormalities, although, clinical outcomes are worse in ALPORT. Sometimes, there are also mild abnormalities of GBM unable to be classified into ALPORT or TMD without any immunological or hemodynamical abnormalities in the kidney. We compared clinical and pathologic findings among ALPORT, TMD, and GBM abnormalities not classified (GBM NOS) diagnosed by renal biopsy.

Method: Among 18,134 adult patients who underwent kidney biopsy from 1979 to 2018 in 17 hospitals in Korea (number of IRB: B1707/408-106), we selected patients with ALPORT, TMD, or GBM NOS diagnosed by renal biopsy. GBM NOS was defined as any abnormality of GBM structure of lamellation, thickness, and integrity by electron microscopic examination, which are not able to classify into specific pathologic diagnosis. We excluded ALPORT, TMD, and GBM NOS combined to the other pathologic diagnosis or showing electron dense deposit. We collected clinicopathologic findings at renal biopsy and the last visit to clinics and incidences of mortality and end stage renal disease during follow-up period.

Results: There were 179 (0.99%) TMDs, 33 (0.18%) ALPORTs, and 8 (0.04%) GBM NOSs among all patients. The clinicopathologic findings were presented in Table 1. Age and gender proportion at renal biopsy were not different among groups. Patients with ALPORT showed the lowest level of estimated glomerular filtration rate by MDRD equation (eGFR) ($p<0.001$) and the highest level of urine protein to creatinine ratio (UPCR) ($p<0.001$). Patients with GBM NOS had similar levels of eGFR and UPCR compared to patients with TMD at renal biopsy. Under microscopic examinations, segmental sclerosis in glomeruli was most prevalent in patients with ALPORT compared to patients with the other disease. Global sclerosis in glomeruli was prevalent in patients with ALPORT and GBM NOS. Other glomerular changes, such as cellular infiltration and matrix change in mesangium, and ischemic glomerular change, were not different among groups. Patients with GBM NOS showed more severe change of interstitial fibrosis and tubular atrophy compared to patients with TMD ($p<0.001$). During 97.9 ± 61.8 months of follow-up period, one (3.0%) patient was dead and 10 (30.3%) patients must have renal replacement therapy (RRT) among patients with ALPORT. The other patients with GBM NOS or TMD had survived and did not need RRT.

Conclusion: Clinical findings of GBM NOS were similar to TMD, although pathologic changes of glomerular global sclerosis and tubulo-interstitial changes are more severe in GBM NOS compared to TMD. GBM changes in GBM NOS might be related to tubulo-interstitial damages which needs to be defined with more studies.
# RISK FACTORS FOR VENOUS AND ARTERIAL THROMBOEMBOLIC COMPLICATIONS IN NEPHROTIC SYNDROME: A COHORT STUDY

Sarah Kelldal, Bawer Tofig, Anne-Mette Hvast, Erik Grove, Christian Fynbo Christiansen and Henrik Birn

Background and Aims: Venous thromboembolic events (VTE) and arterial thromboembolic events (ATE) are serious complications of nephrotic syndrome (NS). Studies are needed to identify patients at high risk for VTE and ATE. We aimed to describe patient-related risk factors for VTE and ATE in a mixed population of nephrotic patients.

Method: This multicentre cohort study included adult NS patients with plasma albumin <30 g/l and urine albumin-creatinine ratio (uACR) >2,200 mg/g, who were hospitalized or followed at an outpatient clinic in the Central Denmark Region between 2014-2018. Using computerized data extraction from medical files, patients were identified and followed until dialysis, transplantation, or end of study. We recorded comorbidities, family history, renal parameters and, histological diagnosis at index time as well as, renal parameters and medication at the time of VTE/ATE event. Categorical and continues data were compared using a risk difference and mean difference respectively. The incidence of event is presented as incidence rate.

Results: Among 531 included patients, 22 patients had their first VTE and 46 their first ATE within the first observation year (median time to event VTE 0.8 vs. ATE 0.9 years). Incidence rates were 11 per 1000 person-years (95% CI: 7-17) for VTE and 24 (95% CI: 18-32) for ATE. Plasma-albumin levels (27 g/l) were identical in the VTE and ATE group at event time, but eGFR was lower (Table 1), and uACR was higher in the ATE group (median uACR; VTE 1055 mg/g vs. ATE 2752 mg/g). Hypercholesterolemia was more prevalent among patients with VTE, and they were more often on corticosteroids.

IQR Interquartile range

*Medication data were collected baseline and 21 days prior to VTE or ATE.
than patients with ATE. Diabetes, hypertension, and heart failure was more prevalent at baseline in patients with ATE resulting in an increased CHADS2-VASC score. Mortality was higher among patients with ATE (83%) than VTE patients (32%).

Conclusion: Patients with NS have a high risk of VTE and ATE. Corticosteroid use was more common among patients with VTE than ATE. ATE was associated with a higher uACR, higher CHADS2-VASC score, and increased mortality compared to patients with VTE.

PATIENT REPORTED OUTCOMES IN GLOMERULAR DISEASES: A NEW MODEL OF CARE BASED ON MEDICAL CARE, TELEHEALTH AND NURSE-COACHING: THE HUMAN-C PROJECT

Elena Seren Cous1, Miguel Giovanni Urial Rivera1, Paloma Livianos Arias-Camión1, Aina Obrador Mulet1, Felipe Igancio Ojea1, Estela de Los Angeles Mas Rodenas2, Sonia Cleofe Jimenez Mendoza1, Francisco Fanjul Losa3 and Isabel Garcia Mendez1

1Hospital Universitari Son Espases, Nephrology, Palma, Spain and 2Hospital Universitari Son Espases, Medical Direction, Palma, Spain

Background and Aims: Glomerular diseases (GD) affect young and working-age people. Questionnaires for assessing health-related quality of life in GD patients are scarce. The implementation of telehealth and nurse coaching support (Humanization Coaching Project: Human-C Project) in a multidisciplinary team may influence the patient-reported-outcomes (PROs), patient-reported experiences (PREMs) and could open new perspectives on these patients, which should be taken into account. We report the results of PROMs and PREMs after the introduction of the Human-C Project. The objective of the study was to describe PROMs and PREMs in a glomerular disease unit of a third-level hospital after the implementation of the Human-C Project.

Method: Telehealth was implemented in 2019, and nurse-coaching support in 2021. The survey was online and anonymous to improve the accuracy of self-reports. The questionnaire consists of 15 items (based on Promis-29 (3 questions), SF-36 (2 questions) scales, and 10 questions previously obtained through personal interviews during nurse-coaching support). The questionnaire was sent to 233 patients included in our telehealth program.

Results: 89 (38%) patients responded to the questionnaire. The mean age (SD) was 46 (14). The questionnaire was stratified into 6 domains and the percentage of responses preference were: employment status (100%), knowledge of the disease (94%), social function (96%), psychological health (86%), type and periodicity of the medical appointments (84%), and therapy preferences (80%). 87% of the patients are of working age, 16% consider that they know little or nothing about their disease, 20% know little or do not know its severity, 53% reported fatigue, 50% their sleep quality is regular or very poor, 40% are not satisfied with their work performance (including at home), 34% reported poor health status; 34% reduced their activity (at work and home) due to emotional problems, 19% do not ask all questions or do not come up with clear information during the appointment, 80% report taking the medication correctly, 80% know what each pill is for, 35% want to retire and or reduce the number of tablets even adding intravenous medication, 53% develop anxiety about the disease, 72% consider that telehealth helps to reconcile work schedule and illness and helps to clarify doubts and in remission period 67% prefer to have an appointment as long as 6-9 months if they can directly access their health team if necessary.

Conclusion: A relevant percentage of GD patients reported health-related quality-of-life problems. Telehealth and nurse coaching support are opening specific perspectives of care in GD patients, with important implications for the health system.

EPIDEMIOLOGY OF GLOMERULAR DISEASES IN THE PRE- AND POST-COVID-19 ERA IN CENTRAL QUEENSLAND, AUSTRALIA

Zaw Thet1,2,3, Thin Han1,4, Leo Francis1, Niyi Aung1, Ken Cha1,2, Shu Kay Ng1,2, Mar Myint3, Jennifer Borg5, Alfred Lam2,9, Tien Khoo10,11 and Dwarkanathan Ranganathan16

1Central Queensland Hospital and Health Service, Nephrology, Rockhampton, Australia, 2Griffith University, School of Medicine and Dentistry, South Port, Australia, 3University of Queensland, Rural Clinical School, Rockhampton, Australia, 4Metro North Hospital and Health Service, Pathology Queensland, Herston, Australia, 5Darling Down Hospital and Health Service, Nephrology, Toowoomba, Australia, 6Metro North Hospital and Health Service, Nephrology, Herston, Australia, 7K & K Kidney Health Service, Nephrology, The Range, Australia, 8University of Queensland, Faculty of Medicine, Brisbane, Australia, 9Cold Coast University Hospital, Pathology Queensland, Southport, Australia, 10University of Wollongong, School of Medicine, Wollongong, Australia and 11Northern NSW Local Health District, Medicine, Lismore, Australia

Background and Aims: Development of new onset and recurrent glomerular diseases (GD) following Covid-19 infection or vaccination are increasingly reported in the literature with various proposed pathogenic mechanisms. Australia reported its first case of Covid-19 in January 2020. Currently in Australia, there has been 11.3 million cases of Covid-19 infection and 98% of individuals aged ≥ 16 years received at least one dose of Covid-19 vaccination. However, there are no studies in Australia that evaluate the risk of GD after Covid-19 infection or vaccination. We compared kidney biopsy results pre- (01/01/2017-31/12/2019) and post- (01/01/2020-31/12/2022) Covid-19 era to assess for potential changes in the epidemiology of kidney biopsy-proven GD.

Method: In this single-centred retrospective study, all renal biopsies performed in Central Queensland (CQ) between 01/01/2017 and 31/12/2022 were reviewed. This pilot study is a subset of Queensland Kidney Biopsy Registry which has captured all renal biopsies of adults residing in CQ with a regional population of 220,912 with a land area of 497,714 km².

Results: Eighty-seven percent of the CQ population received at least one dose of Covid-19 vaccination and 53,234 cases of Covid-19 infection were confirmed by rapid antigen test (RAT) as of the end of January 2023. The total number of kidney biopsies performed pre- and post-Covid-19 era were 47 vs 58, respectively, and the majority were native kidney biopsies (94% vs 95%) in CQ whereby the number of nephrologists in the respective catchment areas and access availability to kidney biopsies remained similar. The mean age of patients was 55.3 years (standard deviation, SD 16.4) vs 55.6 years (SD 15.6) and the majority were males (70% vs 62%) and Caucasians (77% vs 76%). No case of recurrent GD was diagnosed in pre-Covid-19 era whereas 5 cases of recurrent GD (2 membranous nephropathy, 1 minimal change disease, 1 lupus nephritis class III-IV, and 1 ANCA associated vasculitides (AAV)) in post-Covid-19 era, p = 0.025. The commonest cause of GD in the pre-Covid-19 era was IgA nephropathy (IgAN) whereas diabetic nephropathy and AAV was the most common GD during the post-Covid-19 era. The incidence of IgAN decreased from 12 cases (18.1 cases/million person years) in pre-Covid-19 era to 3 cases (4.5 cases/million person years) in the post-Covid-19 era (incidence rate ratio, IRR of 0.25, 95% CI 0.05-0.93, p = 0.020). The incidence of diabetic nephropathy increased from 1 case (1.5 cases million person years) during the three years pre-Covid-19 era to 13 cases (19.6 cases/million person years) for three years post-Covid-19 era (IRR of 3.4, 95% CI 0.86-18.85, p = 0.052). In the post-Covid-19 era, the mean age of patients with diabetic nephropathy was 51.2 years (SD 11.9) and the majority were indigenous Australian (n = 8, 62%) with poor diabetic control. They had kidney biopsies for nephrotic range proteinuria with or without acute kidney injury and haematuria. The incidence of AAV increased from 3 cases (4.5 cases/million person years) during the three years pre-Covid-19 era to 10 cases (15.1 cases/million person years) for three years post-Covid-19 era (IRR of 3.4, 95% CI 0.86-18.85, p = 0.052). In the post-Covid-19 era, the mean age of patients with AAV was 68.4 years (SD 16.1) with Caucasian (n = 10, 100%). PR3-AAV (n = 5) and MPO-AAV (n = 5) are equally prevalent, and 3 patients (30%) had comorbid pulmonary complications. Three cases of AAV each occurred in the first and second years and 4 cases in the third year during the post-Covid-19 era. There was no increase in the incidence rate for other types of glomerular diseases.

Conclusion: Our findings suggest the frequency of incident and recurrent GD may vary with the emergence of Covid-19 and steps taken to minimise viral complications that include primary preventative measures via vaccination. Larger epidemiological studies are required to better elucidate the risk of Covid-19 infection and vaccination in relation to GD.

**Background and Aims:** Chronic myelomonocytic leukemia (CMML) is a hematologic disorder which is an overlap syndrome between myelodysplastic syndromes, and myeloproliferative neoplasms, and can be associated with autoimmune and inflammatory diseases. The objective of this study was to describe kidney involvement in CMML patients, their treatments, and outcomes.

**Method:** We conducted a French and American multicenter retrospective observational study in fifteen centers, identifying CMML patients with acute kidney injury (AKI), chronic kidney disease (CKD), and urine abnormalities.

**Results:** Sixteen patients (males, n = 14, median age 76.5 [71.9-83]) developed a kidney disease 6 months [1.6-25.6] after the diagnosis of CMML. Median urinary protein to creatinine ratio was 2 g/g [1.5-3.4], and median serum creatinine was 2.26 mg/dL [1.46-2.68]. Fourteen patients (87.5%) underwent a kidney biopsy. The two main renal diagnoses were either a lysozyme nephropathy (n = 9, 56%), or a renal infiltration by the CMML (n = 6, 37.5%). Histological findings showed lesions of acute tubular injury with focal tubular epithelial necrosis (n = 4), a vacuolization of the epithelial cells of the proximal tubules (n = 7), and an inflammatory infiltrate with mostly mononuclear myeloid cells (n = 9). Ten patients received a new treatment following the CMML-associated kidney injury. The effect of CMML treatment on kidney injury could be assessed in 10 patients, and renal function evolution was heterogeneous. After a median follow-up of 15 months [9.9-34.9], 4 patients had CKD stage 3, 4 CKD stage 4, 1 an end-stage kidney disease. Two patients evolved to an acute myeloid leukemia (AML), and 5 died. Compared with 116 CMML controls, patients who had a kidney involvement had a higher monocytes count (p<0.001), had more CMML-1 (p = 0.005), were more susceptible to develop an AML (p = 0.02), and were more eligible to receive a specific hematologic treatment, with hydroxyurea, or hypomethylating agents (p<0.001), but no survival difference was seen between the two groups (p = 0.6978).

**Conclusion:** In this largest published cohort of CMML patients with a kidney injury, the two most frequent renal complications were lysozyme-induced nephropathy, and renal infiltration by the CMML. The development of a kidney injury during CMML appears to worsen the patient prognosis.

**ROUTINE CARDIAC BIOMARKERS FOR THE PREDICTION OF INCIDENT MAJOR ADVERSE CARDIAC EVENTS IN PATIENTS WITH GLOMERULONEPHRITIS: A REAL-WORLD ANALYSIS**

Elin Davies1, Garry McDowell1,2, Benjamin Buckley4, Philip Austin5, Gregory Lip1,6 and Anirudh Rao1,3

1Royal Liverpool University Hospital, Liverpool, United Kingdom, 2Liverpool John Moores University, Pharmacy and Biomolecular Sciences, Liverpool, United Kingdom, 3University of Liverpool, Liverpool Centre for Cardiovascular Science, Liverpool, United Kingdom, 4Liverpool John Moores University, School of Sport and Exercise Science, Liverpool, United Kingdom, 5TriNetX, London, United Kingdom and 6Liverpool Heart and Chest Hospital, Liverpool, United Kingdom

**Background and Aims:** Patients with glomerulonephritis (GN) frequently have both proteinuria and decreased kidney function, and together with immunosuppressive therapies used to treat it could lend these patients to a high risk for cardiovascular disease (CVD). We aimed to investigate the prognostic significance of routine cardiac biomarkers (troponin) in predicting incident Major Adverse Cardiovascular Events (MACE) within 5 years of diagnosis of GN.

**Method:** A retrospective cohort study was performed using electronic medical records from a global federated research network from the US (TriNetX). The TriNetX network was searched on 31st January 2023. Data censoring for MACE was invoked prior to the index event of GN. Cardiac biomarkers were the first reported result within 3 months of diagnosis of GN. Cohorts were grouped according to biomarker-specific thresholds and 1:1 propensity-score matched for age, gender, and co-morbidities (hypertension, diabetes mellitus and smoking status). Logistical regression produced odds ratios with 95%CI for 5-year incident MACE. MACE was defined, a priori, as a composite of ischaemic heart disease, angina pectoris, acute myocardial infarction, heart failure, AF, stroke, and all-cause mortality. The analysis was carried conducted by all-cause GN and individual primary GNs: IgA nephropathy (IgAN), membranous nephropathy (MN), focal segmental glomerulosclerosis (FSGS), and minimal change disease (MCD). All statistical analysis was performed on the TriNetX online platform.

**Results:** The results are shown below for all-cause GN. Results that reached statistical significance (p<0.05) are shown. The risk of MACE and its components was consistent across the individual GN sub-types IgAN (N = 1802), MN (N = 1674), FSGS (N = 1844) and MCD (N = 2014).

**Conclusion:** Routinely available cardiac biomarkers can predict incident MACE and outcomes in patients with glomerulonephritis. The results suggest the clinical need for CV mortality and morbidity risk profiling in patients with glomerular disease using a combination of clinical and laboratory variables.

Method: All 9 adult nephrology centres covering a population of over 5 million people report complete data on all kidney biopsies undertaken to the SRR. This includes indication, age, gender and diagnosis. The SRR collects requirement for KRT and death. Risk of KRT at 6 months, 1 year and 2 years from date of first native kidney biopsy in patients with IgAN, MGN or ATIN were recorded.

Results: 5095 native kidney biopsies undertaken in 4702 patients between 01/01/2014 and 31/12/2021 were included. This averages 117.1 biopsies per million population / year. 54.7% were male with mean age 57.2 (SD 17.2) years. 98.2% of kidney biopsies were deemed adequate for diagnosis. Data completeness is over 99%. The commonest indications for native kidney biopsy were acute kidney injury query cause (AKI - 30.0%), chronically reduced eGFR (CKD) (28.1%) and nephrotic syndrome (19.7%). Overall, the commonest diagnoses made were: IgAN nephropathy (IgAN 13.1%), tubulointerstitial nephritis (ATIN 8.5%) and membranous nephropathy (MGN 7.2%). Table 1 shows diagnoses made by biopsy indication.

Conclusion: In a complete national dataset, AKI is the commonest indication for native kidney biopsy and most commonly leads to a diagnosis of ATIN. IgAN remains the commonest primary glomerulopathy diagnosed on kidney biopsy, with MGN being the most likely diagnosis in patients biopsied for indication of nephrotic syndrome. Kidney and patient survival varies at 2 years depending on diagnosis. Table 2 shows that at 2 years the mortality rate (Fig. 1) is highest in patients with MGN (11.4%) and risk of KRT highest in patients with IgAN (10.2%).

Table 2: Overall outcomes for commonest diagnoses made on kidney biopsy: number starting KRT or dying within defined time period.

IN LANCASHIRE, UK
ASSOCIATED VASCULITIS AMONGST INDO-ASIAN PATIENTS
INCIDENCE AND CLINICAL PRESENTATION OF ANCA

Primary MN includes forms of MN in which there is a humoral autoimmune response to a normal podocyte antigen in the absence of secondary features or etiologies of disease. Antigens implicated in primary MN include PLA2R, thrombospondin type-1 domain-containing 7A (THSD7A), neural epidermal growth factor-like 1 (NEIL1), semaphorin 3B (Sema3B), the serine protease high-temperature requirement A1 (HTRA1), protocadherin 7 (PCDH7), and others. PLA2R associated MN is most common MN among primary MN. Nowadays, a significant number of newer antigens implicating MN are being discovered. Research is ongoing for a better understanding of the role of these antigens in pathophysiology, and targeted therapeutic implications in future if possible. We aim to analyze the etiological spectrum associated with different antigens in patients with Membranous Nephropathy. We assessed the renal tissue staining of autoantigens PLA2R, THSD7A, and NEIL-1 in patients with biopsy-proven Membranous Nephropathy.

Method: This was a single center ambispective observational study. The study was performed up till September 2022 for prospective data, and retrospective data from January 2018 to March 2021 was retrieved from the medical records department of the institute. The study included patients with biopsy-proven Membranous Nephropathy (Primary and secondary). The primary outcome was to study the etiological spectrum of Membranous Nephropathy.

Results: A total of 90 patients were included in the study of membranous nephropathy over the period of 4 years. 72 cases had primary MN whereas 18 cases had secondary MN. The mean age was 42.01 ± 14.6 years. Among 18 cases of Secondary MN, the majority of the cases were of lupus nephritis 14 (78%), while other etiologies of secondary MN were malignancy related (11%), rheumatoid arthritis (5.5%) and HCV (5.5%). PLA2R renal tissue positivity was found in 8 (11.1%) cases of primary MN, whereas it was found in 4 (22.2%) cases of Secondary MN. The THSD7A was found in 4 (5.6%) cases of primary MN. One patient of MN was dual PLA2R and NEIL1 positive. Two cases of MN were dual PLA2R and THSD7A positive. Renal tissue staining for NEIL-1 was found in 8 (11.1%) cases of primary MN whereas it was found in 1 (5.6%) case of secondary MN. In terms of clinical presentation, proteinuria is the most common clinical finding present in nearly all the patients (80%). Most of the cases with nephrotic syndrome (60%) belonged to primary MN.

Conclusion: PLA2R is the most common etiology of Primary membranous nephropathy. None of the antigens was exclusive to primary membranous nephropathy. None of the antigens was exclusive to Primary membranous nephropathy. The antigens were also positive in the secondary forms of MN.

Background and Aims: ANCA associated vasculitis (AAV) is a rare autoimmune condition that is predominately seen in white Caucasian populations [1]. Across the UK, Europe and the USA, the prevalence of AAV is between 4.6 - 18.4 per 100,000. Studies have shown significant geographical differences in the presentation and phenotype of AAV. PR3 positivity and granulomatosis with polyangiitis (GPA) is more common in Northern European countries at higher latitudes. In contrast, MPO positivity is seen more frequently in Japanese, Chinese and Southern European populations [1]. Comparatively, few studies have looked at the incidence, phenotype and outcomes in ethnic minority patients in particular Indo-Asian populations.

Method: We completed a retrospective cohort study of patients with AAV from a central referral centre in Lancashire, UK between December 2010 and December 2022. Patients with a diagnosis of AAV according to the Chapel Hill consensus conference and who belonged to the following ethnic groups; ‘Indian, British Indian, Pakistani, British Pakistani, Asian or Asian British,’ were included. Using data from the 2021 census, available from the Office of National Statistics, denominator populations were obtained [2]. Patients ethnic group were determined by self-reported ethnicity records on hospital e-health records or via GP summary care records. Ethical approval was obtained (IRAS 257174).

Results: Using 2021 census data, the total population of Lancashire (Fig. 1), aged >18 years old was 1,149,626. Of this population, the majority identified as white (1,059,000) and the second most common ethnic group was Asian / Asian British (74,523). Black/African/Caribbean/Black British made up <1% of the population and mixed/multiple ethnic groups and other ethnic groups made up just over 1%. Eighteen Indo-Asian patients with newly diagnosed AAV were identified. The mean age was 46 ±16.7 yrs, which is younger than our cohort of white patients who had a mean age of 65.1 ± 14.6 yrs. There was an equal gender split, the majority were PR3 positive (n = 12, 67%) and 6 patients had MPO positive AAV. Nine patients had renal involvement, with only 2 having renal limited disease and 1 requiring dialysis at presentation. Over half of the patients (n = 11, 61%) had ENT involvement. The crude incidence of AAV in Indo-Asian patients in Lancashire was 20.1 per million person years (95% CI 10.7, 28.5). This is higher than that reported in other areas of the UK [3]. When compared to age and gender matched white patients, white patients had more renal involvement (89.5% Vs 50%, P = 0.01) and more renal limited disease (31.6% Vs 11.1% P = 0.13). Pulmonary involvement was similar between the ethnic groups whereas ENT involvement was more prevalent in Indo-Asian patients (61.1% Vs 26.3%, P = 0.03).

Conclusion: Our findings demonstrate that whilst the crude incidence of AAV is lower in Indo-Asian populations compared to white Caucasians, there is a significantly high incidence rate in the Lancashire area, which is greater than in other areas of the UK. Pearce et al. reported an incidence of 10.6 per million person years in Nottingham which was almost half that seen in our cohort [3]. Our Indo-Asian patients were on average younger and had less renal involvement compared to our cohort white patients. This contrasts some studies which report Indo-Asian populations to have more PR3 positivity and higher rates of renal involvement [1]. This may reflect an under diagnosis of extra renal disease and non-renal phenotypes in Indian subcontinent populations. There remains a gap in our understanding as to the genetic role in the pathogenesis and clinical phenotype of AAV disease. Further research is needed to determine if the differences seen between ethnic minorities are due to genetic or environmental factors.
Background and Aims: While immunoglobulin A nephropathy (IgAN) has been shown to be associated with clinical and economic burden, the humanistic burden associated with IgAN is less understood. HONUS is a multi-national, cross-sectional survey study to evaluate the humanistic burden associated with rare kidney diseases, including IgAN, from the patient and caregiver perspectives in the US and Europe.

Method: The study recruited adult patients (≥18 years old) with their care-partners and parents/care-partners of youth (8-17 years old) with IgAN or focal segmental glomerulosclerosis (FSGS). Participants completed an online survey with questions on demographic and clinical characteristics, health-related quality of life (HRQoL) (ie, 12-Item Short Form Survey [SF-12]), anxiety and depression (ie, Generalized Anxiety Disorder Assessment [GAD-7], Patient Health Questionnaire [PHQ-9]), most burdensome symptoms, fear and uncertainty for the future, and disease impact on work productivity (ie, Work Productivity and Activity Impairment [WPAI]). The current analysis is based on information from adults with IgAN and their care-partners in the US before September 2022. Descriptive analyses were conducted, with continuous variables summarized using means, medians, and standard deviations (SD), and categorical variables summarized using frequency counts and percentages.

Results: A total of 96 pairs of adults with IgAN and their care-partners in the US were included in the analysis. The mean age of adult patients was 37.5 and the majority were Caucasian (86.5%) and female (53.1%). Median time since diagnosis was 5.6 years. More than half of patients (59.4%) were in chronic kidney disease stage 3 or 4, while 5.2% were in end-stage renal disease and had received a kidney transplant. Hypertension (31.3%), anemia (25.0%), and depression (18.8%) were the most common comorbidities. In terms of HRQoL, patient’s mean (SD) SF-12 physical and mental component scores (PCS, MCS) were reported at 46.9 (7.4) and 41.1 (9.1), respectively, reflecting worse HRQoL (lower score) than previously published US general population scores (PCS and MCS of 50 [10]). Moderate and severe anxiety was reported by 28.1% and 1.0% of patients, respectively; moderate, moderately severe, and severe depression was reported by 51.0%, 2.1% and 1.0% of patients, respectively. The most burdensome symptoms reported by patients were constipation (82.3%), lower back pain (79.2%), and bone or joint pain (77.1%). Based on a 4-week recall period, 25.0% of adult patients reported being ‘very much bothered’ or ‘extremely bothered’ by bone or joint pain (22.9% for lower back pain, 10.4% for constipation). Most patients (96.9%) reported feeling fear and uncertainty for the future due to their disease, of which 52.1% reported the frequency of fear and uncertainty to be ‘often’. Among employed patients (72.9%), percent absenteeism was reported in 6.9%, presenteeism in 27.1%, overall work productivity loss in 31.4%, and activity impairment in 36.2% because of IgAN-related reasons. Most paired care-partners (87.5%) were partners of patients, with a mean age of 39.5 years. The mean SF-12 PCS and MCS of care-partners were 50.4 and 43.6, respectively. Moderate anxiety was reported in 13.5% of care-partners, with none reporting severe anxiety; moderate and moderately severe depression was reported in 35.4% and 5.2% of care-partners, respectively. Almost all care-partners (99.0%) reported feeling fear and uncertainty for the future due to the disease of their cared ones, of which 39.6% reported the frequency of this worry to be ‘often’. Among employed care-partners (93.8%), 9.8% reported absenteeism, 27.3% reported presenteeism, 33.2% reported overall work productivity loss, and 31.9% reported activity impairment due to IgAN-related reasons.

Conclusion: Patients with IgAN experience impaired HRQoL, depression, anxiety, and poor productivity, compared to previously reported US general population estimates. This also impacts the HRQoL, in terms of mental components, and productivity of care-partners. Both patients with IgAN and their care-partners also report widespread fear and uncertainty for the future.

ASSOCIATION BETWEEN URINARY N-ACETYL-β-D-GLUCOSAMINIDASE AND BISPHENOL AND ITS SUBSTITUTE EXPOSURE IN TAIWANESE ADULTS

Po-Chin Huang1, Yu-Jung Lin1, Wan-Ting Chang1, Hsinchang Chen2 and Jung-Wei Chang3

1National Health Research Institutes, National Institute of Environmental Health Sciences, Miaoli County, Taiwan, Rep. of China. 2Tung-Hai University, Taichung City, Taiwan, Rep. of China and 3National Yang Ming Chiao Tung University, Institute of Environmental and Occupational Health Sciences, Taipei City, Taiwan, Rep. of China

Background and Aims: Urinary N-acetyl-β-D-glucosaminidase (NAG) is a sensitive and reliable indicator of renal damage, like proximal tubular cell injury. Bisphenol A (BPA), a known endocrine disruptor, or its substitute has been reported as a risk factor that caused kidney damage in experimental studies. We aimed to investigate the correlation between urinary NAG and Bisphenol and its Substitute Exposure in Taiwanese Adults.

Method: We collected urine samples including 271 adults (145 female and 126 men) from Taiwan Environmental Survey for Toxictants 2013, and analyzed for three urinary BPA, BPS and BPF by using ultraperformance liquid chromatography–tandem mass spectrometry. The bisphenol and their substitutes in the human urine samples were converted into daily intake (DI) values. We measured by the indicators of renal function, included urine creatinine (crea, mg/dL), microalbumin (mg/dL), NAG (IU/L), etc. We used logistic regression analysis to elucidate their correlations and adjustment for significant covariate.

Results: We found the median levels were 7.96 for BPA, 7.89 for BPF, and 1.96 (μg/L) for BPS, respectively, and yielded a median estimate daily intakes were 3.01 (BPA), 2.99 (BPF), and 0.76 (BPS) (ng/kg/day) in the Taiwanese adults. We found that the ratio of urinary NAG and creatinine (NAG/crea) was a significantly increased trend with exposure doses of BPA, BPF and BPS whereas no similar trend for ACR. After adjustment for age, sex, BMI and other covariate, we found that DI of BPA increased the risk of NAG/crea by 5.8 times (OR Adj: 5.8, p < 0.01, 2nd tertile) and 9.6 times (OR Adj: 9.6, p < 0.01, 3rd tertile).

Conclusion: Our findings supported that the exposure of bisphenol and its substitute may increase the risk of renal tubular injury. Further large and longitudinal studies are warranted.

EPIDEMIOLOGY OF PRIMARY FSGS INCLUDING CLUSTER ANALYSIS OVER A 20-YEAR PERIOD

Thomas McDonnell1, Josh Storrar1,2, Sabena Hughes1, Rajkumar Chinnadurai1,2, Calvin Heal3, Philip A. Kalra1,2 and Smeeta Sinha1,2

1Salford Royal Hospital, Northern Care Alliance NHS Foundation Trust, Renal Department, Manchester, United Kingdom. 2The University of Manchester, Faculty of Biology, Medicine and Health, Manchester, United Kingdom and 3The University of Manchester, Division of Population Health, Health Services Research & Primary Care, Manchester, United Kingdom

Background and Aims: Focal segmental glomerulosclerosis (FSGS) is one of the leading causes of nephrotic syndrome (NS) in adults. This epidemiological study describes a renal centre’s 20 year ‘real world’ experience of patients with primary FSGS including cluster analysis.

Method: This retrospective analysis was conducted on patients diagnosed with primary FSGS at a tertiary renal centre with a catchment population of 1.55 million, over 2 decades. Data collection included baseline demographics, laboratory results, immunosuppression (IS) and outcomes: Complete & partial remission, relapse, progression to renal replacement therapy (RRT) and mortality. A two-step cluster analysis was used to reveal groupings to aid prognostication and treatment decisions. Pre-specified cluster variables were: Serum albumin (sAlb), urine protein: creatinine ratio (uPCR) & estimated glomerular filtration rate (eGFR).

Results: 87 patients were identified with primary FSGS after exclusion of secondary causes. Mean age was 49.3 years, 60.9% male, 86.2% white with median eGFR 46 ml/min, uPCR 284 mg/mmol and sAlb 33 g/l (Table 1). Rates of partial and complete remission were 23% & 49.4% respectively. Progression to RRT occurred in 27.4%, death in 27.4%. Comparing those receiving IS vs not: sAlb was lower 23 g/L vs 40 g/L (p < 0.001), uPCR was higher 795 mg/mmol vs 318 mg/mmol (p < 0.001). The IS group was more likely to achieve complete remission (62% vs 40%, p = 0.041), but relapsed more 48.6% vs 22% (p < 0.027). There were no statistically significant differences between mortality or RRT. The 2-step cluster analysis separated the cohort into 3 clusters, see Fig. 1: Cluster 1 (n = 26) with ‘nephrotic range proteinuria’ mean sAlb 30 g/L, uPCR 778 mg/mmol and eGFR 72 ml/min; Cluster 2 (n = 43) with ‘non-nephrotic range proteinuria’, mean sAlb 39 g/L, uPCR 284 mg/mmol and eGFR 46 ml/min; Cluster 3 (n = 18) ‘NS’ sAlb 20 g/L, uPCR 1117 mg/mmol and eGFR 25 ml/min. IS use was comparable in the NS (cluster 3) and nephrotic range proteinuria (cluster 1) cohorts, but lower in cluster 2 (non-nephrotic range proteinuria) 77.8% & 69.2% vs 11.6% p < 0.001. Rates of complete remission were greatest in clusters 1 & 3 vs cluster 2: 57.7% & 86.7% vs 37.2% though this did not achieve statistical significance (p 0.067).

Conclusion: Although there have been several recent US & Asian reviews of primary FSGS, this study provides a review of the epidemiology of FSGS over a 20-year period in a predominantly white cohort in the UK. In general, the patients who received IS had lower sAlb and achieved remission more frequently. Although the aetiology of primary FSGS is unknown, it is hypothesised that it is due to an undiscovered circulating permeability factor. After the exclusion of secondary causes, KDIGO suggests only making the diagnosis in the presence of NS. Despite this the average sAlb in most epidemiological studies of primary FSGS have been above 30g/L. This is likely because of the inclusion of undiagnosed genetic or adaptive FSGS, but it may also be true that NS phenotype alone is too insensitive to diagnose primary ‘antibody driven’ FSGS. Our cluster analysis highlighted 3 potential FSGS phenotypes: A nephrotic cluster that clearly require IS; a cohort with preserved sAlb and non-nephrotic range proteinuria who will benefit from supportive care; lastly a cluster with heavy proteinuria but a sAlb > 30g/L. This group may still have antibody driven disease and thus benefit from immunosuppression and potentially genetic testing. The study received grant support from CSL Vifor.

PREVALENCE OF ANTIPLA2R ANTIBODIES IN EGYPTIAN PATIENTS WITH NEPHROTIC SYNDROME
Magdy Elsharkawy, Reem Elsharabasy, Mohamed Megahed and Ahmed Emara

1Ain Shams university, Nephrology departemnt, Cairo, Egypt and 2Ahmed Maher Teaching hospital, Nephrology departemnt, Cairo, Egypt

Background and Aims: Primary membranous nephropathy (PMN), a common form of the nephrotic syndrome, is an antibody-mediated autoimmune glomerular disease. Autoimmunity is driven by circulating autoantibodies that bind to one or more antigens on the surface of glomerular podocytes. PLA2R antigen is the most common and prevalent one among these antigens. Anti-PLA2R antibodies are measured in serum and detected within biopsies of primary membranous nephropathy patients. Up to the moment, no clear data about the prevalence of AntiPLA2R antibodies associated PMN in Egyptian patients. The aim of this work was to study the prevalence of antiPLA2R antibodies in Egyptian patients with nephrotic syndrome underwent renal biopsy.

Method: In this cross-sectional study we recruited 70 adult patients presented with nephrotic range proteinuria to Ain-shams university hospital and a private nephrology center in Cairo during a period of 20 months (from March 2020 to October 2021). All patients first presentation for whom laboratory investigations including serum anti-PLA2R antibodies titer by indirect immunofluorescence and kidney biopsy were done. Anti-PLA2R antibodies were measured in serum, checked in biopsies and correlated with biopsy findings.

Results: Membranous nephropathy (primary and secondary) was found by biopsy finding in 25 of 70 patients (35.7%) presenting with nephrotic range proteinuria. 21 patients (84%) of the cases of membranous nephropathy had been diagnosed with primary membranous nephropathy and 4 (16%) had been diagnosed with secondary membranous nephropathy. Circulating anti-PLA2R antibodies were detected within serum in 9 (42.85%) of primary MN cases while detection of anti-PLA2R antibodies within the glomerular extracts of primary MN cases was much higher; 17 patients (80.95%). There was positive correlation between serum AntiPLA2R Antibodies titer and U PCR (r = 0.839, P = 0.005) (Fig. 1).

Conclusion: A we may conclude that, most patients with primary membranous nephropathy have anti-PLA2R antibodies. Detection of anti-PLA2R antibodies within the biopsy has higher sensitivity than serum (80.95% versus 42.85%). Specificity of PLA2R to primary membranous nephropathy is 100%. Patients with high anti-PLA2R titer had higher baseline proteinuria than patients with lower anti-PLA2R titer.

Figure 1: Correlation between serum AntiPLA2R Antibodies titer and U PCR. U PCR: urine protein/creatinine ratio

#5142
THE NATURAL HISTORY OF FSGS IN THE GERMAN CHRONIC KIDNEY DISEASE (GCKD) COHORT
Eleni Stamellou, Jennifer Nadal, Claudia Seikrit, Bruce Hendry, Alex Mercer, Matthias Schmidt, Marcus Johannes Möller, Mario Schiffer, Kai-Uwe Eckardt and Jürgen Floege

1Division of Nephrology and Rheumatology, RWTH Aachen University Hospital, Aachen, Germany, 2Faculty of Medicine, University Hospital Bonn, Department of Medical Biometry, Informatics and Epidemiology, Germany, 3Traveere Therapeutics, Inc., San Diego, United States of America, 4Sweden, 5JAMCO Pharma Consulting, Sweden, 6Friedrich-Alexander University Erlangen-Nuremberg, Department of Nephrology and Hypertension, Germany and 7Charité-Universitätsmedizin Berlin, Department of Nephrology and Medical Intensive Care, Germany

Background and Aims: FSGS is a heterogenic glomerular disease and a common cause of kidney failure in adults. Here we describe the natural history of individuals with FSGS in the German Chronic Kidney Disease (GCKD) cohort.
Method: From 2010 to 2012, 159 patients with biopsy-proven FSGS were included in the GCXD study, a prospective observational cohort study (N = 5217). Inclusion criteria were an estimated glomerular filtration rate (eGFR) of 30–60 ml/min/1.73 m² or overt proteinuria in the presence of an eGFR < 60 ml/min/1.73 m². Baseline date was defined as first study visit. Endpoint endpoints were the composite renal endpoint (MAKE); eGFR decline >40%, eGFR < 15 ml/min/1.73 m² or initiation of kidney replacement therapy. The associations between the incidence of MAKE and clinical parameters were analyzed using the proportional hazards regression model. Data relating to baseline demographics, laboratory, comorbidities, and mortality were used.

Results: The mean age at baseline of patients with FSGS was 52.1 ± 13.6 years. Median proteinuria at baseline was 0.7 g/g (Q1 0.1; Q3 1.8), while mean eGFR was 55.8 ± 23 ml/min/1.73 m². Mean duration of the disease before enrollment was 4.7 ± 6.8 years. The majority (101;63.5%) were male; 69 (43.4%) were diagnosed as primary FSGS using clinical and pathological criteria, 55 (34.6%) as secondary FSGS and for 35 (22%) the etiology was uncertain. At baseline, 37 (23.3%) were under immunosuppressive treatment. Over a follow-up of 6.5 years, 44 reached MAKE, in detail 19 (12%) initiated kidney replacement therapy, an additional 25 (15.8%) experienced a >40% eGFR decline. Albuminuria <0.7 g/g was associated with MAKE, with a HR 0.7/g/g. Higher eGFR at baseline (per 10 ml/min) protected from MAKE with a HR of 0.8 (95% CI: 0.68-0.95).

Conclusion: The GCXD cohort represents a large study population with lengthy and adjudicated follow-up data. Lower eGFR and higher albuminuria are significant risk factors for progressive kidney disease and ESKD in patients with FSGS.

#3476 CHARACTERISTICS AND SURVIVAL DATA OF PATIENTS WITH PRIMARY FOCAL SEGMENTAL SEGMENTAL GLOMERULOSCLEROSIS: TSN-GOLD MULTI-CENTER STUDY

Background and Aims: We aimed to investigate the characteristics and survival data of biopsy-proven primary focal segmental glomerulosclerosis (FSGS) in adult patients across Turkey.

Method: Patients with primary FSGS were included by retrospectively scanning the database of the Turkish Society of Nephrology Glomerular Diseases Study Group (TSN-GOLD). Demographic and laboratory data of the patients at baseline, sixth month, first year, and third year were recorded. Patients with secondary FSGS, missing data were excluded.

Results: The study included 1668 patients with primary FSGS who met the criteria. 1386 patients were included. The mean age of the patients was 41.16±13.88 years, and 712 patients (51.4%) were male. The total follow-up period from the biopsy date was 37.63±40.45 (IQR:1-249) months. The mean blood pressure of the patients, respectively; 130.43±7.63±1.73 mmHg, serum creatinine 1.29±1.28 mg/dl, e-GFR: 86.10±42.70 ml/min/1.73 m², serum albumin: 3.41±0.92 g/dl and proteinuria amount was 4687±4658 g/day. Microscopic hematuria was detected in 40.2% of the patients. The rate of admission with nephrotic syndrome was 45.7%. In light microscopy, the mean glomeruli count was 17.36±10.58, with 3.32±4.08 global sclerosis and 0.08±0.06 glomeruli had segmental sclerosis. Mesangial proliferation was found in 53.1% of the patients and interstitial inflammation was found in 69.7% of the patients. Interestingly, the most common immunoglobulin staining was IgM (19.3%) in the immunofluorescent microscope. The rate of receiving immunosuppressive therapy was 36%. A positive correlation was found in terms of serum creatinine, albumin, and proteinuria in the 3-year follow-up (p<0.001). In the univariate analysis, the group with eGFR < 60 ml/min/1.73 m² was older, hypertensive, uremic, anemic, had more interstitial fibrosis/tubular atrophy and less interstitial inflammation and mesangial proliferation (p<0.001). In terms of quantitative proteinuria, Patients with proteinuria > 3.5 g/day were more hypertensive, hyperlipidemic, hypoalbuminemic and anemic (p<0.05).

Conclusion: Our study presented important data on the status of patients with national primary FSGS. Approximately one-third of patients receive immunosuppressive therapy. The most important factors determining the

IGM POSITIVE MINIMAL CHANGE DISEASE: CHARACTERIZING DISEASE SEVERITY AND OUTCOMES

Ana Cristina Santos Cunha1, Beatriz Gil Braga1, Sofia Sousa1, Sofia Ventura1, Sofia Correia1, Jorge Malheiro1, Andreia Campos1 and Josefina Santos1

1Hospital Geral de Santo António, Porto, Portugal and 2Hospital do Divino Espírito Santo, Ponta Delgada, Portugal

Background and Aims: Minimal change disease (MCD) is the main cause of nephrotic syndrome in pediatric age and it is responsible for 10-25% of the cases in adults. It is characterized by minimal glomerular abnormalities in light microscopy, usually without immunoglobulins or complement deposits in immunofluorescence (IF). There is a subgroup of patients that presents with IgM deposition in IF, which has been described as a more aggressive disease, with frequent relapses [1], dependence of steroids [2] and worse outcomes.

Method: This is a retrospective study that analyses the follow up of 50 adult MCD patients in the nephrology consult, with diagnosis in childhood or adulthood. They had renal biopsies performed between 2009 and 2022. We did not include inappropriate biopsy samples, biopsies without IF or positive for C1q. We compared the characteristics between IgM positive (IgM+) and IgM negative (IgM-) patients at diagnosis, as well as the number of relapses per year, age of presentation and association with steroid-dependence or steroid-resistance.

Results: There were 23 (46%) patients in the IgM+ group and 27 (54%) in the IgM- group, with a mean follow-up of 10.2± 7.8 years. The IgM- subgroup was older at biopsy time (52 (30-74) years vs IgM+ 15 (13-23) years; p = 0.001) and this is probably related with the age of disease presentation, which was younger in the IgM+ group (12 (5-16) years vs IgM- 52 (73-13) years; p = 0.001). The groups were similar in sex distribution (IgM+ male n = 15 (55.6%) vs IgM- male n = 10 (44.0%); p = 0.395). There were no differences in diabetes and dyslipidemia frequencies between the two groups (Diabetes: IgM+ n = 1 (4.3%), IgM- n = 3 (11.3%), p = 0.614; Dyslipidemia: IgM+ n = 7 (30.4%), IgM- n = 7 (25.9%), p = 0.723), but the IgM- group had more patients with hypertension (IgM+ n = 2 (8.7%), IgM- n = 9 (33%), p = 0.046). The estimated glomerular filtration rate based on creatinine (eGFRcr) at biopsy time was higher in the IgM+ group (124 (104-130) ml/min/1.73 m² vs IgM- with 96 (84-111) ml/min/1.73 m²; p = 0.003), but this happens probably due to the age as a confounding variable. In regard to the number of relapses per year, the IgM- group had significantly more relapses than the IgM+ group (IgM+ with 0.61 (0.27-1.00) relapses per year; IgM- with 0.17 (0.01-0.65) relapses per year; p = 0.011). The steroid-dependence (IgM+ n = 15 (65%); IgM- n = 11 (47%); p = 0.084) and the steroid-resistance (IgM+ n = 6 (26%); IgM- n = 3 (11%); p = 0.270) isolated outcomes were not significantly different in the two groups, but when we analyze the composed outcome of steroid-dependence plus steroid-resistance we have worse outcomes in the IgM+ subgroup (IgM+ n = 21 (91.3%); IgM- n = 14 (51.8%); p = 0.04; ORR 9.72; IC 95% 2.37-33.33). An IgM+ patient has 9.7 times the odd of being steroid-dependent or steroid-resistant of an IgM- patient. From our 50 patients, 3 evolved to stage 5 chronic kidney disease with dialysis dependency, being all of those patients IgM+. One of those patients had a recurrence of MCD after kidney transplant. There were 3 deaths with non-related to kidney disease causes, 1 in the IgM+ and 2 in the IgM- groups. Genetic test was performed in 5 of the IgM+ patients, with 4 positive results for mutations. Only 2 IgM+ patients did genetic test, all without mutation’s identification. 

Conclusion: This study supports the evidence that MCD patients with IgM+ biopsies have younger age MCD’s presentation, more relapses per year and more steroid dependence plus resistance. Dialysis was started in 3 IgM+ patients and this group seems to have higher frequency of genetic mutations. This suggests that genetic testing could be important for future prognosis prediction and treatment options in the IgM+ patients, but further studies with a bigger study population need to be done to establish this relation.

Background and Aims: IgAN have a variable clinical course and a considerable risk of ESKD. The 2021 KDIGO guidelines recognize the International IgAN Prediction Tool (IIgAN-PT) as a quantifier of progression risk at the time of kidney biopsy. The possible application of the IIgAN-PT to re-evaluate the risk after treatment and during follow-up is debated. We analyzed the possible association between treatment response and changes of IIgAN-PT risk estimation.

Method: Retrospective study including patients with IgAN undergone kidney biopsy from Jan 2010 to Dec 2020. Inclusion criteria: treatment with glucocorticoids, age > 18, follow-up at 3-6-12-24 months, availability of risk estimation. Progression risk evaluated by IIgAN-PT at time 0 (biopsy) and after 6-12 months. Two risk groups were identified based on the IIgAN-PT at time 0: Low-Intermediate risk group (Low-risk, IIgAN-PT < 23%) and High-risk group (High-risk; IIgAN-PT risk ≥ 23%).

Results: A total of 22 patients were included (59% Low-risk; 31% High-risk). Patients at low-risk had significantly higher eGFR with respect to high-risk group (78 vs 40 ml/min/1.73 m² respectively) (p < 0.001). Age, MAP, and RASi use at biopsy did not differ significantly. Proteinuria was comparable among groups: 3.14 g/24 h in High-risk and 2.49 g/24 h in Low-risk (p = 0.17). In the Low-risk group the median proteinuria swiftly decays below 1.0 g/day already at three months, and below 0.5 g/day after six. Conversely, in the high-risk group, it remained above 1 g/day until 12 months (Fig. 1). Regarding risk progression assessment: 89% of patients at higher risk at baseline became at lower risk at 6 months (Fig 2; Table 1).

Conclusion: Treatment response was associated with a reduction in the IgAN progression risk as demonstrated by changing of IIgAN-PT already after 6 months. These data suggest a possible dynamic use of IIgAN-PT for IgAN progression risk re-evaluation even in the short follow-up period.

Figure 1: Proteinuria and eGFR variation during follow-up in different risk group identified according to IIgAN-PT.
Figure 2: Predicted 5-year risk of progression (IIgAN-PT) at biopsy, 6, and 12 months for each patient on supportive and immunosuppressive therapy and with a follow-up of at least 12 months. Values are presented according to increasing risk of progression at biopsy. Red line separates patients at lower-intermediate risk from those at higher risk. LATE DIAGNOSIS OF IGA NEPHROPATHY IN LOWER SAXONY (GERMANY) – CLINICAL AND HISTOPATHOLOGICAL DATA FROM 246 PATIENTS AT TIME OF INITIAL RENAL BIOPSY
Amelie Gienapp1, Torsten Meyer1, Gabriele Eden1, Bernhard Schmidt1, Kai Schmidt-Ott1, Jan Hinrich Bräsen3 and Jan T. Kielstein1

1Academic Teaching Hospital Braunschweig, Nephrology, Rheumatology, Blood Purification, Braunschweig, Germany, 2Hannover Medical School, Department of Nephrology and Hypertension, Hannover, Germany and 3Hannover Medical School, Department of Nephropathology, Hannover, Germany

Background and Aims: IgA Nephropathy (IgAN) is the most frequent glomerulonephritis and contributes significantly to the burden of dialysis dependence. If not detected in the context of screening health examinations e.g. for the military service, decline in renal function is usually unnoticed due to the lack of specific symptoms. After decades of limited pharmacological options, the advent of new therapies provides opportunities for early intervention. Age and renal function as well as proteinuria at the time of renal biopsy varies depending on healthcare systems but might influence the use of novel interventions. Publications from outside Germany report that eGFR at the time of first renal biopsy in IgAN varies between 73.8 and 94.9ml/min/1.73 m². The age at the time of diagnosis is between 27 and 40 years. The aim of our study was to investigate renal function, degree of proteinuria as well as histological parameters at the time of first renal biopsy in patients with IgANephropathy.

Method: This retrospective study evaluated data from two different tertiary care hospitals in Germany that sent their renal biopsies to the Nephropathology Department at the Hannover Medical School from January 2012 – October 2022. Only initial biopsies from native kidneys were included. Histopathological parameters and clinical as well as laboratory parameters at the month of biopsy were obtained. eGFR was calculated according to the CKD-EPI formula.

Results: First time diagnosis of IgA nephropathy was made in 246 patients at a median age at of 45 (range 4–79) years, 76.8% were male. The median serum creatinine level was 1.44mg/dl, corresponding to a median eGFR of 43.0 (3.8–132) ml/min/1.73 m². Surprisingly 49.5% of all patients were at CKD K/DOQ GFR stage 3B or higher at the time of first biopsy (Figure 1). Median proteinuria was 1.84 (0.08 – 16.5) g/d in those patients where 24h urine collection was performed. 156 of 246 patients had microhematuria at the time of biopsy. Based on the Oxford classification >50% had hypercellularity. Endocapillary hypercellularity was present in 24%. Segmental glomerulosclerosis was almost evenly distributed (S0:116 | S1:112). Tubular atrophy and interstitial fibrosis were visible in most biopsies in 0-25% of cortical area (T0:153 | T1:59 | T2:16). In 27.2% the C-score was analyzed, showing cellular and/or fibrocellular crescent in 26.8% of those patients. Thrombosis and necrosis were rather uncommon in initial biopsies of IgA Nephropathy.

Conclusion: The study shows that an IgA Nephropathy shows severe renal impairment at the time of diagnosis i.e. first renal biopsy, suggesting that patients are referred rather late for this diagnostic procedure. These regional data have to be validated in larger cohorts. If confirmed, measures for earlier screening and referral should be implemented to allow timely intervention thus lowering need for renal replacement therapy.

Figure 1: GFR categories of the IgAN patients at the time of first biopsy.
IS DIABETES MELLITUS ASSOCIATED WITH WORSE KIDNEY OUTCOME IN PATIENTS WITH GLOMERULOPLANITIES?

Otilia Ciurea1,2, Cristina-Stela Capusa1,2, Nicoleta Petre1,2, Eugen Mandache2 and Gabriel Mircescu1,2

1Carol Davila University of Medicine and Pharmacy, București, Romania and 2Nephrology Hospital Dr. Carol Davila, București, Romania

Background and Aims: Diabetes mellitus (DM) is the leading cause of end stage kidney disease and a major risk factor for cardio-vascular disease and death. While it is known that subjects with diabetic nephropathy (DN) have a worse kidney outcome compared to other non-diabetic glomerulopathies, it is not certain whether DM independently influences the kidney outcome in subjects diagnosed with glomerulopathies (GP) other than diabetic nephropathy.

Method: This retrospective study included 1200 adults [50 (95% CI 48 to 51) years, 56% males, eGFR 48.5 (95%CI 45.9 to 51.3) mL/min], with kidney biopsy (KB) proven GP between 1st Jan. 2008 and 31st Dec. 2017. Subjects were followed for a mean of 89 (95%CI 85.5 to 92.4) months until 31st May 2018. The primary endpoints were the initiation of chronic renal replacement therapy (RRT) or death. Subjects with inappropriate biopsy sample, insufficient data and RRT prior to KB were excluded. Demographic, clinical and laboratory data at the time of biopsy were retrieved from medical records. Kidney survival was evaluated by Kaplan-Meier method and a competitive risk to event analysis was used to estimate the risk of RRT, considering death as a competing event. Variables related to kidney outcome were evaluated by the subdistribution hazard function using Fine-Gray model. According to the presence or absence of DM and the types of GP, subjects were divided in three groups: GP without DM (n = 987 pts.), GP with DM (n = 65 pts.), and DN (n = 148 pts.).

Results: GP with DM subjects were older (60 (95% CI 56 to 64) years vs. 55.5 (95%CI 54 to 59) years in DN group vs. 47 (95%CI 45 to 48) years in GP without DM; p<0.001). Males were predominant in all groups, with higher frequency in DN group (66.9% vs. 54.9% - GP without DM vs. 61.5% - GP with DM; p = 0.01). DN group had higher Charlson comorbidity index [5 (95% CI 4 to 5) vs. 2 (95%CI 2 to 2) in GP without DM vs. 3 (95%CI 3 to 4) in GP with DM; p<0.001], lower eGFR (31.3 (95%CI 25.4 to 36.7) mL/min vs. 51.9 (95%CI 48.9 to 55.8) mL/min in GP without DM vs. 43.2 (95%CI 35.4 to 51.3) mL/min in GP with DM; p<0.001) and higher proteinuria (4.9 (95%CI 3.8 to 6) g/g in GP without DM vs. 2.6 (95%CI 2.35 to 2.9) g/g in GP without DM vs. 4.3 (95%CI 2.7 to 6.7) g/g in GP with DM; p<0.001]. During the follow-up period, 24.3% needed RRT, while 11.4% died. The highest RRT initiation and death frequency was in DN group (40.5% vs. 21.7% in GP without DM vs. 27.7% in GP with DM; p<0.001, and 18.2% vs. 10% in GP without DM vs. 19.9% in GP with DM; p = 0.004). In the univariate time-dependent analysis, subjects with DN had the worse kidney outcome (log rank p<0.001) (Fig. 1), however the kidney survival was similar between GP with DM and GP without DM subjects (log rank p = 0.1). In the competitive risk time to event analysis where death is considered the competing event, diabetic nephropathy subjects had worse kidney survival than GP with DM subjects [CIF 2.3 vs. 1.3, p<0.001], while GP with DM had similar survival with GP without DM (CIF 1.3; p = 0.2) (Fig. 2). After adjusting for the risk factors for CKD progression, DM was not associated with an increased risk of

Method: 6575 dialysis patients were divided into baseline 3 groups (ALLO
treatment categories. In CVD events, ALLO indicated preventive effect of HR
< 0.81 versus control (p = 0.001). There was no difference of preventive effect between ALLO and FEB for all cause mortality, but each drugs indicated preventive effect in each base line XOR treatment categories. In CVD events, ALLO indicated preventive effect of HR 0.81 versus control (p = 0.001). But FEB did not indicated preventive effect of HR 0.98 (95% CI: 0.91 - 1.04). ALLO was estimated preventive effect for CVD events against FEB in HR 0.83 (95% CI 0.75-0.92).

Conclusion: ALLO and FEB had a prevent effect for all-cause mortality, further FEB was not inferior to ALLO in all-cause mortality in the realm of XOR inhibition. Nevertheless, FEB could not indicate preventive effect for CVD events compared with ALLO and control, which is assumed of ABCG2 inhibitory effect. But was not increase risk for all cause mortality or CVD events compared with ALLO and control. This study provide a new suggestion that it is important for CKD patients to apply extrarenal excretion pathway ABCG2 of uremic toxin and uric acid to prevent CV events because of impaired renal function. In humans 70% of uremic toxin is excreted from urine, and 30% from gut. It is required further investigation and treatment strategies of uric acid lowering therapy should be considered about excretion of uremic substances outside of the kidneys.

**FEBUXIOSTAT AND ALLOPURINOL VERSUS NON-TREATMENT IN HEMODIALYSIS PATIENTS WITH OUTCOMES**

**Takeo Ishii**¹,²

¹Yokohama City University School of Medicine, Department of Medical Science and Cardiorenal Medicine, Yokohama, Japan and ²Yokohama Daichi Hospital, Internal medicine, Yokohama, Japan

**Background and Aims:** Uric acid is relatively low in hemodialysis because it is removed during dialysis. The therapeutic intervention for hyperuricemia is controversial. RCT of allopurinol and febuxostat has been performed in hyperuricemic patients to inhibit xanthine oxidoreductase (XOR) and reduce uric acid levels further improve outcomes. Nonetheless, we reported preventive effect of XOR inhibitors for dialysis patients on Sci Rep 2017, but the difference in the protective effect for CVD events and mortality between XOR inhibitors is insufficient in dialysis patients. Furthermore, febuxostat is also known to be a potent ATP-binding cassette transporter subfamily G member 2 (ABCG2) inhibitor that promotes the accumulation of uremic toxins by excretion from the gut in dialysis patients and hyperuricemic patients. We investigated the preventative effect of XOR inhibitors on outcomes under three year observation for 6575 hemodialysis patients.

**Method:** 6575 dialysis patients were divided into baseline 3 groups (ALLO group, FEB group, non-treatment group). Outcomes were all-cause mortality and CVD events, defined by ICD coding using longitudinal data. Causal associations for outcomes of allopurinol (ALLO) or febuxostat (FEB) were analyzed using 3 years of longitudinal data versus control at each visit, including concomitant drugs, marginal structural models (MSM) that examined the causal effect of ALLO or FEB versus control with weight for adjust covariate using multiple imputation for missing data.

**Results:** Over all all-cause death was 1167 / 6575 (17.74%) cases. In non-treated group 993 / 4827 (20.57%), ALLO-treated group 98/778 (12.60%), and 136 / 970 (14.20%) in FEB-treated group. CVD events 14723, and number of

Conclusion: In conclusion, AKI, glomerulonephritis (GN) and tubulointerstitial nephritis (TIN).

**ACUTE KIDNEY INJURY, GLOMERULONEPHRITIS AND TUBULOINTERSTITIAL NEPHRITIS FOLLOWING VACCINATION: VIGIBASE ANALYSIS**

Soo-Young Yoon¹, Hayeon Lee², Jin Sug Kim³, Kyunghwan Jeong³, Dong Keon Yon⁴ and Hyeon Seok Hwang⁴

¹Kyung Hee University Hospital, Division of Nephrology, Department of Internal Medicine, Seoul, Rep. of South Korea, ²Kyung Hee University, Department of Biomedical Engineering, Yongin, Rep. of South Korea and ³Medical Science Research Institute, College of Medicine, Kyung Hee University, Center for Digital Health, Seoul, Rep. of South Korea

**Background and Aims:** Vaccination is the long-term established measure for disease prevention and worldwide outbreak of COVID-19 necessitates mass scale vaccination. However, there is a public concern on the risk of renal adverse reactions from several types of vaccination.

**Method:** We analyzed VigiBase (n = 120,715,116 reports), the World Health Organization pharmacovigilance database from Dec 1967 to Jul 2022 using disproportionate Bayesian reporting. Information component (IC) compares observed and expected values to find the associations of vaccines with acute kidney injury (AKI), glomerulonephritis (GN) and tubulointerstitial nephritis (TIN).

**Results:** We found 5,484 AKI (13.8% fatal), 2,846 GN (29.4% fatal) and 289 TIN reports (23.2% fatal) as vaccine-associated adverse reactions. Almost reports indicated single drug suspected cases (>99.5% reports). The cumulative number of reports on vaccine-associated AKI, GN and TIN gradually increased and Americas was most prevalent regions of reporting. Examining the different vaccines separately, reporting count of COVID-19 mRNA vaccines sharply increased and it solely was associated with significantly higher reporting of AKI (IC025 1.09) and TIN (IC025 0.48). Patients aged 12-17 years had the highest IC values for COVID-19 mRNA vaccine-associated AKI and TIN. Hepatitis B (IC025 3.22), influenza (IC025 2.64) and COVID-19 mRNA vaccine (IC025 2.89) were prominently over-reported among ten types of vaccines with significant signals of GN.

**Conclusion:** In conclusion, AKI, GN and TIN substantially occurred following vaccination and it was most noticeable in patients exposed to COVID-19 mRNA vaccines. Clinicians should consider the increased risk of renal adverse reactions after vaccination.

**Figure 1:** Preventive effect for All-Cause Mortality and CVD events in MSM models.
LONG-TERM OUTCOMES IN A COHORT OF PATIENTS WITH SYSTEMIC VASULTIDIES (SV) AND KIDNEY INVOLVEMENT

Ioannis Petrikis1, Kleio Dermitzaki2, Kostas Palamaris3, Eleni Drosataki2, Savvati Alexandra Maragkou1, Christos Pleros4, Nikos Kroustalakis1, Ioanna Styrakaki1, Harikelis Gkakopoulou1 and Kostas Stylianou1

1University General Hospital of Heraklion, Nephrology, Heraklion, Greece and 2National Kapodistrian University of Athens, Pathology, Athens, Greece

Background and Aims: Many randomized trials address the issue of SV therapy. Nevertheless, individualized treatment in patients with SV and renal involvement requires long term data and is often center specific. We present the experience of our center, a tertiary University hospital in Crete, Greece.

Method: Medical records were reviewed for clinical signs and symptoms. Statistical analysis was performed using SPSS 20 (IBM). Data were tested for normality, statistical significance was set at <0.05. Chi-Square test, Student’s T-Test, Multiple-Regression analysis were utilized for statistical analysis.

Results: We examined 58 patients (37 females) with a mean follow-up of 5 years (Range 1-31) and a mean age of 66 years (Range 12-102). Serology revealed 46 pANCa+ve (79%), 8 cANCa+ve (14%) and 4 p/c ANCA negative patients (7%). Nine patients lost renal function and 16 patients died during follow-up. All patients received immunosuppressive induction therapy (Cyclophosphamide N = 42, Rituximab N = 7, Steroid monotherapy N = 9). All patients with pulmonary hemorrhage underwent plasmapheresis. The severity of clinical manifestation was associated with need for plasmapheresis and rapid renal function deterioration. Plasmapheresis resulted in the remission of pulmonary hemorrhage in all patients. Renal death was associated with renal function decline in months 1 and 6 post diagnosis. Treatment with cyclophosphamide or rituximab did not affect outcome (death or renal death). Number of relapses (14 patients), surprisingly, was not associated with renal function deterioration. Death was not associated with renal function deterioration in months 1 and 6 post diagnosis. Loss of follow up was associated with increased mortality.

Conclusion: In this cohort either cyclophosphamide or Rituximab does not seem to affect prognosis. plasmapheresis efficiently contains pulmonary hemorrhage and, as expected, loss of follow-up is associated with poor outcomes.

Background and Aims: Anti-CDD20 monoclonal antibody has become one of the first-line therapies for the treatment of moderate and high-risk primary membranous nephropathy (pMN). A novel glycoengineered type II anti-CD20 antibody, MIL62 with a nearly completely afucosylated N-glycans in Fc region, has demonstrated superior activity compared with rituximab and obinutuzumab in vitro and in vivo, respectively. To evaluate the safety, tolerability, pharmacokinetics, pharmacodynamics and efficacy of MIL62 in pMN, we conducted a multicenter, randomized, controlled, open-label, phase Ib/II study (NCT05398653).

Method: This study aims to investigated MIL62 or Cyclosporine for the treatment of Chinese pMN. Eligible patients with pMN diagnosed by kidney biopsy, proteinuria of at least 3.5 g per 24 hours received intravenous MIL62 (two infusions, 600 or 1000 mg each, administered 14 days apart; repeated at 6 months) or Cyclosporine (starting at a dose of 3.5 mg per kilogram of body weight per day for 12 months). Patients were followed up for up to 104 weeks. The primary outcome was one of complete or partial remission of proteinuria and stable eGFR at 76 weeks. Laboratory variables and safety were also assessed.

Results: From February 23th, 2022 to December 21th, 2022, 85 patients were randomly enrolled from 19 centers in China, and received at least one dose of MIL62 or Cyclosporine. At the data cut-off date (January 30th, 2023), 60 patients were followed up for at least 12 weeks, 24/40 (60%) patients in the MIL62 group and 7/20 (35%) patients in the Cyclosporine group achieved complete or partial remission; 26 patients were followed up for at least 24 weeks, 11/18 (61.1%) patients in the MIL62 group and 2/8 (25%) patients in the Cyclosporine group achieved partial remission. In the 56 patients who were positive for anti-PLA2R antibodies (≥14RU/mL) at baseline and followed up for at least 12 weeks, 29/38 (76.3%) patients in the MIL62 group achieved immunological remission (PLA2R Abs<14RU/mL), which was superior to the Cyclosporine group where 8/18 (44.4%) patients achieved immunological remission (P<0.05). The remission to MIL62 in our study was rapid because 61.1% of patients achieved complete or partial remission at 24 weeks compared with the 35% 6-month response rate reported in the Membranous Nephropathy Trial of Rituximab study [1]. Among the 85 safety-evaluable patients, treatment emergent adverse events (TEAEs) occurred in 23/30 (76.7%) patients in the MIL62 600 mg group, 26/30 (86.7%) patients in the MIL62 1000 mg group and 24/25 (96.0%) patients in the Cyclosporine group respectively; Grade 3 or above TEAEs were observed in 5 (16.7%), 1 (3.3%) and 2 (8.0%) patients in the MIL62 600 mg, MIL62 1000 mg and Cyclosporine group respectively; Grade 3 or above TEAEs were observed in 5 (16.7%), 0 (0.0%) and 2 (8.0%) patients in the MIL62 600 mg, MIL62 1000 mg and Cyclosporine group respectively. Only one patient in the MIL62 600 mg group experienced serious treatment-related thrombocytopenia and has recovered so far; Other SAEs are not related to treatment. B cell depletion occurred within 24 hours after MIL62 infusion and could last for 24 weeks.

Conclusion: The 12-week immunological remission rate in the MIL62 group was significantly higher than the Cyclosporine group. MIL62 had a manageable safety profile. This phase Ib/II preliminary data warrant further phase III clinical trials of MIL62 in pMN.

**UPDATED INTERIM RESULTS OF A PHASE 1/2 STUDY OF BION-1301 IN PATIENTS WITH IGA NEPHROPATHY**

Jonathan Barratt¹, Laura Kooienga², Irfan Agha³, Pablo Ruiz-Ramon⁴, Arvind Madan⁵, Hanna Thomas⁶, Bess Sorensen⁷, Jocelyn Leiske⁸, Zeeshan Khawaja⁹, Andrew King³ and Charlotte Jones-Burton⁹

**Background and Aims:** Immunoglobulin A nephropathy (IgAN) is the leading cause of primary glomerulonephritis worldwide with limited treatment options, especially for high-risk patients. Approximately 30-45% of IgAN patients progress to end-stage kidney disease over a period of 20-25 years and proteinuria is the strongest predictor of disease progression [1]. BION-1301 is a novel humanized monoclonal antibody that blocks a proliferation-inducing ligand (APRIL), a cytokine that is elevated in patients with IgAN. APRIL promotes the production of pathogenic galactose-deficient IgA1 (Gd-IgA1), leading to immune complex deposition and subsequent kidney injury. Blocking APRIL with BION-1301 is a potential disease-modifying approach to directly target the pathogenesis of IgAN. In a Phase 1/2 study (NCT03945318) in healthy volunteers and patients with IgAN, BION-1301 was well-tolerated with no serious adverse events (SAEs) and durably reduced free APRIL, IgA, Gd-IgA1, IgM and to a lesser extent, IgG [2].

**Method:** For the ongoing phase 1/2 open-label, multicohort trial, eligibility criteria include adults with biopsy-proven IgAN, eGFR > ≥0.5 g/g, and proteinuria > 0.5 g/24 hrs or UPCR > 0.5 g/l and on stable/optimized RASi (or intolerant). Cohort 1 received 450 mg of BION-1301 administered IV every 2 weeks, transitioning to SC at 600 mg every 2 weeks at least after 24 weeks. Cohort 2 received 600 mg of BION-1301 SC every 4 weeks.

**Results:** In both Cohorts 1 and 2, BION-1301 was generally well-tolerated, with no SAEs or terminations due to AEs as of the last reported interim analysis (November 2022) [2]. Durable reductions in serum levels of free APRIL and immunoglobulins were observed in both cohorts. No anti-drug antibodies have been observed in patients with IgAN to date. In Cohort 1, clinically meaningful reductions in proteinuria were seen as early as 12 weeks (30.4% geometric mean UPCR reduction, n = 7), and were sustained through 24 weeks (48.8% geometric mean UPCR reduction, n = 8) and 52 weeks (66.9% geometric mean UPCR reduction, n = 8). Reductions in proteinuria were consistent in Cohort 2 (53.8% geometric mean UPCR reduction, n = 9) at 24 weeks. Significant and durable reductions in serum Gd-IgA1 concentrations were observed and were consistent across both cohorts. Updated data will be reported at the time of presentation.

**Conclusion:** BION-1301 offers disease-modifying potential by directly targeting the initiating pathogenesis of IgAN. Interim biomarker and clinical activity responses support advancement of BION-1301 into later-stage development for patients with IgAN.

**Background and Aims:** Distal renal tubular acidosis (dRTA) is a rare disease, inherited or acquired, characterized by hyperchloremic metabolic acidosis leading to negative effects on growth, bone and kidney, with growth retardation, rickets in children and osteomalacia in adults, nephrolithiasis and chronic kidney disease. No alkalizing treatment, necessary to control the metabolic acidosis and its consequences in growth, bone and kidney, has been shown, to date, to control the disease in the long term. The aim of this clinical study is to describe a cohort of adult and pediatric dRTA patients treated during 6 years by Sibnayal®, a new prolonged-release alkalizing formulation, in term of metabolic control, growth and long-term complications on bone mineralization and kidney function.

**Method:** Thirty patients with genetic dRTA taking Sibnayal® previously treated with alkalizing standard of care and enrolled in the short-term B21CS study, were followed up for six years on average in a multicenter open-label extension trial (B22CS) to evaluate long-term impact of treatment on standard deviation score (SDS) of height, SDS weight, body mass index (BMI), Z-score spine bone mineral density (BMD), phosphocalcic metabolism (up to 4 years). Glomerular filtration rate (GFR), nephrolithiasis, metabolic acidosis control, safety and compliance were also evaluated. Paired t-tests were done from baseline to end of study (EoS) when appropriate. The covariance ANCOVA test was performed to analyze spine BMD Z-score. Data are presented as mean ± standard error of mean.

**Results:** Clinical observations in this cohort, after an average of six years of treatment with Sibnayal®, confirmed the adequate control of metabolic acidosis (plasma bicarbonate from 22.0±6.0 mmol/L at baseline to 22.8±5.6 mmol/L at study end). The phosphocalcic metabolism analysis, from baseline to Month 48, demonstrated no significant change on Z-score for age of blood bone alkaline phosphatases, and a significant decrease of Z-score for age of blood phosphorus level (from -0.5±0.7 to -1.3±1.0, p = 0.03). From baseline to EoS, SDS of height and weight increased significantly (-0.6±1.0 to -0.3±0.9 p = 0.04 and 0.2±1.5 to 0.7±1.4 p = 0.03, respectively), without significant difference in BMI. The spine BMD Z-score, relevant skeletal area for both pediatric and adult patients, underwent a continuous and significant increase of the change from baseline values over 6 years of treatment (difference [95% CI] = 0.404 [0.170; 0.639]). At EoS, spine BMD Z-score was improved in pre- and post-pubertal patients (mean 0.76±0.54 and 0.56±0.22 respectively), while it was stabilized in pubertal patients (mean -0.01±0.39). There was no significant variation of GFR between baseline and EoS. Nephrolithiasis increased slightly according to the increased age of the patient, without surgical intervention for stones removal. Safety and adherence to treatment remained good throughout the study.

**Conclusion:** Our data show the positive effect of the long-term treatment with Sibnayal® on growth and spine BMD, nicely improved, in the dRTA patients who participated to this long-term follow-up clinical study. The kidney function is also stabilized in these patients during the follow-up. This is the first report describing the prevention effect on the long-term complications of the distal Renal Tubular Acidosis patients under 6 years of Sibnayal® treatment.
MATCHING-ADJUSTED INDIRECT COMPARISON OF SPARSENTAN VS DELAYED-RELEASE FORMULATION Budesonide FOR PROTEINURIA REDUCTION IN ADULTS WITH IGA NEPHROPATHY

Xinglei Chai1, Mark Bensink2, Sophie Gao3, Wu Gong2, Ulysse Diva2, Bruce Hendry4, Alex Mercer4 and Jenny Zhou4

1Analysis Group, Inc., Boston, United States of America, 2Travere Therapeutics, Inc., San Diego, United States of America, 3Analysis Group, Inc., Los Angeles, United States of America, 4JAMCO Pharma Consulting, Enskede, Sweden and 5Analysis Group, Inc., London, United Kingdom

Background and Aims: Immunoglobulin A (IgA) nephropathy is a rare kidney disorder characterized by deposition of IgA in the glomeruli and associated with a reduction in renal function and increased risk of kidney failure [1,2]. In the absence of head-to-head trials, this study used matching-adjusted indirect comparison (MAIC) of randomized control trial data to compare 9-month efficacy outcomes between potential treatment options for IgA nephropathy, sparsentan and recently FDA and EMA approved delayed-release formulation budesonide [4,5].

Method: An unanchored MAIC was conducted using individual patient level data from the PROTECT trial for sparsentan and aggregate data from the NefIgArd trial for delayed-release formulation budesonide. Patients in the sparsentan arm of PROTECT were weighted to match the key baseline characteristics of patients in the budesonide delayed-release formulation arm of NefIgArd. After matching, the percentage reduction of urine protein-creatinine ratio (UPCR) at Month 9 relative to baseline were compared between sparsentan and delayed-release formulation budesonide. A two-tailed z-test was performed to estimate the p-value.

Results: Assessment of cross-trial heterogeneities suggested that PROTECT and NefIgArd trials were sufficiently similar in terms of patient population, key inclusion and exclusion criteria, and outcome definitions; however, due to differences in control arms (renin-angiotensin system blocker [RASB] optimization), an unanchored MAIC (comparing treatment arms directly) was selected. After matching, all matched baseline patient characteristics were well-balanced between corresponding treatment arms of the two trials. The comparative results showed that patients treated with sparsentan achieved a greater mean percentage reduction in UPCR at 9 months from baseline compared to budesonide-treated patients (p-value withheld pending FDA approval of sparsentan due to regulatory requirements).

Conclusion: The MAIC results showed that sparsentan was associated with a significantly larger percentage reduction in UPCR, a recognized surrogate of long-term kidney outcomes, from baseline to month 9 compared with delayed-release formulation budesonide.

REFERENCES
Background and Aims: Focal segmental glomerulosclerosis (FSGS) is a disease of podocytes. Complications include nephrotic syndrome and progressive kidney failure. FSGS is a condition with high unmet need and there is no approved treatment. The angiotensin II receptor type 1 (ATIR) and chemokine receptor 2 (CCR2) are G protein coupled receptors that form functional heteromers. Simultaneous antagonism of these receptors suggested synergistic renoprotective effects in preclinical and early phase clinical studies of proteinuric kidney disease. DMX-200 (repagerranium) is a C-C chemokine receptor type 2 (CCR2) inhibitor that, when administered concurrently with an angiotensin II receptor blocker (ARB), is designed to inhibit recruitment of monocytes implicated in the inflammatory chemokine environment of chronic disease. In a Phase 2a open-label study of 27 patients with proteinuric chronic kidney disease, 25% of patients achieved >50% reduction in uPCR with combined use of DMX-200 and irbesartan. A Phase 2a placebo-controlled cross-over study in 8 patients with primary FSGS receiving stable dose of irbesartan demonstrated evidence of promising efficacy with clinically relevant reduction in uPCR of 17% with DMX-200 compared with placebo. These encouraging data suggest that treatment with DMX-200 may result in relevant reduction in uPCR of 17% with DMX-200 compared with placebo.

Results:

- Eligible patients are adults (18-80 years) with biopsy-proven primary FSGS, genetic FSGS or FSGS of undetermined cause (FSGS-UC), and uPCR efficacy of DMX-200 in patients with FSGS receiving an ARB.
- The ACTION3 study design is a Phase 3 randomized, placebo-controlled efficacy and safety trial which evaluates the novel approach of combining an investigational CCR2 inhibitor, DMX-200, with angiotensin receptor blockade in patients with FSGS.
- The study is currently open in 11 countries at approximately 75 investigational sites and will be expanded to include more countries and sites subject to a successful first interim analysis.
- Results: ACTION3 is a trial in progress and is expected to be completed in 2026.
- Conclusion: ACTION3 is a Phase 3 randomized, placebo-controlled efficacy and safety trial which evaluates the novel approach of combining an investigational CCR2 inhibitor, DMX-200, with angiotensin receptor blockade in patients with FSGS.

ASSIST STUDY DESIGN: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, CROSSOVER STUDY OF ATRASENTAN IN PATIENTS WITH IGA NEPHROPATHY (IGAN) ON SGLT2i

Hiddo Lambers Heerspink1, Jonathan Barratt2, Jose Luis Gorriz Teruel1, Srdaha Kotwal3, Soo Kun Lim3, Irene L Noronha1, Valeria Beckett1, Marianne Camargo2, Charlotte Jones-Burton1, Andrew King3, and Amy K. Mottl8

1University Medical Center Groningen, Groningen, Netherlands, 2University of Leicester, Leicester, United Kingdom, 3University of Valencia, Valencia, Spain, 4The George Institute for Global Health, Newtown, Australia, 5University of Malaya, Kuala Lumpur, Malaysia, 6Hospital Beneficiencia Portuguesa de Sao Paulo, Sao Paulo, Brazil, 7Chinook Therapeutics, Seattle, United States of America and 8University of North Carolina at Chapel Hill, Chapel Hill, United States of America

Background and Aims: IgA nephropathy (IgAN) is the leading cause of primary glomerulonephritis. Approximately 30-45% of IgAN patients progress to ESKD over a period of 20-25 years and proteinuria is the strongest predictor of disease progression. Endothelin A (ET\(_{\alpha}\)) receptor activation drives proteinuria, kidney inflammation and fibrosis. Atrasentan, a potent and selective ET\(_{\alpha}\) antagonist, has potential to reduce proteinuria and preserve kidney function in IgAN. Interim results of a phase 2, open-label study in patients with IgAN (AFFINITY, NCT04573920) demonstrated that atrasentan was well tolerated and resulted in clinically meaningful and label study in patients with IgAN (AFFINITY, NCT04573920) demonstrated and CKD (SONAR), 6 week treatment with SGLT2i and atrasentan (n=230) resulted in substantial reduction in proteinuria in patients with IgAN who were also on stable background SGLT2i and RASi therapy.

Methods: The ASSIST trial is a randomized, double-blind, placebo-controlled, crossover clinical trial. Approximately 52 patients with biopsy-proven IgAN and eGFR ≥ 30 mL/min/1.73 m\(^2\) (CKD-epi) who are receiving maximally tolerated RASi for at least 12 weeks prior to screening will be enrolled. Patients on a stable dose of SGLT2i prior to screening (SGLT2i stable) must have total protein of >0.5 grams/day at screening. Patients who are not currently on SGLT2i or are not on a stable dose of SGLT2i must have total protein of >0.5 grams/day at screening and enter a run-in period during which they receive SGLT2i for 8 weeks (SGLT2i run-in), after which they must have a total protein of >0.5 grams/day confirmed at the Week-1 visit (Figure). Choice of SGLT2i will be at the discretion of the principal investigator and per local treatment standards. Thereafter, all eligible patients will be randomized 1:1 to sequence AB or sequence BA in which they receive SGLT2i for 8 weeks (SGLT2i run-in), after which they may have a total protein of >0.5 grams/day at screening and enter a run-in period during which they receive SGLT2i for 8 weeks (SGLT2i run-in), after which they may have a total protein of >0.5 grams/day confirmed at the Week-1 visit (Figure). Choice of SGLT2i will be at the discretion of the principal investigator and per local treatment standards. Thereafter, all eligible patients will have follow-up evaluations for safety approximately 4 weeks after the end of treatment. Fifty-two subjects will provide approximately 83% power using a two-sided pairwise test (α=0.05) to detect a treatment effect of at least 0.288 in natural log transformed UPCR (25% reduction) between atrasentan and placebo.

Results: Primary and secondary endpoints are change in proteinuria (UPCR from baseline to week 24), percentage of patients who achieve treatment success (at least 25% reduction in UPCR), and change in eGFR from baseline to week 24. Type, incidence, severity, seriousness, and relatedness of adverse events will be evaluated. Change in eGFR from baseline to week 24 in Treatment Period 2 will be evaluated as an exploratory endpoint.

Conclusion: Atrasentan is a potent and selective ETA antagonist. Interim results from the AFFINITY Phase 2 open-label study demonstrated that atrasentan resulted in reduced, significantly meaningful reductions in proteinuria in patients with IgAN. The phase 2 ASSIST study will examine the effects of atrasentan in combination with SGLT2i in patients with IgAN who are also receiving maximally tolerated RASI.

SGLT2 INHIBITORS IN IGA NEPHROPATHY: REAL-WORLD CLINICAL PRACTICE

Clara García Carro1, Arianne Aifill Meneses2, Marina López Martínez3, Mercedes Velo1, Antolina Rodriguez-Moreno1, Maria Jose Soler Romeo3 and Ana Sanchez Fructuoso1

1San Carlos University Clinical Hospital, Nephrology, Madrid, Spain and 2Vall d’Hebron University Hospital, Nephrology, Barcelona, Spain

Background and Aims: Immunoglobulin A nephropathy (IgAn) is a common type glomerulonephritis that often progresses to advanced CKD despite the use of ACEi/ARBs and immunosuppression. DAPA CKD has demonstrated that dapagliflozin reduced the risk of CKD progression in patients with IgAn at high risk of progression (mean eGFR, 43.8 mL/min/1.73 m\(^2\), and median urinary albumin-to-creatinine ratio, 900 mg/g) for a median follow up of 2 years. EMPA KIDNEY demonstrated that empagliflozin was associated to a lower risk of progression of CKD than placebo in a pool of 853 patients with glomerular diseases also at higher risk of progression at 2 years of follow up. Based on both RCT, SGLT2i have been proposed as new therapeutic tools for management of IgAn. However, there is a lack of studies in real-world clinical practice. Thus, we aimed to evaluate the renal effect of SGLT2i at 12 months in a cohort of patients with biopsy proven IgAn.

Method: Multicenter retrospective observational study including all patients with biopsy proven IgAn who received SGLT2i in 2 hospitals in Spain. Results: 19 patients were included, followed up for 12 months. 73.7% were men with a mean age of 48.37±16.74 and a mean evolution of IgAN of 3.5 years before SGLT2i initiation. 21% presented type 2 DM. Oxford scores were: M0 68.42%, M1 26.31%; E0 78.95%, E1 5.79%; S0 68.42%, S1 26.31%; T0 84.21%, T1 5.26%, T2 5.26%. No patient presented with crescents, and 63-42% presented IF and TA. Before SGLT2i, 21% have received immunosuppression, and 2 were on steroids at the time of SGLT2i initiation (one budesonide). 94.7% were on ACEi/ARBs, 59.9% received dapagliflozin, 15.8% empagliflozin and 26.3% canagliflozin. At baseline, patients showed creatinine 1.10 (0.91-1.49) mg/dL, eGFR 69.84±28.46 ml/min/1.73 m\(^2\), and UACR 315.00 (210.75-590.75) mg/g. As showed in Table 1, there is a transient decline in eGFR at month 1 after SGLT2i but then, there was a tendency to an improvement in eGFR (from 69.84±28.46 at baseline to 87.83±31.33), and a tendency to a decrease in UACR from 315.00 (210.75-590.75) at baseline to 152.00 (86.75-423.75) at month 12. From month 3 after SGLT2i, a significant decrease in uric acid was observed, and, at month 6, better systolic and diastolic BP control was achieved. A tendency to higher Hb levels was also observed, as well as a decrease in weight at the end of follow up. Interestingly, SGLT2i withdrawal was only necessary in 1 patient who presented acute pyelonephritis and AKI.
Background and Aims: IgA nephropathy (IgAN) is the leading cause of primary glomerulonephritis and has limited treatment options, especially for high-risk patients. Approximately 30–45% of IgAN patients progress to end-stage kidney disease over a period of 20–25 years and proteinuria is the strongest predictor of disease progression [1]. BION-1301 is a novel, humanized monoclonal antibody that blocks a proliferation-inducing ligand (APRIL), a cytokine that is elevated in patients with IgAN. APRIL promotes the production of pathogenic galactose-deficient IgA1 (Gd-IgA1), resulting in immune complex formation and subsequent glomerular deposition, leading to inflammation and kidney injury. Blocking APRIL with BION-1301 is a potential disease-modifying approach to treating IgAN. Interim results from a Phase 1/2 trial of BION-1301 in patients with IgAN (NCT03945318) demonstrate rapid and durable reductions in proteinuria in Gd-IgA1 and sustained, clinically meaningful reductions in proteinuria with an acceptable safety profile [2].

Methods: CHK02-02 is a Phase 3, randomized, double-blind, placebo-controlled study to evaluate the effect of BION-1301 in adults with primary IgAN at risk of progressive kidney function loss. Approximately 272 patients will be enrolled across North America, South America, Europe and Asia-Pacific. Key eligibility criteria include biopsy-proven IgAN within the past 10 years (not due to secondary causes), eGFR ≥ 30 ml/min/1.73 m² (CKD-EPI) and total urine protein ≥ 1.0 g/day at screening. Patients must be stable on a maximally tolerated dose of angiotensin-converting enzyme inhibitor (ACEI)/angiotensin II receptor blocker (ARB) for at least 12 weeks prior to screening or intolerant to ACEI/ARB. Patients may also be on a stable dose of SGLT2i, mineralocorticoid receptor antagonists, and/or endothelin receptor antagonists for at least 12 weeks prior to screening.

The study will be comprised of a screening period (6 weeks), a double-blind treatment period (104 weeks), and a safety follow-up period (24 weeks). Patients will be randomized 1:1 to receive subcutaneous 600 mg BION-1301 Q2W or placebo for 104 weeks. Randomization will be stratified by region (Asia vs. Rest of World), baseline proteinuria (≥ 2 g/day vs. < 2 g/day) and eGFR (< 45 ml/min/1.73 m² vs. > 45 ml/min/1.73 m²). An additional – 20 patients with eGFR 20 to < 30 ml/min/1.73 m² will be enrolled into an exploratory cohort not included in the primary or secondary analyses.

Results: The primary endpoint is change in proteinuria (UPCR from a 24-hour urine collection) from baseline to week 36. The key secondary endpoint is change in eGFR from baseline to week 104. Additional secondary endpoints will evaluate the effect of BION-1301 vs. placebo on composite clinical outcomes including patients experiencing at least one of the following: 30% or 40% reduction in eGFR, eGFR < 15 ml/min/1.73 m², dialysis, kidney transplantation or all-cause mortality. Safety endpoints include type, incidence, severity, and relatedness of adverse events (AEs) and serious AEs. Exploratory endpoints include impact of BION-1301 on disease biomarkers and health-related quality of life as well as analysis of BION-1301 pharmacokinetics and immunogenicity.

Conclusion: BION-1301 provides a potentially disease-modifying approach for the treatment of IgAN by directly targeting the disease pathogenesis. Interim results of the Phase 1/2 open-label trial demonstrated proof-of-concept for BION-1301 to reduce pathogenic Gd-IgA1 and provide sustained, clinically meaningful reductions in proteinuria while supporting SC dosing at 600 mg
Q2W [2]. The Phase 3 trial will evaluate the effect of BION-1301 vs. placebo on proteinuria, eGFR and composite clinical endpoints and key safety measures in adult patients with IgAN at risk of progressive kidney function loss.

TARGETING BAFF AND APRIL IN IGA-NEPHROPATHY
Kirill Komissarov1,2, Darya Nizheharodava3, V. Pilotovich4 and Maryna Zafranskaya4
1Minsk Scientific Practical Center of Surgery, Transplantation and Hematology, Nephrology, renal replacement therapy and kidney transplantation, Minsk, Belarus, 2Belarusian Medical Academy of Postgraduate Education, Urology and Nephrology, Minsk, Belarus, 3Belarusian Medical Academy of Postgraduate Education, Immunology and Biomedical Technology Department of Scientific and Research Labour, Immunology, Minsk, Belarus and 4International Sakharov Environmental Institute of Belarusian State University, Immunology Department, Immunology, Minsk, Belarus

Background and Aims: B-cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL) are critical factors in the differentiation and longevity maintenance of the B-cells pool thereby mediating humoral immunity. BAFF and APRIL are involved in initiating B-cells to become self-reactive and elevated levels of these cytokines are detected in the sera of patients with systemic autoimmune diseases. The aim of the study was to estimate role of APRIL and BAFF in IgA-nephropathy (IgAN) patients and to determine the appropriate IgAN treatment based on the assessment of BAFF and APRIL dynamics in IgAN patients’ sera after 6 months of different treatments.

Method: The 52 IgAN patients aged 32.0 (27.0; 36.0) y.o., male/female ratio as 34/18 despite using of renin-angiotensin-aldosterone system inhibitors (RAASIs) for 6 months with PU 1,8 (1,0; 1,9) g/day and estimated glomerular filtration rate (eGFR) 78 (61; 103) ml/min were divided into 3 treatment groups: 1 group (n = 20) – received glucocorticoids (GC) regimen Pozzi protocol, 2 group (n = 20) – received hydroxychloroquine (HCQ) twice a day, 3 group (n = 12) – received (RAASIs) in maximal tolerated dose. The control group included age- and sex-matched healthy donors (n = 10). The number of B-cells in peripheral blood was identified by flow cytometry method. The concentrations of total IgM, IgG, IgA, IgE, APRIL and BAFF were determined by ELISA method using commercial kits. Statistical analysis was done using Statistica 10.0.

Results: Despite the absence of statistically significant differences in the number of B-lymphocytes the increased levels of total IgM, IgA and IgE (p = 0.001) as well as APRIL (5336 (3574;5965) pg/ml vs 4543 (4518 ÷ 4755) pg/ml (p = 0.05) and BAFF 378 (191;541) vs 336 (257;424) pg/ml (p = 0.07) were established in sera of IgAN patients as compared to control group, respectively. The initial APRIL level was correlated with the degree of tubular atrophy with interstitial fibrosis (R = 0.40, p = 0.05) and serum IgG level (R = 0.35, p = 0.05) in IgAN patients. After 6 months of treatment proteinuria was significantly reduced in HCQ (p = 0.03) and GC (p = 0.02) groups while kidney function was stable in all patients. The dynamic of immunological parameters is presented in the Table 1. It was established that HCQ treatment in IgAN patients decreased the production of IgM (p = 0.01) and IgG (p = 0.02) as well as serum concentration of the APRIL factor (p = 0.05) which correlated with the tendency to eGFR increase (R = –0.46, p = 0.06) as well as with clinical effect of therapy improvement of (R = –0.45, p = 0.04). There were no statistical changes in the level of the BAFF factor in patients with HCQ. After GC treatment a decrease in the synthesis of serum IgA (p = 0.01) as well as trend to decline of B-cells number (p = 0.07) were determined, while in patients treated with RAASIs a significant increase in IgE production (p = 0.05) and tendency in elevation in BAFF levels (p = 0.06) were observed.

Conclusion: Immunological changes may be the determining factors in the choice of treatment in IgAN patients.
blood pressure and serum K+ that received only standard treatment. Protein excretion in 24 h urine, eGFR, received 25 mg of eplerenone daily besides ACEi or ARBs, and a control group with ACEi or ARBs. Patients were divided in the active treatment arm, who

Method:
In this prospective open-label study, we evaluated the effects of treatment in patients with kidney disease due to glomerulonephritis.

deterioration. Nevertheless, there is scanty evidence on the effect of eplerenone in patients with kidney disease due to glomerulonephritis. Type 1 receptor blockers (ARB) can delay kidney disease progression, but plasma aldosterone levels may increase to a significant extent even after the initiation of such treatment. Thus, administration of mineralocorticoid receptor antagonists such as spironolactone, on top of treatment with ACEi or ARBs, can further reduce proteinuria and systolic blood pressure in patients with chronic glomerulonephritis.

A PROSPECTIVE STUDY OF EPLERENONE IN THE TREATMENT OF PATIENTS WITH GLOMERULONEPHRITIS

Marios Papasotirou, Georgia Andriana Georgopoulou, Adamantia Bratsiakou, Theodoros Ntrinias, Dimitrios Goumenos and Evangelos Papachristou

University Hospital of Patras, Department of Nephrology and Kidney Transplantation, Patras, Greece

Background and Aims: Clinical evidence suggests that high aldosterone plasma levels contributes to progressive kidney disease. Although administration of angiotensin-converting enzyme inhibitors (ACEi) or angiotensin type 1 receptor blockers (ARB) can delay kidney disease progression, plasma aldosterone levels may increase to a significant extent even after the initiation of such treatment. Thus, administration of mineralocorticoid receptor antagonists such as spironolactone, on top of treatment with ACEi or ARBs has been shown to reduce albuminuria and slow down kidney function deterioration. Nevertheless, there is scanty evidence on the effect of eplerenone in patients with kidney disease due to glomerulonephritis.

Method: In this prospective open-label study, we evaluated the effects of eplerenone in patients with biopsy proven glomerulonephritis already treated with ACEi or ARBs. Patients were divided in the active treatment arm, who received 25 mg of eplerenone daily besides ACEi or ARBs, and a control group that received only standard treatment. Protein excretion in 24 h urine, eGFR, blood pressure and serum K+ levels were measured at 3, 6 and 12 months after study initiation.

Results: Out of 83 patients who were screened, 62 patients were included in the final analysis. Twenty-six received eplerenone and 36 were treated with ACEi (25) or ARBs (9) alone (controls). After 1 year of treatment with eplerenone, proteinuria decreased from 1597 to 1145 mg/24 h while it did not alter in controls. Eplerenone reduced proteinuria especially in those with baseline proteinuria of >1000 mg/24 h. Kidney function remained stable (from eGFR: 82.51±22.6 to 84.68±31.7 ml/min/1.73 m², p = 0.8) and showed a non significant deterioration in controls (from eGFR: 68.39±26.2 to 66.63±29.8 ml/min/1.73 m², p = 0.08). Systolic blood pressure was significantly reduced in the active treatment arm (from 128±17.3 to 126.3±10.93 mmHg, p = 0.03), whereas eplerenone did not increase serum K+ levels or had any other significant adverse effect.

Conclusion: Administration of eplerenone at a dose of 25 mg/day, on top of treatment with ACEi or ARBs, can further reduce proteinuria and systolic blood pressure in patients with chronic glomerulonephritis.

JAPANESE AND WHITES SHARE SIMILAR IPTACOPAN PHARMACOKINETICS AND PHARMACODYNAMICS

Robert Schmouder1, Guido Jung2, Prasanna Nidamarthy3 and Kenneth Kulmatycki4

1Novartis Pharmaceuticals Corporation, East Hanover, United States of America, 2Novartis Pharma AG, Basel, Switzerland, 3Novartis Healthcare Pvt. Ltd., Hyderabad, India and 4Novartis Institutes of BioMedical Research, Cambridge, United States of America

Background and Aims: Iptacopan (LNP023) is a first-in-class, oral, proximal complement inhibitor that specifically binds to Factor B and inhibits the alternative complement pathway (AP). Current Phase III studies of iptacopan focus on diseases associated with AP activation, such as paroxysmal nocturnal hemoglobinuria, C3 glomerulonephritis, IgA nephropathy, and atypical hemolytic uremic syndrome. These studies are enrolling patients across geographical regions and ethnicities, including those from Japan. The aim of this study was to evaluate the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of iptacopan in Japanese patients.

Method: CLNP023 × 1102 was a randomized, subject-blinded, placebo-controlled, single-dose Phase I study conducted in Japan in healthy Japanese male subjects to assess safety, tolerability, PK, and AP blood biomarkers (Wieslab, Bb) in three dose cohorts, 25, 100, and 400 mg (8 active/2 placebo per cohort). Subjects were dosed on day 1 and observed for 96 hours post-dose. PK and PD data from this study was compared to White data from the similarly designed, previous CLNP023 × 2101 first-in-human study.

Results: Iptacopan was well tolerated in both Japanese and White subjects. White subjects were on average 15.7 years older and 19.5 kg heavier than Japanese subjects. Iptacopan mean (±SD) Cmax and AUCinf as well as mean (±SD) % change from baseline at 12 hours post-dose for Wieslab and Bb by dose are shown in the table below. All three dose groups manifested a general trend of increased systemic exposure and increased AP biomarker inhibition with increasing dose in both Japanese and White subjects.

Conclusion: Japanese and White healthy subjects had similar PK and PD results at all dose levels. The slightly higher Cmax and AUCinf in Japanese subjects may be explained in part by the lower average weight of these subjects. This study provides reassurance that there are no clinically meaningful differences in the human pharmacology of iptacopan between these ethnic groups.

PROTOCOL AND PRELIMINARY RESULTS OF DAPAGLIFLOZIN IN INACTIVE LUPUS NEPHRITIS CROSS-OVER RANDOMIZED TRIAL

Gisele Vajgel1, Carlos Miranda Filho2, Camila Oliveira1, Denise Maria Costa1, Maria Alina Cavalcante1, Brazilian Silva Junior3, Camilla Lima3, Paula Sandrin-Garcia3 and Lucila Valente4

1Hospital das Clínicas, EBSERH/Universidade Federal de Pernambuco, Division of Nephrology, Recife, Brazil, 2Universidade Federal de Pernambuco, Centro de Ciências Médicas, Recife, Brazil and 3Universidade Federal de Pernambuco, Instituto LIKA, Recife, Brazil

Background and Aims: Sodium-glucose co-transporter 2 (SGLT2) inhibitors slow the progression of chronic kidney disease (CKD) with and without type 2 diabetes. Lupus nephritis (LN) patients under immunosuppression were excluded from the most important trials with SGLT2 inhibitors. Thus, efficacy and tolerance of these drugs are unknown in such patients. The present trial will assess the effect of Dapagliflozin in patients with inactive Lupus Nephritis with residual proteinuria.

Method: For this cross-over randomized trial, we will include adult patients with LN class III, IV (+/- V) without active nephritis but with proteinuria ≥ 20mg/24h or UPC > 200mg/g and eGFR ≥ 20ml/min, in the maintenance treatment. RAAS inhibition should be stable for at least four weeks before the randomization. We will exclude patients with other etiologies of CKD, those with active LN lesions on the recent biopsy (AI>2), use of induction therapy in the last 12 months (Cyclophosphamide, Mycophenolate Mofetil > 2 g/day and Calcineurin inhibitors) and prednisone dose ≥ 20 mg/day. Due to safety issues, we will exclude patients with recurrent urinary infections (> 3 times/year). They will be randomized to receive Dapagliflozin 10mg on top of standard of care therapy or not. After 24 weeks the groups will be switched and those without Dapagliflozin will receive it for the next 24 weeks. Primary endpoint will be reduction of proteinuria compared to baseline at 6 and 12 months. Secondary endpoints will include sustained reduction of eGFR > 30%; changes in weight and blood pressure compared to baseline; and number of infections on Dapagliflozin treatment versus exclusive standard of care therapy. The sample size was calculated for 28 patients enrolled providing 80% power to detect a 25% relative risk reduction in proteinuria (α level of 0.05).

Results: From 85 screened class III, IV (+/- V) LN patients under maintenance therapy, we excluded 65 due to active nephritis, low proteinuria or low eGFR. Until now we included 17 patients that were randomized 1:1 to start the treatment with Dapagliflozin on top of standard care or remain with the usual therapy for 24 weeks. Patients' baseline characteristics are described in Table 1. All patients randomized were using Mycophenolate Mofetil ≤ 2 g/day and RAAS inhibition and 14 of them were receiving Hydroxychloroquine.

Conclusion: We expect that the present trial will determine whether the SGLT2 inhibitor Dapagliflozin, added to LN maintenance therapy, could safely reduce the residual proteinuria of inactive LN patients.

Table 1: Patients’ baseline characteristics.

Iptacopan (LNP023) is a first-in-class, oral, proximal complement inhibitor that specifically binds to Factor B and inhibits the alternative complement pathway (AP). Current Phase III studies of iptacopan focus on diseases associated with AP activation, such as paroxysmal nocturnal hemoglobinuria, C3 glomerulonephritis, IgA nephropathy, and atypical hemolytic uremic syndrome. Early modeling efforts suggested that an iptacopan concentration of ~1000 ng/mL would provide near-maximal AP inhibition. The aim of this study was to evaluate the PK of oral iptacopan in healthy subjects to determine the dose that results in a steady-state concentration over the entire 12-h dosing interval.

**Background and Aims:** Iptacopan (LNP023) is a first-in-class, oral, proximal complement inhibitor that specifically binds to Factor B and inhibits the alternative complement pathway (AP). Current Phase III studies of iptacopan focus on diseases associated with AP activation, such as paroxysmal nocturnal hemoglobinuria, C3 glomerulonephritis, IgA nephropathy, and atypical hemolytic uremic syndrome. Early modeling efforts suggested that an iptacopan concentration of ~1000 ng/mL would provide near-maximal AP inhibition. The aim of this study was to evaluate the PK of oral iptacopan in healthy subjects to determine the dose that results in a steady-state concentration over the entire 12-h dosing interval.

**Method:** In this blinded, controlled, randomized study, a total of 32 healthy subjects were enrolled into 5 cohorts receiving twice-daily dosing for 14 days: placebo (n = 8) or iptacopan 25, 50, 100, or 200 mg (n = 6 per group). Plasma iptacopan concentration was intensively measured for 72 hours post day 14 dose using a validated LC-MS/MS assay (LLOQ = 1 ng/mL).

**Results:** Iptacopan treatment was safe and well tolerated at all dose levels. Iptacopan steady-state concentration-time curves are shown below (Figure 1). The mean half-life was moderately long at 18 to 25 hours. The inter-subject variability (CV%) of iptacopan Cmax and AUCinf was low at approximately 12% to 27%, and both parameters were under-dose proportional with increasing dose. At all time points from 0 to 12 hours, mean iptacopan concentration for the 200-mg dose cohort was >1000 ng/mL.

**Conclusion:** Iptacopan was rapidly absorbed, had low inter-subject variability, and a moderately long half-life. Only the 200-mg b.i.d dose produced mean iptacopan concentrations of >1000 ng/mL over the dosing interval, and thus is expected to result in near-complete, continuous AP inhibition. These results support the rationale for use of iptacopan 200 mg twice daily as the therapeutic dose in ongoing clinical trials and provide evidence of durable AP inhibition in patients administered oral iptacopan therapy.

**Conclusion:** Combined oral diuretics with furosemide, amiloride and hydrochlorothiazide is more effective and safer than intravenous furosemide for the treatment of refractory nephrotic edema. These results make amiloride a promising diuretic and further trials with larger sample sizes and longer follow-up are needed in this regard.

**Method:** We conducted a prospective randomized trial in 22 patients with diuretic resistant nephrotic edema. Based on a computer-generated randomization we assigned patients to receive either intravenous furosemide (40 mg bolus and continuous administration of 5 mg/h) or oral furosemide (40 mg/day) and hydrochlorothiazide/amiloride (50/5 mg/day). Clinical and laboratory measurements were performed daily, for five days (body weight, urinary output, blood pressure and hydration status by bioimpedance twice, creatinine, urea, albumin, hematocrit, Na, K, Ca, Mg, bicarbonate, pH). The primary outcome was weight and hydration status change from baseline to day 5. Secondary outcomes were safety outcomes (low blood pressure, severe dyselectrolytemia, acute kidney injury or aggravated hypervolemia).

**Results:** The patients were equally distributed between the two groups. Mean age was 47.77 ± 15.97 (34.5% females and 45.5% males). Half of the patients had membranous nephropathy (45.5%), followed by minimal change disease (22.7%) and lupus nephritis (9.1%). 86.4% of patients had their first episode of nephrotic edema. The mean weight decrease was of significantly larger magnitude in the combined oral diuretics group compared with the intravenous furosemide group (-7.97 ± 2.83 [SD] vs -4.5 ± 2.6 [SD] kg; p = 0.018). Although the increase in 24-hour urine sodium excretion was higher in combined oral diuretics as compared to intravenous furosemide group, this increment was not statistically significant different (26.79 ± 33.48 [SD] vs 16.04 ± 42.81 mmol/24 h [SD]; p = 0.5). Mean values for changes in systolic and diastolic BP, 24-hour urine volume, hydration status measured by bioimpedance were not significantly different between the two groups. A total of 5 patients could not be followed through, 4 in the intravenous furosemide (two patients experienced low blood, one patient had no response to iv furosemide and one patient suffered from insomnia due to iv pump) and one patient in the oral combination of diuretics group had severe hyperkalemia (>6.5 mmol/l).

**Conclusion:** Combined oral diuretics with furosemide, amiloride and hydrochlorothiazide is more effective and safer than intravenous furosemide for the treatment of refractory nephrotic edema. These results make amiloride a promising diuretic and further trials with larger sample sizes and longer follow-up are needed in this regard.
Conclusion: 3 months after treatment with prednisone 1mg/kg was initiated, reducing proteinuria to 6g/day, and stabilized at that level, so proteinuria dropped from 9g to 6g/24H, and stabilized at that level. Immunofluorescence was negative. EVOLOCUMAB was stopped and promoted. No increase in cell number was observed by light microscopy and showed minimal changes in disease. There was a mild focal mesangial proliferative glomerulonephritis. AST and ALT, transaminase, and hepatitis B and C serology were performed.

Results: The occurrence of reversible glomerular lesions reported here should be considered as a potential adverse effect when administrating a prolonged treatment of EVOLOCUMAB. We suggest performing urine test at least once a week, to detect early proteinuria in patients receiving this medication.

FIRST REPORT OF AN EVOLOCUMAB INDUCED NEPHROTIC SYNDROME
Kayisi Saleh1,2,3, Hanaa Badawaki1, Mahmoud Baz4 and Ibrahim Farah4
1 CHU Brugmann, Nephrology, Bruxelles, Belgium. 2 ULB Solbosch, Faculty of Medecine, Ixelles, Belgium and 3 Grand Hospital Eastern Francilien Meaux, Nephrology, Meaux, France

Background and Aims: Proprotein convertase subtilisin/kexin type 9 inhibitors (PCSK9 inhibitors) reduce LDL-C and short-term risk of cardiovascular events by acting on the proprotein convertase subtilisin/kexin type 9 (PCSK9), an enzyme produced in the liver. This article highlights the case of a 69-year-old man who developed nephrotic syndrome (NS) secondary to EVOLOCUMAB injection. To our knowledge, this is the first time that minimal change disease is described as associated with EVOLOCUMAB.

Method: Case Report describing a 69-year-old male with coronary artery disease who started EVOLOCUMAB injection every two weeks. Six weeks later, after the third dose of EVOLOCUMAB, he developed edema, and high blood pressure 180/90 mmHg. Laboratory tests showed a creatinine of 88 μmol/l and a GFR of 77 ml/min/m² associated with severe proteinuria of 9g/24H, normal level of anti-PLA2R, negative ANA (<1/80) and ANCA (<1/80), and negative hepatitis B and C serology.

Results: Kidney biopsy was obtained to investigate this nephrotic syndrome and showed minimal change disease. There was a mild focal mesangial prominence not exceeding three or four cells per segment by light microscopy (LM). Immunofluorescence was negative. EVOLOCUMAB was stopped and proteinuria dropped from 9g to 6g/24H, and stabilized at that level, so treatment with prednisone 1mg/kg was initiated, reducing proteinuria to 3g/24H one month later with clinical improvement.

Conclusion: The occurrence of reversible glomerular lesions reported here should be considered as a potential adverse effect when administrating a prolonged treatment of EVOLOCUMAB. We suggest performing urine test at least once a week, to detect early proteinuria in patients receiving this medication.

A COMPARATIVE RETROSPECTIVE STUDY OF PATIENTS WITH ADPKD: FIRST RESULTS RELATING TO THE USE OF TOLVAPTAN
Theodora Oikonomaki, Alexandros Nikolaos Liatsos, Angeliki Paikopoulou, Dimitris Avgikos, Vasiliki Choutlidou and Christallenia Christodoulidou
Evangelismos General Hospital, Nephrology, Athens, Greece

Background and Aims: Autosomal Dominant Polycystic Disease (APKD) is the fourth leading cause of End Stage Renal Failure (ESRD). Since 2015, the administration of Tolvaptan has been approved in patients with APKD at high risk of progression to ESRD (Mayo classification criteria, classes 1C-D).

Method: In this study we compare the characteristics of APKD patients who received Tolvaptan (45/15 mg) in relation to those who did not receive but followed the periodic check-up. There are 33 people with an average age of 44.17 ± 13.6 years. Tolvaptan was administered to 9 (27.3%) patients who met the Mayo classification criteria for its administration. The mean follow-up time for all the patients was 11.41 ± 4.7 months and for those taking tolvaptan it was 10.6 ± 3.9 months. Values of urea, creatinine, plasma sodium, specific gravity and urine osmolarity were determined at the start of follow-up and compared with those at the last visit.

Results: A significant reduction was observed in the values of urea, osmolality and specific gravity of urine after one year of tolvaptan use compared to the group that did not receive the treatment and thus no titration of the drug dose was needed. In the same group, marginally higher values of the plasma sodium were observed, but within normal limits. The indicators of renal function in both groups did not show any change.

Conclusion: At one year of follow-up, APKD patients who received Tolvaptan did not exhibit worsening of the kidney function. We observed changes in the values of urea, urine specific gravity and urine osmolality associated with our instructions to drink more water, showing good compliance with the treatment.

EXTENDED LOW DOSE RITUXIMAB REGIMEN FOR THE TREATMENT OF ADULT PATIENTS WITH STEROID-DEPENDENT AND FREQUENTLY RELAPSING MINIMAL CHANGE DISEASE
Irene Mínguez Toral, Javier Villacorta Pérez, Maria García Vallejo, Jorge Sánchez Iglesias, Guillermo Fernández, Marcos Piris, Fernando Caballero Cebrían, Esther Casillas, Vanessa Lopes and Milagros Fernandez Lucas
Hospital Universitario Ramón y Cajal, Nephrology, Madrid, Spain

Background and Aims: Patients with frequently relapsing and steroid-dependent minimal change disease (MCD) imply a therapeutic challenge for nephrologists. The use of steroid sparing agents such as cyclosporine, rituximab and mycophenolate, allows minimization of steroids exposure among these patients. In children and adults, Rituximab has demonstrated safety and efficacy in some studies although there is no established treatment regimen. This study aims to demonstrate that a low dose extended regimen of rituximab is an effective alternative for preventing relapses among these patients.

Method: This is a single-centre retrospective descriptive study of a case series of adult MCD patients from Ramón y Cajal Hospital in Madrid, Spain. Since 2019, patients with steroids-dependent or frequently relapsing MCD were treated with a low dose extended protocol of Rituximab as follows: 500 mg of rituximab once remission is achieved with steroid therapy, and four additional doses at month +6, +18 and +30 during the follow-up. Relapse free survival was analyzed after rituximab therapy.

Results: Eight patients with a median age of 42 years (22–70 years) who received at least one dose of intravenous rituximab were included. Four of the patients (50%) had previously received additional immunosuppressive regimens (including cyclophosphamide, chlorambucil cyclosporine, mycophenolate or ACTH). Two of them (25%) had frequent relapses and the remaining six (75%) had steroid-dependent behaviour. After a median of 2 years (IQR, 1-3.3) of follow-up, 6 out of 8 (75%) patients stayed under remission.

Table 1: Values of urea, creatinine, plasma sodium, specific gravity and urine osmolality at the start of follow-up and at the last visit, of the two groups of the study.

REFERENCES
experiencing the remaining two one relapse at one month and at one year, respectively, after the first rituximab dose. Comparing relapses during the two years-period before and after rituximab use, the median relapse rate per patient dropped from 2.8 (IQR, 2-4) to 0.5 (IQR, 0-1; P = 0.001) (Fig. 1). No patient experienced rituximab related side effects nor infections during the study period.

Conclusion: In MCD patients, the administration of rituximab in an extended low-dose regimen as corticosteroid-sparing therapy appears to be safe and effective in most of the patients for preventing relapses. This regimen allows minimization exposure to rituximab as well as disease remission during a longer period of time.

Background and Aims: IgA nephropathy (IgAN) is the most common cause of primary glomerulonephritis in Turkey, as well as all over the world. Along with the frequent occurrence, deleterious renal outcome odds make treatment approaches important. Additionally, for high-risk individuals immunosuppressive treatment (IST) is recommended. However, studies to date revealed conflicting results regarding IST. Therefore, we aimed to investigate IST results among IgAN patients which is the leading primary glomerulonephritis in Turkey.

Method: The data of 1656 IgAN patients in the Primary Glomerular Diseases Study of the Turkish Society of Nephrology Glomerular Diseases Study Group (TSN-GOLD) were analyzed. A total of 506 primary IgAN patients (63.4% male, mean age 38.9±12.5 years) were included and divided into two groups according to treatment protocols as isolated corticosteroid (69.6%) and combined IST (30.4%) groups. The median follow-up duration was 24 (3-218) months.

Results: Remission (66.6% partial remission, 33.4% complete remission) was achieved in 70.6% of patients. Systolic and diastolic blood pressures, urea, creatinine, and proteinuria levels were lower, and eGFR levels were higher in responsive patients (Table 1). There was no difference between the treatment groups in terms of remission rates (p = 0.147) and remission types' rates (p = 0.279). Remission rates were different between treatment subgroups. However, there was no difference between the treatment subgroups according to the remission types (p = 0.132) (Table 2). Complete remission was lower in the S1 and T1 categories (p = 0.003 and 0.039, respectively). The serious infection was higher in the combined IST group (17.1% vs 2.9%). The outcome data of 229 individuals was evaluated, 40 of 229 (17.5%) developed ESRD and 8 were dead. In the multivariate analysis, eGFR (OR 1.007, 95%CI 1.001-1.013, p = 0.020), proteinuria (OR 1.000, p = 0.009), MEST-C T2 (OR 1.912, 95%CI 1.216-3.065, p = 0.005), MEST-C T2 (OR 0.226, 95%CI 0.102-0.501, p = 0.001) were found to be significant regarding remission.

Conclusion: IST provides remission in high-risk IgAN patients but was associated with serious adverse events. The fact that the remission rates were similar between the treatment groups and that the complete remission rate was low in chronic changes supports the necessity of determining the treatment choice according to patient characteristics.

Figure 1: Box plot of the number of nephrotic syndrome relapses during the two years-period before and after rituximab administration in the study group.
The proportion of unaffected glomeruli was independent predictor of kidney outcome in patients with ANCA-associated GN.

THE PROPORTION OF UNAFFECTED GLOMERULI IS A ROBUST PROGNOSTIC FACTOR OF KIDNEY OUTCOME IN PATIENTS WITH ANCA-ASSOCIATED GLOMERULONEPHRITIS

Seung Min Song, Hyun Suk Lee, Minhyung Kim, Min Young Jang, Jeunseok Jeon, Hye Ryoun Jang, Gee-Young Kwon, Woosung Huh, Yoon-Goo Kim and Jung Eun Lee

Samsung Medical Center, Division of Nephrology, Department of Medicine, Seoul, Korea, Rep. of South Korea

Background and Aims: Anti-neutrophil cytoplasmic antibody (ANCA) associated glomerulonephritis (GN), the most common form of secondary GN in elderly (>60 years), requires immunosuppressive treatment that may increase risk of opportunistic infections. This study evaluated the prognostic value of clinical factors and histopathologic findings affecting kidney outcome in ANCA-associated GN patients.

Method: From 2000 to 2018, we identified 106 adults (≥ 18 years old) who were pathologically confirmed as ANCA-associated GN. The number of normal, crescent, and sclerotic glomeruli was recorded for each biopsy by slide review. The primary outcome was incident end stage kidney disease (ESKD).

Results: The age was 67 (57-73) years, the estimated glomerular filtration rate (eGFR) was 19 (11-36) mL/min/1.73 m², and % of normal glomeruli in kidney specimen was 25 (11-47) %. Overall kidney survival was 85% and 76% at 1 and 5 years, respectively. Among clinical variables, lower eGFR (<15.7 mL/min/1.73 m²) was independently associated with increased risk of incident ESKD. Multivariate Cox proportional hazard model including both clinical and histological variables demonstrated that % of normal glomeruli (aHR, 0.960; 95% confidence interval [CI], 0.935-0.986; p < 0.001) was independently associated with increased risk of incident ESKD, independently of eGFR and other pathological findings. When the % of normal glomeruli was divided by quartiles, the risk of incident ESKD in the lowest quartile was significantly increased compared to the highest quartile (<11%; HR, 5.986; 95% CI, 2.114-16.950 vs. > 46%; p < 0.001).

Conclusion: The proportion of unaffected glomeruli was independent predictor of kidney outcome in patients with ANCA-associated GN.

A LOW DOSE GLUCOCORTICOID, LOW DOSE CYCLOPHOSPHAMIDE, RITUXIMAB TREATMENT PROTOCOL AS INDUCTION THERAPY IN ANCA ASSOCIATED VASCULITIS PATIENTS

Georgios Spanos, Styliani Paschou, Marianna Bakou, Alexandros Atalla, Christos Bantis, Stylianos Fragidis, Livia Karmen Armetzoiou and Gerasimos Bamichas

General Hospital of Thessaloniki “G. Papanikolaou”, Nephrology Department, Thessaloniki, Greece

Background and Aims: There has been a considerable improvement in the survival of patients with ANCA associated vasculitis (AAV) since the introduction of immunosuppressive therapy. Nowadays early deaths are attributable to infection while cardiovascular disease, infection and malignancy are the most common causes in long term mortality in these patients. High-dose glucocorticoids and cyclophosphamide have numerous dose-dependent adverse effects and are associated with those events. The aim of this study is to investigate the efficacy and safety a low dose glucocorticoids, low dose cyclophosphamide, rituximab treatment protocol in AAV patients.

Method: This is a single-centre cohort study of patients on a combination of reduced-dose oral glucocorticoids, rituximab and low-dose pulsed intravenous cyclophosphamide followed by a maintenance regimen of rituximab and tapered steroid for the treatment of AAV (table). Data shown as median (IQR).

Results: Nine patients (3 women) aged 62.4 (55/67.8) years, with serum creatinine (sCr) 2.15 (1.8/2.5) mg/dL, eGFR CKD-EPI 28 (20/39) ml/min/1.73 m², albuminuria 0.98 (0.57/1.45) g/24 h and BVAS 14 at baseline were treated with the mentioned protocol. Seven patients had MPO and 2 had double MPO/PR3 positivity. Two were already on dialysis and 4 had pulmonary involvement. The median follow-up was 19 (12.5/39) months. One patient required the addition of plasma exchange and extended treatment due to aggressive disease and one was lost to follow-up after four months. The rest of the 7 patients were dialysis free with a sCr 2.15 (1.8/2.5) mg/dL, eGFR 28 (20/39) ml/min/1.73 m² at the end of follow-up. Patient and renal survival were 88% and 100% respectively. 85.7% of patients achieved ANCA-negative status and all remained B cell

deplete at 6 and 18 months. There were no major relapses, while two patients had infection related hospitalization. No unexpected side effects were observed during follow-up.

**Conclusion:** These findings confirm the literature that a combined regimen provides early disease control with low relapse rates, without significant adverse effects from immunosuppression. A regimen like this may provide the basis for further refinement of remission induction protocols in AAV, potentially allowing early withdrawal of corticosteroids.

**STUDY OF THE EFFECT OF TWO BARIATRIC SURGERY TYPES ON RENAL FUNCTION AND MCP-1 LEVELS**

Alaa Sabry and Ahmed Bahy
Mansoura, Mansoura, Egypt

**Background and Aims:** Bariatric surgery has been the most effective and permanent treatment for severe obesity and has resulted in significant improvement or reduction of comorbidities due to obesity. To evaluate and compare the outcome of two types of bariatric surgery (LMGB and LSG) on renal functions and urinary MPC-1 level in morbidly obese patients after three months of surgery.

**Method:** Forty morbidly obese patients underwent bariatric surgery between October 2018 and July 2019. Two types of bariatric surgery were done; laparoscopic mini gastric bypass (LMGB) and laparoscopic sleeve gastrectomy (LSG). Group A include 26 patients underwent LSG and Group B include 14 patients.

**Results:** There were no statistically significant difference in the postoperative mean weight, BMI, neck circumference, WC, Hip circumference, WHR, SBP and DBP in the cases between the 2 types of surgeries (LSG and LMGB) also, there were no statistically significant difference in the mean post urinary MCP1 (73.53±21.25 & 75.43±26.17, P>0.5), post microalbuminuria (8.83±6.26 & 8.6, P>0.05), post urinary creatinine (109.21±43.22 & 99.19±48.65, P>0.05), post MCP1/Cr ratio (0.78±0.36 & 0.75±0.37, P>0.05), post CRP (5.73±3.04 & 5.77±3.17, P>0.05), post serum creatinine (0.74±0.05 & 0.75±0.07, P>0.05), eGFR (100.32±9.54 & 104.39±9.54, P>0.05), s.cholesterol, s.HDL and s.TGs in the cases who had either LSG operation (group A) or LMGB operation (group B).

**Conclusion:** There were no statistically significant difference as regard renal function, urinary MCP-1 level and weight loss between LSG and LMGB.

Background and Aims: We aimed to evaluate the effect of glomerular C3 deposits on clinical and laboratory findings and outcome in patients with idiopathic membranous nephropathy (MN) included in the Primary Glomerular Diseases Study of Turkish Society of Nephrology Glomerular Diseases Study Group (TSN-GOLD).

Method: The data of 1595 patients with MN in the database has been evaluated. 114 patients were excluded due to lack of data about C3 staining, 54 patients due to secondary MN and 523 due to lack of data about the follow-up. Patients with glomerular C3 deposits were compared with those with no C3 staining.

Results: Glomerular C3 deposits were detected in kidney biopsy specimens of 601 patients of the 888 patients analysed. The demographic data, clinical and laboratory findings at the time of diagnosis of C3 (+) and C3 (-) groups are presented in Table 1. They were similar except serum albumin level that was lower in C3 (+) group. Subepithelial deposits and interstitial fibrosis was more prominent, IgG, Kappa and Lambda staining more intense, positivity for C1q and IgA was more frequent in C3 (+) group (Table 2).

The study groups were similar regarding remission rates after the first immunosuppressive treatment (p = 0.582). 155 patients (25.8%) had partial, 152 (25.3%) had complete remission while no remission was detected in 92 patients (15.3%) in C3 (+) group. 69 patients (24.0%) had partial and 81 patients (28.2%) had complete remission; 40 patients (13.9%) had no remission in C3 (-) group. The relapse rates were 17.6% and 19.9% in C3 (+) and C3 (-) groups (p = 0.360). The percentage of patients who died or needed renal replacement therapy (RRT) were higher C3 (+) group (p = 0.013) (Figure 1).

Conclusion: Need for RRT and mortality is higher in patients with C3 deposition showing the importance of C3 deposition in the prognosis of MN. More prominent interstitial fibrosis may be related with the worse outcome.

ANTICOAGULANT-RELATED NEPHROPATHY – AN UNDERDIAGNOSED COMPLICATION

Tefik Islami1, Marilena Gregorini2, Gioacchino D’Ambrosio2, Paolo Del Vino1, Eleonora Francesca Pattonieri1, Miriam Fusli3, Pietro Canu4, Carlo Maurizio Montecucco5 and Teresa Rampino6

1University of Pavia, Dipartimento di scienze clinico-chirurgiche, diagnostiche e pediatriche, Pavia, Italy, 2University of Pavia / IRCCS Fondazione Policlinico “San Matteo”, Department of Internal Medicine and therapeutics, Pavia, Italy, 3University of Pavia, Department of Internal Medicine and therapeutics, Pavia, Italy, 4IRCCS Fondazione Policlinico “San Matteo”, Nephrology, Dialysis and Transplant Unit, Pavia, Italy, 5University of Pavia, Scuola di Specializzazione in Nefrologia, Pavia, Italy, 6University of Pavia, Scuola di Specializzazione in Medicina Interna, Pavia, Italy, 7University of Pavia / IRCCS Fondazione Policlinico “San Matteo”, Reumatology, Pavia, Italy and 8University of Pavia / IRCCS Fondazione Policlinico “San Matteo”, Nephrology, Dialysis and Transplant Unit, Pavia, Italy

Background and Aims: Anticoagulant-related nephropathy (ARN) is an underdiagnosed complication of anticoagulant therapy (AT).

Method: We report 3 cases of ARN.

Patient 1: 31 year-old male (M), kidney transplanted for reflux nephropathy, with normal renal function (Rfx) and urinalysis (U), on therapy with tacrolimus (FK), everolimus and mycophenolate. He started edoxaban (E) (60 mg od) for deep vein thrombosis (DVT). After 10 days he developed hematuria and Acute Kidney Injury (AKI). Ruled out urological and infectious causes, we performed kidney biopsy (KB) which showed extensive tubular necrosis (TN), erythrocyte casts (cRBC) and glomerular hemorrhage (EG). Perl’s stain (PS) showed iron deposits in tubular cells released by erythrocytes lysis (Fig. 1). Although E posology was adequate the concomitant intake of FK by reducing CYP3A4 metabolism of E resulted in over anticoagulation (OAC), demonstrated by the dosage of the factor Xa (FXa) at peak. Upon withdrawal of AT, Rfx and U normalized.

Patient 2: 73-year-old M with hypertension and mild chronic kidney disease (CKD) on antiplatelet therapy (ASA 100 mg od) for biological valve prosthesis and AT with Enoxaparin sodium (Es) (4000UI od) for DVT prophylaxis. He was admitted to the hospital for fever and hypotensive episodes. Microbiological, neoplastic and immune investigations were negative. A progressive worsening of Rfx associated with macro-hematuria was observed, requiring renal replacement therapy (RRT). KB showed a post-infectious glomerulonephritis, but in the hypothesis that tubular damage was enhanced by antiplatelet/AT, PS was performed and resulted positive. OAC was confirmed by the dosage of the factor Xa (FXa) at peak. After withdrawal of therapy, progressive improvement of the Rfx and hematuria were observed, such as to allow the suspension of the RRT.

Patient 3: 54 year-old M with kidney and lung involvement of ANCA-associated vasculitis. After rituximab induction therapy he showed marked improvement on lung and renal function and antibody titer (c-ANCA PR3 positive). He experienced an unusual worsening of Rfx and hematuria after starting a AT (Es 6000 UI BID) to treat a DVT. A KB was performed in the suspicion of ARN. The histology revealed an extensive TN, numerous cRBC with extracapillary glomerulonephritis and PS positive. IF was negative. OAC was confirmed and adjustment of anticoagulation dose for glomerular filtration rate resulted in improvement of Rfx.

Results: ARN is a not uncommon occurrence in cases of OAC and glomerular fragility (Table 1).

Conclusion: ARN should be suspected in predisposed patients in whom glomerular hyperfiltration or preexisting GN during OAC facilitate EG. Attention should be given to drug interactions that can induce an unrecognized OAC. The cases described underline the need for careful monitoring of U, Rfx and FXa activity to promptly treat this complication, avoiding permanent damage.

Figure 1: Histology and pathophysiologic hypothesis.

MYCOPHENOLATE MOFETIL AS IMMUNOSUPPRESSIVE THERAPY IN IGA NEPHROPATHY

Henry Barrington-White1, Abigail Pomeranc2, Conor Murphy2 and Farid Ghalli2,3

1University Hospitals Sussex, Sussex Kidney Unit, Brighton, United Kingdom, 2University Hospitals Sussex, Sussex Kidney Unit, Brighton, United Kingdom and 3Brighton and Sussex Medical School, Brighton, United Kingdom

**Background and Aims:** IgaNephropathy is the commonest cause of primary Glomerulonephritis in developed countries. It is characterised by Iga-deposits on the mesangium. Classical presentation with asymptomatic non-visible haematuria or episodic visible haematuria 24-48 hours after an upper respiratory tract infection, raised BP and Proteinuria. End-stage renal disease (ESRD) can occur in up to 20-50% of patients. Treatment with ACEI/ARB has strong evidence in managing Iga. If there is evidence of progression, steroids and immunosuppression are recommended. Mycophenolate Mofetil's effectiveness in IgaNephropathy is controversial. KIGO guidelines authors suggest not to use it. In this work, we reviewed immunosuppression with mycophenolate Mofetil (MMF) retrospectively in IgaNephropathy patients managed at Sussex Kidney unit – Brighton -UK.

**Method:** We retrospectively reviewed 25 patients who had a diagnosis of IgaNephropathy and were treated with mycophenolate mofetil as immunosuppression for Iga nephropathy under the care of the Sussex Renal Unit at University Hospitals Sussex. Patients reviewed, had been diagnosed between 2011-2020. Data collected from our department's electronic system, including laboratory results, histopathology reports, clinic letters and medications. Data were collected until January 2023 for patients who had renal survival. For patients who started on renal replacement therapy (RRT), data were collected until the start of RRT. The work aimed at looking at MMF efficacy in IgANephropathy.

**Results:** We reviewed 25 patients, 13 male and 12 female. Twenty-four patients (96%) were of white Caucasian ethnicity while one patient (4%) was Asian. The mean age was 42.4± 16 years. All the patients were diagnosed with both clinical pictures and renal biopsies. Oxford classification score showed M1 (21) patients, E (5 patients), S (19 patients), T (1 = 10 patients, 2 = 4 patients), and C (1 = 15 patients, 2 = 4 patients). On presentation, 5 patients presented with a sore throat, 8 with skin rash and 7 with macroscopic haematuria. Seventeen patients (60%) presented with AKI. Eleven patients (44%) had nephrotic range proteinuria on presentation. The average duration of the disease was 6.1 years at the time of assessment. MMF was used in the 25 patients, five of them had prednisolone and cyclophosphamide for 3 months followed by MMF maintenance. Twenty patients were treated with MMF alone or in combination with steroids (17 patients) from the start. The average duration of treatment was 2 years, and the average dose was 1 gm twice daily. Five patients (20%) progressed to ESRD and three of them had renal transplantation while twenty patients (80%) maintained renal survival. For the 80% who maintained renal survival the mean eGFR at diagnosis was 54.5± 34.1 and at the time of assessment was 56.1±26.6. Of the 17 patients presented with AKI five patients (29%) recovered to normal renal function, five patients had ESRD (29.4%) and four had improvements of eGFR while three patients showed a decrease of eGFR (Mean 45.6± 1.1 ml/min) to eGFR (Mean 32± 8.2 ml/min). In total, 70.6% of AKI patients recovered either to normal or to CKD level and 80% of the total patients had renal survival without RRT during the time of review. Twenty patients (80%) achieved more than 50% reduction of proteinuria, with five patients (20%) having proteinuria less than 0.3 g/24 hours and 9 (36%) patients less than 0.5 g/24 hours. Comparison between the proteinuria at diagnosis and at the time of assessment was significant (P<0.001).

**Conclusion:** Mycophenolate mofetil was effective in maintaining renal survival and improving proteinuria in Iga nephropathy patients who were indicated for immunosuppression based on histopathology and risk of progression. It was well tolerated by patients. A randomised controlled trial is needed to compare the MMF effect in comparison with currently available therapies.

KIDNEY TUBULE POLYPLOIDIZATION DURING PHYSIOLOGIC AGEING IN MICE

Elena Lazzeri1, Giulia Antonelli1, Carolina Conte1, Maria Lucia Angelotti1, Benedetta Mazzinghi2, Giulia Carangio1, Letizia De Chiara1 and Paola Romagnani1,2

1University of Florence, Department of Biomedical, Experimental and Clinical Sciences "Mario Serio", Florence, Italy and 2Meyer Children's University Hospital, Nephrology Unit and Dialysis Unit, Florence, Italy

**Background and Aims:** The aged population is constantly increasing, and kidney-aging is a risk factor for both acute kidney injury (AKI) and chronic kidney disease (CKD). Accordingly, CKD is a major global health problem with an increasing prevalence in older population. Therefore, there is an urgent need to understand the age-related mechanisms underlying CKD development and progression. Renal function parameters were assessed at 2, 5, 11 and 20 months before sacrifice. Kidneys were analyzed for senescence and interstitial fibrosis at 2, 5, 11 and 20 months of age. Results: Genetic and single-cell transcriptomic approaches in mice were used to investigate TC polyploidization during physiologic ageing in mice. We retrospectively reviewed 25 patients who had a diagnosis of IgaNephropathy and were treated with mycophenolate mofetil as immunosuppression for Iga nephropathy under the care of the Sussex Renal Unit at University Hospitals Sussex. Patients reviewed, had been diagnosed between 2011-2020. Data collected from our department's electronic system, including laboratory results, histopathology reports, clinic letters and medications. Data were collected until January 2023 for patients who had renal survival. For patients who started on renal replacement therapy (RRT), data were collected until the start of RRT. The work aimed at looking at MMF efficacy in IgaNephropathy.

Of the 17 patients presented with AKI five patients (29%) recovered to normal renal function, five patients had ESRD (29.4%) and four had improvements of eGFR while three patients showed a decrease of eGFR (Mean 45.6± 1.1 ml/min) to eGFR (Mean 32± 8.2 ml/min). In total, 70.6% of AKI patients recovered either to normal or to CKD level and 80% of the total patients had renal survival without RRT during the time of review. Twenty patients (80%) achieved more than 50% reduction of proteinuria, with five patients (20%) having proteinuria less than 0.3 g/24 hours and 9 (36%) patients less than 0.5 g/24 hours. Comparison between the proteinuria at diagnosis and at the time of assessment was significant (P<0.001).

**Conclusion:** Mycophenolate mofetil was effective in maintaining renal survival and improving proteinuria in Iga nephropathy patients who were indicated for immunosuppression based on histopathology and risk of progression. It was well tolerated by patients. A randomised controlled trial is needed to compare the MMF effect in comparison with currently available therapies.
and an age-related decline of renal function starting from 5 months of age. Collectively, these results suggest TC polyploidization is a potential trigger for CKD development and progression during physiologic kidney ageing in mice.

**Conclusion:** This study demonstrates the increase of TC polyploidization, which is associated with a progressive fibrosis, senescence and CKD development during physiologic kidney ageing in mice.

Medical University of Vienna, Department of Pediatrics and Adolescent Medicine, Vienna, Austria, 4. INSEME 1033, Lyon, France and 5. Cardiovascular Research Institute Maastricht, Maastricht, Netherlands

**Background and Aims:** Patients with advanced stages of chronic disease (CKD) suffer from 30-times higher risk of cardiovascular disease (CVD) as compared to the general population, vascular calcifications are prevalent. Underlying molecular mechanisms are only partly understood. Children are devoid of lifestyle and aging related CVD risk factors and therefore allow for a highly sensitive and specific analyses of CKD induced pathomechanisms.

**Method:** Arteriolar tissues of 55 children with normal renal function and 29 children with CKD5 (median age 9.2 years) underwent digital histomorphometry, calcium deposits were assessed by Von Kossa staining and 18F-sodium fluoride positron emission tomography (18F-NaF PET). Gene set enrichment analysis (GSEA) and Ingenuity pathway analysis were performed on multi-omics data sets obtained from micro-dissected ontal arterioles from children with normal renal function and with CKD5 (n = 7/group; age 7.3 ± 3.6/8 ± 3 years). Based on literature review, we established a vascular calcification (VC) pathway library comprising 442 biological processes/molecular functions and extracted linked genes from Gene Ontology database. Key identified mechanisms were validated in independent patient cohorts (n = 32) and controls (n = 20) by quantitative immunostaining.

**Results:** Significant arteriolar lumen obliteration was present in CKD5 children (p < 0.0001 and p = 0.02). Von Kossa staining was negative, but 18F-NaF PET revealed microcalcifications in children with CKD5. Subendothelial arteriolar inflammatory cells (CD68+ macrophages) were present in CKD5 cohort (p < 0.0001 compared to non-CKD controls) and correlated with serum inorganic phosphorus (R2 = 0.18; p = 0.04). GSEA identified top enriched pathways including telomere extension by telomerase and chromatin histone methylation. IPA cross-omics showed suppression of actin cytoskeleton, tight junction signaling, and focal adhesion. VC pathway analysis identified 30/442 pathways related to actin cytoskeleton, Wnt signaling, extracellular matrix (ECM) organization, complement activation, apoptosis, endoplasmic reticulum stress and ossification regulation. Fibronectin-1 (FN1) was identified as Hugene, involved in ECM regulation. In independent age-matched cohorts, complement factor C3d was higher in CKD5, vascular endothelial growth factor and endothelial cell number/μm endoluminal circumference were reduced. Arteriolar osteoglycin, a protein inducing ectopic bone formation, was increased and correlated with serum PTH (R2 = 0.61; p = 0.01). FN1 was less abundant in arterioles from CKD5 children and negatively correlated with serum creatinine levels (R2 = 0.62; p = 0.02).

**Conclusion:** Vascular disease and microcalcifications are present in young children with CKD5. We provide the first comprehensive analysis of the underlying molecular mechanisms associated with the vascular calcifications and identified specific molecular pathomechanisms, of which several represent potential therapeutic targets.

**TRANSCRIPTION FACTOR ATF3 EXACERBATES RENAL FIBROSIS THROUGH RECRUITING HISTONE ACETYLASES**

**Lina Yang**, **Tilong Chen**, **Ping Fu**, **Liang MA** and **Haoping Yu**

1. West China Medical School, West China Hospital, Sichuan University, Kidney Research Institute, Cheng Du Shi, P.R. China and 2. West China Medical School, West China Hospital, Sichuan University, Biomedical Big Data Center, Cheng Du Shi, P.R. China

**Background and Aims:** Chronic kidney disease (CKD) threatens public health around the world. Renal fibrosis is a final common pathology in renal diseases of different etiologies. However, no efficient, broadly applicable anti-fibrotic therapies exist. Histone acetylation is an epigenetic modification involved in the regulation of multiple disease-specific gene expressions, balanced by histone acetyltransferases and histone deacetylases (HDAC) enzymes. Transcription factors (TF) could recruit histone-modifying enzymes and alter gene expression. But now, much remains unknown about the role of histone acetylation and whether there exists the regulator of it in fibrosis of CKD. Here, we for the first time explored a novel aspect of ATF3 promoting kidney fibrosis via recruiting the histone acetylases to fibrosis-related genes in CKD.

**Method:** We constructed a CKD mouse model by using adenine and oxolate. Serum were taken for the measurement of BUN and creatinine. Kidneys were harvested and processed for histological, sequencing, qRT-PCR, and western blotting analysis. RNA-seq and ChIP-seq (antibody: H3K27ac) of mouse kidneys were conducted for profiling the differential gene expression and H3K27ac. GO and KEGG analysis was performed for annotation of the function. Motif analysis was applied for searching the regulator of H3K27ac. Biopsies samples of patients with common CKD were used for immunohistochemical analysis. ATF3 KO mice were also conducted for defining the function of ATF3 in CKD. To profile the ATF3 binding site on chromatin, Chip-seq of ATF3 in mice kidneys of normal control and CKD were also performed. Besides, the data contained ATF3 interact protein in databases (Chip-atlas and BioGrid) and the results of protein interaction prediction were integrated for finding the protein-protein interaction of ATF3. Pip3 samples of patients with common CKD were used for immunohistochemical analysis. ATF3 KO mice were also conducted for defining the function of ATF3 in CKD. To profile the ATF3 binding site on chromatin, Chip-seq of ATF3 in mice kidneys of normal control and CKD were also performed. Besides, the data contained ATF3 interact protein in databases (Chip-atlas and BioGrid) and the results of protein interaction prediction were integrated for finding the protein-protein interaction of ATF3. Pip3 samples of patients with common CKD were used for immunohistochemical analysis. ATF3 KO mice were also conducted for defining the function of ATF3 in CKD. To profile the ATF3 binding site on chromatin, Chip-seq of ATF3 in mice kidneys of normal control and CKD were also performed. Besides, the data contained ATF3 interact protein in databases (Chip-atlas and BioGrid) and the results of protein interaction prediction were integrated for finding the protein-protein interaction of ATF3. Pip3 samples of patients with common CKD were used for immunohistochemical analysis. ATF3 KO mice were also conducted for defining the function of ATF3 in CKD. To profile the ATF3 binding site on chromatin, Chip-seq of ATF3 in mice kidneys of normal control and CKD were also performed. Besides, the data contained ATF3 interact protein in databases (Chip-atlas and BioGrid) and the results of protein interaction prediction were integrated for finding the protein-protein interaction of ATF3. Pip3 samples of patients with common CKD were used for immunohistochemical analysis. ATF3 KO mice were also conducted for defining the function of ATM5 regulated gene expression.

**Results:** Firstly, compared with the normal control, histone modification H3K27ac repertoire was changed in chronic kidney disease. H3K27ac/47 peaks specific to CKD, and L4996 H3K27ac peaks specific to healthy mice kidneys were found. The binding intensity of these regions has altered dramatically in the kidney of CKD. Pearson correlation analysis and function annotation showed that CKD-specific changes of H3K27ac were associated with fibrosis gene expression. Motif analysis showed that ATF3 in the top 10 TFs that may interact with H3K27ac. Among those TFs, ATF3 elicited the highest expression. Besides, ATF3 could co-localize with H3K27ac along the mouse genome globally. By immunohistochemical staining analysis, we observed the upregulation of ATF3 in the kidneys of patients with biopsy-proven CKD. We found that knocking out the ATF3 could significantly reduce kidney damage in CKD mice. In parallel with improved morphological injuries, the level of kidney fibrosis gene expression was also significantly reduced in AT3+/− mice. Furthermore, the H3K27ac on the mice chromatin altered along with the knockout of ATF3, and several fibrosis-related gene expressions which elevated in CKD were decreased by deficiency of ATF3. On the region of gene cd2, H3K27ac disappeared with the knockout of ATF3 in CKD. We found that ATF3 could interact with histone acetyltransferases (CBP, KAT7, P300) to promote the H3K27ac. Further evidenced by Chip-qPCR of fibrosis gene cd2, we found that ATF3 could recruit the histone acetyltransferases on the fibrosis gene to promote the H3K27ac to provoke the gene expression in the cell model.

**Conclusion:** We profiled the landscape of H3K27ac in CKD, explored the epigenetic regulator of H3K27ac, and revealed that ATF3 promotes renal fibrosis in CKD. Notably, we for the first time explored a novel mechanism of ATF3 about recruiting histone acetyltransferases to regulate the H3K27ac on fibrosis gene. Our data highlighted that ATF3 might represent a potential therapeutic target against fibrotic kidney diseases.
POLYPLOID TUBULAR CELLS INITIATE A TGF-BETA CONTROLLED LOOP THAT SUSTAINS POLYPLOIDIZATION AND TUBULOINTERSTITIAL CROSSTALK DURING AKI-CKD TRANSITION

Letizia De Chiara1, Elena Lazzeri1 and Paola Romagnani2

1Università degli Studi di Firenze, Department of Experimental and Clinical Biomedical Sciences, Firenze, Italy and 2University Hospital Meyer, Nephrology Unit and Dialysis Unit, Firenze, Italy

Background and Aims: Acute Kidney Injury (AKI) is characterized by a sudden kidney failure accompanied by a transient decrease of kidney functionality. It is regarded as an important risk factor for chronic kidney disease (CKD) development, but the link is still elusive. Renal fibrosis, especially tubulointerstitial fibrosis, is the final manifestation of CKD and is characterized by an excessive synthesis and deposition of extracellular matrix associated with inflammatory infiltration, tubular epithelial (TC) cell damage and fibroblast activation. Although no targeted therapy yet exists to slow the progression of tubulointerstitial fibrosis, recent findings contributed to clarify the cellular and molecular mechanisms underlying its development and progression, posing TC at the center of this process. Accordingly, we have recently demonstrated that fibrosis and senescence are trade-offs of TC polyploidy occurring immediately after AKI to support fast kidney function recovery, but promoting consequent CKD. However, the mechanisms turning TC polyploidy to senescence and fibrosis still need to be elucidated. In this study, we propose that TC polyploidy is the primary driver of CKD progression after AKI.

Methods: Polyploid TC are characterized by an increased DNA content in the absence of cell division. To discriminate polyploid cells from actively proliferating cells, we employed a series of in vitro and in vivo transgenic models based on the Fluorescence Ubiquitin Cell Cycle Indicator (Fucci) technology. AKI was triggered by unilateral ischemia reperfusion injury (IRI) or glycerol-induced rhabdomyolysis. This technology allows to follow the cell cycle phasing of living cells. Cell sorting and cytfluorimetric techniques were employed to isolate and characterize a subpopulation of polyploid TC that progressively accumulate DNA damage after AKI. These results were further corroborated by single cell RNA-sequencing (scRNA-seq) analyses in vitro and in vivo.

Results: In this study, we found that immediately after AKI, expression of cell cycle markers mostly identifies a population of DNA damaged polyploid TC. Employing transgenic mouse models and single cell RNA-sequencing we showed that after AKI, polyploid TC accumulate DNA damage and survive eventually resting in the G1 phase of cell cycle, while diploid cells do not survive DNA damage. This suggests that after AKI, polyploidization is a means to survive injury. Sorting of DNA-damaged polyploid TC showed that they express p21 and acquire a pro-fibrotic phenotype culminating in TGF-β signaling expressed by the cell. Cell cycle phases of living cells were identified by the Fluorescence Ubiquitin Cell Cycle Indicator (Fucci) technology. AKI was triggered by unilateral ischemia reperfusion injury (IRI) or glycerol-induced rhabdomyolysis. This technology allows to follow the cell cycle phasing of living cells. Cell sorting and cytfluorimetric techniques were employed to isolate and characterize a subpopulation of polyploid TC that progressively accumulate DNA damage after AKI. These results were further corroborated by single cell RNA-sequencing (scRNA-seq) analyses in vitro and in vivo.

Method: In strict accordance to the admission criteria, collect peripheral venous blood and kidney samples of healthy donors and newly diagnosed IgAN patients, prepare single cell solution, verify cell viability by flow cytometry, and perform single-cell RNA-seq using a BD Rhapsody platform. Meanwhile, the clinical data of healthy donors and IgAN patients were collected and analysed. Finally, the correlation and association of differential expressed genes (DEGs) and cell clusters-identified by single-cell RNA-seq with the clinical data of IgAN were investigated.

Results: First, we established immune cells and kidney cells landscape of IgAN. The differentially expressed genes (DEGs) between the control group and IgAN were mainly concentrated in the NK cell-mediated cytotoxicity and cell killing pathways. Interestingly, we found significant decreases in NK cell numbers and cytotoxicity, and NK cell numbers and marker genes were negatively correlated with clinical parameters, including urinary protein creatinine ratio (UPCR) and serum galactose-deficient IgA1 and IgA. In contrast, B cell DEGs were enriched in different viral infection pathways, and one specific B cell subgroup showed inhibition of NFκB signaling, which was positively correlated with clinical parameters. In addition, a subpopulation of monocytes expressing interferon-inducing genes was positively associated with clinical severity of IgAN. In case of the kidney tissue, compared with the control group, mesangial cells of IgAN patients up-regulated extracellular matrix, transcription factors, kidney development and genes related to the regulation of Wnt signaling pathway. The expression of structural protein ITGAA8 on mesangial cells was significantly decreased, indicating the mesangial cells were damaged in early IgAN. Pseudo-time analysis indicated that extracellular matrix-related genes were involved in mesangial cell lesion. We also found that the mesangial cells expressed IgA1 and IgA, and the level of angiogenesis and VEGF-related genes. Moreover, podocytes of IgAN patients expressed genes of cytoskeletal recombination and FGFR activation.

Conclusion: We successfully established the single-cell landscapes of peripheral blood immune cells and kidney cells in early IgAN patients, which revealed changes in the number and status of immune cells and kidney cells closely related to clinical manifestations and phenotypic transformation. Our study offers new insights for the diagnosis and treatment of IgAN.

#STING IS INVOLVED IN THE CELLULAR SENESCENCE PROCESS ASSOCIATED WITH RENAL AGING

Lucia Tejedor1,2, Laura Marquez-Exposito3, Córdoba David4, Gina Marcela1, Jorge García-Giménez2, Vanessa Marchant1,2, Pamela Estefania Basantes3,2, Antonio Tejera3, Raul Rodrigues Diez3, Sandra Rayego-Mateos3,4, Alberto Ortíz1, Marta Ruiz-Ortega1,2 and Adrián Mario Ramos Cortassa2

Background and Aims: Cellular senescence is an adaptive process in response to damage or stress. It consists of a cell-cycle arrest (CCA) alternatively to the programmed cell death process, which is necessary for the regeneration of damaged tissues. However, permanent senescence promotes an immunosuppressive and inflammatory response associated to chronic diseases, fibrosis and aging. One of the mechanisms which triggers cellular senescence is the DNA damage response (DDR) activation, that leads to the emergence of a cellular senescence-associated secretory phenotype (SASP), inflammation and fibrosis. Sting is a detection protein of pathogenic DNA derived from cellular damage and genotoxic and environmental stresses, starting an innate immune response and inflammation. A deregulated DDR response and thus the process of senescence itself, are also able to activate Sting. Nevertheless, the role of Sting in senescence associated to renal aging is an unknown fact. The aim of this study is to evaluate the role of STING in aging-associated pathological changes in the kidney.

Method: Studies were carried out in C57BL/6 mice (wild type mice) and in mice with a phenotype deficient in the Sting gene (Ihog/Sting), of different ages: 3 (young) and 18 (aged) months. Renal function parameters, histology and aging. One of the mechanisms which triggers cellular senescence is the DNA damage response (DDR) activation, that leads to the emergence of a cellular senescence-associated secretory phenotype (SASP), inflammation and fibrosis. Sting is a detection protein of pathogenic DNA derived from cellular damage and genotoxic and environmental stresses, starting an innate immune response and inflammation. A deregulated DDR response and thus the process of senescence itself, are also able to activate Sting. Nevertheless, the role of Sting in senescence associated to renal aging is an unknown fact. The aim of this study is to evaluate the role of STING in aging-associated pathological changes in the kidney.

Method: Studies were carried out in C57BL/6 mice (wild type mice) and in mice with a phenotype deficient in the Sting gene (Ihog/Sting), of different ages: 3 (young) and 18 (aged) months. Renal function parameters, histology and gene expression were measured.

Results: Single-cell RNA-seq analysis of immune and kidney cells of young (3 months) and aged (18 months) mice revealed changes in the number and status of immune cells and kidney cells closely related to clinical manifestations and phenotypic transformation. Our study offers new insights for the diagnosis and treatment of IgAN.
basal levels in aged KO-Sting mice. However, Klotho gene expression levels are downregulated in all 18-month-old mice, wild type and KO mice.

**Conclusion:** In conclusion, these findings suggest that the absence of STING prevents age-related renal cellular senescence in a Klotho independent manner in a murine experimental model.

THE ROLE OF REGORAFENIB IN THE TREATMENT OF PERITONEAL FIBROSIS
Yan-Hua Su1, Shuei-Liong Lin1,2, Yi-Ting Chen1,4, Pei-Shiue Tsai5 and Yi-Hsin Liang6

1National Taiwan University, College of Medicine, Graduate Institute of Physiology, National Taiwan University College of Medicine, Taipei, Taiwan, Rep. of China, 2National Taiwan University Hospital, Renal Division, Taipei, Taiwan, Rep. of China, 3National Taiwan University Hospital, Division of Blood purification, Department of Integrated Diagnostics & Therapeutics, Taipei, Taiwan, Rep. of China, 4National Taiwan University Hospital, Division of Nephrology, Department of Internal Medicine, Taipei, Taiwan, Rep. of China, 5National Taiwan University, Department of Veterinary Medicine, School of Veterinary Medicine, Taipei, Taiwan, Rep. of China and 6National Taiwan University Hospital, Department of Oncology, Taipei, Taiwan, Rep. of China

**Background and Aims:** Peritoneal fibrosis is an unmet issue for patients with peritoneal dialysis. Previously we proved imatinib, one kind of tyrosine kinase inhibitor, attenuated peritoneal fibrosis by blocking Platelet-derived growth factor receptor (PDGFR) β signaling, and blockade of chemokine (C-C motif) ligand (CCL) 17 signaling also attenuated peritoneal fibrosis by inhibiting inflammatory macrophages in mice models. Regorafenib is also tyrosine kinase inhibitor and anti-cancer agent. In this study, we aimed to clarify the effect of regorafenib in the treatment of peritoneal fibrosis.

**Method:** Mouse model of peritoneal fibrosis was induced by intraperitoneal hypochlorite injection. Mice were then treated by daily oral gavage of different doses of regorafenib or vehicle PBS for 7 days. Primary antibodies against the following protein were used for immunolabeling: α-smooth muscle actin (SMA) for detecting myofibroblasts and cluster of differentiation molecule (CD11b) for macrophages detection. Peritoneal fibrosis was quantified in Masson trichrome-stained paraffin section. Modified peritoneal equilibrium test (PET) and ultrafiltration amount were measure to monitor peritoneal function.

**Results:** The thickness of injured peritoneum, the number of α-SMA+ myofibroblasts and CD11b+ macrophages were decreased in regorafenib groups in a dose-dependent manner (P < 0.005; 0.005; 0.05, respectively). Peritoneal function tests displayed more ultrafiltration and higher D/D0 dialysate glucose in regorafenib groups (P < 0.005 and < 0.5).

**Conclusion:** Regorafenib attenuated peritoneal fibrosis by decreasing myofibroblasts and macrophages. And regorafenib also maintained peritoneal function. Regorafenib is a potential medication in the treatment of peritoneal fibrosis.

POLYCYSTINS ARE REQUIRED FOR RENAL TUBULOINTERSTITIAL FIBROSIS
Yufeng Xing, Ming Wu and Chaoyang Ye

Shanghai Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Department of Nephrology, Shanghai, P.R. China

**Background and Aims:** Renal fibrosis is the common pathway of various chronic kidney diseases progressing to end stage renal failure. Polycystin-1 (encoded by PKD1 gene) and polycystin-2 (encoded by PKD2 gene) form a transmembrane complex and function as a stress sensor, which is located in the primary cilia. Polycystins are involved in the disease condition of different organs. Mutation of PKD genes causes autosomal dominant polycystic kidney disease and deletion of polycystin attenuates heart injury induced cardiac fibrosis. The role of polycystins in renal tubulointerstitial fibrosis is currently unclear.

**Method:** Unilateral ureteral obstruction (UUO), unilateral ischemia-reperfusion injury (UIRI), aristolochic acid or folic acid induced mouse models of renal fibrosis were established for this study.

**Results:** Here we showed that polycystin-2 is up-regulated in these three mouse models of renal fibrosis and tightly correlated with the expression of collagen-1 in a time dependent manner. Treatment with triptolide inhibited the expression of polycystin-2 and pro-fibrotic markers in UUO and UIRI models. Moreover, triptolide or PKD2 siRNA inhibited the expression of polycystin-2 and pro-fibrotic markers in vitro. Using Pkd2 conditional knockout mice, we showed that genetic deletion of Pkd2 reduced the expression of pro-fibrotic markers in UUO kidneys. Polycystin-1 was also up-regulated in renal fibrotic models and conditional deletion of Pkd1 reduced the expression of pro-fibrotic markers in UUO or folic acid induced fibrotic kidneys. Furthermore, the expression of the methyltransferase EZH2 is positively correlated with the expression of polycystins in fibrotic kidneys. Conditional knockout of EZH2 attenuated the anti-fibrotic responses induced by Pkd1 deletion in UUO kidneys.

**Conclusion:** In conclusion, polycystins are up-regulated in fibrotic kidneys and promote renal tubulointerstitial fibrosis through up-regulation of EZH2, suggesting that primary cilia are required for renal tubulointerstitial fibrosis.

QUANTITATIVE CHANGES IN INTRACARDIAC FLOW PARAMETERS DURING HEMODIALYTIC SESSIONS
Michela Musolino, Jolanda Sabatino, Pierangelo Calvelli, Pierangela Presta, Giuseppe Fabiano, Nazareno Carullo, Michele Andreucci, Davide Bolignano, Ciro Indolfi, Salvatore De Rosa and Giuseppe Coppolino

“Magna Graecia” University of Catanzaro, Catanzaro, Italy

**Background and Aims:** Hemodialysis sessions exert an acute impact on cardiac geometry and mechanics. The recent development of quantitative measurement of intracardiac fluid-dynamics and analysis of vortexes offers a new opportunity to better understand the fine changes in intracardiac hemodynamic associated with hemodialysis sessions. Vortexes rise in cardiac chambers from blood flow and they are defined as circular fluid structures with rotational movement around a central virtual axis, capable of storing kinetic energy during rotation. They must be distinguished from turbulences, in which various vortexes of different sizes coexist chaotically, resulting in a rapid dissipation of kinetic energy. Our aim was to assess the impact of a hemodialysis session on new parameters originated from intracardiac flow dynamics.

**Method:** We included 26 consecutive patients on chronic hemodialysis in clinically stable phase. They underwent echocardiography including intracardiac fluid-dynamic analysis by Color Vector Flow Mapping (Hyperdoppler) before and after a single dialysis session (Fig. 1-A). Patients with hemodynamically relevant valvular disease were excluded. A complete fluid-dynamics evaluation included the measurement of multiple parameters such as vortex area (VA); vortex length (VL); vortex depth (VD); Bland Altman Plot has been used to assess intra and inter-observer variability. Changes in fluid dynamics after dialysis sessions were tested using the Wilcoxon matched-pairs test.

**Results:** The Mean Vortex Area (VA) (p = 0.034) (Fig. 1-B), Vortex Depth (VD) (p = 0.024) (Fig. 1-C) and Vortex Length (L) (p = 0.037) (Fig. 1-D) were significantly reduced after the dialysis session. A similar trend towards the reduction of Direct Flow (DF) parameter after the session was found, which was significantly larger for patients with larger baseline left ventricular (V) end-diastolic diameter (r = 0.446; p = 0.037) (Fig. 1-E). On the other hand, mean Vortex Intensity (VI) was significantly increased after dialysis (p = 0.046) (Fig. 1-F). Among energy parameters, the intradialytic change in Kinetic Energy Dissipation (KEF) (r = 0.4; p = 0.058) and Shear Stress Fluctuation (SSF) (r = 0.435; p = 0.038) (Fig. 1-G) were most closely correlated with intradialytic weight change. Fluid dynamic parameters had similar trends of intradialytic change, with stronger correlations among geometric parameters. Delta changes in VA were closely related to changes in VI (p = 0.001) or LV (p < 0.001). VI was also correlated with VL (p < 0.001) and with Kinetic Energy Dissipation (KEF) (p = 0.030), which was also correlated with VL (p = 0.044). KEF was correlated with KED (p = 0.001) and SSF (r = 0.022). Finally, changes in SSF were correlated with those in Flow Force Parameter (p = 0.033) and Flow Force Angle (p = 0.034), that were very closely correlated each other (p < 0.001).

**Conclusion:** This is the first study assessing the impact of hemodialytic sessions on intracardiac flow dynamics. Measurement of hyperdoppler indices on hemodialysis chair was feasible and reliable in the whole population. Our results uncovered quantitative changes of echocardiographic parameters of vortex geometry and energy during hemodialysis.
EPAC1- MEDIATED CAMP SIGNALLING PROMOTES CELLULAR ENERGY ADAPTATIONS IN PODOCYTES TO PROTECT FROM GLOMERULONEPHRITIS

Lilia Abdal, Maximin Detrait, Panagiotis Kavvadas, Lisa Melis, Sabrina Hadji, Dorian Bergonnier, Frank Lezoualch and Christos Chatziantoniou

1Common and Rare Kidney Diseases (CoRaKid) - UMR 1155, Tenon hospital, Paris, France and 2Metabolic and Cardiovascular Research Institute (I2MC) - UMR 1297, Toulouse, France

Background and Aims: Many efforts are made to identify new therapeutic targets to slow down, prevent or even reverse Chronic Kidney Disease (CKD) progression. One of the therapeutic approaches is activating the renoprotective CAMP pathway, especially by stimulation of its downstream effector, the protein kinase A (PKA). PKA was considered as the unique cAMP effector, however, the exchange factor directly activated by cAMP 1 (EPAC1) has been recently identified as a novel, PKA-independent, mediator of cAMP signalling. EPAC1 is a guanine exchange factor that promotes the exchange of GDP for GTP regulating important cellular functions. Epac1 activation exerts a renoprotective effect during acute kidney injury, via maintenance of epithelial adhesion and protection from oxidative stress. However, the role of EPAC1 in CKD remains poorly understood. Here we aim to determine the role of EPAC1 in CKD progression.

Method: Nephrotoxic serum glomerulonephritis (NTS-GN) is induced in genetically modified mice with total and conditional EPAC1 deletion. Then isolated glomeruli from mice with conditional EPAC1 deletion in podocytes are analysed by RNA-sequencing. The main metabolic energy pathways are studied in podocytes in vitro experiments in podocytes, including XOI and anakinra.

Results: Following the induction of NTS-GN, mice with genetic deletion of EPAC1 show aggravated renal disease, characterized by increased proteinuria, glomerular damage, tissue inflammation and fibrosis compared to wild-type mice. Conversely, pharmacological activation of EPAC1, with the agonist 8-pCPT-2-OMe-cAMP, delays NTS-GN progression. Since in human and wild type mouse kidney tissues we observe EPAC1 expression in podocytes, mice with conditional deletion of EPAC1 in podocytes (Nphs2Cre;epac1) are generated. Similar to the whole-body knockout, mice with EPAC1 deletion in podocytes show increased renal damage and worsened disease progression compared to control mice. RNA-sequencing analysis of glomeruli isolated from these mice show that gene expression of proteins linked to the pathway of glycolysis are abolished in early stage of NTS-GN (day 4). These data suggest that EPAC1-mediated activation of glycolysis in podocytes is essential to limit GN progression. This is substantiated by the in vitro experiments in podocytes, in which EPAC1 activation under oxidative stress promotes glycolysis with cellular energy production independently from mitochondrial respiration. The EPAC1-mediated glycolysis protected podocytes by increasing cell viability, decreasing LDH release and activating the AKT pathway.

Conclusion: Our results suggest a protective role of podocytes-derived EPAC1 against the development of GN through cellular energetic adaptations based on metabolic switch to glycolysis. Activating the cAMP-EPAC1 signalling axis could represent a therapeutic option to delay the development of CKD. Further investigations are needed to define its relevance in human CKD.

FEBUXOSTAT IN COMBINATION WITH ANAKINRA OR PH NEUTRALIZATION IMPROVE THE OUTCOMES IN HYPERURICEMIA-RELATED URIC ACID CRYSTALLURIA IN MICE

Louisa Ehreiser, Qiubo Li, Li Li, Juliane Anders and Stefanie Steiger

Hospital of the University Munich, Ludwig-Maximilians University, Department of Medicine IV, Division of Nephrology, Munich, Germany

Background and Aims: Currently, it is unknown whether CKD patients with hyperuricemia (HU)-related uric acid (UA) crystalluria, also known as chronic UA nephropathy, would benefit from targeting HU, UA crystallization, and/or inflammation to slow down the progressive decline of kidney function. Although large multi-center RCTs with xanthine oxidase inhibitors (XOIs) such as allopurinol and two Mendelian randomization studies have disproven a causal link between HU and CKD progression, one cannot rule out that XOIs may still represent a viable therapeutic approach for patients with HU-related UA crystalluria in order to prevent CKD progression. This issue requires clarification. To address this, we used our well-established CKD mouse model of HU with UA crystalluria and tested numerous therapeutic approaches including XOIs and anakinra.

Method: Alb-creERT2;Glut9lox/lox (male and female) mice were injected with tamoxifen and placed on an acidogenic diet with the purine inosine to induce HU and crystalluria-related CKD. After chronic UA nephropathy was established on day 14, mice were treated either 1) with the XOIs allopurinol or febuxostat, 2) with sodium bicarbonate supplementation to neutralize urinary pH to prevent UA crystallization, or 3) with anakinra to inhibit IL-1β-driven inflammation, or 4) a combination of the aforementioned therapies for 2 weeks. Saline was used as control. On day 0, 14, and 28, GFR (as primary endpoint) as well as serum UA levels and urinary UA crystals (as secondary endpoints) were determined. At the end of the study, we quantified kidney injury, immune cell infiltration, inflammation, and interstitial fibrosis using histological analysis, ELISA, RT-qPCR, and flow cytometry.

Results: Therapy with XOIs but not with sodium bicarbonate and anakinra reduced serum UA levels in mice with HU and UA crystalluria. Treating mice with febuxostat improved kidney function (increase in GFR) by preventing
Kidney injury, UA crystalluria, UA crystal granuloma formation, and interstitial fibrosis compared with the control group, while allopurinol worsened the outcomes of chronic UA nephropathy. On the other hand, sodium bicarbonate supplementation had no effects on serum UA levels, kidney inflammation, immune cell infiltration and interstitial fibrosis but improved kidney function due to less urinary UA crystal deposition (neutralization of urine pH) and granuloma formation as compared with saline-treated mice. As expected, anakinra did not slow down the progression of chronic UA nephropathy as noticed by similar GFR decline compared with the control group. Although, anakinra reduced the number of infiltrating immune cells and the mRNA expression of inflammatory mediators in the kidney as well as the serum IL-1/β concentrations, we observed more interstitial fibrosis. In combination, allopurinol with anakinra did not improve the outcomes of chronic UA nephropathy despite the inhibitory effect of anakinra on the inflammatory response. Use of allopurinol triggered tubulointerstitial nephritis and vasoconstriction. Interestingly, both combination therapies febuxostat with anakinra and febuxostat with sodium bicarbonate were protective by improving kidney function and preventing UA crystal deposition, kidney injury, inflammation, interstitial fibrosis and UA crystal granuloma formation compared with the single therapies.

Conclusion: Our interventional study is the first pre-clinical study, which reveals that the XOIs allopurinol and febuxostat have differential effects on the outcomes of HU-related UA crystalluria. While allopurinol contributes to the progression of CKD by causing tubulointerstitial nephritis in mice, febuxostat rather seems to be renoprotective similar to urinary pH neutralization with sodium bicarbonate. We identified both combination therapies febuxostat with anakinra and sodium bicarbonate as most beneficial in order to prevent CKD progression in mice. Thus, febuxostat in combination with IL-1β inhibition or prevention of urinary UA crystallization may represent therapeutic approaches for patients with chronic UA nephropathy.

Background and Aims: Kidney fibrosis is one of the main pathological processes of chronic kidney disease (CKD), although the pathogenesis of renal scar formation is not fully understood. Calpains (CAPN) are intracellular cysteine proteases that play a key role in multiple biological processes linked to tissue damage and repair mechanisms, such as fibrosis and epithelial-mesenchymal transition. However, CAPN contribution in CKD genesis and progression remains to be fully elucidated. The aim of this study was to investigate the possible role of CAPN in the development of CKD and renal fibrosis in an experimental model of CKD induced by adenine and in human kidney proximal tubular cells (HK-2).

Method: C57BL/6 mice were treated with an adenine-supplemented diet (0.2% adenine) or control diet for eight weeks. At the end of treatment, kidney function was assessed (serum creatinine, proteinuria), animals were euthanised, and the kidneys removed. A transverse section of the kidney was prepared for histology. Whole kidney cortical tissue was analysed using two-dimensional correlated spectroscopy (2D-COSY), a form of proton nuclear magnetic resonance (NMR) spectroscopy. Biochemical species, including metabolites and lipids, within the tissue were identified and compared with respective histological tubulointerstitial fibrosis level and traditional serum markers of kidney function, plasma creatinine and blood urea nitrogen. A 2D-COSY spectrum can be found in Figure 1A.

Results: The adenine-supplemented diet induced tubulointerstitial fibrosis, mirrored by increases in serum creatinine and blood urea nitrogen, indicating decreased kidney function. The 2D-COSY analysis demonstrated numerous changes in metabolites with parallel increasing levels of fibrosis that were detected. Increases in metabolites belonging to the glycolysis (D-glucose, glucose-6-phosphate and lactate) and pentose-phosphate (myo-inositol, D-ribose-5-phosphate) pathways were observed, as well as a decrease in lipid. Additionally, increases in creatinine, creatine and a number of amino acids were also observed. These changes are displayed in Table 1 and Figure 1B.

Conclusion: The primary cell type of the kidney cortex is the proximal tubular epithelial cell. Due to its unique function in water and solute transport, this cell has a very high metabolic demand and utilizes fatty acid oxidation as its primary source of energy. However, when these cells are under pathological stress that contributes to tubulointerstitial fibrosis, such as those present within this animal model of chronic kidney disease, metabolic dysfunction occurs. We observed significant decreases in various lipid signals belonging to fatty acids within the cell. These fatty acids are not being utilised and are instead esterified to triglycerides that accumulate in the kidney, causing lipotoxicity. Increased levels of glucose-6-phosphate, lactate and D-glucose, as well as increased myo-inositol, glucuronic acid D-ribose-5-phosphate are indicative of increased utilisation of the glycolysis and pentose phosphate pathway respectively as primary methods of energy metabolism. Here, we provide evidence that in tubulointerstitial fibrosis within the kidneys leads to a shift in the primary energy pathway used by proximal tubular epithelial cells. The study provides new insights into the changes in biochemical pathways that occur in the kidney during the development of CKD and its progression.

Background and Aims: Tubulointerstitial fibrosis is the common pathological manifestation in chronic kidney disease (CKD) and can indicate whether a patient will progress to kidney failure. The metabolic consequences of developing fibrosis are not well understood. This project aimed to investigate metabolic changes in the kidney cortex using an adenine-diet murine model of progressive CKD.

Method: C57BL/6 mice were treated with an adenine-supplemented diet (0.2% adenine) or control diet for eight weeks. At the end of treatment, kidney function was assessed (serum creatinine, proteinuria), animals were euthanised, and the kidneys removed. A transverse section of the kidney was prepared for histology. Whole kidney cortical tissue was analysed using two-dimensional correlated spectroscopy (2D-COSY), a form of proton nuclear magnetic resonance (NMR) spectroscopy. Biochemical species, including metabolites and lipids, within the tissue were identified and compared with respective histological tubulointerstitial fibrosis level and traditional serum markers of kidney function, plasma creatinine and blood urea nitrogen. A 2D-COSY spectrum can be found in Figure 1A.

Results: The adenine-supplemented diet induced tubulointerstitial fibrosis, mirrored by increases in serum creatinine and blood urea nitrogen, indicating decreased kidney function. The 2D-COSY analysis demonstrated numerous changes in metabolites with parallel increasing levels of fibrosis that were detected. Increases in metabolites belonging to the glycolysis (D-glucose, glucose-6-phosphate and lactate) and pentose-phosphate (myo-inositol, D-ribose-5-phosphate, glucuronic acid) pathways were observed, as well as a decrease in lipid. Additionally, increases in creatinine, creatine and a number of amino acids were also observed. These changes are displayed in Table 1 and Figure 1B.

Conclusion: The primary cell type of the kidney cortex is the proximal tubular epithelial cell. Due to its unique function in water and solute transport, this cell has a very high metabolic demand and utilizes fatty acid oxidation as its primary source of energy. However, when these cells are under pathological stress that contributes to tubulointerstitial fibrosis, such as those present within this animal model of chronic kidney disease, metabolic dysfunction occurs. We observed significant decreases in various lipid signals belonging to fatty acids within the cell. These fatty acids are not being utilised and are instead esterified to triglycerides that accumulate in the kidney, causing lipotoxicity. Here, we provide evidence that in tubulointerstitial fibrosis within the kidneys leads to a shift in the primary energy pathway used by proximal tubular epithelial cells. The study provides new insights into the changes in biochemical pathways that occur in the kidney during the development of CKD and its progression.
Figure 1: *Ex vivo* whole tissue NMR spectroscopy of chronic kidney diseased kidneys induced by an adenine-supplemented diet (0.2% adenine). (A) Representative 2D-COSY spectrum of a treatment mouse kidney. Individual peaks indicate hydrogen containing functional groups of different molecules. These peaks were assigned to specific metabolites and lipids and their respective volumes were used to measure the relative concentration of the metabolite within the tissue. (B) Fold change (FC) versus *p*-value of various identified biomolecule peaks with in the tissue. Blue indicates a decrease in the treatment from control, while red indicates an increase in treatment from control. Dotted lines show thresholds of *p*=0.05 and FC=1. Data was normalised for tissue weights, log₂ transformed and auto scaled. P-values were calculated using unpaired *t*-tests with welch correction.
Table 1: Metabolite changes occurring in the kidney with adenine-diet induced tubulointerstitial fibrosis compared to control. The chemical shift of a molecule indicates the “coordinates” of the specific functional group in a 2D-COSY spectrum (see fig. 1A).

**MYELOID CELL-DERIVED HMGB1 AGGRAVATES THE PROGRESSION OF CHRONIC KIDNEY DISEASE INDUCED BY CHRONIC OXALATE EXPOSURE**

Meisi Kuang1, Hans-Joachim Anders2, Stefanie Steiger2 and Yoshihiro Kusunoki1

1Kidney Immunology Laboratory, University Hospital Ludwig-Maximilians University Munich, München, Germany and 2Kidney Immunology Laboratory, University Hospital Ludwig-Maximilians University Munich, Munich, Germany

**Background and Aims:** HMGB1, long form High Mobility Group Box 1, a highly conserved DNA chaperone stabilizes chromatin in the nucleus, regulates gene transcription, and supports DNA repair. In the cytosol, it regulates mitochondrial function, autophagy, and apoptosis. In addition, when secreted or passively released into the extracellular space during cell necrosis, it acts as danger signal (DAMP). As such HMGB1 amplifies necroinflammation in ischemic and toxic acute kidney injury. In contrast, little is known about the contribution of HMGB1 release from infiltrating immune cells in this context. We hypothesized that HMGB1 from resident and infiltrating myeloid cells would contribute to the progression of CKD by driving tubular atrophy and tissue remodeling.

**Method:** We generated myeloid deletion of HMGB1 by crossing Hmgb1 floxed mice (Hmgb1flox) with endogenous Lys2 promoter (LysZCre) to investigate the role of myeloid cell HMGB1 in a model of chronic kidney disease induced by sodium oxalate-rich diet (50 μmol/g), i.e., calcium oxalate nephropathy. The LysZCre mice were on a C57BL/6J background and crossed with mice homozygous for the floxed Hmgb1 gene in all myeloid cells. We used littermates of 6- or 8-week-old males for all experiments. Mice with no LysZCre but the homozygous of floxed Hmgb1 gene served as wildtype controls (LysZCre−Hmgb1flox WT) and mice with LysZCre and the homozygous of floxed Hmgb1 gene were used as LysZCre Hmgb1flox KO. The primary endpoint for the comparison between LysZCre Hmgb1flox KO and WT mice was glomerular filtration rate at 21 days of oxalate feeding, assessed by FITC-sinistrin clearance. Plasma samples were collected only on day 21 before sacrifice by cervical dislocation. Urine samples were collected as well and as GFR was measured from all experimental groups on day 0, day7, day14 and before sacrifice by caval dislocation on day 21. Kidneys were harvested after sacrifice. The kidney was divided into two equal parts. One part was kept in RNA later solution at −80°C for RNA isolation and the second part was kept in 4% formalin to be embedded in paraffin for histology analysis.

**Results:** KO animals did not reveal any abnormalities within an observation phase of 6 months. Healthy mice showed normal kidney function parameters in urine and blood. Observation is continued and will be supplemented by histopathological analyses at the age of 12 months. Primary endpoint: Deletion of HMGB1 from myeloid cells attenuated the decline of GFR as compared to WT control mice. Secondary endpoints: The difference in GFR was consistent with the respective levels of serum creatinine at day 21 upon oxalate-rich diet compared with controls. The ablation of HMGB1 in myeloid cells was associated with less tubulointerstitial fibrosis at day 21 after oxalate-rich diet.

**Conclusion:** Our data suggest that HMGB1 release from myeloid cells promotes crystal-induced chronic kidney injury, which is consistent with the role of HMGB1 as an extracellular DAMP and persistent inflammation in CKD. However, this effect may also relate to the intracellular role of HMGB1 as a transcriptional regulator.
Figure 1: The deletion of intracellular HMGB1 mitigated chronic kidney injury at day 21 after oxalate-rich diet. (A) The renal glomerular filtration from day 0 to day 21 in crystal-induced nephrocalcinosis. (B) The mice serum level of creatinine in crystal-induced nephrocalcinosis at day 21. (C) The renal tubular damage was quantified on periodic acid-Schiff (PAS), sirius red staining represented tubular fibrosis, crystal deposition indicated by pizzolato staining. MC (Lyz2^{cre}^{−}/Hmgb1^{f/f} control mice) and MH (Lyz2^{cre}^{+}/Hmgb1^{f/f} knockout mice). *P<0.05, **P<0.01, ***P<0.001, ****P<0.0001.
IDENTIFICATION AND CHARACTERIZATION OF URINARY AND SERUM AMINOACIDS IN DIABETIC KIDNEY DISEASE PATIENTS USING MS-HPLC

Background and Aims: Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease, but few biomarkers of early identification of DKD are available. The aim of the study was to assess new urinary and plasma biomarkers in early stages of DKD, especially in normoalbuminuric type 2 diabetes mellitus (DM) patients.

Method: This cross-sectional pilot study performed an integrated metabolomic profiling of blood and urine in 90 patients with type 2 DM, classified into 3 stages (30 normo-, 30 micro-, and 30 macroalbuminuric, respectively) and 30 age- and gender-matched healthy controls through high-performance liquid chromatography and mass spectrometry (UPLC-QTOF-ESI* MS). Metabolites were discovered and processed by the advanced MetaXaminer 5.0. online software using multi- and univariate untargeted analysis. Both multivariate and univariate bioinformatics confirmed the relevance of certain amino acids as biomarkers to be responsible for the occurrence of early renal involvement in the course of type 2 DM.

Results: A total of 5 metabolites, namely Taurine, Tiglylglycine, Tryptophan, Kynurenic acid, and L-acetylcarnitine were discovered as potential biomarkers for the early identification of DKD. UPLC-QTOF-ESI* MS revealed that: (1) the urinary amino acids levels were increased in normoalbuminuric type 2 DM patients as compared with healthy control subjects; (2) a number of key biomarkers have been identified in the urine, which reflect kidney injury at specific sites in the nephron, including glomerular injury and tubular damage, oxidative stress, inflammation, and activation of the intrarenal renin-angiotensin system.

Conclusion: High-performance liquid chromatography coupled with mass spectrometry showed that the urinary amino acids levels were increased in normoalbuminuric type 2 DM patients. The results of the study provide a particular metabolomic profile related to blood and urine metabolites which could impact both the glomeruli and the tubules, even in the early stages of DKD.

IMPACT OF SYMBIOTICS ON UREMIC TOXINS PRODUCTION, RENAL FUNCTION AND PEW SYNDROME IN SHIME AND CKD MICE MODELS

Alice Beau1, Bérengère Benoit1, Marie Jammes1, Claudio Pinteur1, Denis Fouque1,4, Giert Glorieux4, Hubert Vidal1, Jane Natividad4 and Laetitia Koppe1,2

1Laboratoire CarMeN, INSERM U1060, INRA 1397, Université Claude Bernard Lyon 1, Pierre Benite, France, 2Lyon Sud Hospital Center, Pierre-Bénite, France, 3Ghent University Hospital, Nephrology Section, Department of Internal Medicine and Pediatrics, Gent, Belgium and 4Nestlé Health Science SA, Lausanne, Switzerland

Background and Aims: Alterations in gut microbiota in CKD patients have been linked to CKD progression, cachexia, and mortality. Gut dysbiosis is associated by modification of gut-microbiota-derived metabolites, including a decrease of short-chain fatty acids (SCFAs), an increase in gut-derived uremic toxins. Therefore, modulation of gut microbiota seems to be an attractive therapeutic approach. In silico studies led to the selection of bacterial species able to increase SCFAs production, improve gut function without having the enzymatic machinery for producing uremic toxins. The propose of this study is to indentify the impact of two different symbiotics containing the selected bacteria: 1) on both uremic toxins and SCFAs production using a Simulator of the Human Intestinal Microbial Ecosystem (SHIME) colonized with fresh feces from CKD or healthy controls (HC) and subsequently 2) on renal function, metabolic parameters, intestinal microbiota and gut-microbiota-derived metabolites in a mouse model of CKD (5/6 nephrectomy).

Method: 1) The SHIME® system manufactured by ProDigest (Ghent, Belgium) consists of systems comprising five double-wall biowessels simulating the stomach (ST), small intestine (SI), ascending colon (AC), transverse colon (TC), and descending colon (DC). The supernatant of the homogenized fecal slurry was inoculated into the AC (25 mL), TC (40 mL), and DC (30 mL), respectively. After fecal inoculation, SHIME system were fed in ST twice day with two different symbiotics (P1 or P2) for 10 days. After 7 days, we applied a diet amino acid (AA) challenge to all the groups. SCFAs and uremic toxins were quantified every day. 2) CKD mice received either P1 or P2 admix for 6 weeks. We measured food intake, body composition and renal function including renal fibrosis quantification. Plasma metabolomic and feces metagenomic analyses were performed.

Results: In vitro, the concentration of precursor of uremic toxins (indols and p-cresol) tended to be higher in DC colonized by feces from CKD patients and AA challenge increased uremic toxins production more significantly in CKD compared to HC. CKD microbiome showed a lower butyrate concentration at baseline and higher propionate and acetate production. Both P1 and P2 significantly limited uremic toxins production during AA challenge and increase SCFA production. In vivo, both symbiotics increased body weight (+14%) and food intake (+31%) compared to CKD mice on chow diet. Treatment did not impact lipid or glucose metabolism but fat accretion in epididymal was restored with P1. Both diets, but particularly P1, significantly reduced plasmatric urea, proteinuria, and kidney fibrosis. Symbiotics improved intestinal barrier with a greater expression of Occludin in the ileum. Metagenomic analyses of the gut microbiota indicated that the alpha-diversity was different across groups while the beta-diversity was similar to the sham group if CKD mice were treated with symbiotics. Both symbiotics reduced significantly plasma levels of deleterious uremic toxins such as p-cresyl sulfate and indoxyl sulfate and symbiotics reduce fecal module of tryptophan degradation and other modules related to AA metabolism. Both diets increased fecal bacteria modules related to SCFAs production.

Conclusion: We have shown both in vitro and in vivo that a symbiotic association can reduce uremic toxins production and increase SCFA production by inducing a significant change in gut microbiota composition and function. These metabolic changes are associated with improved appetite, decreased uremic cachexia, and preserved renal function. This data needs be confirmed in a human clinical trial.
HOW WELL INFORMED ARE PATIENTS ABOUT DIALYSIS INITIATION?

Jenny Wrackefeld1, Nicholas Chesnaye2, Fergus Caskey3, Claudia Torino4, Christiane Drechsler5, Friedo W. Dekker5, Maciej Szymczak7, Christoph Wanner5, Kitty J Jager2, Marie Evans2 and Marie Evans8

1Karolinska University Hospital, Rosenlund Hospital/PD-unit, Stockholm, Sweden, 2Netherlands, 3United Kingdom, 4Italy, 5Germany, 6Germany, 7Poland and 8Sweden, for the EQUAL study group

Background and Aims: Studies indicate that 30% of patients on dialysis feel inadequately informed about various dialysis options and also lack involvement in the decision-making process surrounding dialysis initiation. The aim of this study was to 1) describe the provision of information to older patients with chronic kidney disease before KRT and 2) to study the association between the perceived amount of information received before dialysis and patients satisfaction with treatment post dialysis initiation.

Method: The EQUAL study is a multicenter, prospective cohort study in six European countries (Germany, Italy, Netherlands, Poland, Sweden, and United Kingdom). Inclusion criteria are older adults >65 years with an incident eGFR < 20 ml/min/1.73 m². Patients were followed up every 3-6 months and received routine medical care as provided by the nephrology clinic in each country. Standardized data were collected at each visit, including demographics, lifestyle, comorbidities, uremic signs and symptoms, quality of life, treatment satisfaction according to renal treatment satisfaction questionnaire (RTSQ-11), nutritional status, medication and routine blood and urine biochemistry. We described patient characteristics and perceived information provision at different time points (incident eGFR<20, eGFR<15, eGFR<10 ml/min/1.73 m²). Subsequently, we compared patient characteristics between those who reported receiving more versus less information at the last eGFR before start of KRT (or end-of follow-up in patients with eGFR <10 ml/min/1.73 m²).

We used multivariable logistic regression models to investigate if perceived information provision before start of dialysis was associated with a treatment satisfaction.

Results: We included 1372 patients at baseline with a median age of 76 (IQR 70–81), 34% (n = 462) women. Over follow-up, 997 of these patients progressed to an eGFR<15, and 573 to an eGFR<10 ml/min/1.73 m². The proportion of patients who reported having received enough information about the decision on when to start dialysis increased with decreasing eGFR (53.2% at baseline to 61.2% (eGFR<15) and 70.9% (eGFR<10)). Among the 638 patients progressing to KRT or eGFR <10 ml/min/1.73 m², the mean eGFR was 8.9 ml/min/1.73 m² (SD 3.4) at their last pre-dialysis visit. Patients who reported that they had received sufficient information regarding dialysis timing were in general younger, where median age was 74 (IQR 69.4-79.3) years for those receiving information and 76 (IQR 70.7-81.4) years for those perceiving not having enough information, but there were otherwise no major differences in patient characteristics. Among these patients, 32% had still not decided on which dialysis modality to start with. There was not any statistically significant difference in RTSQ-11 score associated with type of dialysis modality (hemodialysis versus peritoneal dialysis) post dialysis initiation. Among 302 patients who started dialysis, those reporting to have received more information (highest quartile) before start of dialysis also reported being more satisfied with their treatment post dialysis (OR: 1.22; 95% CI 1.05-1.37).

Conclusion: Although most patients report having received pre-dialysis information, many patients with low kidney function still perceive not having received enough information to make an informed decision. Patients who are well informed are more satisfied with their treatment.
Background and Aims: Cellular senescence is associated with renal disease progression. Accelerated tubular cell senescence promotes the pathogenesis of renal fibrosis no matter caused by natural aging or disease. However, the underlying mechanism is unknown.

Method: Proteomic analysis of natural aging kidney from 20-week mice was used to find potential target protein which is acyl-CoA synthetase medium chain family member 3 (Acsm3). After finding it, two Acsm3 inhibitor (4-Methylsalicylic acid and 2-hydroxyoctanoic acid) were used separately to treat natural aging and pathological aging (unilateral ureteral obstruction induced renal fibrosis) mice. Renal histological injury was measured by HE and Masson's trichrome staining. SA-β-gal staining was used to check cellular senescence. Renal tissues of the mice were analysed by western blot and qPCR assay for the expression of Acsm3, fibrosis and cellular senescence related proteins and genes. In order to avoid drug toxicity, tubular epithelial cells were treated with Acsm3 SiRNA to explore the effects of Acsm3 in vitro.

Results: Firstly, we confirmed that cellular senescence happened in both elderly mice and UUO mice and found SA-β-gal positive cells were mainly tubular epithelial cells. After analysing proteomic sequencing data, Acsm3 is the protein which increased dramatically as the top one protein in elderly mice. We also found Acsm3 increased in tubular cells specifically in adult mice compared with fetal mice from KIT single cell database, which suggested that Acsm3 might have effects for kidney development. After validating changes and location of Acsm3, we treated natural aging and UUO mice with two Acsm3 inhibitor to check the function of Acsm3, separately. Administration of Acsm3 inhibitor (no matter 4-Methylsalicylic acid or 2-hydroxyoctanoic acid) could induce renal histological injuries, renal fibrosis, with significantly increased COL6, α-SMA and FN expression in both natural aging and UUO induced renal fibrosis. The cellular senescence was also observed to increase after Acsm3 inhibitor treatment with growth P21 and P16 expression. In addition, pro-inflammatory senescence-associated secretory phenotype (SASP) including IL6 and MCP1 increased as well. In order to avoid kidney injury induced by drug toxicity instead of by inhibition of Acsm3, we transfected Acsm3 SiRNA in tubular epithelial cells to check in vitro. Similarly, the inhibition of Acsm3 augmented cellular senescence and SASP of tubular epithelial cells as what we found in vivo. It supported that inhibition of Acsm3 could induce senescence of tubular epithelial cells and thus to promote kidney fibrosis.

Conclusion: These findings suggested that Acsm3 could be an important protector for renal fibrosis by inhibiting cellular senescence of tubular epithelial cells. The underlying mechanism needs to explore more.
TUBULE CELL-DERIVED ANGIOPOIETIN-2 EXACERBATES INFLAMMATION AND IS DETRIMENTAL TO RENAL FIBROSIS
AN Jie Luo¹, Fan-Chi Chang² and Shuei-Liong Lin¹,²
¹National Taiwan University College of Medicine, Graduate Institute of Physiology, Taipei, Taiwan, R.O.C. and ²National Taiwan University Hospital, Renal Division, Department of Internal Medicine, Taipei, Taiwan, Rep. of China

Background and Aims: Our previous studies have shown that angiogenic growth factors are dysregulated in fibrotic kidneys. In murine models of progressive renal disease, angiopoietin-2 (Angpt2) was upregulated in injured tubule epithelial cells. We hypothesize that overexpression of Angpt2 in tubule epithelial cells would exacerbate renal fibrosis and inflammation.

Method: The unilateral ureteral obstruction (UUO) and unilateral ischemia-reperfusion injury (UIRI) are used as the murine model of chronic kidney disease. We use the tetracycline/doxycycline-controlled Tet-on system to induce tubule cell-specific overexpression of Angpt2 before the induction of renal fibrosis. Transgenic mice carrying both Pax8-rtTA and pTetos-hAngpt2 genes (double transgenic mice) are used for Angpt2 overexpression. Littermates that inherit single or no transgene serve as experimental controls. Doxycycline is administered to adult (8 weeks) mice to overexpress Angpt2 in tubule epithelial cells.

Results: Doxycycline administration induce overexpression of human Anp2 in the tubule epithelial cells of both sham and fibrotic kidneys. Compared to littermate controls after the UUO and UIRI surgery, the expression of fibrosis-related genes, Col1a1, Col3a1, and Acta2 are higher in the kidneys of double transgenic mice. Deposition of picrosirius red-stained collagen fibrils is significantly higher in double transgenic mice. Inflammatory cell infiltration is also significantly higher in double transgenic mice.

Conclusion: Overall, these findings suggest that increased Angpt2 in tubule epithelial cells deteriorate renal fibrosis through detrimental inflammation. Further studies are necessary to explore the participating cellular components and pathogenic mechanisms.

TRANSGENIC INDUCTION OF EPITHELIAL SENESCENCE PROMOTES RENAL FIBROSIS INDEPENDENT OF INJURY
Marie-Helena Docherty¹, Ross Campbell¹, Laura Denby³, David Baird¹, Katie Mylonas¹ and David Ferenbach¹

Results: Doxycycline administration induce overexpression of human Anp2 in the tubule epithelial cells of both sham and fibrotic kidneys. Compared to littermate controls after the UUO and UIRI surgery, the expression of fibrosis-related genes, Col1a1, Col3a1, and Acta2 are higher in the kidneys of double transgenic mice. Deposition of picrosirius red-stained collagen fibrils is significantly higher in double transgenic mice. Inflammatory cell infiltration is also significantly higher in double transgenic mice.

Conclusion: Overall, these findings suggest that increased Angpt2 in tubule epithelial cells deteriorate renal fibrosis through detrimental inflammation. Further studies are necessary to explore the participating cellular components and pathogenic mechanisms.
Background and Aims: Chronic Kidney Disease (CKD) affects over 850 million people worldwide. Progressive renal fibrosis is a hallmark of CKD, irrespective of the initiating aetiology. Any episode of acute kidney injury (AKI) significantly increases the risk of development of CKD, even after apparent complete resolution of the initiating injury. This risk is exacerbated by age and pre-existing CKD. This implies that factors persist within damaged/aging kidneys which drive functional loss, impair complete repair and promote ongoing fibrosis. Senescent cells (SCs) are metabolically active, permanently growth arrested cells produced in response to stress and DNA damage. SCs accumulate with age and persist at the sites of previous disease and injury. Their depletion in animal models is safe and extends organ function and healthspan. We have shown that pharmacological SC depletion in kidneys significantly improves kidney function and reduces fibrosis post injury. However, models of renal injury induce changes in multiple cell lineages, and pharmacological depletion is non-specific both in terms of cell lineage (i.e. epithelial vs mesenchymal vs leukocyte) and characteristics of senescent cell (i.e. acute vs chronic, primary vs secondary). We hypothesised that induction of epithelial senescence in the absence of other renal injuries is sufficient to initiate renal fibrosis. We developed a transgenic mouse allowing selective senescence induction in renal epithelia in the absence of injury, with tdTomato labelling of induced cells.

Method: By crossing existing strains, we produced a triple transgenic Pax8\textsuperscript{CreERT2}/mdm2\textsuperscript{flfl}/tdTom\textsuperscript{LSL} mouse allowing conditional senescence induction by tamoxifen via mdm2 deletion in Pax8 expressing renal epithelia, alongside tdTomato expression. Levels of renal fibrosis, p21cip1 and tdTomato induction were quantified by picrosirius red staining, immunofluorescence and flow cytometry, with downstream image analysis on QuPath 0.3.2. \textit{CDKN1A} gene expression was quantified by qPCR.

Results: Examination of kidneys and livers from young mice ± tamoxifen demonstrated that tdTomato induction was tissue specific and restricted to renal epithelia (Fig 1A-C). Administration of Tamoxifen resulted in increased expression of tdTomato and \textit{CDKN1A} expression at day 7 in transgenic but not in WT mice. (Fig. 1C, 2 A-F). We observed a rapid induction of fibrosis in the first 7 days after tamoxifen induction in both young (Fig. 3A,C) and old mice (Fig 3C). This persists to day 42 (Fig. 3B). This demonstrated that epithelial senescence alone was sufficient to induce renal fibrosis in young mice, and exacerbate fibrosis in old mice. Further studies assessed the longer-term impact of acute senescence induction, with fibrosis stabilising in both young and old mice at 6 weeks post induction (Fig. 3D).
Conclusion: Using a novel transgenic mouse line, we demonstrate for the first time that induction of renal epithelial senescence in the absence of injury is sufficient to induce renal fibrosis in the early aftermath of SC induction. The evolution and/or clearance of senescent cells over time is the focus of on-going study and will be presented at the ERA.

PHOSPHATIDYLSERINE EXPOSURE AND SHORTENED LIFE SPAN OF ERYTHROCYTES IN RENAL ANEMIA
Momoko Seki1,2, Nobuto Arashiki2, Norio Hanafusa3, Junichi Hoshino3, Ken Tsuchiya3 and Fumio Nakamura2

1Tokyo Women’s Medical University, Department of Nephrology, Tokyo, Japan, 2Tokyo Women’s Medical University, Department of Biochemistry, Tokyo, Japan and 3Tokyo Women’s Medical University, Department of Blood Purification, Tokyo, Japan

Background and Aims: The lifespan of erythrocytes in patients with renal anemia is shortened (~70 days) compared to that of healthy erythrocytes (120 days), but the pathological mechanisms and causes are unclear. Senescent erythrocytes express phosphatidylserine (PS) on their outer membrane, which is a signal for being removed by macrophages. The PS localization in the cellular membrane is mainly regulated by two transporters: flippases and scramblases. Flippases, type IV P-type ATPases (P4-ATPases), maintain PS localization in the inner leaflet by transporting PS from the outer leaflet of the cell membrane. When scramblases are activated, they facilitate equal distribution of phospholipids between the inner and outer lipid bilayers, resulting in the exposure of PS on the outer leaflet. Recently, we have revealed that reduced flippase activity contributes to PS exposure in healthy senescent erythrocytes [1]. In this study, we examined the percentage of PS-exposed cells and the transporter activity in erythrocytes from renal anemia to elucidate the mechanism of the shortened lifespan.

Method: This study was approved by the Ethics Committee of Tokyo Women’s Medical University (#3835, #4822R2). Erythrocytes from the renal anemic patients undergoing maintenance hemodialysis were separated with the centrifugation using Percoll-density gradient according to our previous report. Resultant heavy and light fractions were used as senescent and young erythrocytes, respectively. We analyzed the percentage of PS-exposed cells (n = 12), flippase/scramblase activities (n = 7), and the factors involved in those enzymatic activities such as intracellular K+ (n = 10) and ATP concentration (n = 9). We also measured protein 4.1a/b and HbA1c as an index of erythrocytes’ age.

Results: The cells from renal anemia were separated to heavy (senescent) and light (young) fractions, which was similar to the distributions previously performed on healthy erythrocytes. The PS-exposed erythrocytes in the heavy fraction were slightly more than those of the light fraction (p < 0.01, Wilcoxon test), and the flippase activity of the heavy fraction decreased more than that of the light fraction (p < 0.01, paired t-test). Intracellular K+ concentration decreased in the heavy fraction more than in the light fraction similar to the healthy senescent erythrocytes, but there was no statistical difference in the intracellular ATP concentration between the heavy and light fractions. The measurement of protein 4.1a/b and HbA1c in these fractions is still in progress.

Conclusion: Similar to healthy erythrocytes, reduced flippase activity contributes to PS exposure in senescent erythrocytes of renal anemia, maybe due to the decreased intracellular K+ concentration. This may occur in an earlier stage of senescence than the healthy ones, which may explain the mechanism of the shortened life span.

ROLE OF THE TUBULAR EPITHELIAL CELL NLRP3 INFLAMMASOME DURING HYPERGLYCEMIA AND GLUCOSURIA IN DIABETES
Tamisa Honda1, Julian Marschner2, Danyang Zhao1 and Hans-Joachim Anders1
1University Hospital of the Ludwig Maximilians University, Renal Division, Department of Medicine IV, Munich, Germany, 2Lehrstuhl für Pharmazeutische und Medizinische Chemie, Department Pharmazie, Munich, Germany and 3Medizinische Klinik und Poliklinik IV, LMU Klinikum, Renal Division, Department of Medicine IV, Munich, Germany

Background and Aims: Diabetes is a prominent risk factor for the progression of CKD because hyperglycemia and glucose filtration increase the hemodynamic and metabolic workload to the nephrons, which imposes adaptive mechanisms. Tubules adapt to diabetes by enlargement and epithelial cell hypertrophy but an exceeding metabolic workload promotes oxidative stress, cytokine signaling and tubular epithelial (TEC) cell demise leading to tubular atrophy and interstitial fibrosis. Several studies propose a role of the NLRP3 inflammasome in tubulointerstitial inflammation in diabetic and non-diabetic kidney disease. The NLRP3 inflammasome is a sensor of cellular damage responsible for regulating the IL-1β and IL-18 production, playing important role during the progression of CKD. However, the role of NLRP3 in diabetes-induced tubular adaptation is unknown.

Method: scRNAseq analysis showed previously that the TECs do not express NLRP3 or inflammasome components. However, a group of patients diagnosed with Cryopyrin-Associated Autoinflammatory Syndromes, have a mutation that overexpress NLRP3, which is associated with chronic and systemic inflammation. To investigate the role of NLRP3 in tubular cells under diabetes conditions, we generated a mouse line by crossing mice bearing LoxP-target A350V allele with Pax8-driven Cre transgenic mice. Animals carrying the A350V allele have overexpression of NLRP3 in tubular cells. The combination of unilateral nephrectomy and treatment with multiple low doses of streptozotocin (60 mg/Kg) accelerate the kidney injury caused by hyperglycemia. Kidney function, histology and gene expression were evaluated at the end of 16 weeks of diabetes. In vitro experiments carried out using TECs isolated from Pax8-A350V, and stimulated with LPS (1μg/ml) and/or ATP (20 mM).

Results: In silico analysis showed TECs do not express NLRP3 or inflammasome components. A350V-TECs under inflammasome activation did not produce IL-1β or IL-18. However, the Nlrp3 overexpression upregulated kidney injury markers, as well IL-6 and TNF. Moreover, the increase in kidney inflammation was associated with significative upregulation of fibrosis markers (Tgfβ1, Asma, and Fni1) and extracellular molecules (Ctgf, AnxaII, and Chd2). Diabetic mice carrying the A350V mutation did not have significative differences in blood glucose, albuminuria, or body weight when compared with diabetic control mice. The overexpression of NLRP3 in tubular cells was associated with significative reduction in GFR and BUN when compared with controls mice, even though no differences in tubular injury markers observed. Furthermore, Pax8-A350V diabetic mice expressed significantly more Nlrp3 and Il1b than control group. Although, no differences observed in cryopyrin staining.

Conclusion: Our data suggest the NLRP3-associated damage in tubular epithelial cells occurs in a non-canonical manner.

URINE DERIVED STEM CELL AMELIORATES RENAL FIBROSIS VIA KLOTHO ACTIVATION
Dae Eun Choi1,2, Kang Wook Lee1, Ki Ryang Na1, Young Rok Ham1, Young-Kyung Chang1, Eu Jin Lee1, Heyrim Park2, Jin Young Jeong2 and Jin Ah Shin1
1Chungnam National University Hospital, Nephrology, Daejeon, Rep. of South Korea, 2Chungnam National University, Medical Science, Daejeon, Rep. of South Korea and 3Daejeon St. Mary Hospital, Nephrology, Daejeon, Rep. of South Korea

Background and Aims: After renal IRI, regeneration and recovery of the renal tubular cell occurs. However, if the renal repair process is maladaptive, it progresses to renal fibrosis. The role of stem cells in kidney regeneration or fibrosis has not been fully elucidated. we evaluated the urine derived stem cells (UDSC) for renal inflammation and fibrosis after renal ischemia reperfusion (IR).

Method: 10 week old babie nude male mice were used. sham, sham with UDSC, IR, IR with UDSC. UDSC were infused 3 times via tail vain at 6, 7, 8th day after renal IR. Urine NGAL/creatinine (Cr) were checked. The kidneys
tissue were harvested at day 14 day. In vitro, TGF-β treated HK2 cell were co-cultured with UDSC. Klotho siRNA silencing was performed in UDSC.

**Results:** Urinary NGAL/Cr were significantly increased in IR mice after 14 day IR, compared to sham mice. Urinary NGAL/Cr significantly decreased in UDSC treated IR mice, compared to IR mice. In H&E stain, renal tubulo-interstitial injury were significantly decreased in UDSC treated IR mice, compared to IR mice. In Masson trichrom stain, renal fibrosis area were significantly decreased in UDSC treated IR mice, compared to IR mice. The renal expression of TGF-β, α-SMA, and collagen IV were significantly decreased in UDSC treated IR mice, compared to IR mice. The renal expression of Klotho were increased in UDSC treated IR mice, compared to IR mice. In vitro, UDSCs were stem cells that expressed Klotho protein more strongly than other mesenchymal stem cells (MSCs). UDSCs also suppressed fibrosis by inhibiting transforming growth factor (TGF)-β in HK-2 human renal proximal tubule cells in an in vitro model. Klotho siRNA silencing reduced the TGF-β-inhibiting ability of UDSCs.

**Conclusion:** UDSC attenuate renal fibrosis after renal IR. Klotho-secretion of UDSC play a role in these anti-fibrotic effects.

**ITGAM PROMOTES MACROPHAGE ALTERNATIVE ACTIVATION IN HYPERURICEMIA-RELATED CHRONIC KIDNEY DISEASE**
Jing Liu, Fan Guo, Liang MA and Ping Fu
West China Medical School, West China Hospital, Sichuan University, Division of Nephrology, Cheng Du Shi, P.R. China

**Background and Aims:** Hyperuricemia is an essential risk factor in chronic kidney disease (CKD), while urate-lowering therapy to prevent or delay CKD progression is controversial. Alternatively activated macrophages in response to local microenvironment play diverse roles in kidney injury, repair, and fibrosis. Here, we aim to investigate whether and how macrophage ITGAM contributes to hyperuricemia-related CKD.

**Method:** In vivo, we explored dynamic characteristics of renal tissue in hyperuricemia-related CKD. By incorporating mRNA and protein sequencing data, we analyzed gene expression profile, hub genes and potential pathways responsible for disease development, which was further confirmed using qPCR, western blotting, and immunofluorescent stainings. In vitro, we validated bioinformatic findings under different conditions of macrophages with interventions corresponding to core nodes in pathway.

**Results:** Hyperuricemia-related CKD was characterized by the rise in serum uric acid, decline in renal function, macrophage alternative (M2) polarization, and kidney fibrosis. Integrated bioinformatic analyses revealed ITGAM as the potential core gene mediating disease progression which was associated with FAK/Akt1/β-catenin signaling. Notably, we confirmed the upregulated macrophage ITGAM, activated pathway, and macrophage M2 polarization in injured kidneys and Raw 264.7 macrophages. In vitro, we verified ITGAM/FAK/Akt1/β-catenin pathway participated in promoting macrophage M2 polarization through silencing Itgam and inhibiting FAK or Akt1 phosphorylation, where the expression of M2 phenotype macrophage markers and downstream molecules in pathway were down-regulated.

**Conclusion:** In hyperuricemia-related CKD, ITGAM promotes macrophage M2 polarization contributing to renal fibrosis through FAK/Akt1/β-catenin signaling pathway. Targeting macrophage ITGAM might be a promising therapeutic approach for preventing or delaying CKD.

**Figure 1:** Progressive renal dysfunction and kidney fibrosis in hyperuricemia-related CKD mice.
Figure 2: Bioinformatic analyses revealed ITGAM as the hub gene associated with downstream FAK pathway.

Figure 3: ITGAM expression and macrophage M2 polarization in vivo.
Figure 4: Interventions of ITGAM, FAK, and Akt verified the participation of pathway ITGAM/FAK/Akt/β-catenin in macrophage M2 polarization in hyperuricemia-related CKD.

LOSS OF GASDERMIN D LEADS TO AN EXACERBATION OF KIDNEY DAMAGE IN NEPHROCALCINOSIS-RELATED CHRONIC KIDNEY DISEASE

Yoshihiro Kusunoki1,2, Stefanie Steiger3, Andreas Linkermann4,5 and Hans-Joachim Anders1

1University Hospital of the Ludwig-Maximilians-University, Department of Medicine IV, Division of Nephrology, Munich, Germany, 2Hokkaido University, Department of Rheumatology, Endocrinology, and Nephrology, Faculty of Medicine and Graduate School of Medicine, Sapporo, Japan, 3University Hospital of the Ludwig-Maximilians-University, Department of Medicine IV, Division of Nephrology, Munich, Germany, 4University Hospital Carl Gustav Carus at the Technische Universität Dresden, Department of Internal Medicine 3, Dresden, Germany and 5Albert Einstein College of Medicine, Division of Nephrology, Department of Medicine, New York, United States of America

Background and Aims: Gasdermin D (GSDMD) is a membrane-targeting and pore-forming protein that is primarily expressed in immune cells. In the proinflammatory cell death process known as pyroptosis, cleaved GSDMD plays a crucial role through cell membrane pore formation, leading to the release of proinflammatory cytokines and membrane rapture. Despite this, the majority of GSDMDs other physiological functions remain to be elucidated. Previous reports have implicated GSDMD in the pathogenesis of kidney disease, utilizing some acute kidney injury (AKI) animal models and a few chronic kidney disease (CKD) animal models. However, it remains uncertain if GSDMD contributes to the pathogenesis of nephrocalcinosis-related CKD. Therefore, this study aimed to investigate the role of GSDMD in this context.

Method: In our study, 8-week-old GSDMD-knockout (KO) mice and wildtype (WT) mice received an oxalate-rich diet (50 μmol/g sodium oxalate) for three weeks. All mice were sacrificed on day 21 and kidneys were harvested after the sacrifice. Plasma and urine samples were collected at different time points before the sacrifice. The glomerular filtration rate (GFR) was measured on day 0 and day 20 to assess kidney excretion function. Histological analysis was performed using Periodic Acid-Schiff (PAS) staining to assess renal injury, Sirius Red staining to check renal fibrosis, Pizzolato staining to evaluate calcium crystal deposition, F4/80 staining to evaluate the infiltration of macrophages, TUNEL staining to check for cell death, RIPK3 and phosphorylated MLKL (pMLKL) staining to detecting necroptosis. And GSDMD staining was also performed to examine the expression of GSDMD in the kidney.

Results: Pizzolato staining showed no differences in calcium crystal deposition between WT mice and KO mice. GFR was decreased in both WT mice and KO mice after the oxalate-rich diet (day 0 WT: 199.5±40.1 μl/min vs KO 175.0±44.8 μl/min, day 20 WT: 156.5±37.9 μl/min vs KO: 73.0±48.1 μl/min), and ΔGFR was much greater in KO mice (WT: −22.4±26.5% vs KO: −59.4±19.3%). The level of blood urea nitrogen was significantly higher in KO mice (WT: 41.9±3.90 mg/dl vs KO: 58.7±22.5 mg/dl) in accordance with the result of the GFR. PAS staining revealed more severe kidney injury in KO mice, and Sirius Red staining indicated a higher degree of renal fibrosis in KO mice. Furthermore, F4/80 staining showed greater infiltration of macrophages in KO mice. Although TUNEL staining showed no significant differences in positive cells between WT and KO mice showed greater positive areas implicating more necroptosis in RIPK3 and pMLKL staining. GSDMD staining revealed that injured tubular cells during the chronic phase express GSDMD (Fig. 1). In vitro experiments, we evaluated the functionality of macrophages such as phagocytic ability and migratory ability using bone marrow-derived macrophages (BMDMs), but we didn’t find any significant disparities between BMDMs from WT mice and those from KO mice.

Conclusion: Genetic deletion of GSDMD resulted in more severe kidney injury, macrophage infiltration and fibrosis in mice with nephrocalcinosis-related CKD. Our results suggest a potential role for pyroptosis, especially GSDMD, in contributing to renal tubular cell necroptosis, a process downstream of calcium-oxalate crystal formation and deposition, in the progression of nephrocalcinosis-related CKD, similar to previous reports in mouse models of AKI.
glomerulopathy caused by mutations in the genes encoding the α-chains of type IV collagen, the most abundant component of the glomerular basement membrane (GBM). Alport patients lack effective therapies beyond blockade of the renin-angiotensin system. This work describes the repurposing of two FDA-approved chemical chaperones (4-PBA and TUDCA) to rescue two AS mouse models: a knock-in and a compound heterozygous model bearing the Col4a3-p.Gly1332Glu mutation, recapitulating the most common mutation in Cypriot patients. Samples were collected after therapy and histological effects of chaperones on treated mice, kidney, blood, and urine (WT) mice received chaperones or vehicle daily. To examine the biochemical reduction of lesions and a decline of the lesions-severity in the GBM of 4-PBA treated AS mice. No adverse effects were noted in the GBM of the control and TUDCA groups. The lack of GSDMD, it shows more severe kidney injury.

**Method:** In either a short-term or long-term treatment, AS and wild type (WT) mice received chaperones or vehicle daily. To examine the biochemical and histological effects of chaperones on treated mice, kidney, blood, and urine samples were collected after therapy.

**Results:** Electron microscopy studies showed that the GBM of the 4-PBA treated AS mice after the long-term treatment has a considerable improvement in morphology, compared with vehicle-treated or TUDCA-treated AS mice. Importantly, EM measurements displayed a significant (p-value <0.0001) reduction of lesions and a decline of the lesions-severity in the GBM of 4-PBA treated AS mice. No adverse effects were noted in the GBM of the control and TUDCA groups. The lack of GSDMD, it shows more severe kidney injury.

**Conclusion:** Together, these results suggest a therapeutic potential for the 4-PBA agent in combating renal dysfunction in AS.

**THE ROLE OF GENDER DIFFERENCES AND MENOPAUSE IN OBESITY-RELATED RENAL DISEASE, RENAL INFLAMMATION AND LIPOTOXICITY**

Aaron Afonso-Alí1, Esteban Porrini1,2, Silvia Teixidó-Trujillo3, Jose Antonio Perez-Perez4, Sergio Luis-Lima3, Nieves Guadalupe Acosta-González4, Irene Sosa-Paz4, Laura Diaz Martin4, Covadonda Rodriguez-González4 and Ana Elena Rodriguez-Rodriguez3

1Instituto Tecnologías Biomédicas, Spain, 2Hospital Universitario de Canarias, Spain, 3Hospital Universitario de Canarias, Research Unit, San Cristobal de La Laguna, Spain, 4Universidad de La Laguna, Department of Animal Biology, Edaphology and Geology, Faculty of Biology, Spain and 3Hospital Universitario de Canarias, Central Laboratory, Spain

**Background and Aims:** The pathogenesis of obesity related-renal disease is unknown. Gender differences may have a role in renal damage in obesity. In particular, menopause can promote renal disease in obese women. In a previous study we observed that obese male and female mice developed albuminuria, hyperfiltration and glomerulomegaly, and these changes were more severe in those obese ovariectomized females. In this study we evaluated renal inflammation and lipotoxicity in that model.

**Method:** Twenty-two males and 57 females C57BL6/J mice were randomized to standard diet (SD) or high fat diet (HFD) for six months. A group of female animals on SD o HFD was ovariectomized to induce menopause. In renal tissue we evaluated cytokines: NF-κβ, IL-1β, MCP-1, TNF-α and total lipid content, lipid classes, fatty acid profile and fatty acids in lipid classes. Part of the lipidomic analysis was performed in urine.

**Results:** Obese males and females showed higher NF-κβ, IL-1β, MCP-1, TNF-α and TUDCA treated AS mice. No adverse effects were noted in the GBM of the control and TUDCA groups. The lack of GSDMD, it shows more severe kidney injury.

**Conclusion:** Obese males and females showed higher NF-κβ, IL-1β, MCP-1 and TNF-α compared with obese female not-ovariectomized (Fig. 1B). Obese animals showed lower pro-inflammatory fatty acids (16:0, 16:1n-7 and 18:2n-6) and higher anti-inflammatory fatty acid (22:6 n-3) (Fig. 2A). This pattern was also observed in specific lipid classes and urine. Finally, obese females ovariectomized had a more exacerbated pattern, with high 18:0 in phosphatidylethanolamine and low 16:0 in triglycerides (Fig. 2B-D).

**Conclusion:** Obese females ovariectomized had a more exacerbated pattern, with high 18:0 in phosphatidylethanolamine and low 16:0 in triglycerides (Fig. 2B-D).

**Conclusion:** Obese females ovariectomized had a more exacerbated pattern, with high 18:0 in phosphatidylethanolamine and low 16:0 in triglycerides (Fig. 2B-D).

**Conclusion:** Obese females ovariectomized had a more exacerbated pattern, with high 18:0 in phosphatidylethanolamine and low 16:0 in triglycerides (Fig. 2B-D).

**Conclusion:** Obese females ovariectomized had a more exacerbated pattern, with high 18:0 in phosphatidylethanolamine and low 16:0 in triglycerides (Fig. 2B-D).
Figure 1: Quantitative analysis of each inflammation marker in males and females. A) Males in HFD showed higher NF-κβ, TNF-α, MCP-1 and IL-1β in renal tissue. B) Females in HFD showed higher NF-κβ, TNF-α and MCP-1 in renal tissue; and obese females ovariectomized (HFD-OVX) had higher IL-1β and TNF-α compared to females in HFD. Data are represented as mean ± standard deviation. * M-SD vs. M-HFD p≤0.01. M-SD: male standard diet; M-HFD: male high fat diet. a, F-SD vs. F-SD-OVX p≤0.01; b, F-HFD vs. F-SD p≤0.0001; c, F-HFD-OVX vs. F-HFD and vs. F-SD-OVX p≤0.0001; d, F-SD vs. F-HFD p≤0.01; e, F-HFD-OVX vs. F-SD-OVX p≤0.0001. F-SD: female standard diet; F-HFD: female high fat diet; F-SD-OVX: female standard diet ovariectomized; F-HFD-OVX: female high fat diet ovariectomized.
CALCIUM ISOTOPE RATIOS IN SERUM ARE THE STRONGEST PREDICTOR OF BONE CALCIUM BALANCE IN PATIENTS ON DIALYSIS

Rukshana Shroff1,2, Anton Eisenhauer1, Alexander Heuser1, Ana Kolevica3, Patrick D’haese4, Catherine Shanahan5 and Pieter Evenepoel*

1Great Ormond Street Hospital for Children, London, United Kingdom, 2University College London, London, United Kingdom, 3GEOMAR Helmholtz-Zentrum für Meeresforschung Kiel, Kiel, Germany, 4Antwerp, Belgium, 5King’s College Hospital, London, United Kingdom and 6UZ Leuven, Leuven, Belgium

**Background and Aims:** Dysregulated mineral homeostasis is common in chronic kidney disease (CKD) and associated with bone demineralization and vascular calcification. The balance between bone formation and resorption, which reflect the bone calcium (Ca) balance (BCaB), cannot be determined without bone biopsy which is invasive and not easily repeatable. Recently, we have shown that stable (i.e. non-radioactive) Ca isotopes, 42Ca and 44Ca, can be measured in serum and bone and arterial biopsy samples using a multi-collector inductively-coupled plasma mass spectrometer (Thermo Fisher Scientific, Germany).

**Method:** Adults receiving chronic dialysis who underwent bone and arterial biopsies at the time of kidney transplantation were recruited. Patients who had parathyroidectomy or received cinacalcet or anti-resorptive agents were excluded. All participants had Dual Energy X-ray Absorptiometry (DXA) of the hip and lumbar spine. Ca44 and Ca42 measurements were performed in serum and bone and arterial biopsy samples using a multi-collector inductively-coupled plasma mass spectrometer (Thermo Fisher Scientific, Germany).

**Results:** Nineteen patients, median age 59.8 years, 84% male, median time on dialysis 3.3 years were included. δ44/42Ca was significantly higher in serum compared to bone or arterial biopsy samples (p < 0.0001), with the lowest isotope ratios in bone (Fig. 1A). δ44/42CaBone was significantly lighter than δ44/42CaArtery (p = 0.0002; Fig. 1B), δ44/42CaArtery correlated positively with the osteoblastic markers BAP and P1NP (p = 0.0006, R² = 0.51 and p = 0.009, R² = 0.31) and inversely with PTH and the osteoclastic marker RANKL (p = 0.0017, R² = 52 and p = 0.02, R² = 0.29 respectively; Fig. 2). Both the DXA hip and lumbar spine T-scores and z-scores correlated positively with δ44/42CaBone. δ44/42CaSerum showed an inverse correlation with the osteoid area (p = 0.04, R² = 0.22) and a positive correlation with the absolute mineralized area and the trabecular thickness (p = 0.0004, R² = 0.58 and p = 0.013, R² = 0.34 respectively). The were no significant correlations with δ44/42CaArtery. On multivariable linear regression analysis significant predictors of 44/42CaSerum were 44/42CaBone (p = 0.018, 95%CI = −1.35 to −0.15), age (p = 0.02, 95%CI = 0.02 to 0.02) and BAP (p = 0.019, 95%CI = 0.04 to 0.38), together predicting 71% of the variability in δ44/42CaSerum. The only significant predictor of 44/42CaBone was the δ44/42CaSerum: p = 0.004, 95%CI = −1.6 to −0.37, model R² = 69%.

**Figure 2:** Lipidomic analysis in renal tissue. A) Total fatty acids profile in renal tissue of male and female animals in percentage relative area (RA %). a, M-SD vs. M-HFD p < 0.001; b, F-HFD vs. F-SD p < 0.001 and vs. F-SD-OVX p < 0.05; c, F-HFD-OVX vs. F-SD p < 0.001 and vs. F-SD-OVX p < 0.01. B) Percentage Relative Area (RA %) of fatty acid profile from phosphatidylcholine; C) phosphatidylethanolamine and triglycerides in renal tissue. Data are represented as mean ± standard deviation. g, F-HFD vs. F-HFD-OVX and vs. F-SD-OVX p ≤ 0.05, h, F-HFD-OVX vs. F-HFD and vs. F-SD-OVX p ≤ 0.05, i, F-HFD-OVX vs. F-HFD and vs. F-SD-OVX p ≤ 0.05, j, F-HFD vs. F-SD p ≤ 0.05, k, F-HFD vs. F-SD and vs. F-SD-OVX p ≥ 0.05, l, F-HFD-OVX vs. F-SD-OVX and vs. F-SD p ≥ 0.05 and vs. F-HFD p = 0.052. n, F-HFD-OVX vs. F-SD-OVX and vs. F-SD p = 0.058. M-SD: male standard diet (white square), M-HFD: male high fat diet (hard grey square), F-SD: female standard diet (white circle), F-HFD: females high fat diet (hard grey circle), F-HFD-OVX: female high fat diet ovariectomized (light grey circle), F-HFD-OVX: female high fat diet ovariectomized (black circle).
Figure 1: 

Figure 2: 

Conclusion: $\delta^{44/42}\text{Ca}_{\text{serum}}$ is a significant and independent maker of BCaB, correlating with bone histology measures, and may provide a more sensitive measure than DXA or bone biomarkers. Further studies are required to determine the clinical utility of using $\delta^{44/42}\text{Ca}_{\text{serum}}$ to guide management of mineral bone disease in CKD.

RAPAMYCIN AGGRAVATES KIDNEY LESIONS IN RATS FED HIGH PHOSPHATE

Ana Isabel Raya-Bermúdez, Ángela Vidal, Azahara Espartero Castro, Carmen María Pineda Martos, Ignacio Lopez Villalba, Stanislav Kolosov and Escolástico Aguilera-Tejero

Faculty of Veterinary Medicine, University of Cordoba, Department of Animal Medicine and Surgery, Cordoba, Spain

Background and Aims: Rapamycin is currently used to prevent rejection after kidney transplantation. mTOR blockade by rapamycin may slow the progression of diabetic kidney disease. Rapamycin promotes phosphaturia by inhibiting renal tubular transport of phosphate. Excessive tubular load of phosphate produces kidney damage by inducing tubular injury and interstitial fibrosis. The aim of this work is to evaluate the effect of rapamycin on kidney pathology in rats fed different phosphate levels.

Method: Thirty four female Wistar rats were used in this experiment. Rats, aged 2 months at the beginning of the studies, were allotted to 6 groups (n = 4-6). Rats with intact renal function were fed a standard diet containing either normal (0.6%, NP), low (0.2%, LP) or high (1.2%, HP) phosphate. Half of the groups received placebo treatment (NP, LP, HP) and the other half were treated with rapamycin (NP-Rapa, LP-Rapa, HP-Rapa) at a dose of 1.3 mg/kg/day, for 22 days. Plasma concentrations of urea, creatinine, and phosphate as well as urine creatinine and phosphate were measured by spectrophotometry. Microscopic evaluation of the kidneys was performed in tissue sections fixed with formaldehyde solution and embedded in paraffin. Kidney sections were stained with hematoxylin-eosin, Masson Trichrome, periodic acid Schiff, and Von Kossa staining. Thirty non overlapping fields were evaluated. Chronic interstitial fibrosis and renal calcification were measured with a point counting grid and the result was expressed in percentage. Atrophic tubules were counted and the result was expressed as number of atrophic tubuli/field. Values are expressed as the mean ± standard error (SE). The difference between means was assessed by ANOVA. Fisher LSD test was used as a post-hoc procedure. A correlation study was carried out using the Pearson test. p < 0.05 was considered significant.

Results: Kidney lesions were more severe in rats treated with rapamycin and fed high phosphate diet. Areas of chronic interstitial fibrosis, with interstitial fibrosis and lymphoplasmacytic infiltrate, as well as atrophic tubules with thickened and wrinkled tubular basement membrane, loss of the brush border and flattening of the tubular cell cytoplasm, were observed. Calcification foci, mainly located in the corticomedullary junction, were identified with Von Kossa staining. Thirty non overlapping fields were evaluated. Chronic interstitial fibrosis and renal calcification were measured with a point counting grid and the result was expressed in percentage. Atrophic tubules were counted and the result was expressed as number of atrophic tubuli/field. Values are expressed as the mean ± standard error (SE). The difference between means was assessed by ANOVA. Fisher LSD test was used as a post-hoc procedure. A correlation study was carried out using the Pearson test. p < 0.05 was considered significant.

Fractional excretion of P was higher in all the groups treated with rapamycin, and the differences reached significance in HP-Rapa rats. Fractional excretion of P showed an excellent correlation with kidney lesions: chronic interstitial fibrosis ($r = 0.822$), calcification ($r = 0.827$) and tubular atrophy ($r = 0.855$).

Conclusion: The phosphaturic action of rapamycin aggravates renal lesions in rats fed high phosphate diets. Thus, rapamycin could be deleterious for the kidneys in the context of high phosphorus intake.
Table 1: Renal histopathology and biochemical parameters in rats fed different P levels with and without rapamycin. * p < 0.05 vs its non-rapamycin (placebo) control.

THE ASSOCIATION OF TAMOXIFEN TO THE CONSERVATIVE CKD TREATMENT PROMOTED ADDITIONAL ANTIFIBROTIC EFFECTS IN A MODEL OF HYPERTENSIVE NEPHROSCLEROSIS
Camilla Fanelli1, Ana Laura Rubio Francini2, Paloma Noda3, Leandro Iannuzzi1, Giovanna Celestrino3, Felipe Ornellas3 and Irene L Noronha3

1University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil
2University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil
3University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil

Background and Aims: Chronic kidney disease (CKD) is an insidious, progressive and highly debilitating condition, which leads to the loss of renal function and to the need of life-sustaining renal replacement therapy. The conservative treatment of CKD is mainly based in the blockade of the renin-angiotensin-aldosterone system (RAAS), which can be associated to immunosuppressant drugs, according to the etiology of the renal injury. However, this pharmacological approach is not able to prevent CKD progression completely. Until the present moment, medical community still lack of a specific drug to effectively stop the progression of renal fibrosis associated to CKD, which once triggered became irreversible. Tamoxifen (TAM) is an estrogen receptor antagonist, widely employed for the clinical treatment of breast cancer, and responsible for saving a number of lives worldwide, in the past decades. This well-tolerated and cost-effective drug have been reported to exert antifibrotic effects in both experimental and human peritonedal fibrosis. Moreover, our research group already demonstrated that TAM efficiently prevented albuminuria, glomerulosclerosis, and interstitial fibrosis in a model of CKD. In the present study, we investigated if the association of TAM to the classic conservative treatment of CKD, here obtained by the association of Losartan (LOS) and Micofenolate Mofetil (MMF), could promote further renoprotection in an experimental model of hypertensive nephrosclerosis, induced by the chronic nitric oxide synthase blockade, obtained by the oral administration of L-NAME (NAME), associated to a high sodium (HS) diet, in rats.

Method: The experimental protocol was approved by the local Research Ethics Committee (CAPPesq) and was developed in strict conformity with the international standards for care and manipulation of laboratory animals. Thirty male Wistar rats were kept with a 3.2% HS diet for 15 days of adaptation, before the protocol start. After this period, the animals continued to receive the HS diet and were divided among 5 groups. CONT: receiving no further drugs or treatments, NAME: treated with 70 mg/kg/d of L-NAME, diluted in drinking water, LOS: NAME rats treated with 50mg/Kg/d of LOS, also diluted in drinking water, MMF: NAME rats treated with 10 mg/Kg/d of MMF given by gavage, TAM: NAME rats treated with 10 mg/Kg/d also by gavage, and LOS+MMF+TAM: NAME rats treated with all the drugs simultaneously. Systolic blood pressure (SBP), urinary albumin excretion (24 h uAE), glomerulosclerosis (GS), glomerular ischemia (GI), interstitial fibrosis (INT), tubulointerstitial infiltration of macrophages (CD68) and T-cells (CD3), as well as renal cortical interstitial collagen I (COLL1) and fibronectin (FIBRO) accumulation were evaluated after 30 days of treatment.

Results: The association of TAM to the classic treatment of CKD improved the renoprotection obtained by LOS+MMF. The triple combined treatment significantly reduced hypertension, albuminuria, glomerular structural damage, renal macrophage and T-cell infiltration in NAME rats, compared to the animals treated with the respective monotherapies. Moreover, both TAM alone or the association, were equally effective in reducing interstitial collagen and fibronectin accumulation, in NAME rats. Data are presented as Mean ± SE. For One-way ANOVA statistical analysis, we considered: p<0.05 vs.*CONT, #NAME, †LOS, §MMF, &TAM.

Conclusion: Our preliminary results shown TAM to be effective in reducing renal inflammation and fibrosis in the chronic nitric oxide synthase blockade model and to exert additional renoprotective effects when associated to LOS and MMF in all the analyzed parameters. Although further studies with different nephropathy models are still required in order to confirm our findings, here we suggest TAM to be a potential adjuvant in the conservative management of CKD.

COMPARATIVE TRANSCRIPTOMICS OF THREE CANONICAL MOUSE MODELS OF CHRONIC KIDNEY DISEASE
Michael Christensen, Adam Bogh Marstrand-Jorgensen, Frederikke Emilie Sembach, Maria Ougaard, Mikkel Christensen-Dalsgaard, Martin Ronn Madsen, Stine Bak, Ditte Jensen, Henrik Björk Hansen and Louise S. Dalboe
Gubra aps, Denmark

Background and Aims: A range of mouse models are available in preclinical chronic kidney disease (CKD) research but differ in their disease etiology and pathological hallmarks. To enable better selection of the mouse CKD model optimal for preclinical drug discovery studies, we characterized the kidney transcriptome signature of three well-established models of CKD induced by unilateral ureter obstruction (UUO), unilateral ischemic reperfusion injury (uIRI) and adeno-supplemented diet feeding (ADI).

Table 1:
Method: Male C57BL/6J mice were used in all studies. UUO or sham surgery was performed in 9 weeks old mice, which were terminated two weeks post-surgery. uIRI or sham surgery was performed in 10 weeks old mice terminated 6 weeks post-surgery. 12 weeks old mice received an adenine-supplemented diet or a control diet for 6 weeks. Endpoints included plasma biochemistry, kidney histology and RNA sequencing on kidney samples.

Results: Compared to corresponding controls, plasma urea was only increased in ADI mice. All three models presented with increased inflammation (F4/80, UUO > ADI > uIRI) and fibrosis (Col1A1, UUO = uIRI > ADI) in the histological analysis. Compared to corresponding controls, all three models demonstrated substantial increases in differential expressed genes (DEGs, UUO, n = 12,046; uIRI, n = 12,236; ADI, n = 11,468), with significant overlap in transcriptome signatures between the models. Three models presented with a substantial increase in differential expressed genes (DEGs, UUO, n = 12,046; uIRI, n = 12,236; ADI, n = 11,468), with significant overlap in transcriptome signatures between the models. Gene expression markers of inflammation (e.g., Ccl2, Cd68 and Il1b), fibrogenesis (e.g., Tgfb1, Serpine1 and Col1a1) and kidney injury (e.g., Htrc1, Lcn2 and Spp1) supported histological findings in the three models. Interestingly, several molecular targets pursued in CKD drug discovery were significantly regulated, however with different directionality, in UUO (upregulated Atg7, Bax, Ednrb/a, Gli2, Fshr, Shh; downregulated Glp1r, Nr3c2, Pth1r, Scl5a2), uIRI (upregulated Edf1r, Glu2, Glp1r, Fshr, Nr3c2; downregulated Agrp, Egfr, Scl5a2), and ADI mice (upregulated Agrp, Atg7, Bax, Ednrb; downregulated Ednrb, Egfr, Fhr1, Nr3c2, Pth1r, Scl5a2).

Conclusion: UUO, uIRI and ADI mouse models demonstrate histopathological hallmarks of CKD, characterized by increased macrophage infiltration and fibrosis, which was corroborated by their individual transcriptome signatures. Despite similarities in histological phenotype, the models were distinguished based on kidney transcriptome changes, with several current drug targets regulated in a model-specific fashion. In conclusion, the current work will enable researchers to select the mouse model optimal for profiling individual preclinical test drugs with therapeutic potential in CKD. Also, our data may serve to enable further development of CKD mouse models with improved clinical translatability.

MIR-451B AND CHRONIC KIDNEY DISEASE: A NOVEL TARGET TO MODULATE RENAL VEGF SIGNALING

Alejandro Chade¹, Rhys Sitz² and Alfonso Eirin³

¹ University of Missouri - Columbia, Medical Pharmacology and Physiology; Medicine, Columbia, United States of America, ² University of Missouri - Columbia, Medical Pharmacology and Physiology, Columbia, United States of America and ³ Mayo Clinic - Rochester, Medicine, Div. of Nephrology and Hypertension, Rochester, United States of America

Background and Aims: Chronic kidney disease (CKD) is a progressive disorder that affects over 15% of adults worldwide. A major component of CKD pathophysiology is renal microvascular rarefaction and loss that pairs the progression of the disease and complications. We developed a translational swine model of CKD and showed that loss of renal function associates with a significant decrease in renal vascular endothelial growth factor (VEGF) signaling and progressive microvascular (MV) rarefaction. VEGF is a key endogenous cytokine for MV proliferation and repair, but underlying mechanisms of renal VEGF downregulation in CKD are unknown. We hypothesized that micro-RNA (miRNA)-mediated processes contribute to the downregulation of renal VEGF signaling in CKD.

Method: Unbiased renal micro-RNA (miRNA)-seq was performed in a swine model of CKD stage 3 (14 weeks of bilateral renal artery stenosis + atherogenic diet) and normal controls (n = 5/group). Micro-RNAs up (≥1.4 FC, p < 0.05) and down-regulated (<0.7 FC, p < 0.05) were identified, followed by target prediction analysis (miRwalk 3.0, Target Scan 7.2). Renal gene and protein expression of VEGF was measured by qPCR and western blot, respectively, and renal MV architecture was studied by 3D micro-CT.

Results: Unbiased miRNA-seq and target prediction analysis identified four miRs upregulated in the kidney of CKD pigs vs. controls, of which miR-451b (validated by qPCR), broadly conserved among species, was capable of downregulating VEGFA (FC = 4.46, p = 0.04). Renal gene and protein expression of VEGF was downregulated in CKD vs. controls, associated with significant cortical and medullary microvascular rarefaction (Figure 1).

Conclusion: Our data suggest that post-transcriptional modulation of renal VEGF signaling may serve as a prominent mechanism of VEGF downregulation, which leads to MV rarefaction and disease progression in CKD. Furthermore, this work in progress identified a novel candidate (miR-451b) and may set the stage for its targeted modulation to preserve VEGF signaling as a potential strategy to protect the renal microvasculature in CKD.
DI(2-ETHYLHEXYL) PHTHALATE INDUCES RENAL PROXIMAL TUBULAR CELLS TO UNDERGO EPITHELIAL-MESENCHYMAL TRANSITION VIA AHR SIGNALING

Wen-Chin Lee1, Kai-Fan Tsai1, Chien-Te Lee1 and Chia-Te Kung2

1Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan, Division of Nephrology, Department of Internal Medicine, Kaohsiung, Taiwan, Rep. of China and 2Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan, Department of Emergency Medicine, Kaohsiung, Taiwan, Rep. of China

Background and Aims: Environmental factors account for the majority of identified risks associated with CKD of uncertain etiology (CKDu). Among the various environmental factors, plasticizer di(2-ethylhexyl) phthalate (DEHP) is widely used in modern life. The exposure to DEHP is extensive but mostly underestimated in the general population. The link between DEHP exposure and renal injuries has been scarcely reported but the underlying mechanisms are largely unknown. This study aimed to examine the mechanisms by which DEHP causes renal tubular injuries.

Method: Human proximal tubular cells (PTC), HK2 cells, were used as a cellular model to test the central hypothesis of this study. Cells were treated with various concentrations of DEHP at different time points. WST-1 assay was used to examine the impacts of DEHP on cell viability. Bright field microscopy and immunofluorescence were used to analyze the morphological evidence of epithelial-mesenchymal transition (EMT). Western blots were used to investigate the changes in the expression of EMT-related proteins and arylhydrocarbon receptor (AhR) signaling. Inhibitors of AhR signaling were employed to investigate the crucial roles of AhR signaling in DEHP-induced EMT in HK2 cells.

Results: By using WST-1 assay, we found that DEHP did not affect cell viability when the examined concentration was below 50 μM, which resembled the low-level environmental exposures. However, when the concentration was higher than 100 μM, DEHP reduced the cell viability in a dose-dependent manner. In response to DEHP, HK-2 cells changed from cuboid to spindle shape when cultured with DEHP (25 μM). This morphological evidence became evident when the treatment time was longer than 48 hours. At the protein levels, DEHP resulted in down-regulation of e-cadherin and upregulation of vimentin and α-SMA. DEHP also lead to upregulation of AhR. The inhibitor of AhR signaling, CQDP (chloroquine diphosphate) reversed the DEHP-induced EMT, which were evidenced by morphology and by the expression patterns of EMT-related proteins.

Conclusion: At cellular level, our results suggested that low-level environmental exposures of DEHP led to EMT in renal PTC via AhR signaling.

THROMBO-INFLAMMATORY BIOMARKERS OF CARDIORENAL SYNDROME IN PATIENTS UNDERGOING MAINTENANCE HEMODIALYSIS IN END STAGE RENAL DISEASE

Vinod Bansal1, Pranathi Karumanchi2, Jawed Fareed2, Fakiha Siddiqui2 and Debra Hoppensteadt2

1Loyola University Medical Center, Nephrology, Maywood, United States of America and 2Loyola University Medical Center, Pathology, Maywood, United States of America

Background and Aims: Cardiovascular disease is a highly common complication in patients with end stage renal disease (ESRD) on maintenance hemodialysis. In the ESRD patient population, cardiovascular mortality is 20 times higher compared to the general population. The strong relationship of both illnesses can be explained through cardiorenal syndrome (CRS). CRS encompasses a spectrum of disorders involving both the heart and kidneys in which acute or chronic dysfunction in one organ may induce similar effect in the other organ. The diagnosis, prognosis and risk stratification of CRS is poorly understood. Current literature reveals that inflammation and thrombosis are integral to CRS development and key cardiac and renal biomarkers are elevated in CRS patients. Hence, this study aims to demonstrate that thrombo-inflammatory biomarkers and laboratory parameters give a telling narrative of ESRD progression to CRS.

Method: Plasma samples were collected from 95 ESRD patients which were recruited with an approved IRB protocol at Loyola University Medical Center hemodialysis unit. Normal human plasma (NHP) was obtained from a commercial source (George King Biomedical, Overland Park, KS). Thrombo-inflammatory biomarkers, including Annexin V, MPO, Troponin, L-FABP, VEGF, D-dimer, TNF-alpha, IL-6, CRP, eNOS, Nitrotyrosine, MDA, NEFA, NO, vWF and MCP-1 were measured using commercially available ELISA methods. Cardiovascular comorbidities and laboratory parameters were obtained from EPIC chart analysis. Results were then statistically analyzed using GraphPad Prism v.9; the results were compiled into mean ± SEM, percent change comparison to NHP, analyzed for significance.

Results: Several cardiovascular comorbidities were seen in the 95 ESRD patient samples including AF (22%), PAD (29%), HF (24%), CAD (22%), DVT (15%), COPD (6.5%), and PE (5.3%). Overall, 25% of the ESRD patients have CRS. Laboratory parameters, ferritin (521.99 ±289.33) and PTH (442.91 ±1.50) were elevated in ESRD patients. Most of the thrombo-inflammatory CRS biomarkers were elevated in ESRD patients. Biomarkers including Annexin V (ESRD 7.57 ±5.24, 23.64% vs. 6.12 ± 8.29, p < 0.001), L-FABP (106599.4 ±1676.28, 1983% vs. 5116.3 ± 1767.88, p < 0.0001), D-dimer (ESRD 14477.0 ±142.91 ±1.06, 35.87% vs. 1.85 ± 1.20, p < 0.0001), IL-6 (ESRD 5.211 ± 10.36, 317.21% vs. 1.25 ± 1.24, p < 0.0001), CRP (ESRD 14.53 ± 14.11, 22.44% vs. 0.63 ± 0.99, p < 0.0001), NO (ESRD 34.74 ± 19.74, 151.74% vs. 13.8 ± 5.60, p < 0.0001), vWF (ESRD 200.7 ± 25.89, 183.03% vs. 70.91 ± 23.13 p < 0.0001) and MCP-1 (148.4 ± 56.09, 67.49% vs. 88.6 ± 27.25, p < 0.0001) showed significant increase when compared to NHP.

Conclusion: This study suggests that thrombo-inflammatory biomarkers and laboratory parameters may be helpful in indicating CRS in ESRD patients. Ultimately, these biomarkers can now be readily used to correlate against other biomarker findings and studied further to determine their accuracy in prognosis and diagnosis of CRS.

EFFECT OF OMEGA-3 FATTY ACID ON MITOCHONDRIAL MEMBRANE FATTY ACID AND COMPARISON WITH ERYTHROCYTE MEMBRANE IN ADENINE INDUCED UREMIC RATS

Dong Eun Yang1, Su Mi Lee2, Jun Chul Kim3 and Won Suk An2

1Dong-A University Hospital, Internal Medicine, Rep. of South Korea, 2Dong-A University, College of Medicine, Internal Medicine, Busan, Rep. of South Korea and 3CHA Gumi Medical Center, CHA University, Internal Medicine, Rep. of South Korea

Background and Aims: The kidney has the second highest mitochondrial content in the human body. Fatty acids (FAs) are one of the important energy sources and main constituents of cell membranes. Higher erythrocyte membrane oleic acid contents are related to acute coronary syndrome and omega-3 FA can reduce oleic acid contents. We investigated whether omega-3 FA modifies not only erythrocyte membrane FA but also mitochondrial membrane FA of kidney in adenine-induced uremic rats.

Method: Male Sprague-Dawley rats were fed diets containing 0.75% adenine and 2.5% protein for three weeks. Next, rats were randomly divided into six groups that were fed diets containing 2.5% protein and saline with cholecalciferol (3000 IU/kg/week) or omega-3 FAs (300 mg/kg/day) with cholecalciferol were supplemented by gastric gavage for four weeks: normal control (n = 7), adenine control scarified at 3 weeks (n = 6), adenine control scarified at 5 weeks (n = 5), adenine control scarificated at 7 weeks (n = 5), omega-3 FAs group scarificated at 7 weeks (n = 5), and omega-3 FAs group scarificated at 7 weeks (n = 5). The mitochondrial isolation kit was used for renal mitochondria extraction. The mitochondrial and erythrocyte membrane FA contents were measured using gas chromatography.

Results: Compared to the normal control group, serum creatinine levels in adenine control group was significantly increased and improved in omega-3 FA group. Compared with adenine control, erythrocyte and mitochondrial membrane monounsaturated FA contents including oleic acid and arachidonic acid (AA) levels were significantly decreased in omega-3 FA group. FA compositions were similar between erythrocytes and mitochondrial membranes in each group. Monounsaturated FA contents including oleic acid, and eicosapentaenoic acid were higher and saturated FA was lower in the mitochondrial membrane than erythrocyte membrane in adenine control group.

Conclusion: Omega-3 FA affects not only erythrocyte membrane FA but also mitochondrial membrane FA in uremic rats. Erythrocyte membrane FA contents can reflect mitochondrial membrane FA contents of the kidney.

CELLULAR PRION PROTEIN ACTIVATES THE TBK1-IRF3 SIGNALING PATHWAY TO AGGRAVATE RENAL FIBROSIS

Tantan Long, Yuanyuan MA, Miaomiao Zhou, Jingyi MA, Fengxin Zhu and Jing Nie

Nanfang Hospital, Southern Medical University, Division of Nephrology, Guangzhou, P.R. China

Background and Aims: Chronic kidney disease (CKD) is an irreversible degenerative disease characterized by gradual loss of renal function, contributing to high morbidity and mortality as well as heavy economic cost to society. Clinically, there are few available strategies to slow CKD progression. Because the uremic phenotypes include many features of aging, CKD is considered as a premature aging syndrome. Neurodegenerative diseases, such as Alzheimer’s disease, and Parkinson’s disease are extensively studied aging-related diseases, in which cytotoxic proteins misfolding and aggregation in neural cells is the main characteristic. The misfolding and aggregation of the prion protein is tightly linked to the development of prion diseases. Interestingly, a remarkable elevation of cellular prion protein (PrPC) in the urine and plasma of CKD patients was reported. However, the role of PrPC in the pathogenesis of kidney diseases remains largely unknown. The aim of the current study is to investigate the role of PrPC in renal fibrosis.

Methods: Immunohistochemistry staining was conducted to evaluate the expression of PrPC in renal biopsies from CKD patients. Enzyme linked immunosorbent assay (ELISA) was performed to detect urinary PrPC of CKD patients. Animal model of renal fibrosis was induced by unilateral ureteral occlusion (UUO). Western blot, real time PCR and immunofluorescence staining were performed to evaluate the expression and distribution of PrPC. Proximal tubular epithelial cells (PTCs) overexpressed PrPC were collected for RNA-seq analysis. TBK1 inhibitor amlexanox, and IRF3 siRNA were used to block TBK1-IRF3 pathway in rat tubular epithelial cells (NRK-52E), respectively. Amlexanox was administered orally to UUO mice. H&E, Masson and Sirius red staining were used to estimate renal pathology.

Results: The protein expression levels of PrPC both in renal biopsies and urine from CKD patients were elevated and significantly correlated with the severity of interstitial fibrosis and the decline of eGFR. PrPC proteins were significantly increased, and aggregated in proximal renal tubules in fibrotic renal tissues induced by UUO. Compared with wild-type littermates, PEPCK-Prnp-KO mice had significantly lower levels of PrPC in the kidneys, indicating a protective role of PrPC in renal fibrosis.

Figure 1: Schematic illustration of how PrPC triggers the production of profibrotic genes, ultimately aggravating renal fibrosis.
mice showed reduced extracellular matrix accumulation and interstitial inflammation at day 7 after UUO. PrPC provokes profibrotic response of renal tubular cells via the TBK1-IRF3 pathway. TBK1 inhibitor amlexanox or silencing endogenous IRF3 significantly inhibited PrPC-induced profibrogenic phenotypic transformation in NRK-52 cells. Amlexanox attenuated interstitial fibrosis induced by UUO.

Conclusion: Our experimental results indicate that PrPC-TBK1-IRF3 pathway plays a detrimental role in profibrogenic transformation of renal tubular cells and thus contributes to interstitial fibrosis. Blocking TBK1 activation is a plausible strategy for therapeutic intervention of chronic kidney disorders.

SUBCAPSULAR INJECTION OF EXTRACELLULAR VESICLES FROM MESENCHYMAL STEM CELLS, PROMOTED ADDITIONAL RENOPROTECTION IN AN EXPERIMENTAL MODEL OF CKD
Paloma Noda1, Felipe Ornellas2, Giovanna Celestino3, Flavio Teles3, Irene I. Noronha2, and Camilla Fanelli2
1University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil; 2University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil; 3University of São Paulo Medical School, Laboratory of Cellular, Genetic, and Molecular Nephrology, Renal Division, São Paulo, Brazil

Background and Aims: Chronic kidney disease (CKD) is considered a public health concern worldwide, both due to its insidious and highly debilitating feature and to its high global prevalence. Clinical management of CKD is often achieved by the blockade of the renin-angiotensin-aldosterone system (RAAS). However, this treatment alone is not efficient to prevent CKD progression completely, motivating the scientific community to search for alternative treatments to control CKD progression and to detain its evolution to the end-stage renal failure. In this context, we have recently shown that the association of a single renal subcapsular injection of 2 × 10^6 adipose-derived mesenchymal stem cells (ASC) to RAAS blockade with the AT1RB Losartan (LOS) promoted greater renoprotection when compared to LOS monotherapy, leading to the normalization of urinary protein excretion (UPE) and to the regression of established glomerulosclerosis (GS), in experimental CKD. Since there are methodological limits for the number of ASC that can be injected under the renal capsule, and based on the current literature, which suggests the main beneficial effects of ASC are not due to direct in situ cell differentiation, but to paracrine factors produced and released by the ASC, in the present study we aimed to investigate if the association of a renal subcapsular injection of extracellular vesicles (EV) derived from ASC, to the oral treatment with LOS would promote additional renoprotective effects in a model of experimental CKD.

Method: The present experimental protocol was approved by the Ethics Committee for the Use of Experimental Animals of the University of São Paulo Medical School (CEUA-FMUSP No 1761/2022). EV were obtained from ASC isolated from gonadal adipose tissue of 5 male Wistar rats. Cells were cultured until P4, characterized by flow cytometry and in vitro differentiation, and kept under serum deprivation for 24 h. The conditioned culture media, containing the EV released by these cells, was ultracentrifuged and the resulting EV pellets were diluted in 100 μL of sterile PBS and used for the renal subcapsular injections. Experimental CKD was induced in 25 male Wistar rats through the surgical ligation of 2 from the 3 branches of the left renal artery, followed by the total nephrectomy of the right kidney, resulting in a 5/6 renal ablation. Additional 10 Sham-operated rats were used as control. After 15 days from surgery, the animals submitted to renal ablation were stratified into 3 groups, with closely similar mean values of body weight (BW), systolic blood pressure (SBP), UPE and urinary albumin excretion (UAE), before the start of the different treatments. Animals from CKD group were kept untreated, LOS and LOS + EV animals received diary 50 mg/Kg/d of Losartan, diluted in drinking water and LOS + EV rats underwent a second surgery for the renal subcapsular application of EV. All animals were followed until 30 days after CKD induction, when BW, SBP, UPE and UAE were analyzed again. Animals where then euthanized for the assessment of serum creatinine (Scr) and blood urea nitrogen (BUN) concentration, as well as for histological studies to determine the percentage of GS and the renal interstitial infiltration by macrophages (CD68).

Results: The association of a single subcapsular injection of EV derived from ASC, to the oral treatment with the AT1RB LOS, significantly improved the effects of this antihypertensive drug. CKD + LOS + EV animals exhibited normal SBP, in spite of having only 1/6 of functioning renal mass. Moreover, the combined treatment significantly reduced UAE and numerically diminished the percentage of glomerulosclerosis, compared to LOS alone. Detailed obtained results are presented in Table 1. Data are presented as Mean ± SE. Differences among groups were analyzed by one-way ANOVA: p < 0.05 vs. CONT. *CKD, †LOS, ‡CKD + LOS; as Mean ± SE.

Conclusion: Despite the small number of animals in the association group, our preliminary results suggest EV from ASC to exert additional renoprotective effects when associated to LOS, especially regarding the control of SBP and the protection of the glomerular filtration barrier integrity.

POST-BURNS PERSISTENT INFLAMMATION LEADS TO KIDNEY PROGRAMMED CELL DEATH THROUGH ACTIVATION OF THE CASPASES SIGNALING PATHWAY

Guang Yang, Lishan Tan, Zheng Fengping and Zibo Xiong
Peking University Shenzhen Hospital, Division of Renal Medicine, Shenzhen, P.R. China

Background and Aims: The underlying mechanism for the increased incidence of chronic kidney disease (CKD) in burn patients discharged from hospital remains unclear. Recent studies have shown that burn patients are discharged from the hospital with chronic inflammation despite normalization of all physiological parameters. We hypothesized that severe burns accelerate the onset and progression of CKD by activating persistent inflammation. This study aimed to investigate the long-term effects of severe burns on kidney and its possible mechanisms.

Method: The study was divided into three parts. First, to understand the effect of burns on the general population and the CKD population, 4-month-old C57BL/6 mice were divided into a blank control group (Blank) and an adenine-induced CKD group. Some mice were established by burns in a 10% total body burn surface area model at 5-month-old. Experiments were terminated at 7-month-old. The function, morphology, inflammatory response and oxidative stress of the kidney were assayed. Second, the effect of activated macrophages on podocytes was studied by in vitro experiments.

Results: In the Blank group, burns did not cause kidney function and weight alterations, but caused a small amount of organic lesions, glomerular atrophy, apoptosis, and macrophage infiltration. In the CKD group, burns not only significantly reduced kidney function, but also caused kidney atrophy, organic lesions, glomerular atrophy, apoptosis and macrophage infiltration. In addition, burns significantly increased Caspase-1 and -3 pathway expression in all mice. Electron microscopy showed that burns significantly aggravated glomerular injury in the CKD group, including podocyte injury, cell membrane blubbing and rupture. In vitro studies showed that polarized M1 macrophages increased MPCS podocytes death.

Conclusion: Severe burns cause programmed cell death through activation of inflammation-induced Caspase-dependent pathways leading to kidney injury in mice. This phenomenon has a small effect on normal populations and a larger effect on CKD populations. This study has important implications for determining the prognosis of kidney function in burn patients and provides a promising therapeutic strategy.

DEPLETED HDAC3 ATTENUATES HYPERURICEMIA-INDUCED RENAL INTERSTITIAL FIBROSIS VIA MIIR-19B-3P/SF3B3 AXIS
Jiali Wei and Minhui Wang

Hainan General Hospital (Hainan Affiliated Hospital of Hainan Medical University), Department of Nephrology, Haikou, P.R. China

Background and Aims: Hyperuricemia (HN) is a threat for the occurrence of renal interstitial fibrosis (RF). Dysfunctional histone deacetylase 3 (HDAC3) elicits renal fibrosis and damage. This study aimed to explore the role of HDAC3 in HN-induced RF from microRNA-19b-3p/splncing factor 3b subunit 3 (miR-19b-3p/SF3B3) axis.

Method: 1. The HN model was established on rats to induce RF by oral administration of adenine and potassium oxalate; 2. HN rats were injected with related vectors (sh-HDAC3, mimic-miR-19b-3p, sh-HDAC3+miR-19b-3p inhibitor) to suppress and/or promote HDAC3 and/or miR-19b-3p; The detection indicators are listed as follows: (1) Blood samples and urine samples were collected for UA, BUN, Scr and 24 h urine protein measurement; (2) Renal pathological damages, RF index and renal cell apoptosis were measured by HE, Masson and TUNEL staining; (3) α-SMA, TGF-β1 and FN contents in renal tissues were detected by IHC staining; (4) mRNA and protein levels of HDAC3, miR-19b-3p and SF3B3 in renal tissues were detected by RT-qPCR and/or WB. (5) Interaction of HDAC3 and miR-19b-3p was detected by ChIP and dual luciferase reporter gene assay; (6) Interaction of miR-19b-3p and SF3B3 was predicted/detected by bioinformatics website/dual luciferase reporter gene assay.

Results: 1. HN induced renal dysfunction, renal pathological damages, RF and renal cell apoptosis of rats; HN rats showed elevated HDAC3, SF3B3 and reduced miR-19b-3p in renal tissues. 2. Suppressed HDAC3 or promoted miR-19b-3p relieved HDAC3-induced renal dysfunction, renal pathological damages, RF and renal cell apoptosis; HDAC3 bound to the promoter of miR-19b-3p; miR-19b-3p negatively regulated SF3B3; miR-19b-3p depletion abrogated down-regulated HDAC3-induced effects on HN-induced RF.

Conclusion: HDAC3 bound to the promoter of miR-19b-3p to regulate SF3B3. Depressed HDAC3 relieved HN-induced RF by restoring miR-19b-3p and knocking down SF3B3. Targeting HDAC3 and miR-19b-3p/SF3B3 axis may be a promising therapeutic strategy for preventing HN-induced RF.

ENDOTHELIAL CELL PROTEOME AND SECRETOME ALTERATION UNDER CHRONIC UREMIC EXPOSURE
Juan Manuel Sacnun, Klaus Krotchwilli and Rebecca Herzog

Medical University of Vienna, Wien, Austria

Background and Aims: Dialysis therapies including peritoneal dialysis (PD) are described to lead to premature vascular aging, atherosclerosis and associated cardiomyopathies, which are associated with high cardiovascular morbidity and mortality. Chronic inflammation, incomplete clearance of uremic toxins, and dyslipidaemia, are factors affecting the vasculature system. However, how these factors affect the endothelium, the fist cell layer in contact with these molecules, and the molecular mechanisms triggered by uremic toxins remain poorly understood. In vitro and in vivo studies have shown that cytotoxic and secretory additives (e.g. dipeptide alanyl-glutamine (AlaGln) or kinase inhibitor lithium chloride (LiCl)) to PD fluids reduce peritoneal damage in mesothelial and endothelial (EC) cells. Their potential systemic effects were not studied so far. Here, we demonstrate, in a newly developed model system, the changes induced by chronic exposure to serum of PD patients in the proteome and secretome of endothelial cells, and the effects of cytoprotective additives.

Method: For modelling systemic conditions of PD patients, primary EC were cultured for 5 passages in medium containing 10% serum collected from PD patients (n = 26) during regular PET tests, or from healthy donors (n = 12). Cytoprotective additives were added in parallel experiments. Cells were stably labelled (SILAC) to differentiate cell and donor serum proteins and the cellular proteome and secretome profiles were analysed by quantitative mass spectrometry. Prior to analysis of the secretome, equalizer beads, to enrich low abundant and deplete high abundant proteins, were used. ECIS (Electric Cell-substrate Impedance Sensing), was used to measure barrier function, growth rate, and permeability.

Results: Proteome analysis revealed perturbation of major cellular processes by serum of PD patients including inflammatory related processes such TLR regulation and complement activation, as well membrane related processes such as extracellular matrix interactions and junctions, and plasma lipoprotein remodelling. Addition of LiCl counteracted cell-adhesion related proteins. ECIS analysis showed that in uremic conditions the EC monolayer has a decreased barrier function compared to healthy conditions, and LiCl partially restores the tightness of the membrane. Secretome analysis showed differentially regulated proteins related to oxidative stress, senescence-associated secretory phenotype (SASP) and apoptosis. Interestingly, in the secretome, LiCl addition counter regulated INHBA and tissue factor pathway inhibitor 2, both proteins related to vascular calcification.

Conclusion: Surprisingly few studies have analysed uremic effects on EC using proteomics approaches, and no reports of chronic settings, modelling the patient situation, are available. Our data demonstrates that EC react to serum factors of PD patients with increased inflammation, permeability and a senescence profile. Interestingly, our model reflects many of the known effects on the vasculature, but unravels the molecular mechanism that may induce these processes. We have also identified potential mechanisms by which the addition of cytoprotective additives may counteract some of the uremic effects systemically. Secretomics data identified several proteins secreted by EC that are regulated in uremia with potential for cellular crosstalk with other cells of the vasculature, showing the potential to identify therapeutic targets to reduce the cardiovascular risk of PD patients and current limitations of the therapy.

AGING-RELATED RENAL FIBROSIS WAS ALLEVIATED VIA CONSERVING MITOCHONDRIAL FUNCTION AND AUTOPHAGY IN NLRP3 KO MICE
Yang-Gyun Kim1, Sang-Ho Lee1, Ju-Young Moon1, Su Woong Jung1, Kyung Hwan Jeong2, Hyeon Seok Hwang3, Jin Suk Kim4 and Minhae Cho5

1Kyung Hee University Hospital at Gangdong, Nephrology, Seoul, Rep. of South Korea, 2Kyung Hee University Hospital, Nephrology, Seoul, Rep. of South Korea and 3University of Memphis, School of social work, Memphis, United States of America

Background and Aims: Nod-like receptor family, pyrin domain containing-3 (NLRP3) activation in kidney diseases contributes to aggravating disease progression and fibrosis. However, the role of NLRP3 in renal aging is not clear. This study was designed to identify whether the NLRP3 KO mice could be protected from renal aging.

Method: NLRP3 KO and counterpart wild-type (WT) mice were used at different ages (3 months, 12 months, and 24 months). Plasma, urine, and kidneys were collected.

Results: Plasma creatinine and blood urea nitrogen (BUN) increased with aging, while BUN was significantly decreased in NLRP3 KO old mice (24M) compared with WT old mice. NLRP3 ablation contributed to decreasing tubular vacuolization, tubulointerstitial fibrosis, and atypical autophagosomes with aging. In line with it, renal fibrosis markers, such as connective tissue growth factor, and fibronectin were alleviated in RT-PCR tests. Immunoblot results showed that autophagy with mitochondrial biogenesis increased in old NLRP3 KO mice. In addition, phosphorylated AMP-activated protein kinase and peroxisome proliferator-activated receptor gamma coactivator 1α were increased in old NLRP3 KO mice. Transcriptional expression data using kidney RNA bulk sequencing showed augmentation of autophagy and mitochondrial biogenesis in old NLRP3 KO mice.

Conclusion: NLRP3 absence prevented aging-related renal fibrosis via maintaining renal mitochondrial biogenesis and autophagy.

IDENTIFICATION OF GLYCOSYLATED IGF2 IN HUMAN URINARY PEPTIDOME AND ITS ASSOCIATION WITH CKD
Sonnal Lohia1, Agnieszka Latosinska2, Jerome Zoidakis3, Manoussos Makridakis1, Harald Mischak3, Griet Glorieux1, Antonia Vlahou1 and Vera Jankowski4

1Biomedical Research Foundation, Academy of Athens, Centre of Systems Biology, Athens, Greece, 2Mosaïques Therapeutics GmbH, Hannover, Germany, 3Ghent University Hospital, Gent, Belgium and 4RWTH Aachen University, Institute for Molecular Cardiovascular Research, Aachen, Germany

Background and Aims: Chronic kidney disease (CKD) is prevalent in 10% of world’s adult population, with estimated glomerular filtration rate (eGFR) and albuminuria employed in its diagnosis. Role of protein glycosylation in causal mechanisms of CKD progression is largely unknown. Aim of this study was to identify urinary O-linked glycopeptides in association to CKD for better characterization of CKD molecular manifestations.

Method: Urine samples from eight CKD and two healthy subjects were analyzed by Capillary Electrophoresis-Tandem Mass Spectroscopy (CE-MS/MS) and glycopeptide analysis using Proteome Discoverer 1.4 was performed. Distribution of identified glycopeptides and correlation with Age, eGFR and Albuminuria were evaluated in 3810 datasets from the Human Urinary Proteome database using Spearman’s rank correlation test and multiple linear regression.
regression analysis by statistical software R. The quantification of Insulin-like growth factor-II (IGF2) protein (7.5 kDa) was performed by enzyme-linked immunosorbent assay (ELISA) in two matched (for age, sex, no diabetes and no cardiovascular history) groups of 12 plasma samples each (eGFR < 30 ml/min/1.73m² and eGFR > 90 ml/min/1.73m²). An open-source tool “Proteasix” was used to predict proteases involved in cleavage of the identified glycopeptides. The transcriptomics database and analysis tool “Nephroseq v4” were utilized to investigate the expression of predicted proteases in existing human transcriptomics CKD datasets.

Results: In total, 17 O-linked glycopeptides from 7 different proteins were identified, derived primarily from Insulin-like growth factor-II (IGF2) (n = 6). Glycosylation occurred at the surface exposed IGF2 Threonine 96 position. Further Investigation of the human proteome database containing 3810 datasets, showed that only three unglycosylated urinary peptides of IGF2 were identified, at significantly lower abundance and frequency (0-2.5% in the database) in comparison to the glycosylated forms (frequency of 23-90%). Interestingly, all identified IGF2 peptides belonged to E-domain of IGF2, i.e., 92 – 180 aa; which cleaves after undergoing O-linked glycosylation during the post-translational process yielding the “mature IGF2” (25-91 aa) protein. Results of multiple linear regression analysis indicated that three IGF2 glycopeptides, DVStPPTVLPDNFPRYPVGK [β(1024) = 0.08, p = 1.42*10⁻⁴], DVStPPTVLPDNFPRYP [β(560) = 0.01, p = 5.22*10⁻⁵] and DVStPPTVLPDNFPRYP [β(290) = 0.02, p = 1.07*10⁻⁴], exhibited positive correlation with Age and the glycopeptide tPPTVLPDNFPRYP showed strong negative association with eGFR [β(177) = -0.01, p = 4.21*10⁻⁹]. Along the same lines, the latter urinary IGF2 glycopeptide tPPTVLPDNFPRYP was found at increased [p < 2.2*10⁻¹⁶] abundance in CKD (n = 686) in comparison to healthy control (n = 229) datasets. In addition, IGF2 increased [p = 0.042] plasma levels were observed in CKD patients (eGFR < 30 ml/min/1.73m² group) as supported by ELISA measurements. Protease predictions, considering also available transcriptomics data, suggest activation of cathepsin S with CKD potentially involved in the cleavage of the CKD-associated glycopeptide of IGF2.

Conclusion: Collectively, this study indicates that with aging and deteriorating kidney function, alterations in IGF2 proteoforms take place; which may be reflective of respective changes in the mature IGF2 protein abundance and function; as well as associated protease activity. Further, correlation analyses of the levels of the CKD-associated urinary IGF2 glycopeptide with the plasma IGF2 levels with CKD progression is planned.

* Results of multiple linear regression where regression Co-efficient is β; degree of freedom is stated in (brackets); and p-value <0.05 was considered statistically significant.
Background and Aims: Beta trace protein (BTP) is a low molecular weight protein that has been proposed as an earlier biomarker of decreased
glomerular filtration rate (GFR) and renal damage, than the traditional biomarkers, particularly in the creatinine blind range. Early biomarkers of renal (dys)function are needed to allow, in due time, the detection and treatment, to prevent worsening of the disease. To the authors’ knowledge, neither urine nor serum BTP has been assessed in animals with kidney disease. In the present study, we aimed to concomitantly evaluate BTP and creatinine circulating levels, to compare their value as early biomarkers of renal dysfunction, by performing the studies in rat models of mild and moderate chronic renal failure (CRF) induced by nephrectomy.  

**Method:** Male Wistar rats, 12 weeks old, were randomly divided in three groups: Sham (n = 8, subjected to surgical process without kidney mass reduction), Mild CRF (n = 8, subjected to 1/2 nephrectomy), and Moderate CRF (n = 7, subjected to 5/6 nephrectomy). After five weeks, rats were sacrificed, blood and kidneys were collected. We analysed the circulating levels of BTP and creatinine and studied the association of BTP concentration with the glomerular and tubulointerstitial lesions, and with the traditional biomarkers of renal (dys)function, eGFR and creatinine.

**Results:** The serum levels of BTP were correlated with serum levels of creatinine (r = 0.575, p = 0.004) and also with eGFR (r = -0.453, p = 0.030); additionally, we found positive correlations with the total score of mild and advanced tubular lesions (r = 0.610, p = 0.02 and r = 0.517, p = 0.011, respectively), observed in kidney sections. The circulating levels of BTP increased with disease severity; Mild CRF showed a higher value of BTP than Sham group, although without statistical significance that was reached in Moderate CRF group, as observed for serum creatinine. The combined use of BTP and creatinine did not improve the discriminatory power in early disease detection. Though, the combination showed stronger correlations with the total score of tubular lesions (r = 0.849, p < 0.001 for mild tubular lesions and r = 0.774, p < 0.01 for advanced tubular lesions).

**Conclusion:** In rat models of mild and moderate CRF induced by nephrectomy, serum BTP levels increased with kidney function worsening, and correlated with disease severity, assessed by GFR and the degree of histopathological alterations. However, the earlier diagnostic value of BTP does not outperform serum creatinine in this model.

**EZH2 PROMOTES RENAL INTERSTITIAL FIBROSIS THROUGH DOWNREGULATION OF PHOSPHOENOLPYRUVATE CARBOXYKINASE 1 MEDIATED GLUCONEOGENESIS**  
Yanfang Bai, Ming Wu, Chaoyang Ye and Dongping Chen  
Shanghai Shuguang Hospital affiliated to Shanghai University of Traditional Chinese Medicine, Shanghai, P.R. China, Department of Nephrology, Shanghai, P.R. China

**Background and Aims:** Renal fibrosis is the common pathological pathway of various chronic kidney diseases progressing to the end stage of renal failure. The methyltransferase enhancer of zeste homolog 2 (EZH2) has been identified as a therapeutic target to inhibit renal interstitial fibrosis. However, the mechanism underlying the role of EZH2 in renal fibrosis is not completely understood.

**Method:** Unilateral ureteral obstruction (UUO), unilateral ischemia-reperfusion injury (UIRI) mouse models were established. PCR, cleavage under targets and tagmentation (CUT&Tag) and Western blotting was performed to evaluate the expression of EZH2 and phosphoenolpyruvate carboxykinase 1 (PCK1).

**Results:** Using EZH2 inhibitor 3-DZNNeP and Ezh2 conditional knockout mice, we confirmed the pro-fibrotic effect of EZH2 in unilateral ureteral obstruction (UUO). Through RNA sequence and cleavage under targets and tagmentation (CUT&Tag) sequence analysis, we found that the phosphoenolpyruvate carboxykinase 1 (PCK1), a critical enzyme in gluconeogenesis, is negatively regulated by EZH2 in fibrotic kidneys, which was further confirmed by quantitative PCR, CUT&Tag and Western blotting. We further showed that deletion or inhibition of EZH2 inhibited renal fibrosis and enhanced PCK1 expression and activity in unilateral ischemia-reperfusion injury (UIRI) and folic acid induced mouse nephropathy. Moreover, the dysregulated production of renal glucose and lactate in mouse UUO kidneys was restored after EZH2 inhibition by 3-DZNNeP. Finally, inhibition of PCK1 by 3-mercaptopropionic acid (3-MPA) abrogated the anti-fibrotic effect of 3-DZNNeP in UUO kidneys.

**Conclusion:** We conclude that EZH2 promotes renal interstitial fibrosis through inhibition of PCK1 mediated gluconeogenesis.

**DISRUPTION OF THE INTESTINAL MUCOSAL BARRIER IN CHRONIC KIDNEY DISEASE IS RELATED TO REDUCED EXPRESSION OF THE TIGHT JUNCTIONS’ COMPONENTS**  
Georgia Andriana Georgopoulou1, Marios Papasotiriou1, Pinelopi Bosgana2, Anne-Lise Delastic3, Evangelos Papachristou1, Dimitrios Goumenos1, Vasiliki Zolota1, Konstantinos Thomopoulos4 and Stelios Assimakopoulos5
1 Patras University Hospital, Nephrology and Transplantation, Rio, Greece, 2 Patras University Hospital, Pathology, Rio, Greece, 3 Patras University Hospital, Hematology, Rio, Greece, 4 Patras University Hospital, Gastroenterology, Rio, Greece and 5 Patras University Hospital, Internal Medicine and Infectious Diseases, Rio, Greece

**Background and Aims:** Patients with chronic kidney disease (CKD) present evidence of systemic inflammation without clinical infection. This is partly attributed to intestinal barrier dysfunction resulting in increased gut permeability with microbial and endotoxin translocation. However, the potential mechanism(s) implicated in increased gut permeability remain unclear. In this study, we investigated several parameters of the intestinal barrier in patients with CKD of various stages.

**Methods:** Thirty-three patients with CKD were prospectively enrolled. Patients were divided in stage 1-IV CKD (group A, n = 17, 9 of them with IgA nephropathy) or end-stage kidney disease (ESKD) (group B, n = 16) and were compared with 11 healthy controls (group C). Duodenal biopsies from all subjects, obtained by endoscopy, were examined histologically for evaluation of the villous length and apoptotic bodies in crypt epithelium. Intraepithelial CD3+ T-lymphocytes, expression of occludin and claudin-1 in the intestinal epithelium were evaluated by immunohistochemistry. Circulating endotoxin concentration was measured by enzyme-linked immunosorbent assay and cytokine levels [interleukin (IL)-1β, IL-6, IL-8, IL-10, TNF-α] by flow cytometry.

**Results:** Patients in groups A and B presented significantly higher serum endotoxin, IL-6 and IL-10 levels compared to controls (p < 0.01, both groups). Patients in group B presented additionally significantly higher IL-6 levels compared to controls (p < 0.01). Occludin expression was significantly decreased in groups A and B compared to group C (p < 0.0001 and p < 0.001, respectively). Interestingly, in CKD patients (groups A and B) a gradient of occludin expression along the length of the villi, from crypt to tip was recorded with greater loss of its expression at villous tip. Claudin-1 expression was significantly decreased in crypts in groups A and B compared to group C (p < 0.0001 and p < 0.01 respectively). Endotoxin concentrations were inversely correlated with intestinal occludin (p < 0.0001) and claudin-1 (p < 0.01) expression and positively correlated with serum IL-6 (p < 0.05) and IL-8 (p < 0.001) levels. Subgroup analysis for patients with IgA nephropathy showed similar histological findings for occludin and claudin-1 expression as well as for serum endotoxin levels.

**Conclusion:** Decreased enterocytes’ occludin and claudin-1 expression, might represent an important mechanism of intestinal barrier disruption and increased gut permeability in patients with CKD.

**Table 1:** (%) of occludin (+) enterocytes.

Dietary Magnesium Supplementation Reduces Renal and Cardiac Fibrosis in an Experimental Model of Type 4 Cardiorenal Syndrome

Juan R. Muñoz-Castañeda, Andrés Carmona Muñoz, Julio Manuel Martínez-Moreno, Teresa Obrero, Rodrigo López-Baltanas, Fatima Guerrero, Ana Torralbo Romero, Cristina Membrives, María Encarnación Rodríguez Ortiz, Cristian Rodelo Haad, Cayetana Moyano Peregrín, M. Victoria Pendón-Ruiz de Mier and Mariano Rodríguez

Maimónides Institute for Research in Biomedicine of Córdoba IMIBIC, Nephrology Service, Reina Sofía University Hospital. University of Córdoba, Córdoba, Spain

Background and Aims: In chronic kidney disease (CKD) patients, high serum phosphate (HP) levels are associated with the development of a cardiorenal syndrome type 4 (CRS4). In this syndrome, the heart is damaged by oxidative stress, inflammation, and fibrosis in renal tissue. In this study we have evaluated if dietary Mg supplementation could reduce CRS4.

Method: The in vivo studies were performed in 5/6Nx rats fed a high (0.9%) phosphate diet with high or low dietary content of Mg to evaluate: 1) The effect of dietary Mg supplementation (0.3%) on oxidative stress, inflammation and fibrosis of kidney and heart. 2) The contribution of hypomagnesemia (using a low Mg diet (0.03%)) to the progression of CRS4 in Nx rats and normal rats as controls. 3) Whether dietary Mg supplementation (8 weeks) reduces renal and cardiac fibrosis in Nx rats with established CRS4. In vitro, we evaluated the effects of Mg (MgCl₂) on mesangial and tubular cells and also cardiomyocytes cells exposed to TGF-β.

Results: Dietary Mg supplementation (0.3%) improved renal function, decreased oxidative stress, FGF23 levels, hypertension, renal and cardiac fibrosis and recovered renal expression of Klotho. A low Mg diet increased FGF23 and renal fibrosis but a subsequent switch to dietary Mg supplementation did not significantly improve CRS4 parameters although it reduced the values of blood pressure. In HK2 and rat mesangial cells treated with TGFβ (100 ng/ml), high Mg levels (1.4- and 2.8-times basal levels in the medium) reduced the amount of pro-fibrotic proteins such as α-smooth muscle actin, fibronectin, or renin, recovering Klotho expression and decreasing Smad3 phosphorylation.

Conclusion: Dietary Mg supplementation is a useful tool to improve renal function and prevent CRS4, by reduction the progression of renal and cardiac fibrosis.

EFFECTS OF CKD ASSOCIATED GENETIC VARIATION ON TRANSCRIPTOMIC REGULATION OF RENAL CELLS

Christian van Dijk¹, Ihsan Chrifi¹,², Marianne Verhaar¹, Dirk Duncker² and Caroline Cheng¹,²

¹UMCU Utrecht, Nephrology and Hypertension, Netherlands and ²Erasmus MC, Experimental Cardiology, Netherlands

Background and Aims: Chronic kidney disease (CKD) is an universal health problem characterized by a decline of renal function. This progressive disease leads to kidney failure and CKD patients have a high risk of cardiovascular diseases, including endothelial dysfunction in the heart. Genetic variability in the general population has a strong impact on the risk of CKD development. Genome wide association studies (GWAS) already identified more than 250 single nucleotide polymorphisms (SNPs) associated with renal function. These SNPs are studied in relation with their location in the genome in protein coding regions, however, genetic variability in the genome could also affect the function of DNA regulatory elements (DREs). These non-protein coding regions regulate transcriptional expression of genes by transcription factor binding. These elements are ubiquitously present in the genome and can regulate promotor activity from a long distance (> 100 kb from the start site) via 3D chromatin folding. DRE activity is cell type dependent and also changes in different conditions (e.g. disease). Therefore, genetic variability e.g. SNPs located in DREs and their regulation of gene transcription could play a key role in the development and progression of CKD. Previous studies identified more than 30 DREs localized SNPs in renal cells which could be important in CKD development. We focus on SNP rs881858, a CKD associated SNP region without a protein coding sequence. Moreover, vascular endothelial growth factor (VEGF) is identified as target gene of this SNP which could therefore impact renal cell-endothelial cell interaction. Six possible active DREs were identified in this rs881858 DNA region. We hypothesize that the CKD associated SNP rs881858 induce DRE mediated transcriptional changes that contribute to the development and progression of CKD. We aim to study the effect of the DREs in DNA region rs881858 on transcriptional gene regulation in renal cells.

Method: All variations of the genetic variability in 6 identified DREs in DNA region rs881858 were introduced by site-directed mutagenesis. These variations including the reference variant, were cloned into a luciferase reporter plasmid with a minimal promoter and subsequently transfected in human embryonic kidney (HEK) cells. Luciferase activity was measured using spectrophotometry and represent DRE regulation of transcription. A decline in luciferase activity of one of the variants in a DRE imply a reduced activity of that specific variant compared to the reference variant. To assess the impact of the DREs in the genome, a CRISPR/Cas9 construct was made to knockout each individual DRE on the risk locus rs881858.

Figure 1: Dietary Mg supplementation reduces the development of renal and cardiac fibrosis in uremic rats. 5/6Nx rats were fed a normal (0.6%) P and (0.05%) Mg diet (Nx+0.6%P+0.05%Mg) or received a high dose of P (0.9%) and normal Mg diet (0.05%) (Nx+0.9%P+0.05%Mg) or Mg dietary supplementation (0.3%) (Nx+0.9%P+0.3%Mg). Sham-operated rats fed a normal P and Mg diet (Sham+0.6%P+0.05%Mg) served as controls. (A) Renal content of lipid peroxides (MDA). (B) Klotho positive area quantified by Image J software. (C) Representative images of renal Klotho immunohistochemistry. (D) Representative images of siriusred staining from renal (D) and cardiac (E) tissues. Scale bar represents 200 μm. ap<0.05 vs Sham+0.6%P+0.05%Mg; bp<0.05 vs Nx+0.6%P+0.05%Mg; cp<0.05 vs Nx+0.9%P+0.05%Mg.
Results: We considered a DRE functional if (almost) all variants within this DRE demonstrated a change in luciferase activity. Based on this, we identified 3 DRE DNA regions in which SNPs gave a decline in luciferase activity. CRISPR/Cas9 mediated knockout of DRE in the HEK cells was validated using PCR and qPCR analysis of SNP rs881858 associated genes is planned to confirm the DRE mediated transcriptomic regulation of these genes.

Conclusion: These primary results show that CRISPR associated SNP rs881858 has a negative impact on DRE function compared to the reference variant. Next we will study the effect of DRE mediated gene transcription in the DRE knockout lines using qPCR. Furthermore, CRISPR/Cas9 mediated DRE-knockout will be performed in an iPSC derived renal organoid model. Since this in vitro model consists of both renal and vascular cell types, the interaction between these cell types can be evaluated in a background of epigenetic variability. This study provides new knowledge in the effect of genetic variant in the development of CKD. Results could lead to identification of novel pathways and therefore personalized strategies for intervention. This method is a stepping stone for studying other known genetic variants in other diseases, including renal and cardiovascular diseases.

THERAPEUTIC STRATEGIES TARGETING RAGE IMPROVES RENAL OUTCOME IN LUPUS NEPHRITIS
Kensei Taguchi, Yunosuke Yokota, Gou Kodama, Sakuya Itou and Kei Fukami
Kurume, Japan

Background and Aims: Lupus nephritis (LN) occurs in up to 60% of patients with systemic lupus erythematosus (SLE). Despite of current development of immunosuppressant agents, LN still impairs the survival and quality of life in SLE patients. Receptor for advanced glycation endproducts (RAGE) is a multi-ligand receptor that belongs to the immunoglobulin superfamily, which is strongly associated with innate immune system. In the present study, we examined whether RAGE is involved in the development of LN. Further, we explored the therapeutic impact of DNA-aptamer directed against RAGE on lupus-related kidney injury.

Method: [Protocol 1] RAGE expression in kidneys and urinary RAGE excretion (uRAGE) were determined at 8, 12, 16, 18, 20-week-old by real-time PCR and ELISA, respectively in MRL/lpr, SLE-prone mice. [Protocol 2] LN was induced by peritoneally injecting pristane in wild type and RAGE globally knockout mice. [Protocol 3] MRL/lpr mice were subcutaneously administrated with DNA-aptamer raised against RAGE (RAGE-apt) or Control-aptamer (Ctrl apt) for 10weeks.

Results: [Protocol 1] uRAGE, but not urinary protein excretion, was increased in 8-week-old MRL/lpr mice when compared to that of the control of MRL/MpJ mice. uRAGE is positively correlated with urinary NAG, a tubular injury marker, suggesting that uRAGE can predict the onset and the progression of LN. Immunofluorescence staining demonstrated that RAGE was upregulated in distal tubules but not in glomerulus in early stage, meanwhile RAGE started to be extensively expressed in nephron at late stage of LN. Not only tubules, but RAGE was also found in infiltrated macrophages in glomerulus. In proximal tubules (PTC), RAGE was co-localized with cathepsine D, a lysosomal aspartyl protease, and Rab7, a marker of late endocytosis, suggesting that PTC RAGE is involved in endosome-related protein degradation. [Protocol 2] Pristane-induced the increase in systolic blood pressure was reduced with improvement of renal dysfunction in RAGE knockouts. RAGE knockouts also showed less fibrosis with the decrease in macrophage infiltration when compared to wild type mice in pristane-induced lupus nephritis. [Protocol 3] Similar to RAGE knockouts, administration of RAGE-apt reduced systolic blood pressure and attenuated the renal dysfunction. RAGE-apt also ameliorated mesangial expansion, crescent formation, and macrophage infiltration into glomerulus in MRL/lpr mice. The level of pro-inflammatory cytokines gene expression including IL-6, TNF-a, and MCP-1 was reduced by RAGE-apt, but not Ctrl apt, in MRL/lpr mice.

Conclusion: RAGE could be involved in the pathogenesis of LN, and RAGE-DNA aptamer might be one of the promising therapeutic strategies for preventing the development of LN.

UPEREGULATION OF ADIPOSE TISSUE FATTY ACID-BINDING PROTEIN 4 IN PATIENTS WITH CHRONIC KIDNEY DISEASE: IMPLICATIONS FOR DYSFUNCTIONAL VASCULAR CELLS
Hyunjin Noh1,2,Hyounghae Kim1,2,Moonju Hong3,MIRaY u2,IMPLICATIONSFORDYSFUNCTIONALVASCULARCELLS
1Soonchunhyang University Seoul Hospital, Nephrology, Seoul, Rep. of South Korea, 2Soonchunhyang University Seoul Hospital, Hyonam Kidney Laboratory, Seoul, Rep. of South Korea, 3Soonchunhyang Institute of Med-Bio Science, Cheonan, Rep. of South Korea, 4Soonchunhyang University Seoul Hospital, Surgery, Seoul, Rep. of South Korea, 5Soonchunhyang University Bucheon Hospital, Nephrology, Bucheon, Rep. of South Korea and 6Soonchunhyang University Cheonan Hospital, Nephrology, Cheonan-si, Rep. of South Korea

Background and Aims: FABP4, a fatty acid-binding protein, is predominantly expressed in adipose tissue (AT) and has been shown to be elevated in patients with chronic kidney disease (CKD). Although elevated levels of FABP4 have been linked to cardiovascular disease in end-stage renal disease (ESRD) patients, the cause of this increase is unclear. The aim of this study was to evaluate the expression of AT FABP4 under uremic conditions and its impact on the function of macrophages and vascular smooth muscle cells (VSMC).

Method: We measured the levels of FABP4 in the blood and urine of CKD patients. The expression of AT FABP4 under uremic conditions was analyzed using omental AT obtained from healthy kidney donors and patients with ESRD who received peritoneal catheter insertion. The effect of FABP4 on the function of macrophages and VSMC was also assessed.

Results: The levels of FABP4 in the blood and urine of CKD patients were inversely correlated with their estimated glomerular filtration rate (eGFR). An increase in plasma FABP4 was detected in the blood before its increase in the urine. FABP4 expression was found to be higher in mature adipocytes in visceral AT compared to the stromal vascular fraction (SVF). Adipocytes treated with p-cresol and adipocytes isolated from CKD patients showed higher levels of FABP4 expression compared to healthy individuals. Single-cell RNA sequencing of SVF showed increased FABP4 expression in progenitor cells and macrophages from CKD patients. In THP-1 cells, FABP4 induced more foam cells and increased levels of inflammatory mediators in the presence of palmitic acid. VSMC treated with p-cresol or VSMC isolated from CKD mice induced by an adenine diet showed a pro-calcific phenotype, as indicated by increased calcium content and bone-related gene expression, which was further enhanced by FABP4.

Conclusion: The elevated levels of FABP4 in CKD patients are not solely a result of increased renal clearance but also due to increased production in AT. These higher levels of circulating FABP4 may be associated with dysfunction in vascular cells.

THROMBOINFLAMMATORY BIOMARKERS AND THEIR RELATIONSHIP WITH CIRCULATING GLYCOSAMINOGLYCANS IN END-STAGE RENAL DISEASE PATIENTS
Vinod Bansal1,Madeline Allen2,Fakiha Siddiqui2,Debra Hoppensteadt2,Emily Krupa3,Bulent Kantarcioğlu2 and Jawed Fareed2
1Loyola University Medical Center, Nephrology, Maywood, United States of America and 2Loyola University Medical Center, Pathology, Maywood, United States of America

Background and Aims: End stage renal disease (ESRD) is a complex progressive medical condition that affects multiple organ systems. Given the high risk of morbidity and mortality of ESRD as well as its rising incidence, it is critical to understand the relevance of thromboinflammatory biomarkers in disease development and progression of kidney dysfunction. The purpose of this study is to profile the levels of thromboinflammatory biomarkers in ESRD patients including D-Dimer, C-reactive protein (CRP), von Willebrand factor (vWF), plasminogen activator inhibitor 1 (PAI-1), and thrombin activatable fibrinolysis inhibitor (TAFl). In addition, the levels of anti-F4 IgG and endogenous circulating glycosaminoglycans (GAGs) were measured.

Method: Citrated plasma samples were collected from seventy-three ESRD patients. Control plasma samples (NHP) from healthy, non-smoking adults aged 19 to 53 were obtained commercially. Validated ELISA methods have been used to profile each of the biomarkers. The levels of endogenous GAGs were determined (Redprobes UG, Germany). To compare the levels of thromboinflammatory biomarkers, anti-F4 IgG, and endogenous circulating glycosaminoglycans (GAGs) were measured.

Results: All of the biomarkers and GAGs were significantly elevated, with the exception of TAFI, in ESRD patients. The ESRD patients exhibited varying levels of increase in the D-Dimer, CRP, vWF, PAI-1, anti-F4 IgG, and GAGs as shown in Figure 1 (p < 0.05). D-Dimer showed the most pronounced increase (1075%) followed by PAI-1 (361.31%), anti-F4 IgG (209.78%), CRP (101.77%).
and endogenous GAGs (17.29%). The correlation analysis revealed varying degrees of association among these biomarkers (Figure 2).

**Conclusion:** These results suggest that thromboinflammatory biomarkers offer the potential utility of identifying inflammation in end-stage renal disease. Marked increase in thromboinflammatory mediators due to endothelial damage may result in the upregulation of glycosaminoglycans and anti-PF4 IgG antibodies in the ESRD patients.

**PTEN-INDUCED KINASE 1 HAS ASSOCIATION WITH RENAL AGING PROCESS THROUGH THE CGAS-STING PATHWAY**

Min Heui Ha1, Man S Kim2, Hyun-Ju An1, Min-Ji Sung1, Yu Ho Lee1, Dong Ho Yang1, Jihyun Baek1, Yueun Choi1, So-Young Lee2 and Hye Yun Jeong3

1Seongnam-si, Rep. of South Korea and 2Seoul, Rep. of South Korea

**Background and Aims:** The global increase of an aging population has encouraged the research on renal aging, as the kidney is one of the organs that shows the greatest change as aging progresses. Although the mechanism of renal aging has not been clearly identified, dysfunctional mitochondria has been suggested as one of the factors that induce inflammation of the kidney, which is the major mediator of the pro-aging process of chronic kidney disease. PTEN-induced kinase 1 (PINK1) is a protein involved in the quality control of mitochondria and regulates mitochondrial dysfunction. Although it is known that the mitochondrial DNA release promoted by PINK1 deficiency stimulates cyclic GMP–AMP synthase (cGAS) - stimulator of interferon genes (STING) pathway eventually resulting in the inflammatory response, the role of PINK1 and cGAS-STING pathway in renal aging has not yet been clarified. This study aimed to investigate the relationship between PINK1 and renal aging, especially through the cGAS-STING pathway.

**Method:** To determine the role of PINK1 on the renal aging process, renal fibrosis, and tubular injury were compared in 4- and 24-month-old wild-type (Pink1+/+) and PINK1 knockout (PINK1-/-) mice. To establish in vitro senescence model, hydrogen peroxide (H2O2) treatment on human renal proximal cells (HKC-8) was used. The changes in gene expression levels related to PINK1 were analyzed by RNA sequencing, applying transcriptomic and metabolomic analyses. To validate the results of RNA sequencing, we measured mitochondrial oxygen consumption rate (OCR) by Seahorse Mito Stress Test. To investigate the relationship between PINK1 and renal aging through the cGAS-STING pathway, we explored the change of cGAS-STING expression on senescence-induced HKC-8 cells and additionally used H-151 treatment, a specific STING inhibitor.

**Results:** The renal fibrosis and tubular injury were significantly aggravated in 24-month-old Pink1-/- mice compared to 24-month-old Pink1+/+ mice. Western blot and RT-qPCR confirmed remarkably increased senescence markers and senescence-associated secretory phenotype (SASPs) in 24-month Pink1-/- mice and senescence-induced HKC-8 cells. The RNA sequencing of mice kidneys showed that inflammation-related pathways significantly increased in 24 months Pink1-/- mice and transcriptional and metabolomic analyses showed that PINK1 has an association with mitochondrial metabolism dysregulation. On OCR measurement, the basal respiration, maximal respiration, ATP production, and respiratory capacity significantly declined in H2O2-treated siPINK1 cells, suggesting that PINK1 deficiency might have effects on mitochondrial dysfunction. Finally, the STING pathway was significantly activated in 24-month Pink1-/- mice and senescence-induced HKC-8 cells, which was inhibited by a specific inhibitor of STING, H-151.

**Conclusion:** In conclusion, PINK1 is associated with renal aging, and the dysregulation of mitochondria caused by PINK1 deficiency might lead to aging-related inflammatory responses through the cGAS-STING pathway.
**Conclusion:** Here, we show that enhanced levels of ROS and oxidative DNA damage due to glucose induced TXNIP expression could be diminished using ROS scavengers. These findings show that further antioxidative substances may be potential drugs, which could also be potential drug candidates for use in clinical practice to treat PD patients.

**#3937 URINARY EXCRETION OF LIVER-TYPE FATTY ACID-BINDING PROTEIN DETECTS KIDNEY HISTOLOGICAL ALTERATIONS DURING PROGRESSIVE RENAL FIBROSIS**

Joana del Valle Mercado Hernández1, Sandra M. Sancho Martínez2, Isabel Fuentes-Calvo2, Francisco J. Lopez-Hernandez1 and Carlos Martínez Salgado3

1Institute of Biomedical Research of Salamanca (IBSAL), Salamanca, Spain and 2Universidad de Salamanca, Physiology and Pharmacology, Salamanca, Spain

**Background and Aims:** Subclinical sequelae of acute kidney injury (AKI) are commonly associated with the development of chronic kidney disease (CKD). Despite extensive investigation on AKI to CKD transition on different experimental models, the underlying mechanisms of this transition remain unclear, and there are no known biomarkers monitoring this transition to CKD. The liver-type fatty acid-binding protein (L-FABP) is expressed in the kidney under normal and pathological conditions, and seems to play an important role on kidney injury and repair. We evaluated the efficacy of urinary L-FABP excretion as a prognostic indicator of the progression of renal damage in our AKI to CKD experimental model.

**Method:** 8 week old male Wistar rats were divided in two experimental groups: "Control" group (n = 8): SHAM-operated rats, which received saline solution i.p.; and Cpt-IR2 group (n = 8): 5 mg/kg cisplatin i.p and 2 weeks after renal function normalization, 60 min ischemia-reperfusion on the left kidney. Blood and urine samples were collected at day 0 (basal), day 4 (AKI development), day 8 (normalized renal function), day 24 (1 day after ischemia), and 2 (M2) and 3 (M3) months after first AKI induction. Renal function was estimated analysing by colorimetric methods plasma and urinary creatinine concentrations (pCr and uCr) and creatinine clearance. Animals were sacrificed at days 56 and 90. Tissue samples were stained with haematoxylin-Eosin, periodic acid Schiff and Masson’s Trichrome for histological analysis. Enzyme-linked immunosorbent assay was used to measure urinary L-FABP concentration.

**Results:** Cpt-IR2 rats showed a reduction in renal filtration with respect to control rats even though this decrease does not indicate a severe decline in renal function. This group also presented multiple histological alterations such as fibrosis, loss of brush border membrane, inflammatory infiltrates, basement membrane thickening, tubular dilatation, cellular debris and hyaline casts that worsened markedly from M2 to M3. ul-FABP was greater in Cpt-IR2 rats (52,299 ± 8,407 ng/g uCr M2 and 23,427 ± 4,778 ng/g uCr M3) than in control rats (16,657 ± 2,322 ng/g uCr M2 and 10,636 ± 1,395 ng/g uCr), but this urinary excretion does not correlate with the histological alterations in the last month of the study.

**Conclusion:** Urinary L-FABP may be a potential biomarker for the detection of the presence of histological damage although it is not correlated with the extent and degree of the damage in our AKI to CKD transition model. This research was funded by grants from Instituto de Salud Carlos III (ISICII) P121/00548 and P121/01226 co-funded by the European Union and Red de Investigación Renal RICORS2040 (Kidney Disease), RD21/0005/0004 co-funded by the European Union – NextGenerationEU, Mecanismo para la Recuperación y la Resiliencia (MRR). Joana Mercado-Hernández is recipient of a predoctoral fellowship from the Junta de Castilla y Leon (Spain) and the European Social Fund from the European Commission.

**#5865 BET INHIBITION DIMINISHES CELLULAR SENESCENCE IN CULTURED TUBULAR EPITHELIAL CELLS**

Pamela Estefanía Basante1, Sandra Rayego-Mateos1,2, Lucia Tejedor1,2, Laura Marquez-Exposito1, Raúl Rodrigues Diez2, Vanessa Marchant1,2, Antonio Tejera1 and Marta Ruiz-Ortega1,2

1IIS-Fundación Jiménez Díaz, Madrid, Spain and 2Central University Hospital of Asturias, Oviedo, Spain

**Background and Aims:** Chronic kidney disease (CKD) can be considered an age-related disorder. Recent studies have shown the involvement of the activation of cellular senescence mechanisms in the kidney and aging. Intensive research to develop pharmacological approaches targeting cellular senescence is under investigation. Among novel therapeutic options, epigenetic drugs, such as bromodomain and extra terminal BET inhibitors, are being widely explored in proliferative, immune and chronic inflammatory diseases, including CKD. These drugs regulate the transcription activation of cell cycle control and proinflammatory factors. There are not studies about the potential effect of BET inhibitors on cellular senescence in the kidney despite the fact that tubular epithelial cells are frequently implicated in kidney senescence.

**Method:** To study this, we evaluate the effect of JQ1, a BET inhibitor, on cellular senescence in primary cell culture of murine tubular epithelial cells (TECs) using Adriamycin as a senescence inducer verified by B-galactosidase assay. Next, we evaluated the effect of JQ1 on gene expression levels of cell cycle markers, components of senescence-associated secretory phenotype (SASP) as well as anti-apoptotic and antioxidant markers, all of them related to senescence program.

**Results:** Our results indicated that JQ1 significantly decreased Adriamycin-induced p21 gene upregulation, a primordial cell cycle arrest factor. This BET inhibitor also downregulated SASP genes, such as Tgfb1, Il1b, Ctgf, Cu2 and Il6 overexpression in Adriamycin-treated tubular cells. Likewise, anti-apoptotic Bcl-xl and antioxidant factors Cat, Hmox-1, Nos-4 and Nrf2 mRNA levels were significantly restored by JQ1.

**Conclusion:** In conclusion, the present study highlights the use of JQ1 as a therapeutic option to ameliorate tubular cellular senescence-associated markers. These data support the potential use of BET inhibitors in chronic kidney diseases.

**#4161 DELETION OF PROTEIN TYROSINE KINASES 4A1 AMELIORATE RENAL FIBROSIS INDUCED BY UUO IN MICE**

Dae Eun Choi1,2, Heyrim Park2, Jin Ah Shin2, Yoon-Kyung Chang1, Eu Jin Lee1, Young Rok Ham1, Ki Ryang Na1, Kang Wook Lee1, Hae Ri Kim4 and Jae Wan Jeon4

1Chungnam National University Hospital, Nephrology, Daejeon, Rep. of South Korea, 2Chungnam National University, Medical Science, Daejeon, Rep. of South Korea, 3Daejeon St. Mary Hospital, Nephrology, Daejeon, Rep. of South Korea and 4Chungnam National University Sejong Hospital, Nephrology, Sejong, Rep. of South Korea

**Background and Aims:** Inhibitors of protein tyrosine kinases has been investigated as potential anti-fibrotic agents. protein tyrosine kinases 4A1 belongs to a sub-class of three prenylated protein tyrosine kinases. protein tyrosine kinases 4A1 has been shown to be involved in the promotion of growth, migration and tumor cells. The role protein tyrosine kinases 4A1 has little known in kidney. We evaluated whether the protein tyrosine kinases 4A1 could be target of renal fibrosis.

**Method:** 10 weeks old male background protein tyrosine kinases 4A1 KO mice and wild type mice were divided into 4 groups; wild, protein tyrosine kinases 4A1 KO with unilateral ureteral obstruction. Mice were sacrificed at 7 days after surgery and kidney tissue were collected. Molecular study and Histologic examination were performed.

**Results:** Protein tyrosine kinases 4A1 KO with unilateral ureteral obstruction mice showed decrease of renal tubule-interstitial damage and fibrosis compared to wild type unilateral ureteral obstruction mice. protein tyrosine kinases 4A1 KO with unilateral ureteral obstruction reduced the renal expression of α-SMA and TGF-β in unilateral ureteral obstruction kidney, compared to wild type with unilateral ureteral obstruction mice. Wild type with unilateral ureteral obstruction kidney showed decrease of renal expression of E-cadherin, compared to sham mice. However, protein tyrosine kinases 4A1 KO unilateral ureteral obstruction showed increase of renal expression of E-cadherin, compared to Wild type unilateral ureteral obstruction mice. In vitro, silencing of protein tyrosine kinases 4A1 in TGF-β treated HK2 cell showed increase of E-cadherin and decrease of phosphorylation of AKT and GSK3β.

**Conclusion:** Protein tyrosine kinases 4A1 KO ameliorate renal fibrosis in unilateral ureteral obstruction kidney.

**#5040 UNTARGETED METABOLOMIC ANALYSIS IDENTIFIES A SPECIFIC METABOLIC PROFILE IN PATIENTS WITH EARLY CHRONIC KIDNEY DISEASE**

Mihaela Glavani1,2,3, Florica Gadaleanu1,2, Carmen Socaciu2, Andreea Socaciu2, Octavian Cretu1, Adrian Vlad1, Danina Muntean7,8, Flaviu Bob2,3, Livia Oana Milies1,2, Anca Suteanu-Simulescu1,2, Dragos Jianu9,10, Lavinia Balint1,2, Maria Mogos1,2, Silvia Ianciu1,2 and Ligia Petrica1,2

Background and Aims: Chronic kidney disease (CKD) has become one of the most challenging diseases of the twenty-first century and is characterized by increased mortality and morbidity. The pathogenesis of CKD is heterogeneous and the evaluation of renal function is performed with biomarkers such as serum creatinine and blood urea, which have low specificity and sensitivity. Metabolomics, one of the omics sciences, has become of interest in the nephrology field of research. Metabolic pathways can impact both glomerular and tubular structures and can offer a better understanding of the pathogenic mechanisms of CKD. Also, metabolomics provides more sensitive biomarkers for an early detection of CKD. The aim of this study was to perform metabolic profiling of serum and urine in CKD patients by means of targeted metabolomics in relation with the glomerular filtration rate (eGFR) and to identify potential serum and urinary biomarkers of early CKD.

Method: In this cross-sectional study were included 99 patients with CKD, staged by eGFR in six subgroups, according to the KDIGO Guidelines and 20 healthy control subjects. Serum and urinary metabolomic profiling were performed by using ultra-high-performance liquid chromatography coupled with electrospray ionization-quadrupole-time of flight-mass spectrometry. Blood and urine samples were evaluated by multivariate analysis, followed by univariate analysis. First, the PLSDA score plot and VIP score were applied. By using the cross-validation algorithm for the first 4 molecules identified, a high accuracy, high R² values, and a significant Q² value were obtained. Therefore, the model could be considered predictive. Biomarker analysis and prediction by Random Forest analysis was performed. The specificity and sensibility of the molecules identified as potential biomarkers were evaluated by applying the Receiver Operating Characteristic (ROC) curve and the area under the curve (AUC).

Results: Significant direct correlations with eGFR were demonstrated for serum levels of Oleoyl glycine ($p < 0.05$, Log2 = 0.773), alpha-lipoic acid ($p < 0.05$, Log2 = 0.505), and L-cysteine ($p < 0.05$, Log2 = 0.363). Interestingly, serum levels of 5-Hydroxyindoleacetic acid, Phenylalanine, Pyridoxamine, Cysteinylglycine, Propenoylcarnitine, and Uridine increased gradually from G1 group to subgroups G5. Also, 5-Hydroxyindoleacetic acid, Phenylalanine, Pyridoxamine, Cysteinylglycine, Propenoylcarnitine, Uridine, and All-trans retinoic acid levels correlated negatively with eGFR ($p < 0.05$). Moreover, in urine samples the majority of molecules were increased in group G4 and G5 versus G1-G3b and C groups, respectively. Urinary levels of Inositol sulfate, Glycophospholipins, and Butenylcarnitine correlated negatively with eGFR ($p < 0.05$).

Conclusion: Amino acids, antioxidants, uremic toxins, and acylcarnitines are increased in all CKD stages. The impact of this metabolites on the glomerular and tubular structures, even in the early stages of CKD, can be explained by their dual serum and urinary variation. The study provided a particular metabolic profile that can offer new biomarkers useful for the evaluation of early CKD and its progression, as well as potential therapeutic targets.

Conclusion: The urinary metabolome of kidney transplant recipients with chronic allograft injury and who experienced severe IRI was significantly enriched with long chain fatty acids (FA). We identified a renal FA-related gene signature with low levels of Cpt2 and Acsm5 and high levels of Acsl4 and Acsm5 associated with IRI, transition to chronic injury, and established CKD in mouse models and kidney transplant recipients. The findings were consistent with the presence of Cpt2−, Acsl4−, Acsm5−, PTC− lacking recovery from IRI as identified by single nucleus RNA sequencing. In vitro experiments indicated that endoplasmic reticulum (ER) stress contributes to CPT2 repression, which, in turn, promotes lipids accumulation, drives profibrogenic epithelial phenotypic changes, and activates the unfolded protein response.

Conclusion: ER stress through CPT2 inhibition and lipid accumulation, engages an auto-amplification loop leading to lipotoxicity and self-sustained cellular stress. Thus, IRI imprints a persistent FA metabolism disturbance in the proximal tubule sustaining the progression to chronic kidney allograft injury.

**Figure 1: Novel cell intrinsic model of lipotoxicity.**

**INJURY INDUCED RENAL FIBROSIS PROMOTES CYSTGENESIS AND CYST GROWTH IN ADULT MICE WITH AUTOSOMAL DOMINANT POLYCYSTIC KIDNEY DISEASE**

Yufeng Xing, Ming Wu and Chaoyang Ye

Shanghai Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, Department of Nephrology, Shanghai, P.R. China

**Background and Aims:** Acute kidney injury (AKI) is not a merely transient event, which can lead to a subsequent progression to chronic kidney disease (CKD). Autosomal dominant polycystic kidney disease (ADPKD) is the most frequent inherited kidney disease caused by mutations in PKD1 or PKD2 gene. Previous studies showed that acute kidney injuries promote cystogenesis in adult mice with ADPKD. Fibrosis is a hallmark of AKI to CKD (AKI-CKD) transition, and positively correlated with renal cyst growth in humans. All these data imply a role of AKI-CKD transition in ADPKD. In this study, we aimed to determine the role of AKI-CKD transition in ADPKD.

**Method:** We established AKI-CKD transition model by toxic or surgical injuries, and Pkd gene inactivation in adult mice was performed in different time point of AKI-CKD transition. The progression of renal fibrosis was shown.
by Western blotting analysis in toxic or surgical injury induced AKI-CKD transition model.

**Results:** We showed that renal injury before or after Pkd gene inactivation can both induce renal cyst formation in adult Pkd1 or Pkd2 mice, and the extent of cyst formation was correlated with the initial fibrosis level of three hits (injury and gene inactivation). Inactivation of Pkd1 gene at fibrosis recovery stage in adult Pkd1 mice. Enhanced renal fibrosis by repeated toxic injuries before gene inactivation accelerated renal cyst growth in Pkd1 mice. We further showed that the speed of cyst growth at the early stage in adult Pkd1 mice was decided by the baseline of renal fibrosis. Finally, we showed that conditional knockout of Ezh2 gene attenuated renal fibrosis and cyst growth in adult Pkd1 mice with established renal fibrosis.

**Conclusion:** Fibrotic responses in AKI-CKD transition is a driving force for renal cyst formation and growth in adult kidneys and inhibition of renal fibrosis through targeting EZH2 might be a new therapeutic strategy for adult ADPKD.

**SELF-ASSEMBLED FISETIN NANOPARTICLES WITH ENHANCED BIOACTIVITIES FOR EFFECTIVE HYPERURICEMIC NEPHROPATHY THERAPY**

Qian Ren, MA Liang and Ping Fu

Kidney Research Institute, Division of Nephrology, West China Hospital of Sichuan University, Chengdu, P.R. China

**Background and Aims:** The prevalence of hyperuricemia is rising rapidly around the world, and increasing evidence demonstrates that hyperuricemia is the independent risk factor for chronic kidney diseases (CKD) development and progression. Hyperuricemia-induced renal injury, namely hyperuricemic nephropathy (HN), is characterized by urate crystal formation, tubulointerstitial fibrosis and glomerulosclerosis, which would eventually progress into end-stage renal disease (ESRD). Up to now, the mechanism of HN remains unclear and the treatment still needs further exploration. Fisetin is a natural flavanol with potent antioxidative and anti-inflammatory properties and showed therapeutic effects in mice with HN. However, the poor water solubility, rapid metabolism, and low bioavailability of fisetin largely hampered its clinical application. Herein, we reported the simple and efficient preparation of fisetin-EGCG nanoparticles (EG/FIS NPs) based on a solvent-mediated disassembly/reassembly strategy.

**Method:** The fisetin nano-formulation (FIS/EG NPs) was prepared based on a general solvent-mediated disassembly/reassembly strategy. The physicochemical properties of FIS/EG NPs including morphology, specific surface area and pore size distribution, drug encapsulation rate and loading rate, intracellular distribution were characterized. The potential toxic effects of FIS/EG NPs on RAW264.7 and TCMK-1 cells were investigated by CCK-8. Meanwhile, the anti-oxidative and anti-inflammatory effects of FIS/EG NPs were detected in vivo and in vitro. In vivo small animal imaging was employed to assess the kidney accumulation of FIS/EG NPs. And finally, HN was induced to measure the effect of FIS/EG NPs in mice and PAS staining, Masson staining, RT-qPCR were used to explore underlying mechanisms.

**Results:** EG/FIS NPs with stable water dispersion was prepared by using a general solvent-mediated disassembly/reassembly strategy. EG/FIS NPs contains both features of fisetin and EG NPs, and displayed more potent free radical scavenging ability than fisetin and EG NPs. Meanwhile, it was found that both RAW264.7 and TCMK-1 cells were able to uptake EG/FIS NPs and no proliferation toxicity was observed in these two cell types after incubation with various concentrations of EG/FIS NPs. By in vivo and in vitro experiments, fisetin and EG NPs were shown to have synergistic effects in inhibiting LPS-stimulated NO production after encapsulation. Moreover, fluorescence imaging revealed that EG/FIS NPs preferentially accumulated in the injured kidney of HN mice. Finally, it was observed that EG/FIS NPs exhibited enhanced therapeutic efficiency against HN due to the combined antioxidative, anti-inflammatory, and antifibrotic activities of fisetin and EG NPs.

**Conclusion:** Collectively, these results suggested that EGCG-based nanocarriers might be a novel strategy for the development of therapeutic drugs for HN.
BACKGROUND AND AIMS: Hyperphosphatemia in chronic kidney disease (CKD) is closely linked to medial vascular calcification. Phosphate is able to induce pro-inflammatory effects in vascular smooth muscle cells (VSMC), which could actively augment calcification processes. This study investigated the role of the IL-6 family member leukemia inhibitory factor (LIF) during vascular calcification.

METHOD: Experiments were performed in primary human aortic VSMCs, ex vivo mouse aortic rings and cholecalciferol treated mice, as well as serum samples from CKD patients and healthy controls.

RESULTS: Phosphate exposure induced LIF release in VSMCs, while supplementation of LIF aggravated calcification and expression of pro-calcific markers in VSMCs. Silencing of LIF by siRNA decreased calcification (40.4 ± 1.3 μmol/L, p < 0.05) and were found to be higher in PKD-male rats than in their female counterparts (p < 0.0001). Compared to Control-male rats, PKD-male rats showed decreased maximum relaxation to acetylcholine (55.2% ± 7.7 ±1%, p < 0.05), indicating impaired endothelial function. Contractile responses to phenylephrine (3.0±0.1 g vs. 3.4±0.1 g, p < 0.05) and high potassium (3.3±0.1 g vs. 3.7±0.1 g, p < 0.05) were reduced in the PKD-male compared to Control-male. Additionally, in PKD-male aortas, the concentration-response curve to sodium nitroprusside, an endothelium-independent vasodilator, was shifted to the right compared to Control-male. Morphometric analysis revealed that wall thickness and wall cross-sectional area normalized to body weight, and the wall/lumen area ratio were significantly higher in PKD-male aortas compared to Control-male. Additionally, PKD-male showed increased cleaved PARP-1 immunoreactivity confined to endothelial level compared to Control-male. All these parameters were unchanged in PKD-female rats compared to Control-female.

CONCLUSION: Six month-old PKD-male, not female, rats show endothelial dysfunction, impaired smooth muscle contraction and relaxation, pathological changes in aortic morphometry, and apoptosis in a non-renal vasculature. The rat model of autosomal dominant PKD in males can be used to identify novel targets for the treatment of this disease.

HEART FAILURE IN ASCEND-ND AND ASCEND-D

Ajay K. Singh1,2, Brian L Claggett1,3, Vlado Perkovic4, Thomas Hiemstra5, Kaivan Khavandi6, Mary Ann Lukas7, Prerna Ranganathan8, Jennifer B Shannon8, Janet van Adelsberg9 and Scott Solomon1,3

1Harvard Medical School, Boston, MA, United States of America, 2Renal Division, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States of America, 3Cardiovascular Division, Department of Medicine, Brigham and Women’s Hospital, Boston, MA, United States of America, 4Faculty of Medicine and Health, University of New South Wales Sydney, Australia, 5GSK, Stevenage, Hertfordshire, United Kingdom, 6GSK, Brentford, London, United Kingdom, 7GSK, Albuquerque, New Mexico, United States of America, 8GSK, Collegeville, PA, United States of America and 9GSK, Durham, NC, United States of America

BACKGROUND AND AIMS: Heart failure (HF) is a common cardiovascular (CV) complication in chronic kidney disease (CKD) [1]. Two CV outcome trials (ASCEND-ND [NCT02878635][2] and ASCEND-D [NCT02879035][3]) have provided the principal assessment of CV risk with daprodustat in CKD: both studies showed noninferiority of daprodustat to erythropoiesis-stimulating agent (ESA) in patients with anaemia of CKD not on (ASCEND-ND) or on (ASCEND-D) dialysis. Time-to-first adjudicated major adverse CV event (MACE) was the primary endpoint. Time-to-first MACE or hospitalisation for heart failure (HHF) was assessed as a principal secondary endpoint, and time-to-first HHF was analysed as an additional secondary endpoint. To better understand HF-specific outcomes, post-hoc analyses accounting for competing risk of death were conducted via the composite endpoint of all-cause mortality (ACM) + HHF – more typically employed to evaluate HF-specific outcomes and to assess “hospitalisation-free survival”. Post-hoc subgroup analyses of patients identified as having a baseline HF history were also conducted.

RESULTS: Overall, 3872 and 2964 patients were randomised in ASCEND-ND and ASCEND-D respectively. All key prespecified and post-hoc CV endpoints in ASCEND-ND and ASCEND-D are shown in the Table, and the composite endpoint of ACM + HHF is shown in the Figure. In summary, for components of MACE for daprodustat vs ESA, respectively, ACM and HHF were similar between treatment arms in both studies: ASCEND-ND: 11.6% vs 12.2%; ASCEND-D: 14.8% vs 14.6%. For HHF alone in both studies, event rates for daprodustat vs ESA, respectively, were: 7.2% vs 5.8% (hazard ratio [HR] 95% confidence interval [CI] = 1.22 [0.95, 1.56]) in ASCEND-ND; and 7.5% vs 6.8% (HR [95% CI] = 1.10 [0.84, 1.45]) in ASCEND-D. In post-hoc analyses using the composite endpoint of ACM + HHF in ASCEND-ND, the event rate for daprodustat was 20.3% (n = 393/1937), and the event rate for ESA was 19.0% (n = 368/1935) (HR [95% CI] = 1.09 [0.94, 1.26]). More HHF events were
observed in patients with a history of HF (daprodustat: 20.4% [n = 54/265]; ESA: 13.4% [n = 34/254]). In ASCEND-D, ACM + HHF events were similar for daprodustat (24.4% [n = 363/1487]) and ESA (24.8% [n = 366/1477]; HR [95% CI] = 0.98 [0.85, 1.14]). In this composite endpoint in patients with a history of HF in ASCEND-D, there were also more HHF events in those treated with daprodustat (18% [n = 47/267]) vs ESA (13% [n = 32/254]), but there were fewer deaths with daprodustat (21% [n = 56/267]) than ESA (28% [n = 71/254]). For subgroup analyses of daprodustat vs ESA, the proportion of patients with a history of HF at baseline was greater in ASCEND-D (18.0% vs 17.2%) than ASCEND-ND (13.7% vs 13.1%). Incidence of MACE + HHF was similar between treatment arms in both studies.

**Conclusion:** Our findings showed that there was a higher HHF risk in daprodustat-treated patients who had a history of HF compared to ESA-treated patients. While HF risk was similar between treatments in patients on dialysis (ASCEND-D) when combining ACM + HHF in a post-hoc analysis, the risk remained numerically higher for daprodustat vs ESA in patients not on dialysis (ASCEND-ND). The underlying mechanism responsible for these observations and differences is not known, although patients with advanced CKD and comorbid HF who are not on dialysis are recognised to be at underlying risk of HF decompensation.

EFFECTIVE PREDICTION OF NEED FOR CHRONIC DIALYSIS IN CHILDREN, BASED ON RANDOM FOREST ALGORITHMS USING BLOOD CELL COUNT-DRIVEN PARAMETERS

Anna Kawalec¹, Jakub Stojanowski², Paulina Mazurkiewicz¹, Anna Choma³, Katarzyna Mazur³, Mateusz Pluta³, Michal Szymanski⁴, Aleksandra Bruciak⁴, Tomasz Gołębiowski² and Kinga Musiał¹

¹Wroclaw Medical University, Department of Pediatric Nephrology, Wroclaw, Poland, ²Wroclaw Medical University, Department of Nephrology and Transplantation Medicine, Wroclaw, Poland, ³University Clinical Hospital, Department of Pediatric Nephrology, Wroclaw, Poland and ⁴Wroclaw Medical University, Students’ Scientific Association, Department of Pediatric Nephrology, Wroclaw, Poland

Background and Aims: Persistent, low-grade inflammation is a significant component of chronic kidney disease (CKD) that plays a pivotal role in its pathophysiology, progression, complications, and all-cause mortality. Previous studies have searched for simple, cost-effective, and universally available markers useful in the systemic inflammation assessment in CKD patients. In the adult population, an increase in neutrophil count, correlated with a reduction in lymphocyte count, indicates the rate of progression to dialysis and predicts mortality in hemodialysis and peritoneal dialysis patients. Due to modulating role of platelets within the inflammatory pathways, a mean platelet volume (MPV) and platelet-to-lymphocyte ratio have also been proposed as markers of inflammation. The systemic immune inflammation index (SII) is a newly defined ratio combining neutrophil, lymphocyte, and platelet counts. It is proposed as a prognostic indicator comprehensively reflecting patients’ inflammatory and immune status. Recently, elevated SII has shown a predictive value for mortality risk among CKD adult patients. SII has not been evaluated in the pediatric CKD population so far.

Thus, the study aimed to analyze complete blood cell count (CBC) driven parameters, including SII, in children with CKD and to assess their potential usefulness in the prediction of the need for chronic replacement therapy with the use of artificial intelligence tools.

Method: The study group consisted of 27 predialysis children with CKD stages 4-5 (stage 4 - 11 patients, stage 5 - 16 children) and 40 patients on chronic dialysis (HD - 21 children, APD - 19 patients). The patients’ age ranged from 5 to 18 years, children under 5 were excluded due to the different CBC profile regarding neutrophil – lymphocyte proportions. The evaluated CBC parameters were: hemoglobin, hematocrit, leukocyte, neutrophil, monocyte, lymphocyte, platelet counts and MPV. Kidney function, standard biochemical parameters, CRP and SII were also analyzed. This database was used for further analysis. The recursively selected subsets of input variables constituted the input of random forest classifier (RFC). Each variant has been optimized, taking into account various features (accuracy, AUROC, precision, recall, MCC), then the best model was saved. The aim was to narrow the set of input parameters so that high predictive power is secured, whereas overfitting or overcomplicating could be avoided. Moreover, the GINI importance was measured in order to define the parameter with the largest share in the prediction.

Results: The best Random Forest Classifier contained neutrophil count, MPV, and SII as input variables, and achieved the following values: AUROC 0.9286, accuracy 93.75%, precision 0.9437, recall 0.9375 and MCC 0.87. The statistics for each class were as follows: precision 0.90, recall 1.00 and f1-score 0.95 for children with CKD 4-5 on conservative treatment; precision 1.0, recall 0.86, and f1-score 0.92 for patients on chronic dialysis. The values of mean GINI importance measured for 40 random splits of the base for MPV, neutrophil count and SII, were 0.28, 0.32 and 0.39, respectively.

Conclusion: RFC built up with the input variables of neutrophil count, MPV, and SII, was the best predictor of progression into pediatric end stage kidney disease requiring chronic dialysis. SII turned out the most important parameter...

LOW LEAN BODY TISSUE IS AN INDEPENDENT RISK FACTOR FOR KIDNEY DISEASE PROGRESSION AND MORTALITY IN PATIENTS WITH ADVANCED CHRONIC KIDNEY DISEASE

Deborah Soledad Roldán, Eduardo Gallego Valcarce, Enrique Gruss and Amir Shahaka

Hospital Universitario Fundación Alcorcón, Nephrology, Alcorcón, Spain

Background and Aims: Lean tissue mass is a marker of good health and is associated with a lower risk of death in patients without chronic kidney disease (CKD). A potentially underestimated risk factor for impaired renal function is low serum albumin concentration. Previous studies have shown that even small decreases in serum albumin concentration levels are strongly associated with cardiovascular disease, heart failure, impaired kidney function, and mortality in vulnerable populations. An association between low lean body tissue with mortality in patients with stage 4 and 5 CKD has recently been demonstrated. The aim of this study was to evaluate the effect of lean body tissue index (LTI) measured by multifrequency bioelectrical impedance analysis (BIA) on kidney disease progression and mortality in a cohort of patients with stage 4 and 5 CKD.

Method: We performed a retrospective observational cohort study that included patients with stage 4 and 5 CKD who were referred to the Advanced Chronic Kidney Disease outpatient clinic at our centre between January 2014 and December 2020, in whom a baseline measurement of body composition by using BIA was performed in the first 6 months of follow-up. Baseline clinical and laboratory parameters (serum creatinine, glomerular filtration rate, serum albumin, hemoglobin, cholesterol, triglycerides, calcium, phosphorus, PTH and CRP) were defined as those observed at the time of BIA measurement. Low lean tissue was defined as having LTI values below the 10th centile adjusted by age and sex. Renal survival was defined as the absence of need of renal replacement therapy (RRT) at the end of follow-up.

Results: The study included 145 patients who had a mean age of 72 ± 11.8 years, 69.7% were males, with a mean GFR measured by CKD-EPI of 20.4 ± 4.7 ml/min, mean albumin of 4.1 ± 0.3 g/dl and median urinal albumin-creatinine ratio (uACR) of 413 mg/g (IQR 98-1341). The mean body mass index of the population was 30.1 ± 6.1 kg/m², and BIA showed a mean LTI of 15.4 ± 3.9 kg/m² and fat tissue index (FTI) of 14.1 ± 6.8 kg/m². Nineteen patients (13.1%) had lower LTI. Patients with low LTI were younger (65.9 ± 11.4 years, p = 0.013) and had higher uACR (1444 [484-1815] vs 318 [68-1188] mg/g, p = 0.002) with no differences in sex, GFR, and other laboratory parameters. After a mean follow-up of 27.7 months (IQR 15.3-45.4), 72 (49.7%) showed CKD progression to RRT and 55 patients (37.9%) died. The Kaplan-Meier survival analysis showed that patients with low LTI had a worse renal survival (log-rank 5.5, p = 0.019) and overall survival (log-rank 7.6, p = 0.006).

The multivariable Cox regression analysis showed that low LTI (HR 2.28, 95% CI 1.12-4.62), lower GFR (HR 0.86, 95% CI 0.81-0.92) and higher uACR (HR 1.001, CI 95% 1.001-1.001) were independent risk factors for CKD progression to ESKD, while low LTI (HR 3.16, 95% CI 1.42-7.05), age (HR 1.09, CI 95% 1.05-1.13) and serum albumin (HR 0.31, CI 95% 0.13-0.77) were the factors that were independently associated with mortality.

Conclusion: Low lean body tissue index measured by multifrequency bioelectric impedance analysis is an independent risk factor for CKD progression and mortality in stage 4-5 CKD. Close monitoring of nutritional status by BIA should be followed in these patients to provide timely and adequate nutritional interventions that might help in improving patient outcomes.

IS THE KIDNEY FAILURE RISK EQUATION VALID IN PREDICTING END STAGE KIDNEY DISEASE IN ADULTS WITH GLOMERULONEPHRITIS?

Tudor Sergiu Nicula1, Otilia Ciurea1,2, Nicoleta Petre1,3, Gabriel Mirescu1,4 and Cristina-Stela Capusa1,4

1Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, 2Dr. Carol Davila” Teaching Hospital of Nephrology, Bucharest, Romania, 3Bucharest, Romania and 4“Dr. Carol Davila” Teaching Hospital of Nephrology, Bucharest, Romania, Bucharest, Romania

Background and Aims: The Kidney Failure Risk Equation (KFRE) is a clinical tool that predicts the 2- and 5-year risk of progression to end stage kidney disease (ESKD) in patients with chronic kidney disease (CKD) stages 3a-5. The equation’s accuracy and its predictive performance in subjects with glomerulopathies were not properly evaluated and validated. The current study examined the 4 variable KFRE in subjects with advanced CKD from glomerulopathy etiologies by evaluating discrimination and calibration at 2 and 5 years.

Method: This retrospective, single-center, cohort study included 558 subjects who were diagnosed by kidney biopsy with primary or secondary glomerulopathies between 1st January 2008 and 31st December 2016 and followed until 31st December 2021 for a mean follow-up time of 85.3 (95%CI 78.9 to 91.8) months. Patients with inadequate biopsy samples, histological findings other than glomerulopathy, those with missing data, and those with eGFR > 60 ml/min/1.73 m² were excluded. The 4-variable KFRE using eGFR, urinary albumin to creatinine ratio (uACR), age, and sex was calculated using the data from the first visit. The primary outcome of the study was the need for renal replacement therapy (RRT) initiation (dialysis or kidney transplant). The area under the receiver operator characteristic curve (AUC) and calibration plots were used to measure discrimination and calibration of the KFRE in specific glomerulopathy etiologies: IgA nephropathy, diabetic nephropathy, amyloidosis, endocapillary and crescentic glomerulonephritis, lupus nephritis, minimal change disease, membranous nephropathy, focal segmental glomerulosclerosis and membranoproliferative glomerulonephritis.

Results: In this cohort, most of the patients were males (57.7%) and the median age was 53 (95% CI 53 to 57) years. The median eGFR was 30.5 (95% CI 28 to 32.6) ml/min/1.73 m² and the median uACR 1932 (95% CI 1633 to 2200) mg/g. The most common glomerulopathies were IgA nephropathy (21.3%), diabetic nephropathy (15.4%), and membranoproliferative glomerulonephritis (9.5%). The median 2-year and 5-year KFRE score was 2.2 (95% CI 1.8 to 2.7) % and 18.9 (95% CI 17.8 to 19.7) % respectively. During the first 2 years of follow-up 154 (27.5%) subjects needed RRT and 93 (16.6%) subjects died, while 218 (39%) started RRT and 108 (19.3%) died within 5 years from the kidney biopsy. The 4-variable KFRE provided good discrimination in the whole cohort with an AUC of 0.728 (95% CI 0.686-0.770) for predicting ESRD at 2-years and 0.725 (95% CI 0.686-0.767) at 5 years (figure 1A). There was also a good to excellent discrimination of 2-years and 5-years KFRE across all glomerulopathy etiologies, with statistically significant p-values (p<0.05), with the exception of diabetic nephropathy and endocapillary GN which had a non-significant AUC (Figure 2). Calibration plots were adequate both overall and across glomerulopathy etiologies; however, the predicted risks for kidney failure were overstated across CKD etiologies, especially in those with low to moderate risk in the 2-years model. Notably the...
calibration plot for the 5-years KFRE showed that the predicted risk was near the observed risk across all glomerulopathies (Figure 1B).

**Conclusion:** The 4 variable-KFRE seems to be a good predictive tool in patients with glomerulopathies both for 2 and 5-years, except for diabetic nephropathy and endocapillary glomerulonephritis.

**INSULIN RESISTANCE IS ASSOCIATED WITH INCIDENT CHRONIC KIDNEY DISEASE IN POPULATION WITH NORMAL RENAL FUNCTION**

Eun Hui Bae\(^1\), Su Hyun Song\(^1\), Su In Kim\(^1\), Da Hae Cho\(^1\), Sang Yoeb Lim\(^2\), Soo Wan Kim\(^1\) and Seong Kwon MA\(^1\)

\(^1\)Gwangju, Rep. of South Korea and \(^2\)Ansan, Rep. of South Korea

**Background and Aims:** Insulin resistance is prevalent in chronic kidney disease (CKD) and may accelerate its progression. This study aimed to investigate whether insulin resistance was associated with the development of incident CKD in a population with normal renal function.

**Method:** A total of 3,331 individuals with normal renal function from a community-based cohort formed the study population. We determined the relationship between insulin resistance indices and incident CKD using Cox proportional hazard model and Kaplan-Meier survival analysis.

**Results:** During a mean follow-up of 11.03 ± 4.22 years, incident CKD occurred in 414 (12.4%) participants. The high homeostasis model assessment-insulin resistance (HOMA-IR) level group had an increased risk of incident CKD (HR, 1.40; 95% CI, 1.13-1.74; \(p = 0.002\)) compared to the normal group after adjusting for confounding factors. The risk of incident CKD also increased with lower quantitative insulin sensitivity check index (QUICKI) levels (HR, 0.62; 95% CI, 0.41-0.92; \(p = 0.018\)) and higher leptin-adiponectin ratio (LAR) levels (HR, 1.23; 95% CI, 1.06-1.42; \(p = 0.006\)).

**Conclusion:** Higher insulin resistance indices were associated with the incidence of CKD. Our data suggests that increased insulin resistance may be involved in the development of incident CKD in individuals with normal renal function.
Figure 1: Kaplan-Meier free-CKD probability curve with the log-rank test between high HOMA-IR group and incident CKD. High group is associated with poor free-CKD probability compared to normal group.

CAN WE REPLACE URINE TESTING AND DELIVER A STEP CHANGE IN ACCESS TO RENOPROTECTIVE MEDICATIONS?

Nils Svangård¹, Anders Hildeman¹, Peter Greasley² and Philip Ambery³

¹AI & Analytics, Data Science & Artificial Intelligence, R&D, AstraZeneca, Gothenburg, Sweden, ²Early Clinical Development, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden and ³Clinical Metabolism, Late-stage Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden

Background and Aims: Albuminuria is a medical condition characterized by leakage of albumin into the urine due to kidney damage. The condition is diagnosed by heightened Albumin to Creatinine ratio in the urine (ACR) and is typically categorized into microalbuminuria (ACR ≥ 30, < 300 mg/g mg/g) and macroalbuminuria (ACR ≥ 300 mg/g). Currently, despite compelling data, only a minority of patients with diabetes, and rarely individuals without diabetes, are screened for albuminuria in a systematic way. ACR tests also present high intra-person variability, making it harder to identify meaningful biologic changes and increasing complexity of clinical trials. In this study we develop a method using machine learning to predict ACR level from Electronic Health Records, excluding urine tests, and validated the model for identifying patients with albuminuria. Identifying patients with undiagnosed
albuminuria could help slow progression of kidney disease and be used to speed up recruitment to, and reduce screen failures in, clinical trials.

**Method:** We developed a Quantile Regression model for ACR using US Limited IBM MarketScan Explorys Claims-EMR Data Set (LCED). We included subjects who had an ACR test (0 < ACR ≤ 5000 mg/g) and was of at least 18 years of age. Patient demographics (age, sex), vital signs (BMI, Blood Pressure) and 8 common blood tests (Albumin, Bilirubin, Creatinine, HbA1C, Triglyceride, Glucose, White Blood Cell count & ALT) were used as covariates. A tree based gradient boosting framework (LightGBM) was used to train the quantile regression models, viz., the 25-, 50-, and 75-percentiles of ACR conditioned on the covariates. The model was then validated on all qualified subjects in Optum’s de-identified Clininformatics® Data Mart Database (2007-2021). We evaluated performance using the metrics Area Under the Curve (AUC), precision (PPV), specificity (TNR), and sensitivity (TPR). Finally, we use Kaplan-Meier estimates to compare the risk of progression to kidney failure as identified by ICD codes (Chronic kidney disease, stage 5; End stage renal disease; Dependence on renal dialysis; Unspecified kidney failure; Kidney transplant) of both the predicted and measured ACR values.

**Results:** A final cohort of 63,459 individuals matched the inclusion and exclusion criteria in LCED and 5,857,385 individuals in Optum. Using the 25% quantile to predict patients at risk, the model consistently reaches a PPV greater than 0.8 and a specificity (TNR) greater than 0.99 (Table 1). The risk of progression to kidney failure increases with both increased predicted and measured ACR (Figure 1).

**Conclusion:** The results show that the models have discriminative power in all datasets. It predicts both micro- and macro-albuminuria with a PPV above 80% for the 25-quantile. However, classification performance is lacking in sensitivity, i.e., subjects suffering from albuminuria may not be classified as such. By using the median prediction of ACR we identify patient subpopulations that have a risk of kidney failure at least on par with the true ACR subpopulation targeted. This means that the method can be used confidently to identify at-risk individuals. Therefore, our model is advantageous in applications such as identifying undiagnosed albuminuria and pre-screening for clinical trials, where high PPV is more important than sensitivity. We intend to validate the model further for outcomes prediction in an upcoming CKD trial.

**Table 1:** Classification performance on datasets with three different quantile predictors.

ASSOCIATION OF SERUM 25-HYDROXYVITAMIN D WITH ALL-CAUSE MORTALITY AND KIDNEY OUTCOME IN PATIENTS WITH EARLY STAGES OF CKD
Lin Yuxin, Yuping Zhang, Sheng Nie and Xu Xin
P.R. China

Background and Aims: Although serum 25-hydroxyvitamin D (25(OH)D) deficiency is prevalent in all stages of chronic kidney disease (CKD), the effects of 25(OH)D deficiency on all-cause mortality and kidney outcomes in patients with early-stage CKD remain incompletely understood.

Method: This nationwide retrospective cohort study included 9840 adults with stages 1–3 CKD from 19 medical centers across China. The study outcomes included all-cause mortality, cardiovascular mortality, and kidney disease progression. The associations between serum 25(OH)D concentrations and the risks of mortality and CKD progression were evaluated using a Cox proportional hazard model. A mixed-effects model was used to estimate the slopes of estimated glomerular filtration rate (eGFR).

Results: Of 9840 adults with stages 1–3 CKD, 26.9% had severe (<10 ng/ml) and 38.7% had moderate (10–20 ng/ml) serum 25(OH)D deficiency. Compared with patients having 25(OH)D >20 ng/ml, patients with serum 25(OH)D <10 ng/ml were at significantly higher risks of all-cause mortality (hazard ratio [HR] 1.87, 95% confidence interval [CI] 1.53–2.28), cardiovascular mortality (HR 1.80, 95% CI 1.33–2.44), and CKD progression (HR 2.28, 95% CI 1.74–2.99), and had a steeper decline in eGFR slope (estimate -0.07; 95% CI -0.10 to -0.05 mL/min/1.73 m² per year). Similar results were obtained in subgroups and by sensitivity analyses.

Conclusion: 25(OH)D deficiency is associated with increased risks of all-cause mortality and CKD progression in patients with early-stage CKD. Studies are needed to determine whether early intervention for 25(OH)D deficiency could improve the prognosis of patients with early-stage CKD.

REDUCED TUBULAR MIR-190A-5P: A NOVEL BIOMARKER FOR STRATIFICATION OF PATIENTS WITH CHRONIC KIDNEY DISEASE

David Baird1, Jinnan Zang2, Ryan Wong3, Katie Connor4, Carolyn Cairns5, Maximilian Reck1, Jeremy Hughes1, Patrick Mark3, Alexander Peter Maxwell2, Gareth McKay2, David Simpson2, Laura Denby4 and Bryan Conway4

1University of Edinburgh, United Kingdom, 2Queen’s University Belfast, United Kingdom and 3University of Glasgow, United Kingdom

Background and Aims: Circulating microRNA (miRNAs) have been proposed as potential diagnostic and prognostic biomarkers and are functionally important in disease pathogenesis. In this study, we used an unbiased measurement of circulating miRNAs in patients with type 2 diabetes to identify a miRNA differentially expressed in kidney disease before moving to a larger, unselected cohort of patients with CKD to assess its potential to predict progression in CKD.

Method: MiRNA next generation sequencing (NGS) studies were undertaken to measure differential expression of plasma miRNAs in a discovery cohort of 3 groups; individuals with type 2 diabetic kidney disease (T2DKD, n = 9), age and sex matched patients with type 2 diabetes mellitus and normal renal function (T2DNRF, n = 13) and patients without diabetes and with normal renal function (NDNRF, n = 11). Differentially expressed miRs were validated in a separate cohort of the same groups (each n = 10). The prognostic value of miR-190a-5p in a general CKD population was assessed using the seNSOR cohort (n = 395, excluding patients on RRT, with an eGFR < 20 ml/min/1.73 m² or AKI at recruitment). The primary outcome of CKD progression was defined as reaching ESKD (starting RRT or maintaining an eGFR < 15mls/min) or >30% reduction in renal function from eGFR at baseline. Reaching ESKD alone was used as a secondary outcome.

Results: MiR-190a-5p was the only miRNA differentially expressed between T2DKD and both control groups in both the discovery and validation cohorts. In the seNSOR cohort, miR-190a-5p levels correlated positively with eGFR (rho = 0.12, p = 0.04) and inversely with age (rho = -0.12, p = 0.04). MiR-190a-5p levels below the median predicted CKD progression in individuals with minimal and moderate albuminuria (ACR < 3mg/mmol and 3-300mg/mmol respectively) but not in those with severe albuminuria (ACR>300mg/mmol, see figure). In those without severe albuminuria, miR-190a-5p levels predicted CKD progression in multivariate Cox proportional hazards models (HR 0.8, 95% CI: 0.66-0.96, p = 0.015), independently of baseline eGFR, ACR, age, SBP, DBP and sex. When participants with an ACR > 300mg/mmol were included, miR-190a-5p was not predictive of the composite CKD progression endpoint (multivariate HR 0.86, p = 0.064) but was predictive for reaching ESKD alone (multivariate HR 0.68, 95% CI: 0.5-0.93, p = 0.015). Analysis of miR-190 expression in individual renal cell types in the reversible unilateral ureter obstruction mouse model revealed that it is enriched in proximal tubule cells and falls significantly following injury before increasing again the repair phase.

Conclusion: miR-190a-5p is expressed by healthy proximal renal tubular cells and serum miR-190a-5p levels correlate positively with eGFR. Low serum miR-190a-5p levels may predict progression of CKD in patients with low or moderate proteinuria independently of existing risk factors.

Background and Aims: Use of proton-pump inhibitors (PPIs) is common in patients with chronic kidney disease (CKD). PPIs and many uremic toxins (UTs) are eliminated by a kidney tubular organic anion transporter system. In a cross-sectional study, we sought to evaluate the association between PPI prescription and serum concentrations of various UTs.

Method: We studied a randomly selected subgroup of participants in the CKD-REIN prospective cohort (adult patients with a confirmed diagnosis of CKD and estimated glomerular filtration rate (eGFR) <60mL/min/1.73m2) with available frozen samples collected at baseline. PPI prescription was recorded at baseline. Serum concentrations of 10 UTs were measured using a validated liquid chromatography tandem mass spectrometry technique. Multiple linear regression was performed, with the log UT concentration as the dependent variable.

Results: Of the 680 included patients [median age: 68 years; median eGFR: 32 mL/min/1.73 m²], 31% had PPI prescriptions at baseline. Patients using PPIs had higher levels of certain UTs in comparison to other patients, including total and free indoxyl sulfate (IS), total and free p-cresylsulfate, total and free p-cresylsulfonate (PCG), phenylacetylglycine (PAG), free kynurenine, and free hippuric acid. After adjustment for baseline comorbidities, number of co-prescribed drugs and laboratory data including eGFR, associations between PPI prescription and elevated serum concentrations of free and total IS, free and total PCG, and PAG remained significant.

Conclusion: Our results indicate that PPI prescription is independently associated with serum UT retention. These findings indicate a potential mechanism for side effect of PPIs in CKD patients that will need to be confirmed by longitudinal studies.

MOLECULAR IMAGING OF PDGFR-ß IN KIDNEY FIBROSIS
Barbara Mara Klinkhammer1, Diana Mocek1, Maike Wagner2, Fabian Kiessling2, Twan Lammers2 and Peter Boor1
1RWTH Aachen University Hospital, Institute of Pathology, Aachen, Germany and 2RWTH Aachen University Hospital, Institute for Experimental Molecular Imaging, Aachen, Germany

Background and Aims: Chronic kidney disease affects >10% of the world’s population and is associated with high mortality and morbidity. The best predictor of CKD progression is the extent of fibrosis, e.g., pathological deposition of extracellular matrix (ECM) and loss of functional kidney parenchyma. Currently, there are no specific treatment options and invasive biopsies remain the gold standard for diagnosis. Multiple signaling pathways are involved in fibrosis, including platelet-derived growth factor (PDGF) signaling. Mesenchymal stromal cells express both PDGF receptors PDGFR-α and PDGFR-ß, whose activation drives proliferation, migration and production of extracellular matrix, i.e., key processes involved in fibrosis initiation and progression. Based on these notions, we set out to study the bicyclic PDGFR-ß-binding peptide (BiPPB) for diagnosis, quantitative imaging and treatment monitoring of kidney fibrosis.

Method: The biodistribution and kidney accumulation of Cy7-labeled BiPPB and a scrambled peptide control were visualized and quantified using in vivo computed tomography - fluorescence molecular tomography (CT-FMT), ex vivo fluorescence reflectance imaging (FRI) and microscopy. This was done in three different mouse models of kidney fibrosis: the unilateral ischemia-reperfusion injury (I/R), the adenine-induced nephropathy (Adenine) and a transgenic model with constitutive PDGFR-ß activation specifically in renal mesenchymal cells leading to increased PDGFR-ß expression and expansion of PDGFR-ß+ cells (Mutant). In the latter model, we also monitored pharmacological PDGFR-ß inhibition with imatinib. Kidney fibrosis and therapeutic efficacy findings were verified by immunochemistry (IHC).

Results: In vivo 3D CT-FMT imaging and ex vivo 2D FRI showed strong accumulation in fibrotic kidneys for Cy7-labeled BiPPB, whereas only moderate amounts accumulated in the contralateral (I/R) and healthy (Adenine) kidney over 48 hours after i.v. injection. The accumulation of the scrambled BiPPB was also significantly lower compared to the specific BiPPB. In transgenic Mutant mice with specific activation of mesenchymal cells and primary renal scaring significantly more Cy7-BiPPB accumulated in the kidneys in comparison to healthy wildtype littermates. In combination with imatinib treatment for three weeks (Mutant imatinib) the accumulation of Cy7-BiPPB was decreased (Fig. 1a-c). This was confirmed ex vivo by significantly increased probe accumulation (2D FRI; Fig. 1d) and PDGFR-ß for development of microalbuminuria, randomized to either spironolactone 25 mg per day or placebo. Crude and adjusted Cox models were applied to investigate the association between baseline biomarker levels and development of the primary outcome, persistent microalbuminuria, and development of microalbuminuria in at least one morning void sample, used as a secondary outcome.

Results: In the PRIORITY trial, spironolactone treatment did not prevent progression to microalbuminuria compared to placebo. All biomarkers were measured in 154 participants at baseline and 117 at end-of-study (week 208). Treatment with spironolactone did not affect serum levels of any of the investigated collagen remodeling biomarkers compared to placebo, and there were no differences in delta-biomarker levels between baseline and end-of-study (p ranging 0.277-0.875). In crude analyses, serum endotrophin was associated with both the primary (n = 44) and secondary outcome (n = 74) for a two-fold higher level: 1.58, 95% CI 1.03-2.44, p = 0.037 and 1.62, 1.12-2.35, p = 0.010), whereas serum PRO-C3 was only associated with the secondary outcome (1.89, 1.19-2.99, p = 0.007). After adjustment for sex, baseline age, systolic blood pressure, estimated glomerular filtration rate, urinary albumin-creatinine ratio, and HbA1c, serum endotrophin and PRO-C3 remained significantly associated with the secondary outcome (1.52, 1.03-2.24, p = 0.036 and 1.73, 1.08-2.78, p = 0.022). Levels of PRO-C7, PRO-C8 and CTX-III were not associated with the specified outcomes. Neither baseline levels of serum endotrophin nor PRO-C3 correlated with baseline CKD273 levels (R: 0.00-0.06, p>0.47).

Conclusion: Treatment with spironolactone did not change serum levels of collagen remodeling biomarkers. Serum endotrophin, reflecting collagen type VI formation and the pro-fibrotic molecule endotrophin, and PRO-C3, a biomarker of collagen type III fibrosis, were associated with development of microalbuminuria in at least one urine sample, suggesting that these biomarkers are relevant risk markers for kidney disease development in type 2 diabetes.

#5482
CIRCULATING BIOMARKERS OF COLLAGEN REMODELING AS MARKERS FOR DEVELOPMENT OF MICROALBUMINURIA IN TYPE 2 DIABETES: THE PRIORITY TRIAL
Alexandra Louise Moller1,2, Viktor Rotbas Curovic3, Daniel G. K. Rasmussen1, Federica Genoveze1, Morten A. Karsdal6,7, Tine Hansen1,3 and Peter Rossing1,4
1Nordic Bioscience A/S, Herlev, Denmark, 2Copenhagen University, Department of Biomedical Sciences, Faculty of Health and Medical Sciences, Copenhagen, Denmark, 3Copenhagen Diabetes Center, Copenhagen, Herlev, Denmark and 4Copenhagen University, Department of Clinical Medicine, Faculty of Health and Medical Sciences, Copenhagen, Denmark

Background and Aims: Kidney disease progression is characterized by extensive deposition of extracellular matrix components such as collagen. Therefore, we assessed the effect of spironolactone on collagen remodeling biomarkers and investigated the association between the markers and development of microalbuminuria in serum of persons with type 2 diabetes and normoalbuminuria.

Method: We measured collagen type III (PRO-C3), VI (PRO-C6; endotrophin), VII (PRO-C7), and XVIII (PRO-C28) formation, and a fragment of degraded crosslinked collagen type III (CTX-III) in serum of persons with high-risk (stratified by a urinary proteomics classifier, CKD273)
expression (immunohistochemistry (IHC) Fig. 1e) in fibrotic kidneys, which was diminished by imatinib treatment.

**Conclusion:** Our findings demonstrate the potential of PDGFR-β-based imaging agents for non-invasive and quantitative monitoring of renal fibrosis progression and therapy response.

**Figure 1:** Imaging biomarker and mouse models for diagnosis and staging of kidney fibrosis with molecular imaging of PDGFR-β using BiPPB. a) Examples of biodistribution of Cy7-BiPPB in a transgenic model with PDGFR-β overexpression (Mutant), with imatinib treatment (Mutant Imatinib) or wildtype littermate (WT) quantified by hybrid CT-FMT. The results of the 3D CT-FMT quantification for Cy7-BiPPB in kidneys are shown as bar at 24h (b) and 48h (c) post injection presented as percentage of the injected dose per gram (%ID/g). d) Example 2D FRI of one mouse per group are shown 48h p.i. for all organs (L = Liver; Lu = Lungs; S = Spleen; P = Pancreas; A = Aorta; H = Heart; K = Kidneys; SK = Skin; B = Bone; M = Muscle; I = Intestine; St = Stomach). e) Representative pictures from immunohistochemical stains of PDGFR-β, Collagen III and F4/80 in WT, Mutant, and Mutant Imatinib mice. Bar graph = 50 μm.

**Background and Aims:** Cellular senescence is characterised by irreversible cell cycle arrest and marked changes in transcriptional and secretory activity. It can occur as a physiological component of healthy organismal development or in response to a range of cellular insults including DNA damage, oncogenic mutations and metabolic stress. Renal tubular senescence in response to ageing and injury is proposed as a driver of kidney fibrosis. Senescent cell depletion in mice improves outcomes in multiple organs including the kidney. There are currently no non-invasive biomarkers for quantifying renal senescence available. We are using a multi-omics approach and utilising human renal proximal tubular epithelial cells (hRPTECs) in culture, a murine model of renal senescence and human samples, to identify urinary biomarkers of renal tubular senescence and to determine if they can predict decline in kidney function.

**Method:** In vitro: We modelled a human senescent cell line (RPE-1) in hRPTECs. Senescence was induced in RPE-1 using the inhibitor of Akt N17429. Senescent cells were identified by CDKN1A and reduced LMNB1 and MKI67 in keeping with senescence induction. Other transcripts including CXCL8 and IL6 rose in irradiated cells.

**Results:** Irradiated and Nutlin 3A treated cells had increased mRNA levels of CDKN1A and reduced LMNB1 and MKI67 in keeping with senescence induction. Other transcripts including CXCL8 and IL6 rose in irradiated cells compared to controls. 1272 genes were differentially expressed in the same direction in Nutlin 3A treated cells compared to controls but fell in Nutlin 3A treated cells. The results of the 3D CT-FMT quantification for Cy7-BiPPB in kidneys are shown as bar at 24h (b) and 48h (c) post injection presented as percentage of the injected dose per gram (%ID/g). d) Example 2D FRI of one mouse per group are shown 48h p.i. for all organs (L = Liver; Lu = Lungs; S = Spleen; P = Pancreas; A = Aorta; H = Heart; K = Kidneys; SK = Skin; B = Bone; M = Muscle; I = Intestine; St = Stomach). e) Representative pictures from immunohistochemical stains of PDGFR-β, Collagen III and F4/80 in WT, Mutant, and Mutant Imatinib mice. Bar graph = 50 μm.
IONIZED MAGNESIUM LEVELS IN PATIENTS WITH MODERATE-TO-ADVANCED CHRONIC KIDNEY DISEASE: RELATIONSHIP WITH TOTAL MAGNESIUM AND ASSOCIATED FACTORS

Background and Aims: Magnesium (Mg) is involved in a multitude of essential physiological processes. In chronic kidney disease (CKD), the mechanisms compensating for the decrease in glomerular filtration rate (eGFR) become insufficient and Mg excretion tends to decrease, potentially resulting in hypermagnesemia. On the other hand, hypomagnesemia seems also to be common in CKD, due to changes in Mg intake through diet, reduced absorption and drug-induced hypomagnesemia. To date, a few studies have shown an association between increased cardiovascular risk in CKD and either low or high total Mg levels. However, the physiologically active fraction of extracellular Mg is ionized Mg (iMg), which is not routinely measured. In critical ill patients, the correlation between iMg and total Mg has been shown to be poor. Similar data on patients with CKD would be important to future studies aiming at clarifying the link between Mg and outcomes, and ultimately to determine the interest of iMg assay in routine practice. The objectives of this study are i) to study the correlation between total Mg and iMg and ii) to evaluate the relation between serum ionized magnesium, estimated GFR (eGFR) and demographic and biologic parameters.

Method: CKD-REIN is a French, prospective, nationally representative cohort study of 3033 CKD patients under nephrology care not receiving maintenance dialysis (stage 3-5: eGFR<60 mL/min/1.73 m² based on 2009 CKD-EPI equation). Baseline iMg and total Mg serum concentrations were respectively centrally measured using the NOVA BIOMEDICAL Stat Profile PRIME ES analyser and with Atellica® CH SIEMENS analyser. Normal range of serum total Mg considered was 0.66 to 1.06 mmol/L (from Atellica®). Mean ± standard deviation (SD) ionized Mg level evaluated in a cohort of 457 healthy volunteers (age = 45 ± 17 years; eGFR = 72.3 ± 13 mL/min/1.73 m²) was 0.49 ± 0.05 mmol/L (median [tertile 1 – tertile 3] = 0.49 [0.45-0.52] mmol/L).

Correlation between iMg and total Mg was very high (r = 0.88; p<0.001). (Figure). Ionized Mg was weakly inversely correlated with eGFR (r = -0.22; p<0.001). Consequently, the mean iMg level differed according to CKD stages, being more elevated in the advanced stages (0.65 mmol/L in stages 2-3A; 0.47 mmol/L in stage 3B; 0.50 mmol/L in stages 4-5 (p<0.001)). In a fully adjusted linear regression model, iMg concentration was significantly associated with age, decline of eGFR, history of cardiovascular disease and the use of diuretics, and inversely associated with calcium and triglycerides levels, systolic blood pressure, diabetes, and the use of proton pump inhibitors and potassium chelators. The same factors were associated with total Mg.

Conclusion: Total Mg and iMg were strongly correlated. Decline of kidney function was associated to an increase of iMg in patients with moderate-to-advanced CKD. Additional studies need to compare the difference between total Mg and iMg as a biomarker to predict hard outcomes.
LONG-TERM LONGITUDINAL CHANGES OF PULSE WAVE VELOCITY AND THEIR ASSOCIATION TO CARDIOVASCULAR RISK FACTORS IN MAINTENANCE HEMODIALYSIS PATIENTS

Background and Aims: The incidence of end-stage renal disease (ESRD) is increasing worldwide. The mortality rate in this patient cohort remains unacceptably high. The WHO estimates ESRD as one of the ten global causes of premature death. Approximately half of all death cases are due to cardiovascular complications. A main cardiovascular risk factor is enhanced arterial stiffness. The measurement of pulse wave velocity (PWV) for evaluation of progressive atherosclerosis is known to be an independent risk predictor for cardiovascular and all-cause mortality in chronic dialysis patients.

Method: The study cohort contains patients from the “Risk stratification in end-stage renal disease - the ISAR study”, a multicenter prospective longitudinal observational cohort study. A total of 105 patients on maintenance hemodialysis were examined and followed-up for up to 72 months. Pulse wave velocity was obtained by the Mobil-O-Graph 24h PWA Monitor device at baseline and follow-up. We assessed the PWV change over time and correlated PWV with known cardiovascular risk factors using Pearson correlation coefficient adjusting for age. Longitudinal changes were examined using t-tests for paired and independent samples.

Results: Patients had a median age of 61.2 years (IQR 23.2), 36 (34%) were female. Median baseline dialysis vintage was 105 months (IQR 71), and median adapted Charlson Comorbidity Index 2 (IQR 3). During a median follow-up of 74.1 months there was a significant increase in PWV from baseline (9.25 m/s) to 6YFU (10.18 m/s, \( p < 0.001 \)), a delta-PWV of 0.92 m/s, appropriate to a yearly change of 0.15 m/s. Patients with hypertension had a significant higher PWV (10.47 m/s) than those with normal blood pressure (8.91 m/s, \( p = 0.034 \)). The Pearson correlation coefficient analysis showed after adjustment for age a significant correlation between blood pressure and both 6YFU-PWV (systolic \( r = 0.89 \), diastolic \( r = 0.62 \), \( p < 0.001 \)) and delta-PWV (systolic \( r = 0.71 \), diastolic \( r = 0.48 \), \( p < 0.001 \)). Additionally, after adjustment for age delta-PWV correlated with LDL-cholesterol (\( r = 0.27 \), \( p = 0.023 \)). Neither 6YFU-PWV nor delta-PWV showed significant associations to other traditional cardiovascular risk factors such as diabetes, high cholesterol or obesity.

Conclusion: In this cohort, we found a longitudinal increase of pulse wave velocity over 6 years. However, the average change in PWV per year was significantly lower in our cohort compared to other studies with a shorter observation period. A main reason might be the long follow-up time, with the occurrence of several deaths in the primary cohort of the ISAR-Study before reaching the follow-up point and therefore including more younger and possibly healthier patients. Nevertheless, in this cohort blood pressure in contrast to diabetes, high cholesterol or obesity was a primary factor in the change of PWV. The reasons for the deceleration of cardiovascular and mortality risk after a long term in this sub cohort remains unclear and requires further investigation.

Background and Aims: Renal damage in diabetes can manifest as real diabetic glomerulosclerosis (DN) or non-diabetic renal disease (NDRD). DN and NDRD differ in terms of prognosis and treatment thus kidney biopsies remains the gold standard. The iBEAT study conducted within the frame of IMI project BEAT-DKD (https://www.beat-dkd.eu/; GA No 115974) aims to determine whether renal imaging biomarkers capture by magnetic resonance (MRI) and ultrasound (US) can detect DKD heterogeneity. This ancillary sub-study in iBEAT aims to explore correlations between imaging biomarkers, clinical, molecular and renal histopathological data, in order to identify different DKD phenotypes.
Method: Up to January 2023 we enrolled 69 patients with: ages18-80; diagnosis of type 2 diabetes; eGFR ≥ 15 ml/min/1.73m2. Patients underwent kidney biopsy, US and MRI, along with biofluids and clinical data collection. For each patient, a total of three renal cores were collected, one was fixed in formalin, embedded in paraffin and used for routine diagnostics, the other was split and either included in OCT or used for electron microscopy, while the last was stored in RNA later for omics analysis.
Results: Among the 69 patients enrolled, 57 underwent kidney biopsy and US, with 47 also undergoing MRI. According to the KDIGO guidelines our cohort included: 12 A1 stage patients (1 G1, 1 G2, 2 G3a, 6 G3b, 2 G4); 27 in A2 stage (7 G1, 7 G2, 4 G3a, 7 G3b, 2 G4) and 21 in A3 (2 G1, 6 G3a, 6 G3b, 7 G4). According to the histological classification by Mazzucco et al (Am J Kidney Disease, 2002), 31% of DKD patients were categorized as Class I (diabetic glomerulosclerosis); 33% as Class 2 (vascular and ischemic glomerular changes); 4% as Class 3a (glomerular diseases superimposed on DN); 31% as Class 3b (other glomerulonephritis in the absence of DN).
